Magnesium-based energy storage systems are increasingly recognised as promising candidates in the transition to renewable energy, offering intrinsic advantages such as resource abundance, environmental compatibility, and high volumetric capacity [1]-[5]. Recent progress in electrode design, electrolyte composition, and nanostructured materials has improved safety, stability, and performance [6], [8], [13]. Hybrid approaches, particularly Mg/Li and Mg/Na systems, show potential for overcoming magnesium's sluggish ion diffusion [2], [3].

Despite these advances, most developments remain at TRL 2-4, with no consistent demonstrations of TRL 5-6. Key barriers include limited cathode compatibility, instability of electrolytes, complex manufacturing requirements, and high system costs [6], [10], [12], [17]. Compared with sodium- and zinc-based chemistries, magnesium technologies lag in demonstration projects and supply chain readiness. Furthermore, performance claims often rely on idealised laboratory cells rather than validated prototypes, highlighting the urgent need for harmonised reporting protocols.

5.2 Recommendations

Future research should prioritise the development of scalable cathode and electrolyte materials, targeting stable capacities above 200 mAh/g for more than 100 cycles, alongside

standardised performance reporting and independent validation to ensure comparability across studies.

For industry, investment in pilot-scale prototypes (1-10 kWh class) and hybrid chemistries are essential, supported by robust techno-economic and life cycle assessments. Early demonstration projects in grid and off-grid applications could accelerate readiness progression.

For policymakers, targeted support is needed through incentives for demonstration projects, supply chain development, and the integration of sustainability benchmarks, including life-cycle assessments and recycling pathways, into funding frameworks. Coordinated stakeholder action is therefore critical to move Mg-ESS beyond laboratory prototypes to achieve TRL 5-6 demonstrations that pave the way for commercial viability.

6 FUNDING

The authors received financial support from the South African National Energy Development Institute (SANEDI) for the research, authorship, and/or publication of this article.

ABSTRACT

South Africa remains significantly dependent on fossil fuels despite Africa's abundance of natural resources. The Department of Energy introduced the Integrated Resource Plan (IRP), targeting 17.8 GW of electricity generation from renewable sources by 2030, and launched the Renewable Energy Independent Power Producer Procurement Programme (REIPPPP) in 2011. However, progress has been limited, with only 36% of the target capacity procured to date. This study aims to identify and evaluate the critical risks impacting renewable energy project implementation in South Africa and the attainment of the IRP 2030 goals. Data were collected through structured questionnaires from ten stakeholders in the renewable energy sector, using risk categories derived from a literature review. A subsequent risk assessment workshop facilitated the ranking of these risks. Findings highlight inconsistent REIPPPP rollout and environmental regulatory challenges as the most significant barriers, and the study offers insights to guide future renewable energy planning and policy development.

1 INTRODUCTION

1.1 Background

South Africa's energy system is predominantly powered by fossil fuels, with coal remaining the primary energy source [1]. Despite the country's abundant renewable energy potential—including wind, solar, and hydro resources—there remains a slow transition towards sustainable alternatives. This continued reliance on fossil fuels has adverse economic, social, and environmental consequences. Investment in renewable energy and energy efficiency is essential for sustainable development [2]. Nevertheless, renewable energy policy adoption across Africa has generally been slow, and implementation efforts often lack momentum.

In South Africa, electricity generation is controlled by the state-owned utility, Eskom, which has faced persistent challenges in meeting national electricity demand since 2008. Frequent load shedding caused by breakdowns in aging coal-fired infrastructure has led to widespread energy insecurity [3]. These crises underscored the urgent need to accelerate the deployment of renewable energy solutions.

In response, the National Energy Regulator of South Africa (NERSA) introduced the Renewable Energy Feed-in Tariff (REFIT) in 2009, to alleviate the energy shortfall and reduce reliance on coal-based generation. Initially, the programme prioritized wind, concentrated solar power (CSP), and hydropower, later expanding to include biomass and photovoltaic (PV) technologies. In 2010, the South African Department of Energy released the Integrated Resource Plan (IRP), outlining a strategic path for electricity generation to 2030. The IRP called for a diverse energy mix—combining coal, nuclear, gas, hydropower, and renewables—to double generation capacity and meet growing demand. Notably, it allocated 59% of the planned 29,300 MW capacity to renewable energy sources.

To support these targets, the government launched the Independent Power Producer Procurement Programme (IPPPP), later refined into the Renewable Energy Independent Power Producer Procurement Programme (REIPPPP) in 2011. REIPPPP aimed to install 17.4 GW of renewable capacity by 2030, with short-term goals of 5,000 MW by 2019 and an additional 2,000 MW by 2020. However, as of December 2020, only 6,422 MW had been procured, and just 4,707 MW had been operationalised. The purpose of this study is to identify and evaluate the critical risks impacting renewable energy project implementation in South Africa and the attainment of the IRP 2030 goals.

1.2 Objectives

Achieving the IRP 2030 targets hinges on the successful implementation of renewable energy projects. These projects face a range of risks that can impact timelines, costs, and performance. In South Africa, the implementation of IPPPP and REIPPPP programmes partially mitigated the political, economic, and social risks. Prior research often focuses on specific technologies or investor concerns. This study explores the perspectives of various stakeholders involved in South Africa's renewable energy sector to identify, classify, and evaluate risks that could hinder project delivery and policy goals.

The following research questions were formulated to achieve the research objectives:

1. What risks do the South African renewable energy projects face?
2. Are these risks unique to the industry and type of renewable energy project?
3. Are the risks faced by renewable energy projects in South Africa similar to risks experienced by global renewable energy projects?
4. How do the risks rank relative to the importance, and how are these risks mitigated?

2 LITERATURE REVIEW

2.1 Sources of renewable energy in South Africa

Renewable energy refers to energy derived from natural sources that are replenished over time, such as solar, wind, hydro, biomass, and geothermal resources. These sources offer reduced environmental impacts, primarily due to their low greenhouse gas emissions compared to fossil fuels. The major sources of renewable energy are solar, wind, water, biomass, and geothermal. Globally, the adoption of renewable energy sources has multiplied significantly, but the sector still only accounts for a fifth of the global energy consumption according to the International Energy Agency [4].

In South Africa, coal dominates the energy mix, accounting for approximately 69% of supply, followed by crude oil (14%) and renewables at 11%. According to Eskom's 2020 Integrated Results, 84% of electricity is generated from coal-fired power stations. Despite this, the electricity sector has seen the highest adoption of renewables, aligning with the global adaptation trend, followed by transport applications using biofuels.

The country's renewable energy potential is particularly strong in solar and wind. South Africa receives approximately 2,500 hours of sunshine per year, with an average solar irradiation of 2,000 kWh/m^2 [5]. The Northern Cape, with the highest solar irradiation (up to 3,200 kWh/m^2), hosts most solar projects.

Wind energy potential has been mapped through the Wind Atlas for South Africa (WASA), identifying the Eastern, Western, and Northern Cape provinces as high-resource areas. The Council for Scientific and Industrial Research (CSIR) estimates that 6,700 GW of wind energy could be generated if wind farms were installed nationwide, excluding urban settlements.

To support strategic deployment, the Department of Environmental Affairs has gazetted Renewable Energy Development Zones (REDZs) which prioritizes geographic areas for large-scale solar photovoltaics and wind developments based on resource availability and reduced environmental conflict [6].

2.2 Risks in projects

The concept of risk varies by context, but it generally refers to the uncertainty of achieving objectives due to potential events or conditions. Islam and Tedford [7] state that traditionally, risk is viewed as the potential for loss or failure, but modern definitions also recognize the potential for both negative and positive outcomes. Several studies [8,9] suggest that risk arises from the combination of the likelihood of an event and its potential impact.

According to the APM Body of Knowledge [10], risk management is *"a process that allows individual risk events and overall project risk to be understood and managed proactively, optimizing success by minimizing threats and maximizing opportunities."* Risk management is applicable across all domains—projects, organizations, economies, and societies—and follows an iterative process. Establishing a clear risk context, which includes both internal and external environments as well as stakeholder attitudes and risk appetite, is a critical first step in effective risk management [11].

2.2.1 Risks in construction and engineering projects

Construction and engineering projects inherently face diverse and complex risks. Studies of major South African projects, such as the 2010 World Cup infrastructure and Gautrain, have shown that political, financial, environmental, and technical challenges significantly impacted project outcomes [14]. Key issues included cost escalation, energy shortages due to Eskom's supply constraints, and a shortage of skilled labour, often requiring expensive international expertise. Project success is typically measured against the dimensions of time, cost, quality, safety, and sustainability. Zou, Zhang, and Wang [13] emphasize that risk management is

essential for achieving these objectives. One of the most critical risks identified is a "tight project schedule," which affects time, cost, and quality. Szymański [14] categorized construction project risks according to the project life cycle, as indicated in Table 1.

Table 1: Project risks throughout project life cycle

Types of risk	Risk Description	Project Life cycle
Financial	Inflation, poor cost estimates, political and economic instability	Preliminary and detailed Design, Tender, Construction, Financing
Time-related	Delays in project execution	Preliminary Design, Tender, Detailed Design, Construction
Technical	Design flaws or inappropriate technology selection	Preliminary and detailed Design, Construction
Market	Market response and demand for the project output	Tender, Construction, Financing
Environmental/ Natural	Unanticipated environmental impacts	Detailed Design, Construction, Financing
External	Socioeconomic instability, policy changes	Construction, Financing
Human factor	Health and safety issues during execution	Detailed Design, Construction

2.2.2 Risks in renewable energy projects

Risk in the power generation sector is inherently multi-dimensional and varies significantly by country, technology, and regulatory environment [15,16]. In South Africa, perceived risks such as political instability, limited human capacity, and corruption have historically deterred private investment in renewable energy [17]. However, the introduction of policy frameworks such as REIPPPP has mitigated many of these concerns and attracted significant private sector participation. Seetharaman *et al.* [18] emphasize that renewable energy development is influenced not only by external factors, such as environmental regulations and technological advancements, but also by internal organizational factors, including employee skills and operational stability, as illustrated in Figure 1.

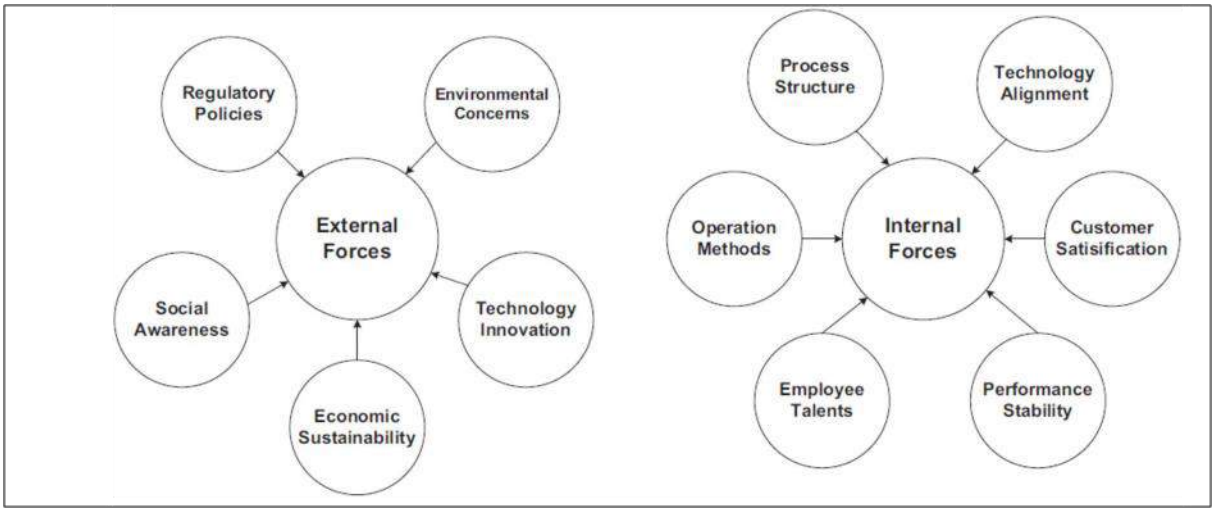

Figure 11: Factors considered to influence renewable energy growth [18]

Global investment in renewable energy technologies has increased rapidly over the years, but investors must understand associated risks and uncertainty through the planning, construction,

and operational phases. Different stakeholders have commissioned many studies to identify the risks in these international renewable projects. Most literature focuses on macro-level political and economic risks or on individual technologies, with limited focus on project-specific operational and construction challenges in South Africa's context.

Globally, key risks in renewable energy projects are generally categorized as:

- **Political / Policy Risks**: Regulatory uncertainty, policy reversals, government instability
- **Financial Risks**: Revenue insecurity, inflation, exchange rate fluctuations
- **Technical Risks**: Resource variability, technology failure
- **Socio-economic Risks**: Public opposition, job displacement
- **Market Risks**: Demand instability, pricing mechanisms
- **Environmental Risks**: Biodiversity impact, land use conflicts
- **Construction Risks**: Cost overruns, delays
- **Operational Risks**: Equipment breakdown, maintenance failures

These categories provide a broad framework for analysing risk across renewable energy projects and inform the risk assessment approach in this study.

2.3 ISO 31000:2018 Risk Management Standard

This research adopts the ISO 31000:2018 risk management framework to systematically identify, assess, and respond to risks in South African renewable energy projects. The methodology integrates both qualitative and quantitative elements, structured around the following core phases:

1. **Risk Identification**: Risk categories from the literature were used to design a semi-structured questionnaire for stakeholder interviews. This phase addressed three key research questions:
    - What risks are prevalent in South African renewable energy projects?
    - Are these risks specific to certain technologies or the sector?
    - How do these risks compare to those in global contexts?
2. **Risk Analysis and Evaluation**: Interview responses were analysed for frequency and thematic significance. The most frequently cited risks were further examined in a stakeholder workshop, where participants assigned scores for *likelihood* and *consequence* based on a defined risk matrix. This phase was to refine the initial questions from the risk identification phase and answer the last research question:
    - How do these risks rank by importance, and how are they mitigated?
3. **Risk Response**: A risk rating was calculated using the formula (Equation 1):

    $$L_e = P_e \times P_i \times L_t \quad (1)$$

    where: L_e = Expected loss I P_e = Probability of risk event I P_i = Probability of impact I L_t = Total potential loss

Risks were then plotted on a risk matrix and categorized into action levels (A–D). Recommendations for mitigation were developed from both literature and stakeholder input.

3 RESEARCH DESIGN AND METHODOLOGY

3.1 Research design and approach

Research design is a framework that provides a structured plan for data collection and analysis to address the research questions [19,20]. This study employed an exploratory research design using a mixed-methods approach to investigate the risks associated with renewable energy projects in South Africa. Risks were identified qualitatively through stakeholder engagement, while the quantitative section assessed the relative significance of these risks.

The philosophical stance underpinning this research is interpretivist, acknowledging that risk perceptions vary depending on stakeholder context. Accordingly, risks were examined from multiple viewpoints across the renewable energy value chain.

To guide the research design, the following foundational questions were considered:

- What is reality? What type of risks are prevalent in renewable energy projects? **Response**: Risks are perceived differently by various stakeholders due to their unique contexts, suggesting that multiple valid interpretations of reality exist.
- What and how can we know about these risks? **Response:** Understanding risks requires direct engagement with stakeholders involved in renewable energy projects, supported by the researcher's engineering experience in project risk assessments.
- How best can the question be researched? What data is available? **Response:** prior research and documented risks will provide a foundation for stakeholder interviews. These will be expanded through qualitative inquiry and validated via quantitative ranking to identify additional risks.
- How can data be collected and analysed? Is this technique appropriate for this research question? **Response:** The collection of data will be conducted in sequential phases. The initial stage will be through interaction with the stakeholders to identify the risks through the subjectivity of the parties. The ranking of these risks will be applied by using the risk assessment tools during a structured workshop, utilising mathematical calculations. The triangulation of data ensured robustness and enriched the findings.

3.2 Research population and sampling

The study targeted a spectrum of stakeholders directly involved in renewable energy projects under the REIPPPP, and the sample included individuals involved in project design, execution, operation, financing, and regulation. The research follows a phenomenological approach to understand lived experiences and perceptions of stakeholders. Based on methodological guidance for phenomenological studies, several studies recommend a sample size of six to ten [21,22,23]. Based on the 112 projects awarded as of December 2020, a sample size of ten respondents was deemed sufficient. All respondents had at least four years' experience and were affiliated with companies actively participating in the REIPPPP. Table 2 lists the respondents' experience and their role in the REIPPPP.

Table 2: Overview of respondents

Respondent	Role and Responsibility in RE	Involvement in REIPPP
Respondent 1: RE1	Electrical Engineer in the role of Renewables Engineer within an OEM who was involved in Bid1-4. The OEM is now working being an IPP for the next bid round for wind energy	IPP previously was an OEM
Respondent 2: RE2	Investment Advisor in the renewable energy environment	High
Respondent 3: RE3	Business Development Manager for an IPP who primarily in solar and wind REIPPPP from rounds 3 and 4	High
Respondent 4: RE4	Design engineer with an IPP who has participated in the wind REIPPPP round 2 to 4b	High
Respondent 5: RE5	Engineering manager in an IPP company during bids 1 to 3	No longer involved
Respondent 6: RE6	Construction Manager with an EPC involved in the REIPPPP	High
Respondent 7: RE7	Environmental researcher focusing on RE integration into a sustainable environment	High
Respondent 8: RE8	Environmental specialist within the RE industry	High
Respondent 9: RE9	Electrical Engineer with Eskom Distribution	Medium
Respondent 10: RE10	Electrical Engineer with Eskom Operations and Technology	Medium

3.3 Data collection

A sequential data collection strategy was employed, beginning with qualitative methods and followed by quantitative validation.

1. Qualitative Phase: Semi-structured interviews were conducted with selected industry stakeholders. These interviews were guided by a structured questionnaire informed by risk categories from the literature. The aim was to capture a wide range of perceived risks affecting renewable energy project delivery under REIPPPP. Interview data included verbatim transcripts and field notes.

2. Quantitative Phase: Based on the qualitative results, a second-phase questionnaire was developed to assess the significance of frequently identified risks. A risk assessment workshop was subsequently conducted with experts, including engineering, procurement, and construction (EPC) personnel, environmental consultants, independent power producers (IPPs), and original equipment manufacturers (OEMs). The participants are involved in different stages of RE projects, and their different companies are involved in the REIPPPP programme. Their diverse skills, renewable type, and role in RE projects provided invaluable insight during risk ranking. Table 3 presents the participants of the workshop.

Table 3: List of participants for the risk workshop

Participant Profession	Company involved in RE Projects
Safety Manager	EPC for RE projects
Construction Manager	EPC for RE projects
Project Manager	IPP
Project Manager	EPC for RE projects
Environmental officer	Environmental consultant for IPP
Design Engineer	IPP in solar and wind
Design Engineer- grid	Transmission at Eskom
Business Development Engineer	OEM, EPC and IPP
Environment Manager	IPP
Electrical Engineer	OEM - solar projects
Legal Counsel	IPP in solar, wind and gas

Participants assigned scores to risks based on defined criteria for likelihood and consequence using a 5x5 risk matrix. The strategies used for data collection are summarised in Table 4.

Table 4: Strategies used for data collection

Data Collection Strategy	Type of strategy used	Research participant involved	Type of data and outcomes
Qualitative Interviews	Semi-structured, in-depth individual interviews.	Renewable energy professionals.	• Interview transcripts and field notes. • Thematic codes.
Quantitative Workshop	Questionnaire with rating matrix.	EPCs, IPPs, Environmental consultants, OEM.	• Risk scores and rankings.

3.4 Data analysis

Interview transcripts were coded using thematic analysis to identify recurring risks. Coding was conducted manually and verified using ATLAS.ti 9 software. Risks with frequencies greater than one were selected for further quantitative analysis. A risk rating matrix was used in the workshop to rank each risk based on:

- **Likelihood**: Number of occurrences in the last ten years or across earlier REIPPPP bid windows.
- **Consequence**: Estimated project impact in terms of schedule delay, cost overrun, and environmental effect.

The likelihood and consequence ranking were assigned using Table 5. The ranking was based on the likelihood of the event happening or the number of occurrences in the last ten years. The consequence scale was developed using the following assumptions [24]: Total project costs from the 74 projects already in operation were estimated to be R 0.024 Bn/MW. Wind project capacity is capped at 140MW, and solar capacity is capped at 75MW for REIPPPP. The resultant cost for wind and solar projects was averaged out, resulting in a project cost of R2.6 billion (Bn).

The energy purchase price is 2.25 R/kWh; RE projects supply the grid on average twelve hours a day. Therefore, the potential electricity lost per day the RE project is late was calculated in gigawatt-hours (GWh). The total loss rating was aligned to Eskom's risk rating for GWh loss. The rating was applied to the project schedule and revenue loss.

It was assumed that significant delays in the project would occur during the construction phase. Even the earlier delays in the bidding phases of the project will result in a shift in the construction completion date. These delays will increase project costs. Construction cost was estimated using a 40-hour work week, about 25 site personnel with an average hourly rate of R1200/hr.

Table 5: Likelihood and Consequences risk rating scale

Score	1	2	3	4	5
Likelihood	Rare < 1 occur-rence	Unlikely ≥1 occurrence	Moderate ≥1 occurrence	Likely ≥3 occurrences	Certain ≥5 occurrences
Consequence	< 1month delay <2% cost increase	≥ 3-6 months delay ≥2-5% cost increase	≥ 6-12 months delay ≥5-10% cost increase	≥12-18 months delay ≥10-15% cost increase	≥ 18 months delay ≥15-20% cost increase

Using these scores, the expected loss was calculated with Equation (1). Each risk was then plotted on a risk matrix, Figure 2, and categorised as follows:

- **A**: Critical – Immediate mitigation required
- **B**: High – Medium-term mitigation required
- **C**: Moderate – Monitoring and long-term planning required
- **D**: Low – Acceptable with current controls

Risk Matrix						
Consequence	5	C	B	A	A	A
	4	D	C	B	A	A
	3	D	D	C	B	A
	2	D	D	D	C	B
	1	D	D	D	D	C
		1	2	3	4	5
		Likelihood				

Figure 2: Risk assessment matrix

4 RESULTS

4.1 Qualitative findings

The questionnaire used for the interviews had two sections. The general section is to assess the suitability of the respondent based on their experience in renewable energy projects. The second section had direct questions on risks utilising categories identified from the literature review. All respondents were affiliated with companies actively participating in REIPPPP and had a minimum of four years' experience in renewable energy project development. Most were involved in both solar and wind energy projects, providing a broad perspective across technologies. Interview feedback was largely positive regarding government efforts to support renewables. However, respondents noted that the inconsistent implementation of these plans introduced significant uncertainty and risk. Using the categorized risk framework, Table 6 summarizes the frequency of risks mentioned across interviews.

Table 6: Frequencies for risks in renewable energy projects

Risk	Frequency
Inconsistent rollout	19
Lack of Policy certainty	14
Regulatory restrictions on the electricity sector	12
Environmental regulations and approvals	9
Grid capacity and connection issues	8
Political commitment gaps	8
Onerous application processes	8
Lack of community engagement	7
Skills and construction capacity gaps	6
Eskom financial instability	5
Local content requirements	5
Reduced production or demand	4
Civil unrests	3
Lack of a transition plan	3
Lack of collaboration- Eskom and RE	2
Long lead times from bidding to economic status	2
Municipality feed-in-tariffs	2
Safety during construction	2

Risks with a frequency rating of 1 included Conservative environmental approach, corruption, environmental sensitivity areas, equipment breakdown, inaccurate cost estimates, land

availability, and power generation vs load demand mismatch. The risks identified for construction and operations were found to be similar and therefore combined. There were no risks cited for reputational, social, or market risk groups. The respondents credited this to the successful implementation of previous REIPPPP projects, community upliftment plans requirements, and the implementation of power purchase agreements (PPAs) between Eskom and IPPs. Political risks dominated, accounting for 69 mentions, far exceeding the frequency of any other category. Notably, risks related to construction, environmental regulation, and technology were also cited but less frequently.

4.2 Quantitative Findings

Quantitative data were collected to assess the significance of the risks identified in Table 6. A questionnaire for risks with more than one frequency was developed, and each risk was assigned a risk code based on its category. Risk groups were political risk (PR), financial risk (FR), environmental risk (ER), construction and operational risk (COR), and technological risk (TR). A risk assessment workshop was held with EPC personnel, an environmental consultant, design engineers from an IPP, and OEM personnel. Participants rated the selected risks using a 5x5 matrix based on the likelihood and consequence risk rating scale in Table 5. Each risk rating was calculated using equation (1), assigned a score (Table 7), and mapped into one of four action categories. Table 7 presents the risk assessment results.

Key Findings (Top Risk Rankings):

- **Ranking A (Critical – Immediate Action Required):**
  - *Inconsistent rollout of REIPPPP*
  - *Environmental regulations and approval delays*
- **Ranking B (High – Medium-Term Mitigation):**
  - Grid infrastructure constraints.
  - Regulatory complexity in the electricity sector
  - Onerous application and bidding procedures
- **Ranking C (Moderate – Monitor and Plan):**
  - Local content requirements
  - Long lead times between bidding and commercial operation
  - Political uncertainty

Risk Details		Risk Analysis		
Risk Code	Risk Name	Likelihood	Consequence	Risk Rating
COR3	Civil unrests	4	1	D
ER1	Environmental regulations and approvals	4	4	A
FR1	Eskom financial instability	3	1	D
TR1	Grid capacity and connection issues	4	3	B
PR1	Inconsistent roll out	4	4	A
COR1	Lack community engagements	2	1	D
PR8	Lack of collaboration- Eskom and RE	2	2	D
COR2	Lack of local skills and construction capabilities	3	2	D
PR2	Lack of Policy certainty	3	3	C
PR4	Lack of political commitment	3	3	C
PR7	Lack of transition plan	3	2	D
FR2	Local content requirements	3	3	C
PR9	Long leadtimes from bidding to economic status	3	4	B
FR4	Municipality feed-in-tariffs	2	1	D
PR5	Onerous application process	4	3	B
FR3	Reduced production or demand	2	2	D
PR3	Regulatory restrictions in electricity sector	4	3	B
COR4	Safety during construction	4	1	D

Table 7: Risk assessment results

Risk Matrix Visualization

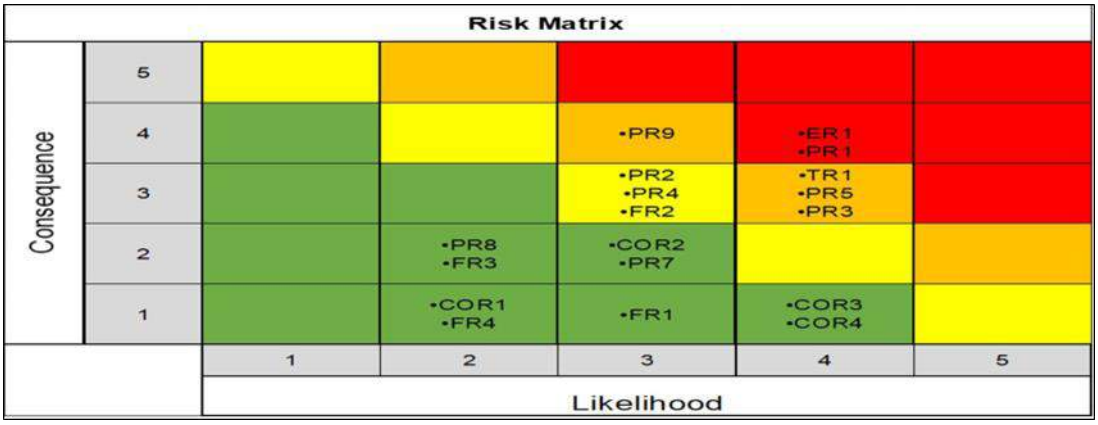

Figure 3: Risk ranking on risk matrix

Figure 3 visualizes the risks on the risk matrix, and the results underscore that political and regulatory uncertainty, as well as environmental approval processes, present the most substantial barriers to renewable energy project delivery in South Africa.

4.3 Discussion

The findings highlight that political and regulatory factors are the most significant risks facing renewable energy projects in South Africa. These risks not only recur often in stakeholder feedback but also rank highest in severity during quantitative evaluation.

Inconsistent REIPPPP Rollout

The most often cited and highest-ranked risk was the inconsistent implementation of the REIPPPP. While initial bid windows (Rounds 1–4) were successful, delays and uncertainty in launching subsequent windows disrupted momentum across the sector. All stakeholders emphasized that regular and transparent procurement cycles are critical to industry stability

and long-term planning. Disruptions in the REIPPPP rollout have cascading effects across the project value chain:

- **Manufacturing**: Original Equipment Manufacturers (OEMs) established local production facilities to meet local content requirements. Delays in procurement cycles led to the closure of these facilities.
- **Skills Development**: Independent Power Producers (IPPs) had invested in training local staff. However, gaps in project rollout forced skilled personnel to leave the sector.
- **Grid Planning**: Due to Eskom's, the national utility, limited resources, it cannot proactively invest in grid infrastructure without predictable REIPPPP timelines, worsening evacuation challenges for renewable projects.

Environmental Approvals and Regulations

The second most critical risk identified was the complexity and delay associated with environmental regulations and land-use approvals. Wind energy projects face high risks due to their dependence on site-specific wind resources, often found in ecologically sensitive areas. These risks manifest in longer approval timelines and project cost inflation.

Efforts such as the gazetting of Renewable Energy Development Zones (REDZs) and the development of generic Environmental Management Plans (EMPs) have reduced the environmental assessment period from 300 days to 100 days. However, further streamlining—especially for wind projects—is needed to reduce approval bottlenecks. This period has the potential to reduce further to 50 days for Phase 2 REDZ since the CSIR has developed a generic EMPR for solar and wind projects, which will fall under these zones.

Secondary Risks and Interconnections

Other risks—such as grid capacity constraints, onerous application processes, and local content enforcement—were ranked lower but remain significant due to their interdependence with political and regulatory factors. For example, regulatory complexity hinders Eskom's ability to plan and integrate new projects; extended bid-to-operation timelines increase costs and reduce investment appeal; and local content requirements, while beneficial for industrialization, are difficult to meet when procurement is irregular and uncoordinated.

5 CONCLUSION

This study aimed to identify and evaluate the risks that hinder the successful implementation of renewable energy projects in South Africa, with a particular focus on the REIPPPP and the country's IRP 2030 targets. Several key findings emerged.

5.1 Key findings and research questions

1. **What risks do South African renewable energy projects face?**

The most critical risks are political and regulatory in nature, specifically, the inconsistent rollout of the REIPPPP and delays in environmental approvals. These risks have widespread effects, impacting project planning, investment confidence, local content development, and grid readiness.

2. **Are these risks unique to the renewable energy industry and technology types?**

Yes. While general project risks (for example, cost overruns and delays) exist across industries, the political and environmental risks faced by renewable energy projects are compounded by their reliance on public sector frameworks and environmental compliance.

Renewable energy projects are reliant on the government to develop policies and mechanisms to advance their development. The South African government understands the importance of

renewable energy and the importance of achieving the IRP 2030 goals. However, changes within the government departments and ministerial offices delay the implementation of renewable projects. In addition, renewable energy projects integrate and are dependent on the existing downstream systems, over which the IPPs have no control. Therefore, the risks faced by renewable energy projects are not the same as other industries in South Africa.

Renewable energy types all face the same political and technical risks identified in the study. However, wind energy faces higher environmental risks than solar. Also, biomass projects are likely to face higher social risks than solar and wind. This is because biomass competes with food security for feedstock.

3. **Are the risks in South African projects like those globally?**

Risk categories such as political, regulatory, financial, and technical are broadly similar to global experiences. However, South Africa's specific challenges, such as Eskom's monopoly, delayed REIPPPP rounds, and lack of independent regulation, make the manifestation and severity of these risks unique.

South Africa has an Eskom monopoly as an electricity supplier, which is also state-owned. The electricity supply industry in South Africa is heavily regulated. The regulatory bodies are not independent of the government. These factors create political risks. Power producers cannot determine the price for supplying energy based on their investment, creating a financial risk. The infrastructure for electrical distribution in South Africa has insufficient capacity to support renewable energy projects.

Globally, political and legal (regulatory) risks were ranked high for renewable energy projects. Political risks were then followed by weather-related volume risks and financing risks during the financing stage. The political risks included changes in legal frameworks and policies, political instabilities and unrest, and wars were perceived as being the key risks faced by renewable energy projects [25]. Technological risks faced by global projects are mainly on resource availability and weather-related volumes. The grid connection issues affected offshore wind energy only [26].

4. How are these risks mitigated?

The stakeholders in renewable energy have implemented measures to mitigate these risks. However, the mitigations have reduced the likelihood of some of the risks, but the consequences remain the same.

- The Department of Energy has introduced new bid windows (e.g., BW5) and a Risk Mitigation IPP Programme (RMIPPPP) to revive investor confidence.
- The REDZ and generic EMPr have reduced environmental approval times but require further refinement, especially for wind energy.
- Greater collaboration between Eskom, the Department of Forestry, Fisheries, and the Environment (DFFE), and the IPP Office is essential to align grid investment and REIPPPP rollout.
- Simplified application processes and standardized templates can improve project turnaround and reduce administrative burden.

5.2 Recommendations

1. **Establish a Predictable REIPPPP Rollout Plan**
   The South African government must commit to staggered, concurrent bid windows from 2021 to 2028 to meet IRP 2030 targets, and regular procurement cycles are essential for investment stability.

2. **Institutional Reform**
   The IPP Office should be moved out of ministerial control and operate independently to ensure continuity and reduce political interference.
3. **Tailor Environmental Processes for Wind Projects**
   Develop specific REDZs and EMPr for wind technology to mitigate land-use conflicts and ecological impacts without delaying development.
4. **Integrate Grid Planning with REIPPPP**
   Eskom should be directly involved in REDZ development and REIPPPP planning to ensure proactive investment in transmission infrastructure.
5. **Streamline Project Application and Evaluation**
   Introduce simplified, standardized application tools to reduce review time and enable faster project approvals.

5.3 Limitations and recommendations for further research

This study focused on REIPPPP projects in South Africa, particularly in wind and solar technologies. The rest of Africa has abundant natural resources, and the implementation of renewable energy in other African countries has also not progressed. Renewable energy projects in South Africa are focused on solar and wind, as this is informed by the REIPPPP determination. As a result, the findings may not fully represent other renewable energy types (e.g., biomass, hydro) or regions in Africa. Future research should explore:

- Risk factors in non-REIPPPP renewable projects
- Comparative studies across other African countries
- Impact of just energy transition mechanisms on long-term risk profiles

ABSTRACT

As infrastructure projects become complex, traditional project management (PM) often falls short of ensuring timely completion, budget adherence, and stakeholder satisfaction. Integrating systems engineering (SE) with PM in civil engineering (CE) can enhance project outcomes by providing structured processes to manage complexity and risks. This study evaluates SE maturity in CE and proposes a framework for its integration with PM, addressing key gaps in the literature. By analysing CE projects in South Africa, the research highlights how SE practices, widely used in aerospace and IT, can be adapted for CE. However, SE adoption remains limited due to insufficient awareness and formal processes. The study identifies the need for formalised PM tools and early-stage SE activities like requirements analysis and validation. It presents a conceptual framework to guide CE firms in strengthening SE maturity, offering practical recommendations to improve project delivery in the South African CE industry.

Keywords: Systems Engineering, Project Management, Civil Engineering, Systems Engineering Maturity.

1 INTRODUCTION

It is paramount for an organisation that the project, product development, or process improvement succeeds. For the most part, time, cost, and performance are key indicators of project success. Performance is painfully subjective and closely tied to the satisfaction of various stakeholders, which may vary according to the project in question [1]. A formal PM approach based on accepted standards and guidelines must be adopted for the practical success of projects. Increasing research proves that traditional PM methodologies are insufficient to ensure project success as project complexity increases. Many projects fail for various reasons related to PM [2]. SE introduces ways of eliminating and improving upon these factors for better project success.

An amalgamation of SE and PM increases the probability of projects finishing within budget, on schedule, and following expectations [3]. Developing a specialised approach in PM and SE proprietary to a project is essential to guarantee success. Many sectors have since adopted a successful SE to manage their systems and projects; some of these include aerospace, information technology and computing. While SE has been pivoted to project management in these industries, the process of SE in the civil engineering (CE) industry has been relatively slow.

Large infrastructure projects generally do not meet Cost and time targets; hence, SE processes are necessary for the industry [4]. CE design is traditionally quite linear and straightforward; it does not accommodate the iterative character of design changes, variations, and delays. This results in an activity-based monitoring approach, often devoid of objective, value-adding progress. However, CE can be multi-dimensional in hydrology, transportation, structural engineering, and geotechnics, with the distinction between consulting and construction work. Because of the complexity of the CE projects, the involvement of several disciplines, and the quite different tie-in disciplines within an industry, developing a more integrated and interdisciplinary approach, such as SE, to counter internal and external factors that affect project outcomes is necessary. As such, projects in CE are complicated; thus, SE has been recommended to improve the success rates in these projects [5]. This study focuses on integrating SE with PM in the CE industry to enhance the maturity of SE processes and ensure project delivery success.

Nevertheless, integrating the SE processes and PM methods may lead to a greater success rate in projects. This has been observed significantly in the aerospace and IT industries, where SE saves time and cost while satisfying the stakeholders' expectations [6]. However, the PM methods are generally the only paradigm for the CE domain, which leads to excess cost and overruns in time, which are permanent features of infrastructure projects. The restricted application of SE in CE projects, particularly in South Africa, raises concern about these projects' significance for the national economy. The onset of mega-infrastructure projects, such as power stations, road construction projects, and water pipelines, is paramount to the economic upliftment of the country, so their success is crucial.

To improve their concurrent application, this paper will study the CE industry's interface between SE and PM processes. In particular, the investigation is intended to determine the extent to which SE currently applies in the CE industry, evaluate the maturity of applied SE practices within the South African CE sector, and propose a framework to enhance SE maturity and its effective implementation. From an industrial engineering perspective, this study is situated within the broader discourse on optimising complex systems and processes.

2 RESEARCH METHODOLOGY

According to Siedlecki [32], descriptive studies aim to observe and describe people, events or situations as they are and not manipulated by any variables. A researcher explains the sample

and/or variables or observes. In descriptive research, the hypotheses are not tested but generated with rather specific objectives and research questions that typically begin with "What", "When", "Where", or "How" but do not have "Why" question marks [7]. Simple descriptive research designs—for example, observational or survey—present results in terms of measures of central tendency (mean, median, mode, standard deviation) or report them in frequencies and percentages.

The most common types of research designs include qualitative, quantitative, and mixed methods. Qualitative design is an analytical approach that generates measures with a quantifiable or discrete value. Quantitative data is gathered using mathematical and statistical methods, focusing on experimental and non-experimental techniques. The qualitative design refers to explaining or getting meaning for the social or human problems in a person's mind[8]. This kind of design assumes that reality is a social construct, that variables are complicated to measure, and that data gathered will consist of a subjective perspective. Interviews, observation, and participation constitute the forms of research used in collecting data. Mixed methods attach both qualitative and quantitative approaches to research design, which are widely used for depth and breadth of understanding and corroboration, as stated by Schoonenboom and Johnson [9]. Typically, this method is used for triangulation, complementarity, developmental, initiation, and broadening when conducting a research study.

This descriptive study, which employs a mixed-method technique, is for complementarity and expansion. In reviewing the existing literature, qualitative design was explicitly used to integrate SE and PM in CE. Most of the studies conducted on the maturity of SE in the CE industry employed quantitative research methods based on survey questionnaires. Although descriptive, the methods provide the systemic insight and structured understanding that industrial engineers rely on when designing process improvement and integration interventions [10]. This explanatory approach reflects an industrial engineering orientation by establishing a baseline understanding of system maturity, a prerequisite for developing optimisation strategies [7].

The CE industry comprises clients, governing structures, consultants and contractors. The different structures are integral in running projects, and they all have project practitioners conducting project management tasks in various project phases. The consultants, however, are involved in all project phases from inception until the closeout phase. As a result, the consultants have project practitioners conducting project management tasks in all the project phases. The research population focused on project practitioners practising within consulting firms. Consulting Engineering South Africa (CESA) is a governing body that governs practising consulting firms, where consulting within the engineering fields needs to be registered. This study focused on project practitioners practising in registered consulting firms.

Sampling and sampling size selection procedures based on relevant effect size parameters have been developed, but rules of thumb often endure when planning multiple regression studies [11]. One reason for this enduring practice might stem from the challenge of establishing a reasonable a priori value for the effect size to be detected. The study aimed to establish the correlation between the application of SE amongst project practitioners and the CE industry, making this a relationship study [12]. The rule of thumb for a reasonable survey sample size is approximately 50 participants. For this study, a minimum of 50 participants was used.

3 LITERATURE REVIEW

3.1 Project Management

All project management techniques and methods, from planning to quality management and cost control to time control, are important in successfully delivering projects. A temporary operation is carried out to create a unique product, service, or result [13]. PM uses knowledge, skills, tools, and techniques applied to project activities to meet defined project requirements. The PMBoK presents a principles structure through which project management will be understood around the knowledge areas and process groups across the project lifecycle. PMBoK defines those knowledge areas, including project scope, time, cost, quality, resource, risk, and communications management. All include broad purchasing processes and applications that advocate successful project completion. PMBoK recommends a structured applied process configurable to particular project requirements [13].

Research comparing PM practice among project practitioners from CE and those from other industries reveals the uniqueness of the needs and preferences of CE project practitioners [14]. On the planning and resource-scheduling side, CE professionals emphasise critical path analysis. The complexities in managing CE megaprojects, which often involve high risks and costs, call for adopting a unique set of approaches to project management [15]. The PMBoK presents an extension that specifically deals with the management of construction projects, detailing the principles and practices unique to the CE industry. The various challenges this extension addresses cover time management, quality assurance, resource management, and risk management, all of which are pivotal to the successful delivery of CE projects. Nevertheless, the prospective methodologies in PMave failed to salvage some of the projects in CE, mainly due to an unprecedented level of growing complexity in construction megaprojects [13].

Poor project management practices were cited as a major contributor to project failure in an analysis of the shortcomings of social housing projects in South Africa [16]. Non-consultative projects and stakeholder engagement without considering project end-users made such failures possible. The PM framework proposed for these projects focused on stakeholder engagement and end-user satisfaction throughout the lifecycle [17]. The country also faces serious challenges regarding providing water infrastructure delivery, delays, cost overruns, poor quality of work, and little or no socioeconomic benefits. These have resulted from well-understood problems such as poor project management, inadequate communication, insufficient resources, and politics [18]. There is a need for a joint approach with all stakeholders in the project.

3.2 Systems Engineering

According to the International Council of Systems Engineering (INCOSE), systems engineering is an interdisciplinary approach that successfully realises the complexity of systems [19]. SE helps ensure that systems satisfy the needs of customers, stakeholders, or users. The systems engineering processes are performed during the entire system lifecycle to ensure the successful delivery of that system. Systems engineering includes a variety of technical processes such as requirements analysis, functional analysis, verification, and validation of systems. These are effective in aerospace, IT, and defence industries requiring interdisciplinary collaboration for complex systems [10]. The application of systems engineering in the CE industry is still nascent, while the associated advantages are becoming more evident.

Increasingly, interest in using SE in civil engineering projects has been articulated over the past several years. Research has turned up several factors that may enhance the successful implementation of SE in CE, such as well-defined requirements, adequate documentation,

interdisciplinary collaboration, and effective decision-making [20]. Such elements are cardinal in assuring that CE projects satisfy their stakeholders on time and within budget. Second, SE deals with the inherent complexity of CE projects, particularly litigation during the tenders [21]. By employing SE principles in the tendering process, CE organisations may reduce the labour associated with preparing competitive offers and ensure that all facets of the project are addressed.

Studies have found that integrating SE and PM processes is an essential success factor in complex projects [2]. The primary concern is that the integration should be done, as it can introduce new complexities otherwise. Other things that SE and PM processes have in common are risk management, quality assurance, and project planning. Integration allows customising project management activities toward the specific project's needs[22].

A joint undertaking between INCOSE, Project Management Institute, and the Massachusetts Institute of Technology integrated SE and PM processes for complex projects. These fields overlap within scope management, schedule management, technical coordination, and system integration. While integrating SE and PM processes, factors such as culture differences in organisations, education-related concerns, objectives, and authority alignment must be considered, as they all appear to be requirements for achieving successful project outcomes [23]. SE provides the architecture for defining, designing, implementing, testing, and delivering the resulting projects' outputs. On that note, PM ensures that these activities are performed in the larger context of the business.

There have been many propositions for creating a standard SE and PM integration guideline that can be adapted to the specific needs of each project [24]. Steps in that guideline will include understanding the project vision, selecting suitable frameworks, grouping project documents, and establishing verification and validation processes.

3.3 Systems Engineering Enablers

SE enablers, like management structure and toolkits, are key to effectively instituting SE for infrastructure projects [25]. Prominent among the enablers is Model-Based Systems Engineering (MBSE), which stresses the development of a system model as a unified whole instead of being document-centric [26]. With models representing system requirements, structure, behaviour, and interactions, MBSE enhances communication, knowledge capture, and design accuracy, lowering development risk. However, MBSE is not receiving attention in CE projects due to low technical knowledge and awareness, especially concerning Africa [27].

Another prominent enabler is Building Information Modelling (BIM), a process based on 3D models that builds better planning, design and management of CE projects [28]. BIM allows data centralisation, cost possession, schedule maintenance and stakeholder collaboration [29]. Integrating SE processes with BIM in CE remains underdeveloped in terms of compliance, verification, and stakeholder management frameworks [30]. Bentley ProjectWise and dRofus are software solutions that enhance project management, document control, and requirements management [31]. These tools assist in managing project information, optimising workflows, and ensuring that design solutions meet the client's requirements [32]. Nevertheless, integration between SE and PM tools in the CE industry is lacking with these advancements, so tapping into their potential benefits remains elusive.

3.4 Systems Engineering Maturity

It includes the degree to which systems engineering activities are effectively employed/implemented in the organisation or project, which is called SE maturity. There are maturity models to assess readiness and capability, while capability maturity models (CMMI) judge current performance [33]. Such models supplement one another. Hence, they are widely favoured in complex sectors such as manufacturing. CMMI [34] indicates 22 core process areas,

which include configuration management, risk management, and project planning, plus four capability and five maturity levels. A tailored SE maturity model for CE projects defines process areas, capability levels, and corresponding maturity stages. This model identifies technological, conceptual, and organisational barriers to SE deployment in the CE industry that hinder collaboration and knowledge exchange with disparate systems and stakeholders [35].

The maturity model divides the SE deployment-readiness levels within its gradation-fives into "initial" (no SE application) to "excellent" (full SE integration). Studies reveal that SE team knowledge was linked with project success. The factors affecting project success include team members' SE expertise, knowledge processes, and organisational support to fill skill gaps. In South African manufacturing, for instance, SE maturity models have been implemented, where core and feedback components are used to assess SE processes in support of a general effort to enhance effectiveness in SE across various projects [10].

4 CONCEPTUAL METHOD

The CE industry has been running projects based on PM processes and tools since its inception. The processes have developed and improved over time, with the Project Management Institute publishing a construction management extension for PMBoK to cater specifically to the CE industry. PM alone has proven insufficient to ensure project success in the CE industry, as in all industries that deal with complexity. PM tools have been used in sectors such as BIM, which have processes similar to SE and aim to promote project success. To promote SE in the CE industry, there is a need to identify such tools and further develop them if necessary.

The two main aims of incorporating SE within CE firms [36]. Firstly, there is a need to enhance and refine working methods to improve the quality of the final product, and secondly, to reduce project failure costs. Project failure costs would be reduced by increasing CE firms' processes' clarity, traceability, and demonstrability. Lemberger [10] grouped SE processes into lifecycle integration, with SE processes and development phasing as the three main processes. These processes complement other frameworks while creating a better structure for SE process frameworks. The implementation of SE is subject to the environment and conditions of implementation, which introduce SE enablers. SE enablers support tools, personnel, knowledge and processes that promote SE implementation. Chen and Jupp [25] adopted the grouping of SE activities and expanded on it by including SE enablers. The identified enablers are people, process, protocol, and technology.

As seen in Figure 1, the proposed conceptual framework used in this study combines frameworks used in previous SE and SE maturity research. The framework uses a CMMI framework for the CE industry and a scale to measure SE maturity and investigate using PM tools resembling SE processes. The two concepts will use the same framework due to their link to SE.

In conceptualising projects within the CE industry, project practitioners mainly utilise PM tools and processes to deal with projects. SE maturity is indeed measured along SE processes and enablers, where PM tools, like BIM, are primarily at work today in the CE industry and have the potential to promote SE. Thus, PM tools in the CE industry are considered SE enablers in delivering CE projects. The framework has included SE enablers such as qualified human resources and proper processes to ensure that SE can be effectively practised through them. The livelihoods are essential, ensuring the sustainability and effectiveness of SE processes for project success.

Table 1 lists the consolidated list of the SE processes and SE enablers considered for this conceptual model. The maturity model proposed to assess the level of application of SE in the CE industry expands on the CMMI. The framework offers a systematic method of evaluating

and improving SE. The maturity model is expected to provide the level of SE maturity and highlight the gaps in the application of SE in the CE industry, if any.

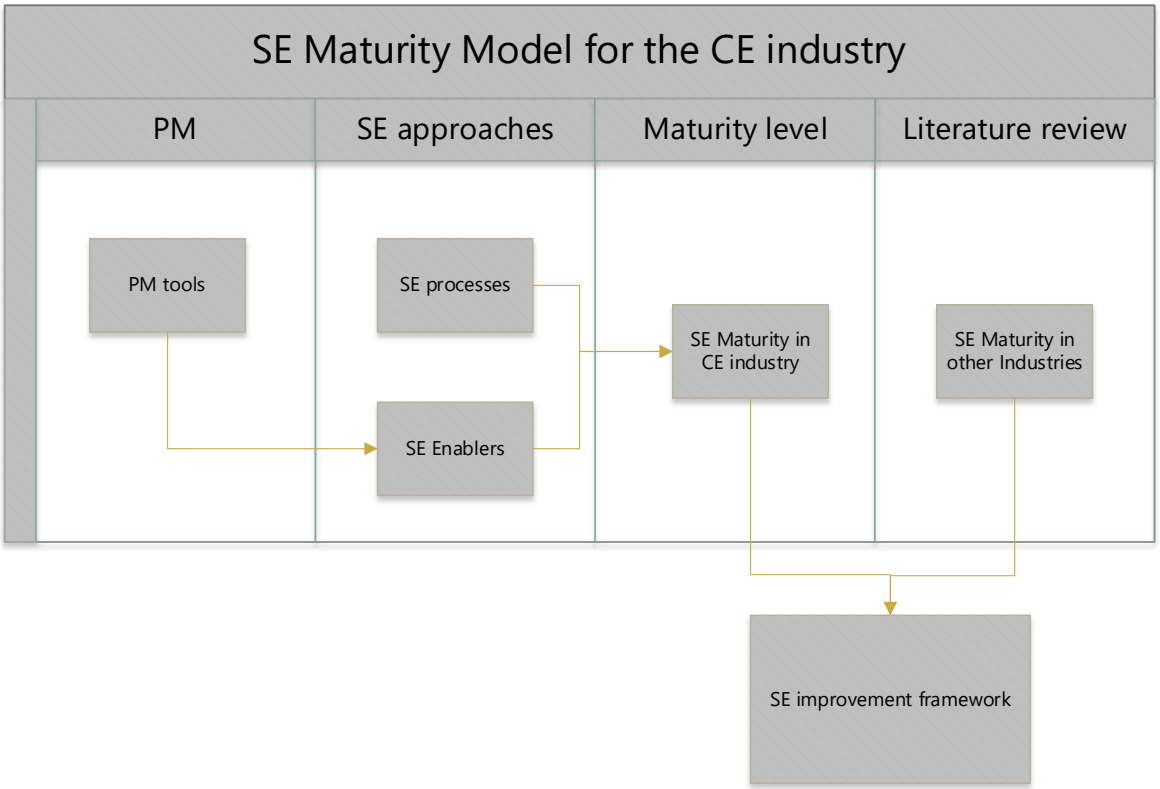

Figure 1: SE Maturity Model Framework for the CE Industry

Table 1: Systems Engineering Approaches

Systems Engineering Process	Systems Engineering Enablers
Verification	Integrated Product Teams
Validation	Systems Integrated Process
Configuration Management	SE Management Plan
Project Planning	MBSE
Project Monitoring and Control	Simulation and Analysis
Product Integration	Trade-off Analysis
Measurement and Analysis	
Requirements Development	
Requirements Management	

The framework seeks to answer the research questions, prove and validate the previous chapter's hypothesis, and further provide a framework to improve the maturity of SE in the CE industry. An ordinal scale will be used to measure or quantify SE maturity, consisting of the following:

- 0 - Not performed
- 1 - Initial definition
- 2 - Repeatable
- 3 - Defined
- 4 - Managed
- 5 - Optimising

5 RESULTS

The questionnaire survey yielded 51 responses, with an average of 38 valid responses and 13 with missing data. Some measures were implemented to extract data from persons of interest. This ensured that the survey was conducted on project practitioners who practice as civil engineers in South Africa and practice within the consulting engineering field. 9,8% (5) of participants responded that they did not practice within the consulting sphere, while 90,2% (46) indicated that they did. Of the participants who stated that they were not project practitioners practising in the consulting engineering space, two did not go further with the study and the other three were not considered for the study. Furthermore, individuals who fit the abovementioned profile were identified, and only the survey link was shared. The survey also had a question that allowed it to terminate if a participant responded that they were not willing to participate in the anonymous survey.

5.1 Descriptive Statistics

The descriptive statistical examination of the survey responses reveals some essential insights into participants' perceptions and experiences regarding SE enablers and processes. In the analysis, SE enablers show relatively high variance and standard deviation, indicating a broader spread in their perception or engagement among the respondents. Such variability suggests that the participants must have had different experiences or interpretations regarding enablers due to organisational context, role, or maturity differences.

Conversely, the skewness of SE processes points to strong left skewness, with most responses bunched towards the higher end of the scale. This indicates that SE processes are generally rated highly, implying that they are widely respected and practised in engineering processes. In contrast to SE processes, which retain a highly normal distribution with a left skew, SE enablers reflect the moderate view of enablers, thus demonstrating much more disagreement on their rating and hence saying that their perception also depends on context to context. The kurtosis values corroborate this interpretation: SE processes responses seem more consistent. SE enablers show more variability, pointing to differences in how people understand or operate these enablers according to their respective projects or organisational contexts.

Table 2 displays each survey item's average, standard deviation, and 95% confidence intervals. Mean scores varied between 2.97 and 4.00, giving the interpretation that most responses lay between the "defined" and "managed" levels as per the level descriptors used in the study. This kind of averaging, however, can misrepresent the situation. For instance, Q10 averaged 4.00, suggesting a high level of maturity, yet qualitative inspection of data showed many responses as 'defined'. This emphasises that one should look at the mean and distribution of responses for better understanding.

Thus, the standard deviation values from 1.18 to 1.64 indicate low to intermediate response variability. Consequently, according to consensus among the participants, the lower the

standard deviation, the more representative the average score is. This is followed by a small 95% confidence interval that talks about high levels of precision and states that responses were reasonably consistent within a sample. For instance, Q5 has a mean of 3.74 with a standard deviation of 1.18 and a more exhaustive reference interval (3.37-4.11), thus backing reliability for the central tendency measure.

Table 2: Degree of Confidence

Question	Mean	Standard Deviation	95% CI Lower	95% CI Upper
Q1	3.61	1.34	3.20	4.02
Q2	3.82	1.28	3.43	4.21
Q3	3.79	1.25	3.41	4.17
Q4	3.95	1.22	3.57	4.33
Q5	3.74	1.18	3.37	4.11
Q6	3.46	1.45	3.02	3.90
Q7	3.74	1.27	3.36	4.12
Q8	3.32	1.40	2.89	3.75
Q9	3.44	1.40	3.01	3.87
Q10	4.00	1.34	3.59	4.41
Q11	3.92	1.23	3.54	4.30
Q12	2.97	1.64	2.46	3.48
Q13	3.45	1.39	3.02	3.88
Q14	3.47	1.40	3.04	3.90

Finally, Q12 has the lowest mean rating at 2.97, while the highest standard deviation is 1.64. This indicates that ratings for Q12 were low, and participants showed a high level of disagreement about what their responses meant. It may indicate an area of concern or a concept poorly understood or applied inconsistently by the people surveyed. In conclusion, the patterns of agreement and divergence regarding how the various aspects of systems engineering practices are perceived surface in the descriptive statistics and confidence intervals. Engineering processes usually apply well and are consistently used, while enabling factors were applied with quite a range, indicating an opportunity for standardisation, training, or inquiry.

5.2 Regression Analysis

A regression analysis was done further to investigate the relationship between SE enablers and SE processes. The study established a robust and statistically significant positive relationship between the two variables. R = 0.769 means that approximately 59.1% of the variance in SE processes is attributable to SE enablers, signifying that the greater the maturity of enablers and the stronger the presence of enablers, the better the extent to which SE processes are carried out in practice.

Due to the F-statistic of 50.580 obtained from ANOVA analysis, which resulted in a p-value of <0.001, it is essential to note that SE processes are statistically related to the maturity of SE enablers and that this relationship is unlikely due to chance. Furthermore, the unstandardized regression coefficient (B) of 0.650 means that the SE processes score increases by 0.650 units for each one-unit rise in SE enablers. The standardised coefficient (Beta = 0.769) thus confirms this relationship's tightness, while the high t-value ($t = 7.112$, $p < 0.001$) justifies the significance of the predictor. Therefore, the regression analysis indicates that SE enablers are a major driver of SE processes' maturity. Enhancing enablers, namely structured planning, tool

usage, and process alignment, is paramount in improving effective SE practice within civil engineering projects.

Table 3: Summary of Regression Analysis

Model Component	Value	Interpretation
Correlation Coefficient (R)	0.769	Strong positive correlation between SE enablers and SE processes
R Square	0.591	SE enablers explain 59.1% of the variance in SE Processes
Adjusted R Square	0.579	Adjusted for the number of predictors
Std. Error of Estimate	0.58025	Moderate predictive error
F-statistic	50.580	Strong model fit
Significance (p-value)	<0.001	Statistically significant relationship
Unstandardized B (SE enablers)	0.650	Each unit increase in SE enablers raises SE processes by 0.65 units
Standardised Beta (SE enablers)	0.769	Strong effect size of SE enablers on SE processes
t-value (SE enablers)	7.112	High confidence in SE enablers as a predictor
Significance (SE enablers)	<0.001	SE enablers are a statistically significant predictor

While the proposed maturity model was designed to reflect the established categorical structure of models such as CMMI, the survey results highlighted variability in the degree of knowledge and implementation of SE processes and SE enablers. This suggests that, in practice, maturity in the CE industry does not always progress in neat, discrete steps but often lies along a continuum. Therefore, it is appropriate to consider a graduated scale in future model refinements, where maturity levels may be expressed as ranges or intervals that capture the spread of practices across different organisations. Such an approach would preserve categorical levels' comparability while acknowledging the nuanced variability observed in the data.

5.3 Hypothesis Testing

5.3.1 H1: The intersection between PM and SE in the CE industry

CE projects are predominantly delivered using PM principles and guidelines, with the Project Management Institute developing a construction-centred extension for PMBoK. The first hypothesis was that an intersection exists between PM and SE processes and tools in the CE industry. According to the literature survey, studies have been conducted on the interception of SE and PM processes that confirm that there is indeed a point of intersection. The literature survey shows that CE uses traditional PM processes that intersect with SE in key processes. The processes include project planning, risk management, quality management, stakeholder management and baseline control. The literature further confirms this with the construction extension of PMBoK, emphasising processes such as quality management, stakeholder management and risk management.

5.3.2 H2: The maturity of the intersection of PM and SE processes in the CE industry

This hypothesis proposed that the maturity of the intersection of SE and PM in the CE industry is high, which was confirmed by the response to the questionnaire survey. The CE industry has a standard of practice to present at least three solutions to a client with a problem, with the differences highlighted and the recommended solution. The literature shows this is a trade-off analysis and an SE activity. The nature of projects in the CE industry is multi-disciplinary, requiring the collaboration of two or more professional teams. Furthermore, CE practitioners use constantly evolving design modelling software for simulations and analysis. Software such as Revit, Civil3D and Prokon allow CE practitioners to create dynamic models and simulations of the final product [25]. The responses of participants in Q8, Q10 and Q14, with a response

rate predominantly in the managed and optimising range, support this hypothesis. Similarly, responses to project planning and project monitoring (Q4 and Q5) are PM processes, as seen in the literature [22].

5.3.3 H3: The maturity of the SE capability in the CE industry

This hypothesis proposes that the overall maturity of SE in the CE industry is low. The data showed mixed results. The overall maturity of SE in the CE industry was measured using the responses to all the survey questionnaire items. While SE maturity in specific areas such as validation and verification is low, the maturity of enablers, such as simulation, trade-off analysis and integrated product teams, is relatively higher. As expected, the questionnaire items that resemble PM processes are generally high in an industry that operates from a PM perspective. Nonetheless, there is a consensus that the overall maturity of SE in the CE industry is still developing.

5.3.4 H4: The maturity of the application of SE tools in the CE industry

This hypothesis posited that the level of SE enablers within the CE is low. The data showed mixed results, similar to the responses to H3, where SE activities, which resemble PM tools, have a high maturity level. The study found that SE tools such as MBSE, SE management plan, and SE integration (Q6, Q9 and Q12) have a low level of maturity. Similar to H3, the overall maturity of SE activities in the CE industry is still developing.

Based on the literature survey, there are PM tools that CE practitioners are currently using that resemble SE enablers and have the potential to promote the application of SE. BIM can be used to realise the product and process systems to create a structure of requirements and systems definition [29]. It can further document and track changes throughout the project lifecycle. Bentley ProjectWise is currently being utilised in the CE industry as a document control tool that enhances collaboration, optimises workflows and resolves design clashes [37]. The definition of requirements and management is currently being facilitated with dRofus software within the CE fraternity, which can easily be seen as an SE enabler.

5.4 Proposed SE Framework for the Civil Engineering Industry

The statistical analysis from the survey showed a positive correlation between SE maturity enablers and SE maturity processes; maturing the SE maturity enablers will increase the SE maturity process's maturity and SE maturity. The results also showed the SE maturity processes and SE maturity enablers that require improvement in the maturity levels of SE in the CE industry.

Figure 2 shows the proposed framework that aims to advance the SE maturity levels in the CE industry. The literature review yielded PM tools that CE project practitioners use within the CE industry that can be considered tools to be used as SE enablers. BIM and Bentley ProjectWise can be used for process verification, validation, and configuration management. The two software packages can also be used as part of MBSE. dRofus is a PM tool that focuses on requirements development and requirements management in CE projects, making it an excellent tool for further improving SE implementation.

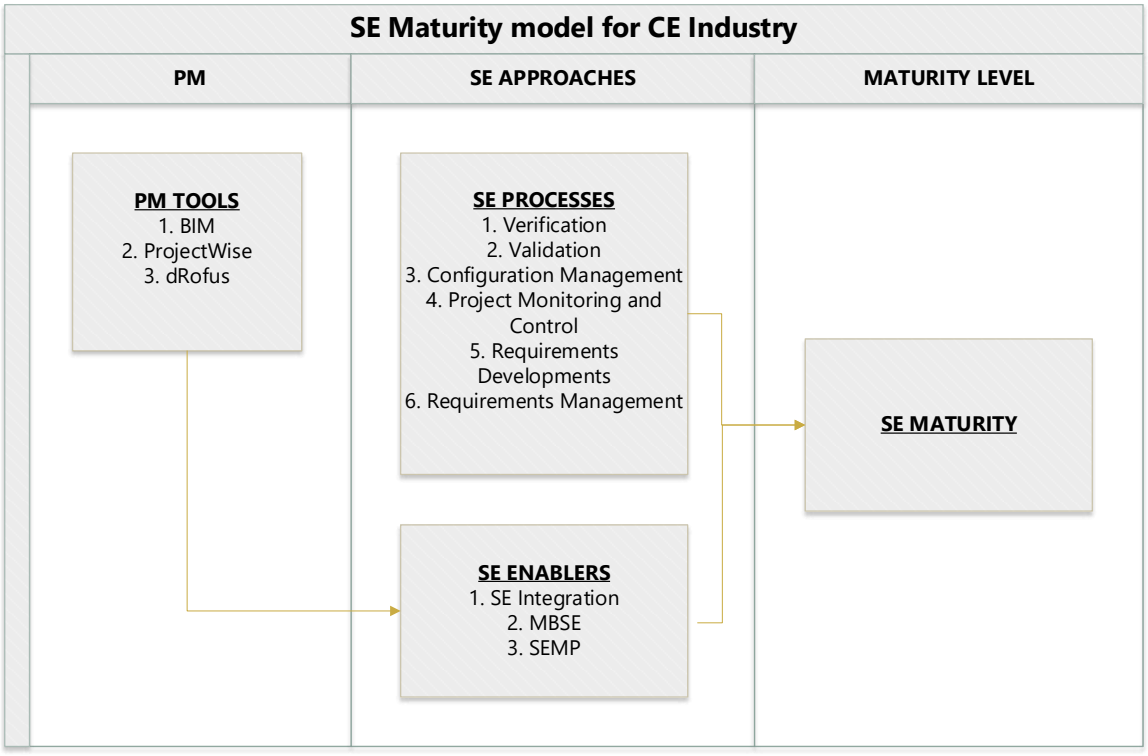

Figure 2: Proposed SE Maturity Model for the CE Industry

The SE processes listed in the proposed maturity model have results from the survey that require improvement. CE project practitioners should consider these processes and the existing CE PM tools to deliver projects. Similarly, CE project practitioners should consider SE integration, an SE management plan, and MBSE as project delivery tools.

6 CONCLUSION

The scope of this study was to scrutinise the synergy between SE and PM in the CE industry, especially how the two disciplines can be combined to drive a project successfully. Reporting at a broad level, the research examined the maturity level of systems engineering in construction engineering. First, the level of maturity concerning those high-maturity processes and tools where SE and PM meet was established. It also identified a few areas that need attention, especially in terms of more formal PM tools that might enhance SE and include SE processes and SE enablers in what is presently called project management. Addressing this gap could go a long way in tremendously improving SE in CE, especially for large and complicated projects. It also showed that the unfamiliarity of many CE project practitioners with SE frameworks, tools, and methodologies prevented them from fully taking advantage of the potential of SE.

Thus, it is implied in this study's literature that the CE industry should consider adopting more formal SE processes, such as Verification and Configuration Management, integrated into their PM frameworks to ensure that their project execution is consistent and rigorous. To further strengthen the integration of SE, practitioners should consider using PM tools such as BIM, ProjectWise, and dRofus, which facilitate SE processes and enhance project data management and flows. These tools provide a platform for improving collaboration, transparency, and efficiency across project teams. Finally, organisations must develop systems that continuously monitor and evaluate their SE process, periodic reviews, and updates of the SE-PM integration framework. This will ensure continuity in improvements over time and quick measures to address any new emerging challenges.

An important implication of this study is that the maturity of SE in CE practice should not be seen as strictly categorical. The descriptive and regression analyses demonstrated varying levels of understanding and implementation across different SE processes and enablers. Therefore, the maturity model presented here may be further enhanced by adopting a graduated scale that reflects these variations. This would allow civil engineering practitioners and researchers to identify whether processes are in place and the degree to which they are consistently and effectively applied. Future iterations of the framework should incorporate graduated maturity indicators, enabling a more realistic assessment of SE adoption in practice.

The study targeted CE practitioners in South Africa's consulting engineering space. As such, the findings may not represent the voice of the entire CE fraternity in the country. Survey questions were also put in terms understood by PM practitioners and shared only with a targeted group, which may have restricted the data collection. Future studies could explore how the proposed frameworks apply to specific categories of CE projects, such as megaprojects versus different-sized infrastructure developments. In addition, knowledge concerning SE processes and terminologies within the CE industry is another aspect of research that may yield a further understanding of how mature SE is in CE.

ABSTRACT

The adoption of the quality fourth industrial revolution (4.0) technologies opens numerous options for enhancing quality management in the construction sector. Small and Medium Enterprises (SMEs) in South Africa encounter various hurdles when using these modern technologies. The research study assesses the barriers to the adoption of the quality fourth industrial revolution (4.0) in the construction industry by Small and Medium Enterprises (SMEs). This research employed a systematic literature review (SLR) methodology in finding related barriers in implementing the quality fourth industrial revolution (4.0) technologies in the construction sector. Furthermore, the research study aims to provide insights on challenges in enhancing the construction SMEs in South Africa. Overcoming these barriers is vital in improving the state of SMEs in the South African construction industry. The research study findings highlight inadequate digital technologies, shortages in skilled workers, financial limitations, and regulatory complexities.

Keywords: Quality 4.0, SMEs, Construction Industry, Digital Transformation

1 INTRODUCTION

The construction sector plays a crucial role in global economic expansion and infrastructure advancement. In South Africa, Small and Medium Enterprises (SMEs) constitute a significant portion of this sector, fostering job creation, innovation, and local development [1]. Nonetheless, the sector encounters ongoing difficulties such as low productivity, quality concerns, and ineffective procedures. To tackle these difficulties, moving from traditional quality management to Quality 4.0 by incorporating cutting-edge technologies within the framework of the Fourth Industrial Revolution (4IR)—commonly known as Quality 4.0 when related to quality management—means switching from manual procedures and human-centred quality assurance to automated, data-driven methods [2]. The integration of Quality 4.0 technology in the construction sector has therefore great potential to improve project quality, efficiency, and safety as several case studies from leading companies have highlighted the immediate advantages of adopting these technologies [3]. However, in this context, SMEs encounter various barriers that impede the efficient implementation of Quality 4.0 technologies. These barriers comprise a lack of awareness, inadequate digital infrastructure, a deficit of skilled workers, and intricate regulatory frameworks, among various others. Grasping these challenges is vital for enabling the effective adoption of Quality 4.0, which is crucial for improving the competitiveness and sustainability of SMEs within the South African construction sector [4].

The advancements and innovations of Quality 4.0 technology are expected to support small and medium construction enterprises in South Africa with the aim of making them more resilient and competitive on the market. Although research on 4IR and digital transformation is growing, investigations into the adoption of Quality 4.0 by SMEs in the construction sector—particularly within a developing context such as South Africa—are still scarce. Many current studies typically emphasise large companies or industrial sectors [5]. This study therefore evaluates the barriers to the adoption of Quality 4.0 by small and medium-sized construction enterprises in South Africa via a systematic literature review (SLR). The study aims to offer practical insights by identifying and classifying the main challenges, which can guide policy, industry strategies, and future research avenues. By doing this, the study adds to the expanding knowledge on digital transformation in construction quality management and aids the progress of SMEs within the changing industrial environment.

1.1 Quality 4.0: Concept and Relevance

Quality 4.0 embodies the fusion of Fourth Industrial Revolution (4IR) technologies with established quality management practices. The 4IR includes digital technologies such as Artificial Intelligence (AI), Internet of Things (IoT), Big Data Analytics, Machine Learning, Cloud Computing, and Cyber-Physical Systems to improve quality control and decision-making processes [6].The initiatives for quality that are used globally include Total Quality Management, Six Sigma, Lean Sigma, and Quality by Design. All these actions for quality were controlled by some of the well-recognised experts such as Deming, Juran, Shewhart, Taguchi, and others. They developed the foundation for a quality method that is practiced in businesses and sectors of community service. The main goal of Quality 4.0 is to transform quality management from a reactive approach to a predictive one, facilitating real-time monitoring, data-driven insights, and ongoing improvement [7].

Within the construction sector, the integration of Quality 4.0 technology in the construction sector has great potential to improve project quality, efficiency, and safety, and gain a competitive advantage. Quality 4.0 has the capability to tackle ongoing issues such as inadequate productivity, delays in projects, budget excesses, and quality shortcomings. Technologies such as Building Information Modelling (BIM), sensor networks, and digital twins

are being utilised more frequently to enhance construction processes, minimise human mistakes, and guarantee quality standards [8].

1.2 Embracing Quality 4.0 in Construction

Quality 4.0 is regarded as an interesting and attractive phenomenon. It includes the use of applications and tools of Industry 4.0 in the creation of an environment with good output in the construction industry. This phenomenon also involves the use of applications of new magnitudes and scopes of design, construction, and management of tasks related to construction [2]. However, worldwide, the construction industry has been tardy in embracing Quality 4.0 technologies in comparison to manufacturing and other sectors. This is due to the fragmented nature of the industry, which is dependent on manual labour, and its project-oriented character. Although large companies may possess the resources to invest in digital transformation, small and medium enterprises frequently face financial and technical limitations [9].

The construction industry faces challenges related to productivity, work organisation, improvement of productivity, and management of processes. Industry 4.0 provides measures to overcome these challenges. Hence, Quality 4.0 uses tools of industry 4.0 that help in making correct decisions, planning, improving on-site productivity, organisational work, using cutting-edge tools, and managing processes [1]. Recent research emphasises that implementing Quality 4.0 in construction can result in better project outcomes, increased collaboration among stakeholders, and anticipatory quality assurance. Nonetheless, these advantages are not uniformly shared, especially in developing nations, where the lack of digital infrastructure and access to skilled workers poses considerable challenges [5].

1.3 Challenges Facing SMEs in Digital Adoption

Small and Medium Enterprises (SMEs) form the foundation of numerous economies, including the construction industry in South Africa. A major challenge in digital adoption comes from the nature of a lot of small and medium enterprises that are labour-intensive and have an aged workforce in most developing countries. Although SMEs are economically important, they also frequently encounter other distinct difficulties regarding digital transformation. These challenges encompass insufficient financial resources, absence of technical skills, poor access to digital tools, and reluctance to change stemming from organisational culture [10].

In the realm of Quality 4.0, small and medium-sized enterprises (SMEs) face additional challenges due to the intricate task of merging various technologies and synchronising them with current quality systems. Research indicates that SMEs face challenges in grasping the strategic importance of digital quality management, which results in insufficient investment in innovation and training. Understanding global trends and learning from effective implementations can provide significant insights for SMEs in the South African construction industry as they navigate the barriers and potential of Quality 4.0 adoption [10].

1.4 The South African Construction Industry Context

To implement Quality 4.0 in the construction SMEs in South Africa, there is a need to understand the aspect of business development and current market trends in the country. The construction industry in South Africa significantly contribute to the country’s economy and boost GDP which provide jobs to many people and stimulate innovation in the construction sector [4]. However, South Africa's construction industry is characterised by significant informality, a lack of skills, regulatory hurdles, and inconsistent economic circumstances. Businesses of this size in this sector are especially susceptible to these systemic problems. The adoption of digital technology is also hindered by inconsistent internet access, expensive technology, and insufficient government backing for digital advancements in construction [11].

Although there are national initiatives aimed at enhancing readiness for 4IR through policy and infrastructure investments, numerous SMEs still lack awareness or readiness for Quality 4.0 execution. As a result, many businesses are struggling to survive and grow. Several studies demonstrate that there is a positive impact of technological implications on the performance of small and medium construction enterprises. Gaining a deeper insight into the particular barriers they encounter is therefore essential for developing focused strategies that aid their journey towards digital transformation, enhance the brand image of the company, attract new customers, and enhance customer satisfaction [12].

2 MATERIALS AND METHODS

This research employs a Systematic Literature Review (SLR) method to identify and examine the barriers to the implementation of Quality 4.0 by Small and Medium Enterprises (SMEs) within the South African construction sector. The SLR method provides a systematic and repeatable procedure for collecting, assessing, and integrating existing research results relevant to the study goals. It is especially well-suited for generating theoretical insights in areas that lack sufficient research and integrating dispersed knowledge from various sources [13]. The objectives of the SLR in this study are (1) to determine the common barriers to the implementation of Quality 4.0 in the construction industry, (2) to examine the unique challenges encountered by SMEs during this transition, (3) to situate the results within the South African construction industry. The search strategy was based on an extensive review of literature that was performed using academic databases such as Clarivate Web of Science and Google Scholar. The search focused on peer-reviewed journal articles, conference papers, and relevant grey literature published between 2020 and 2025. The SLR followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) approach, ensuring transparency and replicability in the research process. Search strings such as '"Quality 4.0" AND construction AND SMEs AND barriers' were applied across multiple databases. A total of 186 records were initially identified, 142 remained after duplicate removal, and 38 full-text articles were screened for eligibility, with 34 meeting the final inclusion criteria. Figure 1 visually represents this selection process.

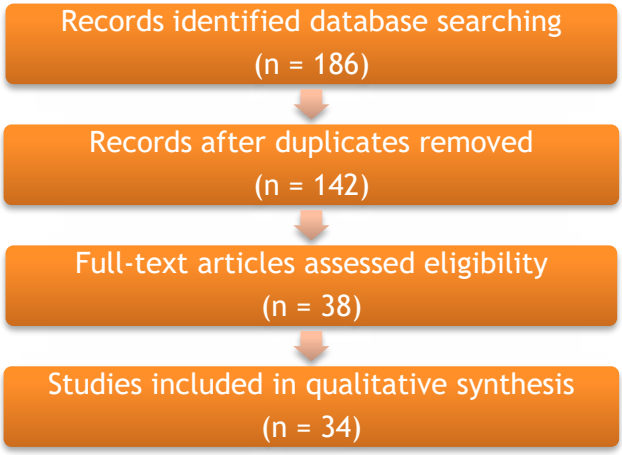

Figure 1. PRISMA flow diagram (Researcher, 2025)

The study focused on research on Quality 4.0 or 4IR technologies in the context of quality management, research addressing SMEs in the construction or related sectors, research published in English between 2020 and 2025, peer-reviewed journal articles, conference papers, and selected grey literature, and research that provided empirical data, frameworks, or conceptual insights on adoption challenges. Relevant studies were first screened based on titles and abstracts. Full-text reviews were then performed for the shortlisted articles. Data

was extracted and coded into thematic categories based on common barriers identified, such as technological limitations, financial constraints, skills shortages, regulatory and organisational challenges. The extracted data were then analysed using thematic synthesis, allowing for the identification of recurring patterns and trends across literature. A qualitative analysis approach was used to interpret how these barriers manifest within the South African context. Each selected study was assessed for quality using criteria such as clarity of research objectives, robustness of methodology, relevance to the research questions, and credibility of data sources. This ensured that the findings synthesized in this review are grounded in reliable and valid evidence.

3 RESULTS AND DISCUSSION

The systematic literature review uncovered multiple recurring barriers that impede the implementation of Quality 4.0 by Small and Medium Enterprises (SMEs) in the construction sector of South Africa. These barriers were classified into four main categories: technological, human resource, financial, and institutional/regulatory. The categorisation of these barriers and their respective sub-barriers is illustrated in Figure 2, providing an at-a-glance view before the detailed analysis of each category.

Technological Barriers	Human Resource Barriers	Financial Barriers	Institutional/Regulatory Barriers
Lack of infrastructure	Skills shortages	High upfront costs	Regulatory complexity
Interoperability issues	Limited training	Ongoing maintenance	Lack of incentives
Cybersecurity risks	Generational gaps	imited funding access	Fragmented policies
Low digital maturity	Brain drain	ROl uncertainty	Procurement barriers

Figure 2. Categorisation of barriers to Quality 4.0 adoption by construction SMEs in South Africa. (Researcher, 2025)

3.1 Technological Barriers

The limited availability of advanced digital infrastructure and resources is a commonly cited obstacle. Many SMEs in the construction industry lack the necessary hardware, software, and connectivity to implement Quality 4.0 technologies, including AI-powered quality analytics systems, Building Information Modelling (BIM), and Internet of Things (IoT) sensors. In rural or impoverished areas, where internet connectivity and technical support are unreliable, this technological disparity grows larger [4]. Furthermore, there are significant implementation barriers due to interoperability issues and the problems of integrating new technology into current systems. SMEs usually employ outdated or basic quality management systems that are incompatible with contemporary digital tools, which leads to disruptions in operations and greater expenses for implementation. The adoption of cloud-based or sensor-driven platforms is made more difficult by legacy systems, which are frequently inflexible and were never intended to be integrated [14].

The absence of platform compatibility and standardisation is another significant obstacle. Although Quality 4.0 technologies include a variety of digital tools and software from many suppliers, the lack of widely recognised standards leads to disjointed systems, higher maintenance expenses, and challenges with data consolidation. For SMEs that depend on smooth operations to preserve dependability and cost-effectiveness, this fragmentation reduces the perceived value of digital integration [15]. Additionally, cybersecurity concerns

are becoming a critical technological barrier. SMEs often operate with minimal IT governance or dedicated cybersecurity infrastructure, making them vulnerable to data breaches and cyberattacks. The digitalisation of quality processes requires the handling of sensitive project data, and without robust security protocols, many SMEs hesitate to migrate to digital platforms out of fear of data loss or reputational damage [15].

Another obstacle is the pace of technological advancement. SMEs find it challenging to dedicate themselves to a particular technology due to the quick development of digital tools causing them to often shy away from investing in Quality 4.0 technology by concerns about obsolescence and the unpredictability of long-term support for instruments. This is further worsened by minimal access to technical support after implementation and a lack of vendor transparency [16]. Lastly, low digital maturity within many SMEs affects their ability to evaluate, select, and implement suitable technologies effectively. Many organisations lack a digital transformation roadmap or strategic alignment between technology and business goals, resulting in expedient or misaligned adoption efforts. Without structured digital readiness assessments or expert guidance, SMEs risk investing in inappropriate or underutilised technologies [17].

3.2 Human Resource and Skills Barriers

The evaluation consistently pointed out a lack of qualified staff as a significant challenge. The implementation of Quality 4.0 necessitates a workforce skilled in data analysis, digital solutions, and new technologies. Nevertheless, numerous SMEs in the South African construction sector function with a limited, generalist team that does not possess specialised digital expertise [18]. This gap in skills is additionally aggravated by insufficient training and awareness. Various studies have observed that owners and managers of SMEs frequently possess a limited understanding of Quality 4.0 and its strategic significance. Lacking this understanding makes it challenging to justify investments or inspire employees to embrace digital practices [19]. Moreover, the aging workforce in many South African construction SMEs further complicates the situation. Older employees may lack exposure to digital tools and often demonstrate resistance to learning new systems, preferring traditional methods that do not rely on automation or data analytics. This generational skills gap reduces the likelihood of widespread digital adoption without targeted retraining initiatives [19].

The absence of structured digital competency development pathways within SMEs exacerbates the challenge. Unlike larger firms that may invest in formal training programs, partnerships with academic institutions, or internal upskilling strategies, most SMEs lack the resources or long-term planning capacity to systematically build digital proficiency. Employees are often trained informally, and, on the job, limits the depth and scope of digital knowledge transfer [20]. Additionally, the lack of access to affordable and context-specific training poses a significant challenge. Available training programs are frequently designed with large-scale enterprises in mind, overlooking the practical constraints and needs of SMEs. The technical language, costs, and delivery modes of such programs often act as barriers rather than enablers, particularly for SMEs in remote or underserved areas [21].

Another dimension is the brain drain phenomenon, where skilled professionals seek opportunities in more advanced industries or abroad, leading to a scarcity of talent in the local construction sector. This migration further intensifies the difficulty of recruiting and retaining qualified personnel capable of managing and deploying Quality 4.0 technologies effectively [22]. Lastly, limited collaboration between academia and industry prevents SMEs from benefiting from recent research, knowledge exchange, and student internships that could otherwise bridge the skills gap. Without institutional support for collaborative programs or incentives for knowledge sharing, SMEs remain isolated from the technological and educational ecosystems necessary for building a digitally capable workforce [23].

3.3 Financial Barriers

One important and recurring element in literature was found to be financial constraints. SMEs typically operate with tighter budgets and less access to capital than larger corporations. One of the biggest barriers to Quality 4.0 implementation is the high upfront costs of purchasing new technology, hiring skilled personnel, and restructuring existing systems [24]. Additionally, SMEs are hesitant to adopt Quality 4.0 due to the perceived risk of investing in unproven or unfamiliar technology, especially when there is uncertainty about immediate financial returns. This is particularly important in the construction sector, where operations are extremely cost-sensitive and cash flow is project-based [25].

A major obstacle is the continuous operations and maintenance expenditure associated with Quality 4.0 technology, which go beyond the original investment costs. These include cybersecurity precautions, technology updates, software subscription fees, and technical support services, all of which SMEs with narrow profit margins may not be prepared for. The financial burden is further increased by the expense of training employees to use new digital systems, particularly when productivity losses during the transition phase are considered [26]. SMEs also have limited access to outside funding, especially in the construction industry where lenders and investors view financial risk as high. A lot of SMEs do not possess the financial records, collateral, or credit history needed to get loans or investment capital. Their activities are therefore frequently financed by short-term project profits, which leaves limited opportunity for strategic investments in digital transformation [27]. Furthermore, because of complicated application processes, a lack of knowledge, or a misalignment with the requirements of the construction industry, state financing and incentive programs meant to encourage digitalisation sometimes fall short of reaching SMEs. When assistance programs are offered, they frequently target high-tech sectors or businesses located in cities, leaving SMEs in the construction industry, particularly those in rural regions, without sufficient funding [27].

The challenge of justifying Quality 4.0 technology's return on investment (ROI) is another significant problem. SMEs may find it difficult to defend investments that do not yield immediate or noticeable returns because many of the advantages of digitalization such as higher quality, better risk management, or improved decision-making are indirect and long-term. Management is unable to allocate funds to long-term digital plans because of this uncertainty [28]. Furthermore, SMEs frequently lack budgeting and financial planning skills, which makes it difficult to make strategic investments in Quality 4.0. Due to their informal operations and lack of formal administrative frameworks, many SMEs find it challenging to assess cost-benefit situations or devote resources to innovation. The gap between the potential of technology and its actual execution is considerably magnified by the absence of financial literacy in digital investment decisions [17].

3.4 Institutional and Regulatory Barriers

Significant barriers to compliance were also noted, including the complexity of rules and the absence of supportive policies. There are possible misunderstandings about the use of digital technologies for quality assurance because the South African construction industry is subject to several standards and compliance requirements. In a digitalised setting, many SMEs find it difficult to understand how current construction and quality management standards apply, especially when legislative frameworks have not kept up with technological changes [29]. Moreover, a lack of government incentives or support initiatives for digital transformation for construction SMEs diminishes the drive for technology adoption. Although broader 4IR strategies exist at the national level, their implementation at the SME level is still limited and lacks sufficient resources. Government-led efforts often focus on larger corporations or tech-based industries, failing to provide tailored interventions that address the specific operational realities of construction SMEs [29].

Fragmentation of regulations makes the issue worse. Construction, labour, and technology rules are governed by a variety of government agencies and business associations, which frequently leads to conflicting or overlapping directives. Due to their limited administrative resources, SMEs have been having trouble navigating this intricate terrain. Decision-making is delayed, uncertainty is increased, and innovation is discouraged when there is no single legal framework for the digital transformation of the construction industry [30]. Additionally, there is a conspicuous absence of institutional coordination and competence to facilitate the implementation of Quality 4.0. The infrastructure and experience needed to provide advice on digital technologies or quality management systems are sometimes lacking in public institutions tasked with assisting SMEs. This results in wasted opportunities for collaborations, technical support, and initiatives to increase capacity that may facilitate more seamless adoption of Quality 4.0 [31]. Furthermore, the use of digital quality tools like digital twins, IoT-based monitoring systems, and Building Information Modelling (BIM) is still not completely accommodated or mandated by building code and procurement procedures in the construction industry. Since immediate adherence to established norms is still adequate for obtaining contracts, SMEs are unlikely to change their current practices in the absence of regulatory pressure or incentives to adopt these technologies [32].

Figure 3 presents the conceptual framework mapping the interdependencies among the identified barrier categories. The diagram illustrates how financial constraints directly influence both technological adoption and workforce development, while institutional and regulatory fragmentation exacerbates each of these dimensions. This interconnected structure underscores the need for coordinated interventions rather than isolated solutions.

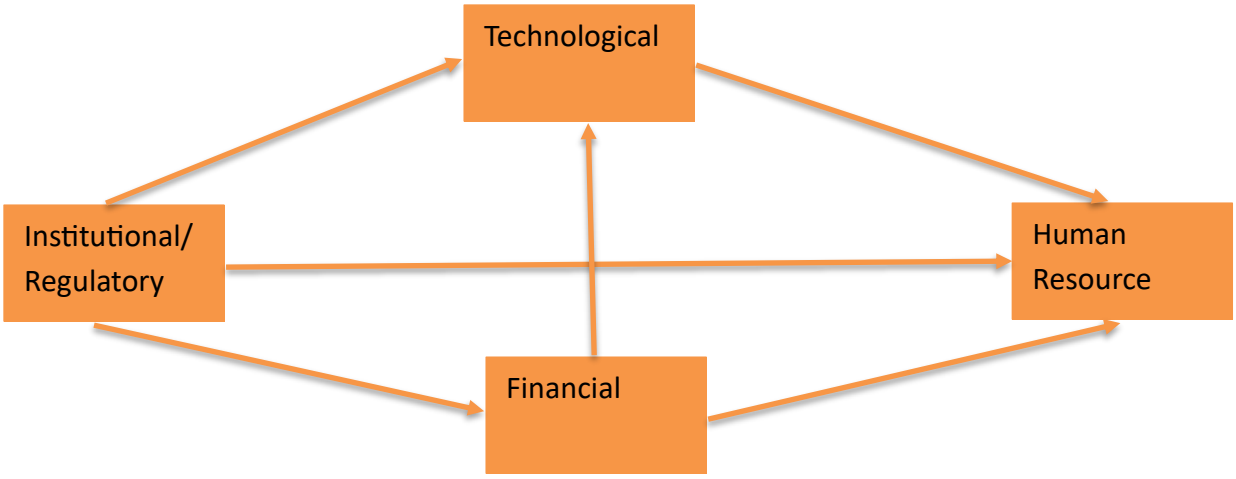

Figure 3. Conceptual framework of interdependencies among barriers to Quality 4.0 adoption by construction SMEs in South Africa.

(Researcher, 2025)

In many cases, SMEs also face institutional biases and access barriers in public procurement processes. Requirements for digital certification, advanced compliance documentation, or e-tendering systems, though intended to streamline procedures, can inadvertently exclude smaller firms lacking the digital infrastructure or administrative know-how to participate. This institutional exclusion limits market access and undermines the competitive positioning of SMEs attempting to embrace Quality 4.0 [33]. The lack of interaction between policymakers and SME stakeholders when developing digitilisation initiatives is another institutional obstacle. The distinct limitations and viewpoints of construction SMEs are frequently disregarded in national policy agendas because of a lack of proper representation or

engagement. Ineffective implementation methods, poorly targeted funds, and misplaced priorities are the outcomes of this top-down strategy [34].

3.5 Discussion

The findings provide a comprehensive perspective of the intricate barriers to the adoption of Quality 4.0 among Small and Medium Enterprises (SMEs) in South Africa's construction sector. The technological, human resource, financial, and institutional problems are all intertwined, resulting in a complicated landscape that prevents SMEs from properly moving to the digital age. One of the most significant findings is the interconnectivity of the identified barriers. For example, inadequate financial resources prevent SMEs from investing in new technologies or training programs. This, in turn, perpetuates the digital skills gap and impedes the capacity to implement advanced Quality 4.0 tools such as BIM, IoT-based sensors, and AI-powered analytics. Furthermore, the lack of financial literacy and strategic planning among SMEs reinforces the problem, resulting in fragmented or ineffective implementation of digital technologies.

From a technological standpoint, access to digital infrastructure alone is insufficient. Even if SMEs have basic internet access or technology, they frequently lack interoperability, cybersecurity protection, and digital maturity required to integrate Quality 4.0 tools. This creates a scenario in which SMEs either underuse or misapply technology, resulting in low ROI and reinforcing resistance to further digital transformation. In terms of human capital, barriers go beyond the availability of skilled workers and include organisational culture and leadership mindset. SME owners and decision-makers frequently misunderstand the strategic importance of Quality 4.0, seeing it as a technical or IT concern as opposed to a driver for business competitiveness and sustainability. This misconception results in a poor priority of digital projects, which adds to stagnation in innovative efforts. The institutional and regulatory dimensions show a systemic inconsistency between national 4IR strategies and their practical implementation at the SME level. Despite the fact that policies exist on paper, their implementation into practical assistance for construction SMEs remains limited. Regulatory fragmentation, lack of guidance on compliance with digital standards, and inadequate public assistance channels all contribute to the implementation gap. Furthermore, procurement methods that reward digitally savvy enterprises may inadvertently marginalise conventional SMEs, contributing to industry inequality. Furthermore, the construction industry's project-based and risk-averse attitude adds an extra degree of complication. SMEs are hesitant to make investments in long-term digital transformation when immediately noticeable financial rewards are uncertain, and contracts are frequently awarded based on cost rather than innovation. Many SMEs opt for remaining within the status quo in the absence of systemic incentives, market demand, or contractual responsibilities for digital compliance.

The study has a broader implication. The digital gap in the construction sector shows much bigger disparities in socioeconomic status in South Africa. Rural and peri-urban SMEs suffer disproportionately because of poor infrastructure, inadequate institutional assistance, and exclusion from digital finance schemes. To bridge this gap, inclusive and context-sensitive interventions need to be implemented in addition to conventional policy recommendations. Nonetheless, the research also recommends numerous paths forward. These include sector-specific training programs, public-private collaborations to help SMEs become digitally ready, and the promotion of pilot projects that demonstrate the real benefits of Quality 4.0. Industry associations, academic institutions, and technology providers can all help to create networks that allow dissemination of knowledge and capacity development for SMEs. Ultimately, the effective implementation of Quality 4.0 by South African construction SMEs necessitates a systematic and coordinated approach. It is not enough to simply provide new technologies; it is also necessary to create the conditions—financial, institutional, human, and technological—

that will allow SMEs to absorb, adapt, and sustain these innovations. A multifaceted strategy that combines policy reform, targeted finance, capacity building, and awareness raising is required to overcome the complex and layered barriers discussed in this study.

4 CONCLUSION

Small and Medium-sized Enterprises (SMEs) in South Africa's construction industry have a significant chance to improve quality control, operational effectiveness, and industry competitiveness by implementing Quality 4.0 technology. However as shown by this study, which is based on a thorough examination of the literature, SMEs encounter a complicated network of interconnected institutional, financial, human resource, and technological barriers that seriously impede this digital transition. Regulatory fragmentation, insufficient digital literacy, restricted financial capacity, restricted access to digital infrastructure, and inadequate institutional support are some of these issues. While personnel limits result from a lack of digital skills and inadequate training resources, technological constraints are exacerbated by cybersecurity concerns, lack of interoperability, and poor digital maturity. In terms of finances, SMEs find it difficult to secure capital and defend investments in technology with dubious returns. Additionally, SMEs are further excluded from national digital agendas due to legislative gaps and misaligned 4IR initiatives. The potential advantages of Quality 4.0—such as real-time monitoring, predictive analytics, and enhanced quality outcomes—remain significant despite these obstacles. A concerted, multi-stakeholder effort incorporating customised government incentives, inclusive policy reforms, public-private training programs, and technology solutions customised to SME restrictions would be necessary to realise this promise. South African construction SMEs can be better equipped to embrace and maintain Quality 4.0 innovations by removing these systemic and structural barriers, which will support the larger objectives of long-term sustainability, industrial transformation, and economic resilience.

ABSTRACT

Stellenbosch, a small town in South Africa (SA), faces severe traffic congestion and parking challenges due to rapid growth and heavy reliance on private vehicles. This research investigated the feasibility of implementing Park-and-Ride (PR) facilities as remedial measures. Key factors for the success of the system, including optimal location, public transport integration and user perception, were identified through literature review and traffic data analyses. The Hub-and-Spoke Model was used to propose a central transit hub and three PR locations. These locations were strategically selected based on Floating Car Data (FCD) from TOMTOM Move, through which the routes with the highest inbound traffic flows were identified. To ensure effective design, implementation and operation, the 6S methodology was adapted to the service delivery industry. This framework emphasised safety, efficiency and sustainability. The results highlighted the potential of PR facilities to reduce congestion, improve accessibility and promote sustainable, people-centric transport planning.

Keywords: Park-and-Ride, Congestion, Sustainable Transport, Hub-and-Spoke Model, 6S Methodology

1 INTRODUCTION

Stellenbosch, a historic university town in South Africa's (SA's) Western Cape Province, experiences persistently high congestion levels and worsening parking shortages [1,2]. Population growth, urban densification and the rapid growth of Stellenbosch University (SU) have intensified the pressure on the limited existing transport infrastructure [3]. The Stellenbosch Comprehensive Integrated Transport Plan (CITP) highlights the importance of reducing private vehicle dependence, expanding the public transport network, and encouraging Non-Motorised Transport (NMT) modes [4].

Park-and-Ride (PR) facilities have proven to be effective in diverting commuter traffic in international contexts [5], yet their application in SA remains limited and typically linked to rail-based transport systems. This creates significant challenges relating to the scarcity of industry standards in the design and implementation of these facilities. Stellenbosch's dense urban layout and dispersed commuter trip origins present a unique challenge for PR implementation, limiting the feasibility of rail-based PR facilities and necessitating the use of bus transport, NMT, or micromobility solutions. The introduction of PR facilities for the Stellenbosch transport network would, consequently, not be similar to design considerations of other similar national projects. This elucidates the need for more detailed planning, underpinning the research conducted.

The paper assesses the feasibility of implementing PR facilities as a solution to Stellenbosch's growing congestion levels and parking shortages through the use of traffic demand analyses, spatial modelling and operational planning frameworks.

2 RESEARCH OBJECTIVES

The study set out to:

- Gain an extensive understanding of PR facilities.
- Review existing facilities, key design features and important considerations.
- Analyse Stellenbosch's congestion and parking challenges.
- Determine optimal PR facility locations based on traffic movement patterns and spatial model guidelines.
- Advocate design, implementation and operational guidelines for PR facilities.
- Provide recommendations for integrated implementation.

3 BACKGROUND TO STELLENBOSCH

3.1 The Town

Stellenbosch is widely known as a student town with Stellenbosch University (SU) largely intertwined into the layout of the town. Several arterial roadways surround Stellenbosch, merging into one arterial, commonly known as the Adam Tas Corridor (R44). The R44 travels through Stellenbosch and collects traffic from the R310, M12, R44, and R304. It thus predominantly serves a mobility function in the roadway system. The major roadways and the origin of these roadways are shown in Figure 1.

Stellenbosch has been experiencing an ever-increasing population, particularly due to the development and expansion of SU [3,6]. With the rapid development and restricted room for expansion, the town has been subject to high levels of congestion and a severe shortage of parking spaces [3,4,6].

Figure 1: The main points into Stellenbosch

The CITP of Stellenbosch highlights the prevalence of the aforementioned issues [4]. The document details the Travel Demand Management (TDM) objectives stated in the 2016 CITP, which include:

- Reducing demand for vehicle use.
- Supporting investment in public transport.
- Promoting NMT.
- Reducing the environmental impact of private transport.

The severe congestion levels and large travel time delays are not only a constant frustration for commuters, but also a large detriment to the economy in terms of hours of potential work lost [7]. The inhibited mobility is further worsened by the parking demand far exceeding the available supply [3]. The consequence of this is that illegal and curb parking have become a part of the Stellenbosch experience, forcing many to accept the accompanying fines. These challenges are recognised by the population, wherein household surveys revealing that congestion was the third most prominent transport problem, with parking ranking ninth and the top two both being related to insufficient public transport systems [1].

3.2 The Transport Dynamics of Stellenbosch

Stellenbosch is subject to a disproportionately high number of vehicles on its transport network [8]. The modal split indicates a heavy reliance on private transport, revealing that 86.6% of passengers are transported by light vehicles [6]. Although e-hailing could bring some relief to the limited parking pressure, it does not alleviate the severe congestion levels Stellenbosch continues to experience. Notably, a large of portion of the road users are of the 20 to 30 age group [6], further demonstrating the impact the student population has on the transport network. As a result, solutions to Stellenbosch's transport challenges cannot be developed in isolation; addressing the challenges requires an integrated approach that incorporates SU as a key stakeholder and influencer in shaping travel demand.

3.3 SU Shuttle Service

The SU shuttle service is provided to students and staff to facilitate seamless traversing between various destinations and decentralised parking facilities [4]. As the primary form of

public transport offered by SU, it is a key element of the transport network in the area. The day services are offered on fixed routes, free of charge to all students and staff [9]. This typically operates using designated routes from 07:30-17:00 (during the academic term), with a 15 to 30-minute service headway. Evening services are provided via a booking system in which students/staff are transported to specific destinations within a 6-kilometre radius of central Stellenbosch [10]. Payment is done through a student or staff card or through the booking system for shuttle reservations.

This service has, however, experienced numerous challenges. Notably, the transport system has failed to develop in the past six years, now servicing fewer areas than it did in 2018 [11]. This is contrary to the preferred future transport scenario highlighted in the CITP of Stellenbosch [4], particularly those related to a modal shift towards public transport and the preferred scenario in which "students mostly use park-and-ride facilities, shuttle bus services or walk/cycle between the university and their places of residence" [4].

The largest challenge is the underutilisation of this service. From February 2024 to August 2024 (i.e., the start of the academic season until the time at which the data was collected), the service recorded 13 790 users boarding the shuttle, with 3 361 boarding in the busiest month, August [12]. The number of students transported from peripheral areas is illustrated in Figure 2. Adjusting for repeat use suggests that less than 1.1% of SU's approximate 38 000 affiliates rely on this service [13]. This underutilisation undermines the vision of the municipality and creates doubt towards the potential for other successful public transport modes without significant changes in how these systems are marketed, operated, and linked to other modes of transport. The 2016 CITP provides insight as to the student travel patterns, stating that the majority of students continue to use private motor vehicles to travel to campus [6], even when travelling relatively short distances [3]. Thus, measures that discourage the use of private vehicles by students have the potential to alleviate congestion levels and parking shortages in the area [6].

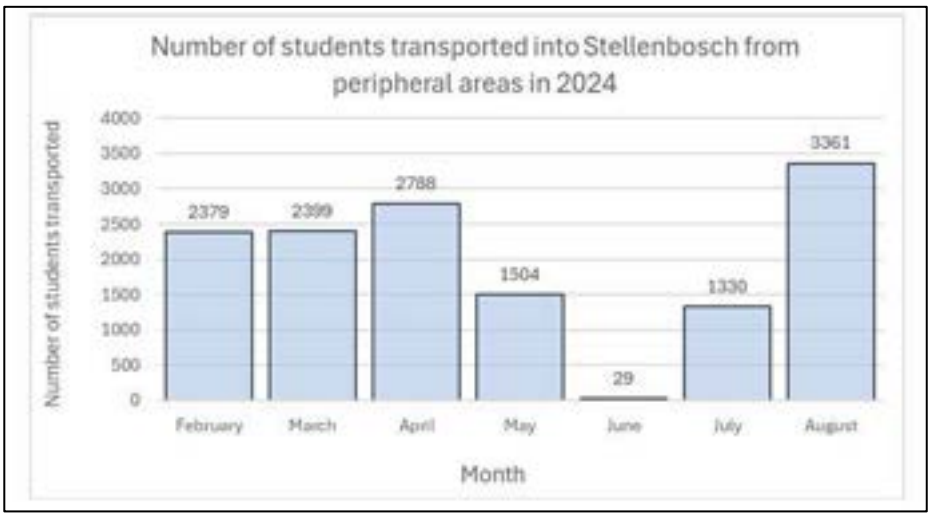

Figure 2: Number of boardings for the SU Shuttle Service in 2024

4 LITERATURE REVIEW

4.1 Parking Choice Behaviour

The search for available parking spaces is a significant contributor to urban congestion. This process increases vehicle traffic in the area, energy usage, vehicle emissions, and the time wasted by drivers looking for parking spaces [14]. The factors that influence a road user's parking location choice are heavily researched due to their complexity and variability in

different environments [15]. These factors, according to Hu, Bao, and Ma [16], can be separated into two distinct categories, namely: external influence factors and attribute factors. These factors are interlinked, adding to the complexity of the design. In layman's terms, different road users have distinct and diverse preferences, characteristics, or motivations in terms of the interaction of cost, parking duration, and time implications in making a decision.

The typical external factors that influence parking choice behaviour include:

- Walking distance to destination from parking area [15].
- Travel time [15].
- Parking time [16].
- Parking fees and related costs [17].
- Security and/or Safety [16].
- Parking space availability: The amount of time it takes someone to find a parking spot [18].

The attribute (personal) factors that may influence parking choice behaviour consist of, but are not limited to, variables such as the purpose of the trip as well as the demographics of the road user [16]. These factors are also relevant to the design of PR facilities, in terms of both the appeal of the parking facilities as well as the aspects that may motivate road users to shift from their traditional transport mode to the newly implemented system.

4.2 PR Facilities

PR facilities have been implemented successfully worldwide, particularly in dense urban areas such as Paris [5]. In essence, these facilities are large parking infrastructures placed strategically to intercept private vehicle users before entering heavily congested urban areas. The PR facilities contain connections to public transport systems, allowing commuters to travel to a designated PR facility, leave their vehicle (or be dropped off), and make use of a means of public transport to complete the remainder of their journey [19]. These facilities can be used as a Travel Demand Management (TDM) tool to convert full-trip private vehicle users into part-trip users, which in turn reduces the number of vehicles entering a city, Vehicle Kilometres Travelled (VKT), urban congestion levels, and parking pressure [5].

4.2.1 Types of PR Facilities

There are several distinguishing characteristics that help identify differences between the types of PR facilities. These characteristics influence the effectiveness of the relevant PR facility, and include factors such as size, geographic location, associated public transport mode, the service level of the facility, and whether they serve an origin or destination function [5]. In terms of the geographic location of the PR facility, an urban fringe facility is most suitable for the Stellenbosch context due to the space limitations and the large multi-directional influx of vehicles.

The lack of rail infrastructure and the densified layout of central Stellenbosch make the bus system the most viable public transport mode to service the PR facility. Due to the existing SU Shuttle Services and taxi-bus industries, integrating the new system with these services is vital for effective social adoption and improved efficiency of the entire transport network.

4.2.2 Benefits related to PR Facilities

PR facilities provide an opportunity for multiple system-level benefits, including:

- **TDM tool:** Reduces peak-hour congestion and VKT [20].
- **Equitable accessibility:** Allows for local and regional access to transit systems [19], linking remote and rural areas to central urban areas for all classes.

- **Cost optimisation:** The use of public transport can assist individuals in avoiding high parking costs associated with urban centres, as well as reduced travel costs if the system is priced correctly [21].
- **Environmental improvements:** Reduces emissions through decreased private vehicle usage and an increase in modal shifts towards public transport [22].

These benefits provide a holistic solution that improves urban accessibility and promotes the use of public transport and micromobility within urban areas. This, in turn, could lead to the construction of more sustainable, green cities. These potential outcomes support Stellenbosch Municipality's car-free, public transport-centric aspirations outlined in the CITP. Additionally, the benefits are significant in terms of the potential to completely shift the culture of private vehicle reliance in Stellenbosch if implemented and rolled out correctly. The role of SU in this shift cannot be understated. With a significant student population, there is a large number of potential NMT and public transport users that could facilitate in reimagining the transport network, given that the appropriate services and facilities are provided [6].

4.2.3 Systemic and Contextual Challenges for PR Facilities

Despite the benefits of PR facilities, some challenges may hinder its successful implementation:

- **Lack of standardised design methodologies:** Most research is extremely case-specific, accredited mainly due to the multi-variable approach required for the design of these facilities [20].
- **Public transport reliability:** Effective transfer of modes at the facilities requires safe, reliable, affordable, and efficient systems.
- **Cooperation of the minibus taxi industry**: The minibus taxi industry accounts for approximately 63% of the modal split in Stellenbosch [4]. Integrating new public transport systems into the network may lead to retaliation from the existing industry.
- **Social constraints**: Ensuring the public transport system and the parking area are safe is vital to ensure the facility is adopted successfully [8].
- **Misuse**: Unaware misuse of the parking area is common and can lead to decreased parking availability for those who make use of the facility [5]. Informal businesses may also form in and around the facility, potentially impacting the cleanliness, safety, and societal perspective of the facility.

These challenges make predicting the impact on congestion alleviation, traffic conditions, and parking pressure difficult. Public acceptance and social support are also difficult to predict, making the potential impact even more uncertain. These issues are exacerbated when applying it to the South African context, where PR facilities are uncommon and formal public transport systems are many times perceived to be unsuccessful, and/or operate sporadically.

4.2.4 Factors influencing the effectiveness of PR Facilities

Extensive research on the identification of the location for a PR facility and what factors influence its effectiveness all indicate the need for a multifaceted approach. Some of the factors influencing the potential success of these facilities include:

- User behaviour and willingness of users to shift to new modes [21].
- Parking capacity and availability [5].
- Parking cost structure [22].
- Frequency and cost of public transport service [21].
- Surrounding land use and traffic conditions [22].
- Integration quality between the PR parking area and the public transport systems [20].

The point of intercept, in particular, is specifically impactful in the effectiveness of the PR facility. To successfully implement these facilities, a systems design approach in which one considers the PR facilities as nodes in a broader transport network is essential. The planning and implementation of the facilities and systems must consider technical constraints, social acceptability, and economic viability.

5 METHODOLOGY

The methodology applied in this research identifies suitable locations for the PR facilities, as well as the key factors and considerations necessary for their design.

5.1 The Hub-and-Spoke Model

The Hub-and-Spoke model is a form of network science with numerous applications in logistics, Information and Communications Technologies (ICTs), and transport networks [23]. This model acted as a guide towards the spatial design of the PR facilities. The hub represents a central point, entity, or structure (in this case, the bus terminus in central Stellenbosch). The spokes (often referred to as nodes) are linked radially from this hub, much like a bicycle wheel, and represent entities, structures or organisations linked to the central hub [23]. These nodes represent the PR facilities located on the periphery of Stellenbosch, through which each spoke can interact directly with the central hub.

The application of this model is associated with several advantages:

- **Centralised coordination and communication:** The system connects all peripheral facilities to a central node, reducing overlapping bus routes and trip redundancies [23].
- **Optimise resource usage:** The hub has a holistic view of the entirety of the network, allowing for continuous, efficient allocation of resources. With the use of information technology, the system could be responsive in real time, lowering time in transit time and creating an adaptable transport network [24].
- **Cost Efficiency:** The logistical efficiency, coordination, and elimination of unnecessary trips reduces costs and maximises economic performance [24].

However, limitations to the model include:

- **Taking care in electing the central hub location:** The bus terminal is the centre for the logistical operations. For it to be as efficient as possible, it should be accessible, expandable in the future, adaptable, and aligned with the nodes in the system [24].
- **Dependency on technology:** Technology is vital for system coordination, monitoring, and real-time adaptability [23].
- **Clear management strategies:** Effective communication and governing of the multi-node system requires clear management strategies [23].

This model framework formed the basis through which the optimal locations for the PR facilities and transit terminal were selected, allowing for integration into the current mobility network observed in Stellenbosch.

5.2 Desktop Study of Traffic Conditions using FCD

To identify the routes and areas most in need of traffic alleviation measures, and hence determine optimal locations for the PR facilities, Floating Car Data (FCD) from the TOMTOM Move platform was used. FCD is data (location, speed, and destination) produced and collected periodically via probes [25]. The TOMTOM Move platform was utilised to analyse origin-destination (O-D) patterns and traffic volumes based on the key arterial routes into Stellenbosch. Although the model does not directly incorporate public transport into the data, the traffic volumes were used as an indicator for which routes experienced the highest congestion levels. Considering the heavy reliance on private vehicles, the model provides

insight as to which routes could benefit the most from modal shifts towards public transport or other transport alleviation measures.

5.2.1 Study Area and Traffic Gates

Stellenbosch central, including surrounding residential areas (Cloetesville, Kayamandi, Idas Valley, Die Boord, Coetzenburg, and Onder Papegaaiberg) was treated as a singular region to evaluate the directional origin of traffic moving towards this central region. The specified borders of the central region were adopted from a similar model used in the analysis of micromobility within Stellenbosch [26], and are shown in Figure 3.

Figure 3: Regions and Gates used in FCD Analysis in TOMTOM

Peripheral communities like Jamestown/DeZalze and Techno Park were designated as independent zones due to the potential for these areas to contribute to congestion along the R44. The primary directions of traffic movement into and out of Stellenbosch described in Figure 3 were used as screen lines ("gates") to obtain traffic counts on these roadways. The gates used were:

- R310 (De Wijnlanden / Kuils Rivier): Combines all traffic from Polkadraai Road (M12) and Baden Powell Drive (R310).
- R44 (Somerset West / Strand).
- 310 (Franschoek / Kylemore).
- R44 (Klapmuts / Paarl).
- R304 (Brackenfell / Belville / Durbanville).

Short internal trips (<5 kilometres) within the Stellenbosch central region were excluded from the analysis in terms of PR facility considerations, as micromobility and NMT solutions were deemed more appropriate for these distances [26].

5.2.2 Date of Analysis and Peak Period Definition

Data was collected and analysed during peak university activity, namely the academic terms, from 1st February to 31st May (Semester 1) and 22nd July to 30th September (Semester 2), for the 2024 academic year [27]. These periods align with the higher shuttle service usage [12], as well as the higher commuter volume experienced during the academic term but before the beginning of the examination periods, where traffic levels begin to decline [12].

Traffic was analysed across three weekday peak periods, adapted from the Technical Recommendations for Highways (TRH26) guidelines [28]:

- Weekday morning peak (06:00 to 09:00).
- Weekday midday peak (12:00 to 14:00).
- Weekday afternoon peak (15:00 to 18:00).

These times were chosen to reflect school and university schedules, working hours, and afternoon travel patterns. Weekends were excluded as weekdays tend to experience larger congestion levels. This is further justified in terms of parking availability, whereby, according to the Mobility Division of Stellenbosch University [12], are most critical on Tuesdays and Wednesdays.

5.2.3 Resultant Model

The TOMTOM model produced data on traffic volumes, O-D patterns and travel times for all the identified gates. This data enabled one to prioritise the corridors most in need for intervention and assisted in determining potential PR facility locations based on actual movement patterns and demand.

5.3 Roll-out: The 6S Methodology

Finding the optimal location for the PR facilities is only one of the elements necessary to ensure the solution is successfully implemented and adopted by the public. To ensure a structured and effective roll-out of the proposed PR facilities and integrated bus systems, an adapted 6S methodology was developed. Fundamentally, the 6S method, which expands on the 5S methodology by adding safety as an element in the model, refers to the premise that disorganised systems are not productive, and organising these systems improves customer and employee satisfaction [29]. Successful implementation and use of this methodology often results in cost reduction, higher quality outputs and substantial improvements in efficiency and productivity [30].

The original 6S model is a management tool which, in its essence, promotes a systematic approach to designing, implementing and maintaining a safe and efficient environment [31,32]. The approach, novel in its application to this specific environment, provides the opportunity for a structured framework that constantly prioritises the end user. In the context of Stellenbosch's transport network, this focus is essential: without addressing the behaviour and needs of the private vehicle users, and different stakeholders of the system, the intervention would fail to achieve any meaningful uptake. By keeping user requirements as a central concept to the framework, the solution itself can be both practical and socially acceptable, thereby improving the likelihood of successful modal shifts. This fills a gap in transport planning literature, demonstrating how this adapted model can be utilised in the holistic design of local mobility interventions and projects.

Key insights gathered from literature and parking behaviour were evaluated to expand on the six elements of the 6S framework, making it applicable to the design and implementation of the PR facilities and relevant transit systems.

1. **Sort:** Identify and prioritise the necessary design and operational needs related to the PR facility and associated transit system [30]. Gather the perspectives of the various stakeholders, and ensure the information is accessible and organised [29,33]. Asset organisation systems should be put in place.
2. **Systems:** Develop logical, user-friendly interfaces for booking and information enquiry [34]. The concept focuses on the visualisation and organizing of the elements of a project [35]. This also encompasses optimising assets through efficient bus routing and real-time communication systems [33].
3. **Shine:** Maintain the cleanliness and aesthetic appeal of the facilities through appropriate interventions [29]. The area should be appealing and comfortable for the users [34]. Design of the facilities should incorporate sustainable and ergonomic design principles and minimise environmental impacts of construction and operation.
4. **Standards:** Establish operational guidelines and rules for the use and management of the PR facilities [30]. Adequate signage should be used to inform users of the rules. Policies, design guidelines and operational standards should be detailed to ensure the systems and PR facilities are designed according to all necessary guidelines, legislature and standards [33]. Measures should be in place to enforce compliance [34]. Furthermore, the development of fixed, reliable bus schedules is vital, fostering user trust and satisfaction in the system [29].
5. **Sustain:** Implement routine inspections, continuous staff development programs and effective communication channels (between the systems and from the system to the users) [30]. Beyond this, sustaining a system requires innovation, development and improvement to remain competitive and not stagnate. These factors require user-feedback to understand how best to serve the public [30].
6. **Safety:** Proactively identify and mitigate risks [35], implementing safety measures that create a safe experience for the users. This can include Closed Circuit Television (CCTV) surveillance, security staff, clear reporting channels, competent drivers and safety reporting systems. This improves user satisfaction and confidence in the project.

The modification of this framework creates a systematic approach through which one can evaluate the requirements and important features of the proposed system, allowing for the potential for improved social adoption and longevity of the system. This framework has the potential to assist in navigating the complexities of these large-scale projects, as well as ensuring all stakeholders and end users' needs are addressed. In this way, key stakeholders such as SU and the local Municipality are encouraged to interact and collaborate with one another.

6 RESULTS

6.1 Traffic Characteristics

6.1.1 Traffic Patterns and O-D Matrices

An OD analysis for the peak morning period revealed that Stellenbosch central is both a trip generator (an area that creates trips) and a prominent destination, with internal trips accounting for approximately 42% of all movements. The second largest contributor was the trips from the M12/R310 gate to Stellenbosch Central, contributing approximately 8-9% of the morning peak trips.

These findings portray the strong reliance users have on private vehicles for short, intra-urban trips, further justified by the underutilisation of alternative modes of transport (such as the SU Shuttle Service). The results presented in the section to follow are representative of the morning peak trips.

6.1.2 Route Choice Through Traffic Demand

When considering Stellenbosch central as a destination, with all other areas and arterials (gates) classified as origins, the traffic demand from each roadway leading into Stellenbosch can be evaluated. The resultant model revealed three dominant traffic corridors:

1. M12/R310 (Polkadraai/Baden Powell) – 37% of inbound trips.
2. R44 from Somerset West (Broadway Boulevard) – 26% of inbound trips.
3. R304 incl M23 from Brackenfell/Durbanville - 23% of inbound trips.

By contrast, Jamestown/De Zalze and Techno Park contributed less than 10% of inbound trips. Although this does impact traffic congestion, these areas are too close to Stellenbosch to justify placing the PR facilities between the area and Stellenbosch central. The trips between these areas and Stellenbosch central could be reduced through the implemented public transport system that serves the PR facilities. Adding an additional stop at these areas would not require large route deviations, but could assist in reducing private vehicle usage and promoting public transport utilisation.

6.1.3 Speed Trajectory Analysis

A speed analysis of the three identified most congested routes was used to confirm the level of congestion these roadways experience. Using TOMTOM Move, the average speed of trips originating from the three aforementioned areas was evaluated, with the average speeds from the most critical route (M12/R310) represented graphically in Figure 4.

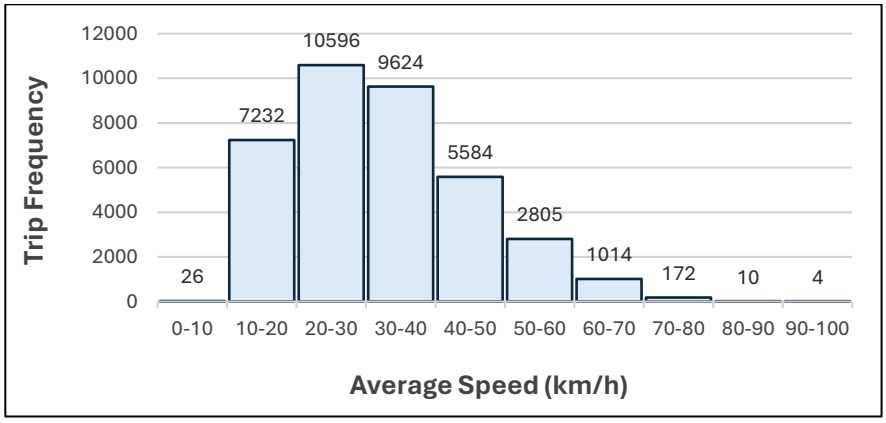

Figure 4: Average Speed of trips originating from the M12/R310 into Stellenbosch Central (06:00-09:00)

The average speed analysis confirmed the severe congestion levels experienced along the M12/R310 corridor, where average speeds dropped to 32.4 km/h and modal average speeds were approximately 20 km/h. This is well below the expected 80 km/h design speed for this U2 road class [28]. This analysis highlights the excessive traffic volumes and diminished level of service (the qualitative feeling of comfort for the road users), elucidating the need for PR implementation. The through traffic was found to be relatively insignificant, confirming that the congestion is predominantly due to the traffic originating in Stellenbosch or travelling into Stellenbosch.

7 KEY FINDINGS AND DISCUSSION

7.1 Recommended Locations of Park-and-Ride Facilities

The analysis of the FCD assisted in the identification of three prominent corridors in Stellenbosch that are in desperate need of congestion alleviation methods, particularly during the peak hours.

The FCD also revealed a significant number of internal trips within Stellenbosch, in which users make use of their private vehicles to commute short distances. The findings from this analysis, alongside the notable reduction in average travel speed along these routes, revealed that the M12/R310 should be prioritised. This aligns with observed congested levels and the Adam Tas Corridor (linked to the M12/R310), which has already been flagged as an area in desperate need of traffic alleviation interventions in the Stellenbosch CITP [4].

Notably, the data highlights the importance of addressing both the shorter, internal trips, and the external trips. SU, in collaboration with the local Municipality, needs to create a public transport system that supports regular residents of the area as well as the students of the town. Furthermore, the heavy reliance on private vehicles for internal trips must be addressed through the implementation of micromobility and NMT solutions (Such as bicycle schemes, more extensive shuttle services, e-scooters and cycling paths). Not only do these options have the ability to highlight the natural beauty and historic buildings the town possesses, but it also creates the opportunity to shift away from a vehicle-centric transport network. SU and the local Municipality could both benefit from the improved safety, reduced congestion levels and improved transport network efficiency, but collaboration is required to maximise the effectiveness and social uptake of the system.

Based on the findings, a phased roll-out of PR facilities is recommended to maximise the effectiveness of the entire system, address the most critical areas first, and allow for the capital, funding, and planning to be done through a staggered approach. The selected locations are illustrated in Figure 5.

The first proposed PR facility is detailed section 7.1.1. Although not detailed further, it is proposed that the second PR facility (along the R44 from Somerset West) should expand upon the existing Stellenbosch Square shopping centre, with the third PR facility being placed nearby the existing residential areas.

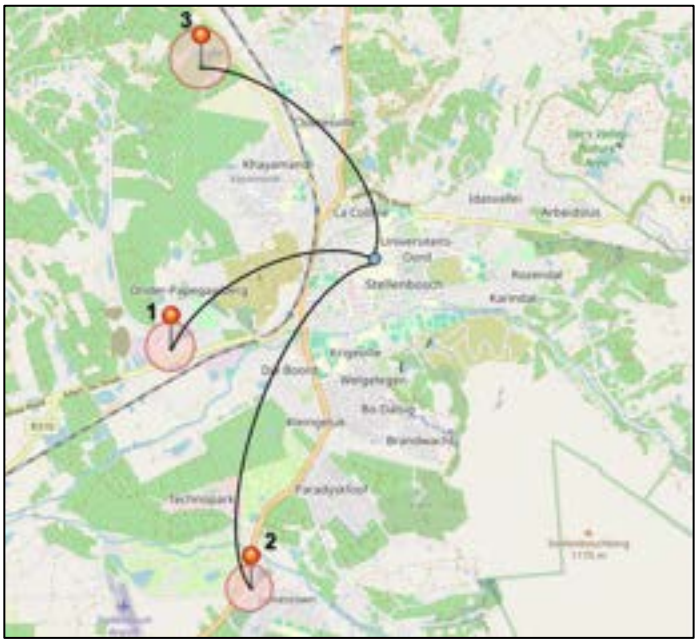

Figure 5: Locations of proposed PR Facilities

7.1.1 PR Facility 1: The M12/R310 Interceptor

Located near "The Woodmill" (an industrial area redeveloped into a mixed-land use development, this facility will intercept traffic from both the M12 and the R310. The proposed area is desolate land, and existing infrastructure (such as padel courts, shops and a spa) exists

nearby. This creates the opportunity for an integrated, mixed-use PR facility development that is appealing and promotes business growth. The area also forms part of the Adam Tas Corridor, meaning it aligns with the Stellenbosch Municipality's Spatial Development Framework (SDF) and Integrated Development Plan, as well as the revitalisation of the Adam Tas Corridor [36]. The integration of public transport and nearby businesses through the use of a PR facility promotes the ideology of the LSDF to "create an integrated urban development corridor that is liveable, safe, resource-efficient, socially integrated, economically inclusive and globally competitive, in which all citizens can actively participate" [36].

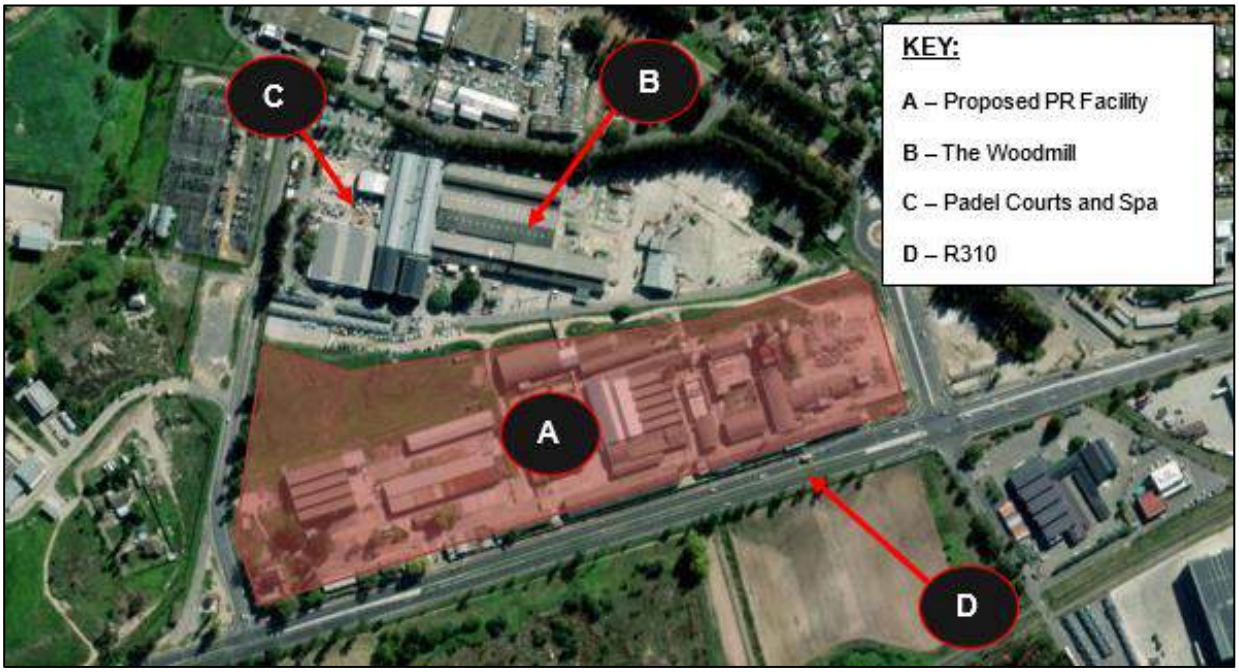

Figure 6: Proposed location of the first PR facility

7.1.2 Central Hub: Stellenbosch Bus Terminal

The proposed terminal is located centrally between Joubert Street and Smuts Road, enabling connectivity between the PR facilities and the bus terminal. The proposed location has two access points and is in close proximity to nearby points of interest, including the SU main campus, numerous private student accommodations, and Eikestad shopping centre. Converting the existing parking, with a current capacity of 183 bays [37], into a public transport terminal supports the modal shift envisioned by SU and the Municipality, whilst also presenting the opportunity for the integration of NMT and micromobility systems due to its proximity to the SU campus.

Figure 7: Proposed location of the central transit terminal (LEFT [37]; RIGHT [38])

7.2 Application of the 6S Methodology in the Roll-out of the PR Facilities

The 6S methodology was utilised to ensure that the design, implementation, and operation of the PR facilities and relevant systems are systematic, achievable, and sustainable. This allows one to be considerate of the complex, multifaceted nature of the system while simultaneously prioritising the end users and the relevant stakeholders. The holistic approach, summarised in Figure 8, ensures PR facilities encompass not only the technical and operational needs but also consider the social, environmental, and economic variables that are crucial for the solution to successfully and seamlessly integrate into the current transport network.

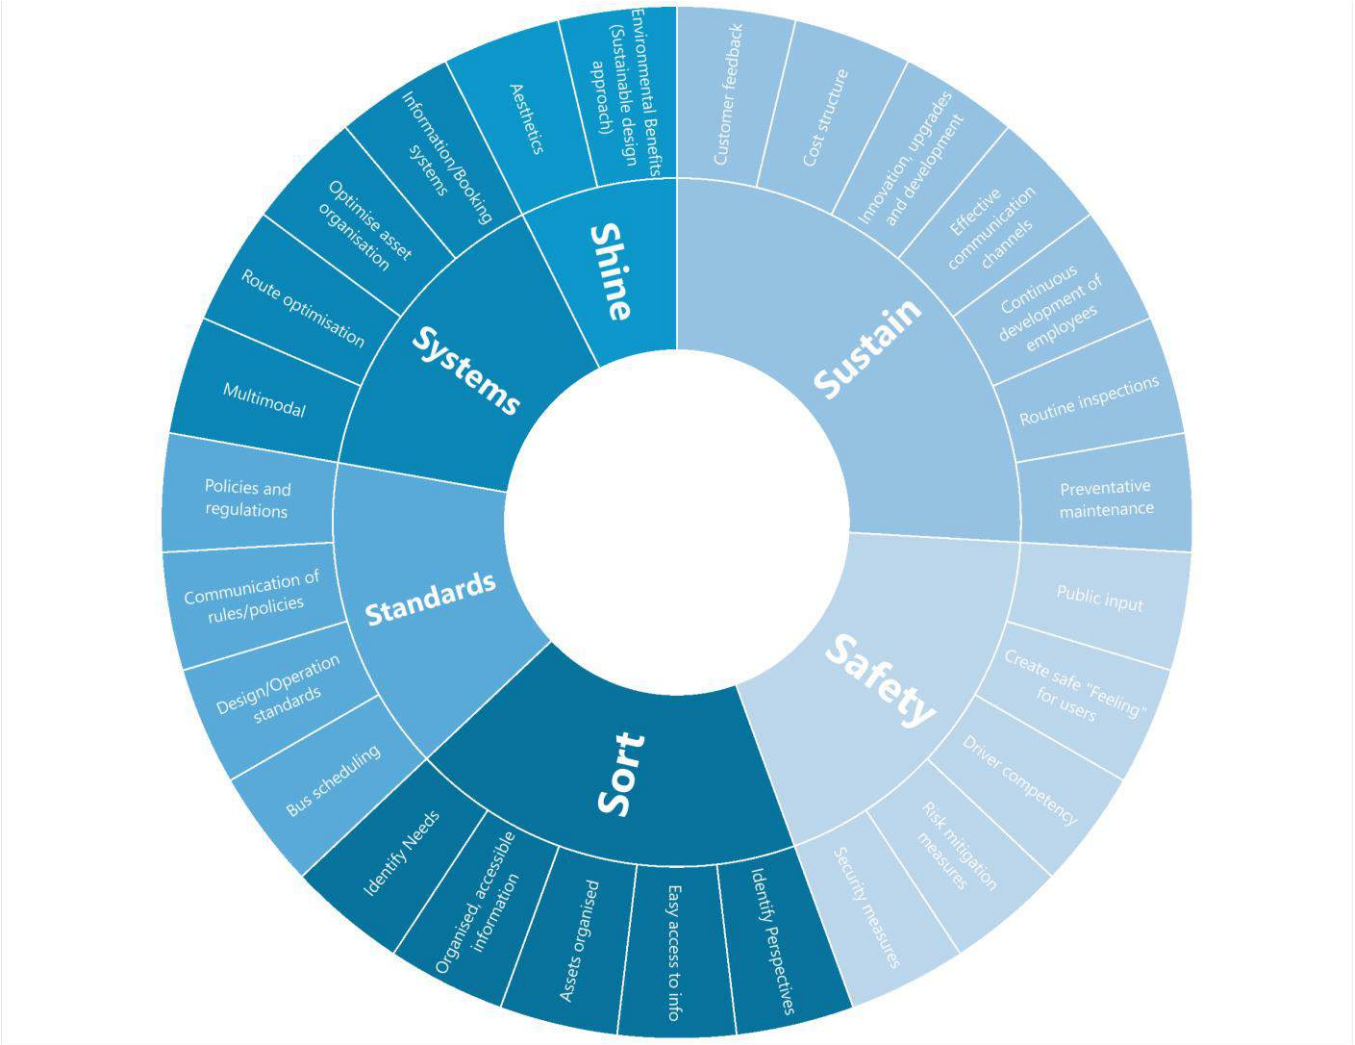

Figure 8: Critical Features of PR Facility Design, Implementation, and Operation

7.3 Limitations and Future Work

It is acknowledged that the design, implementation, and operation of PR facilities are inherently complex and multi-dimensional, influenced by social, technical, environmental, and behavioural characteristics. Some elements that should be investigated further follows:

- The detailed design of bus routes and scheduling for public transport. Future studies should investigate how to optimise these systems.
- Rail as a transport mode was also excluded, given the limited space and infrastructure available. However, these systems could work in tandem with the PR facilities for longer distances of travel.
- The impact of PR facilities on trip generation and congestion should be modelled to quantify the potential benefits of these systems.
- An economic viability assessment should be conducted to ensure the financial viability of the PR facility roll-out.
- A public survey should be conducted on various socio-economic classes and stakeholders to gather perspectives surrounding PR facilities, modal choice, parking behaviour, financial constraints, and what factors could convince the public to shift to these modes of transport.

8 CONCLUSION AND RECOMMENDATIONS

This study assessed the feasibility of PR facilities in Stellenbosch as a mitigation measure to the rising congestion and parking pressures driven by urban growth, private vehicle dependence and the integration of SU with the town. Analysis of FCD identified three critical corridors leading into Stellenbosch as priority routes for intervention, namely the M12/R310, the R44 from Somerset West, and the R304 including the M23 from Durbanville. Speed analyses and traffic volume data revealed the severity of these routes, with significantly lowered travel speeds and high congestion levels. A phased roll-out strategy was proposed for the implementation of the PR facilities, linking PR sites with a central bus terminal in Stellenbosch through the use of the Hub-and-Spoke model.

In the absence of national standards for the design, a tailored 6S methodology was developed to guide the design, implementation, and operation of the system. The developed framework ensures flexibility, efficiency, and a people-centric design approach that aligns itself with the town's broader sustainability and mobility goals. SU was identified as a key stakeholder in the development of the transport network, with the accompanying student population being central to driving modal shifts away from private vehicles and towards more sustainable, safe, and equitable transport modes. However, collaboration between SU, the Municipality, and other stakeholders is essential to curb the worsening congestion levels and parking shortages. As both SU and the town expand, transport solutions must remain user-focused to ensure long-term success. The introduction of PR facilities represents an important first step towards a people- and environment-centred mobility system, creating a safer and more accessible urban environment for the town's students as well as its residents.

DIGITAL KAIZEN: ENHANCING LEAN MANUFACTURING WITH REAL-TIME DATA AND ANALYTICS

C. Schoeman[1], D. Wenhold [2] and J.W. Conradie[3]

[1,2,3]Council for Scientific and Industrial Research (CSIR), South Africa
[1]CMSchoeman@csir.co.za, [2]dwenhold@csir.co.za , [3]JConradiel@csir.co.za

ABSTRACT

Lean manufacturing aims to eliminate waste and improve efficiency; however, traditional approaches often lack real-time data insights – leading to delays in identifying production bottlenecks and quality issues. This paper explores the concept of Digital Kaizen—integrating real-time monitoring and data analytics into continuous improvement using cost-effective sensors. By implementing a digital dashboard, manufacturers can track KPIs, detect inefficiencies automatically, and enhance decision-making. Digital Kaizen enables proactive problem-solving while improving both efficiency and quality. This approach bridges the gap between lean principles and digital transformation by providing real-time visibility to production teams and accelerating continuous improvement. The research presents a practical framework for applying Digital Kaizen in manufacturing, demonstrating how affordable digital tools can drive productivity. By leveraging data-driven insights, manufacturers can shift from reactive to predictive decision-making – creating a more agile, competitive, and efficient production system.

Keywords: Digital Kaizen, Lean Manufacturing, Real-Time Data Analytics, Continuous Improvement, Smart Manufacturing, Process Optimisation, Low-Cost Floor Monitoring, Hands-on SMME Focus.

1 INTRODUCTION

South African manufacturers, particularly small, medium and micro enterprises (SMMEs), face increasing pressure to improve productivity, reduce costs, and remain globally competitive [1]. This promotes renewed interest in Lean practices and locally adaptable forms of digitalisation, which involves using digital technologies to enhance processes and drive innovation.

1.1 Lean Manufacturing in South Africa: Challenges and Context for Digital Kaizen

Lean manufacturing has transformed global manufacturing by driving operational efficiency through its core focus on efficiency, waste elimination, and quality. A central part of the Lean philosophy is Kaizen – a continuous improvement mindset that involves contribution from every level of the workforce. Core techniques such as visual management, just-in-time production, and value stream mapping have enabled manufacturers to reduce inefficiencies and respond effectively to customer demand. -

In South Africa, Lean remains highly relevant, especially for SMMEs navigating global competition, high input costs, and structural barriers to achieving economies of scale [2]. Local manufacturers also face increasing logistical disadvantages, particularly when competing with international competitors that are closer to end markets.

Despite its benefits, many South African companies still rely on paper-based Lean systems and manual tracking. This makes it difficult to recognise issues quickly, delays feedback and slows down decision-making on the manufacturing floor. As factories become more complex and customers expect faster turnaround times, there's a clear need to update how Lean is implemented - utilising faster, more transparent, and data-driven tools.

Recognising these challenges, the Japan International Cooperation Agency (JICA) has introduced Digital Kaizen to enhance lean-focused manufacturing innovations and training in South Africa. The CSIR, whose mandate is to foster industrial development through innovation, has supported this initiative in an advisory capacity by providing contextual support and assisting with the piloting of locally appropriate solutions for SMMEs. This supports more inclusive industrial growth for SMMEs by helping them digitise and modernise their operations. It also aligns with the concept of *translative adaptation* – a process where foreign models are not only transferred through passive adoption, but rather, reshaped through local experimentation, feedback, and ownership [3]. Therefore, Digital Kaizen is shaped and adapted to the realities, constraints, and competitive pressures that are faced by South African SMMEs.

1.2 Why Digital Kaizen? A Practical Path to Digitalisation

Digital Kaizen modernises traditional Lean practices by using real-time data, automation, and visualisation alongside Kaizen routines - without the need for expensive or large-scale digital systems [4]. Rather than simply digitising existing processes, Digital Kaizen serves as a bridge between bottom-up, production floor-driven improvement and top-down digital transformation (DX). While traditional Kaizen focuses on local problem-solving and gradual optimisation, Digital Kaizen introduces tools that allow teams to:

- Track production data in real time, enabling rapid response to anomalies
- Automate routine checks to reduce manual checking, which is reactive instead of proactive
- Visualise performance trends with minimal complexity, allowing for quicker problem detection and solving

By lowering the entry barriers to digital adoption, Digital Kaizen enhances overall responsiveness and decision-making. It uses low-cost devices and open-source platforms to

analyse production data in real time. The approach is designed to be accessible and scalable, allowing companies to start small and expand over time as capacity and confidence grow. By introducing simple forms of digital monitoring and visualisation, Digital Kaizen makes it possible to detect issues earlier, shorten feedback loops, and create a more data-driven improvement culture. Its flexibility supports customisation, making it possible to prioritise and address the current unique, pressing challenges faced by SMMEs.

This approach aligns with Aachen University's Industry 4.0 Maturity Model, seen in Figure 1, which emphasises gradual progression from basic digitisation toward full adaptability. Digital Kaizen helps SMMEs move from computerisation and connectivity to visibility and transparency, without requiring large investments or complex systems. As readiness improves, the same tools can support predictive capabilities and adaptive responses. This positions Digital Kaizen as a practical enabler of stepwise digital transformation.

Figure 1: Adapted from "Industry 4.0 Maturity Model" by Aachen University, [5]

The implementation of Digital Kaizen is currently being piloted through a JICA-led training initiative, with the CSIR providing advisory support to ensure technical relevance and alignment with local conditions. The model presents a scalable, low-barrier path for manufacturers seeking to modernise without the cost, disruption, and high technical demands typically required of full digital transformation.

1.3 Research Aim

This paper investigates the application of Digital Kaizen in South African manufacturing, focusing on its potential to enhance Lean practices through real-time data and low-cost digital tools. It evaluates the practicality, responsiveness, and relevance of the approach for SMMEs operating in resource-constrained environments, to inform scalable and relevant pathways to digitalisation.

2 LITERATURE REVIEW

This section explores the evolution of Kaizen from its traditional origins in Lean manufacturing to its digital adaptation in response to modern production challenges.

2.1 Traditional Kaizen and Lean Manufacturing: Foundations of Continuous Improvement

Kaizen, meaning "continuous improvement", is a philosophy that promotes the incremental and continuous enhancement of all functions and processes within an organisation. Throughout this paper, these terms are treated synonymously. This is done through incremental and daily

improvements and actively involves employees at all levels — from leadership to the production floor [6]. This human-centred approach makes use of structured routines to improve efficiency and standardise overall quality through small, continuous changes.

Various tools are commonly used as part of Kaizen to identify and resolve inefficiencies. Common tools associated with Kaizen include Gemba Walks, 5 Whys, A3 Reports, and visual management systems to address root causes in day-to-day operations [7]. They all encourage direct observation, team-based problem solving, and quick feedback cycles.

Lean Manufacturing, as demonstrated by the Toyota Production System (TPS), expands Kaizen principles into a structured system for delivering maximum value with minimal waste. As visualised in the TPS "house", Kaizen works alongside Heijunka (production levelling) and Standardised Work to provide a stable foundation for the system's two main pillars: Just-in-Time and Jidoka (automation with a human touch, where machines or operators automatically detect and stop production after identifying a problem to prevent the spread of defects) [8]. Together, they aim to achieve the highest quality, at the lowest cost, with the shortest lead time.

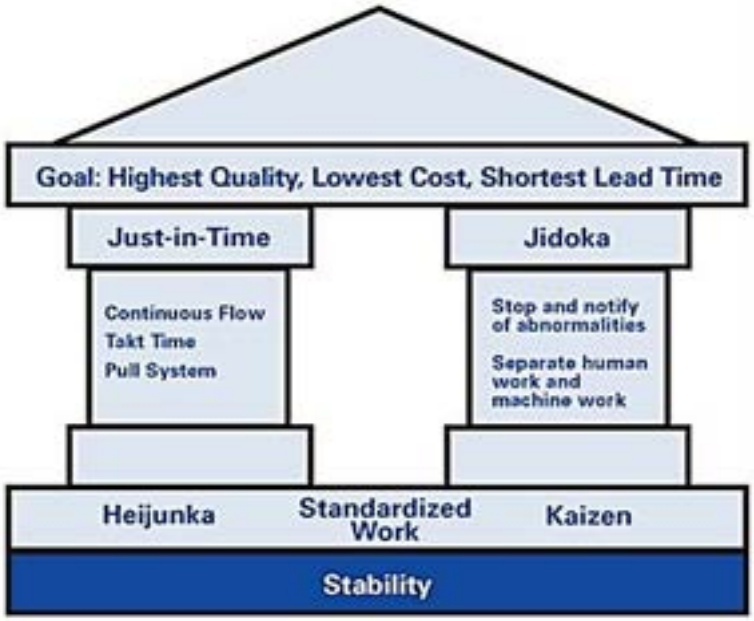

Figure 2: The Toyota Production System, [8]

As shown in Figure 2 Kaizen remains a core enabler and driving force within the TPS system, driving continuous improvement through both structured routines and daily engagement at all levels of the organisation.

2.2 Limitations of Traditional Lean and Kaizen Approaches

While Kaizen and Lean have, for decades, been effective in reducing waste and improving quality, the traditional application often falls short in modern manufacturing environments. Most SMMEs in South Africa still rely on paper-based checklists, manual data collection, and delayed reporting to track performance [4]. Despite increasing awareness of 4IR technologies, many remain unprepared for adoption due to infrastructure deficits, limited technical capabilities, and financial constraints [9].

Relying solely on human observations can limit both the accuracy and timeliness of feedback. This can result in delays to problem identification and solving. In JICA-supported case studies, teams often only become aware of issues such as downtime, overproduction, or inconsistent

cycle times after they've already impacted performance - rather than detecting them in real time [10].

Furthermore, traditional Lean systems assume a certain level of workforce discipline and consistency, but they lack the built-in feedback mechanisms necessary to confirm whether standards are being followed consistently. Continuous improvement cycles become dependent on staff memory and availability, which can introduce a level of variability. In environments with high staff turnover, limited skills development, or minimal digital infrastructure, the effectiveness of traditional Kaizen is weakened.

As production becomes more dynamic with frequent product changes, shorter lead times, and increasing customer expectations, the limitations of traditional Kaizen become more pronounced. These limitations highlight the growing need for Kaizen systems that are more responsive, data-driven, and transparent.

2.3 Digital Transformation and the Emergence of Digital Kaizen

Digital Kaizen extends traditional continuous improvement methods by including real-time data, automation, and digital feedback into Lean routines, utilising low-cost technologies to enable real-time analysis, monitoring, and feedback on production performance. It makes use of low-cost microcontrollers and sensors, together with open-source platforms and dashboards to automate data collection and enable proactive, instead of reactive, intervention. Digital Kaizen not only aims to digitise existing Kaizen methods but also enhance them with immediate insights to improve visibility and decision-making. Digitalisation has been shown to significantly enhance SMME's Lean implementations by improving performance tracking, enabling better information flow and supporting real-time decision-making [11]. Table 1 indicates the benefits of modernised Kaizen application to various important manufacturing aspects:

Table 1: Comparison of Lean Practice Maturity [4]

Aspect	No Kaizen	Traditional Kaizen	Digital Kaizen
Problem Detection	Delayed (reactive)	Periodic and likely delayed	Instant (sensor-based)
Data Availability	None/ Minimal	Manual data records	Automated, real-time data
Feedback Speed	Slow and infrequent	Weekly/ daily meetings	Real-time dashboards
Worker Involvement	Low/ Absent	High (operator-led)	High (data-supported)
Decision-making Basis	Intuition/ Crisis Response	Operator judgement and visual feedback	Data driven

In most SMMEs, full-scale digital transformation (DX) is not achievable due to the associated high cost, complex installation and upkeep, coupled with limited technical capability. Enterprise Resource Planning (ERP) platforms - including SAP, Oracle, and Microsoft Dynamics - are often not an option for most SMMEs due to high implementation, customisation, and licensing costs. Digital Kaizen offers a middle path by enabling manufacturers to adopt meaningful digital capability while remaining grounded in traditional Lean principles. This is evident through its ability to provide real-time cycle tracking, downtime alerts, and dashboards, enabling more accurate root cause analysis. It is not simply the digitisation of existing Kaizen tools, but a structured approach to integrate Kaizen principles into digital transformation [12]. This adaptive implementation of Digital Kaizen aligns with principles of translative adaptation [3], where knowledge transfer is reshaped through local context and experimentation rather than direct model replication.

2.4 Summary of Key Insights from Literature

The existing literature highlights both the relevance and practical limitations of traditional Kaizen, particularly in resource-constrained environments that have older machinery. Digital

Kaizen can be seen as a scalable solution that bridges this gap by retaining the strengths of Lean while enhancing responsiveness through real-time data collection and analysis. To explore this further, the following section outlines the research methodology used to evaluate Digital Kaizen in a South African manufacturing context.

2.5 Practical Applications of Digital Kaizen in Industry

Japanese SMMEs have pioneered Digital Kaizen, achieving significant productivity gains with minimal investment and simple technologies [13]. This has been done without requiring a full-scale digital transformation. The Digital Kaizen case studies [13] below demonstrates how being able to see real-time data, low-cost sensors, and feedback-driven problem solving have an immense practical value for an organisation.

2.5.1 Asahi Tekko (Japan)

Asahi Tekko, a Tier 1 supplier to Toyota, introduced low-cost sensors (e.g. as low as \$0.50 (±R9)[*] for light sensors and \$2 (±R36)[*] for magnet switches) to capture real-time cycle times on older equipment. The sensors revealed hidden downtime and cycle imbalances, leading to:

- JPY 400 million/year (±R49 million/year[†]) in cost savings
- JPY 100 million/year (±R12 million/year[†]) in avoided capital expenditure
- 9% reduction in electricity consumption

Figure 3: Low-cost light sensors and magnet switches used at Asahi Tekko for digital cycle time monitoring [13]

This was done by measuring the performance time of the production line, using sensors instead of manual measurement, and through the acquisition of continuous digital data collection and monitoring. This success catalysed the launch of a dedicated Digital Kaizen spin-off, i Smart Technologies, which now helps other SMMEs adopt similar systems.

2.5.2 Sewing Factory (Japan)

In the garment sector, a sewing plant used AC sensors and low-cost IoT devices (like the M5Stack) to monitor machine activity and differentiate between novice and expert operators. In addition to this, all that was required was a Wi-Fi connection to export the data onto a Google sheet, whereafter the information could be analysed and displayed on dashboards.

[*] Conversions based on the USD/ZAR exchange rate as of May 2025.

[†] Conversions based on the JPY/ZAR exchange rate as of May 2025.

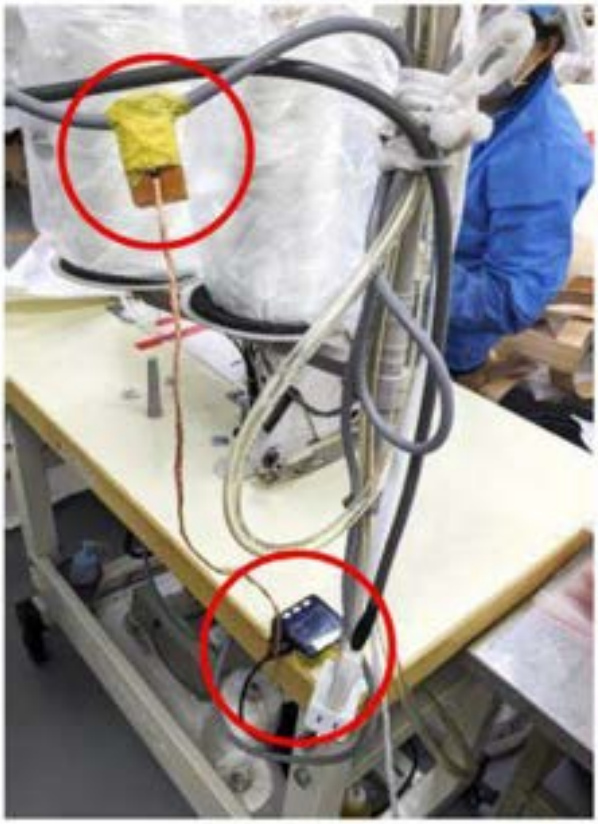

Figure 4: AC sensor and microcontroller (M5Stack) installed on the Sewing Machine [13]

Information such as a general overview of the utilisation rate of the machine, a daily analysis of operation times and inactive times could be visualised in real-time with the use of the dashboards. These insights enabled targeted training, load balancing, and work standardisation, enhancing productivity without expensive upgrades.

2.5.3 QR Code-Based Process Tracking

Multiple factories have implemented QR codes to digitise work instructions, job tracking, and inspection forms. Instead of relying on paper-based processes, operators scanned QR codes using mobile phones to:

- Access digital checklists
- Record inspection results
- Monitor quality parameters

This approach reduced administrative overhead, improved traceability, and facilitated real-time data collection. This is especially useful in environments with limited and older infrastructure. Furthermore, the same barcode/ QR code can be used to track products after sales, which assists with supply chain management.

2.5.4 LiLz Gauge – Water Meter Reading (Japan)

A factory with multiple water sub-meters previously relied on a manager to perform all manual monthly readings and inspections to allocate charges across departments according to their usage [14]. This process was time-consuming, prone to potential error, and offered no insight into the daily consumption patterns. To introduce a Digital Kaizen approach to this problem, a battery-powered IoT camera system (LiLz Gauge) was installed, which resulted in the following:

- Manual reading was eliminated
- Daily water usage data was automatically collected
- Multiple meters could be monitored simultaneously and remotely

Figure 5: LiLz Gauge system installed on factory water meters to automate sub-meter reading [13]

The implementation of the LiLz Gauge on the sub-meter enabled the facility to track usage trends, improve internal cost allocation, and identify opportunities for water conservation - all without modifying the existing infrastructure. The same system has also been applied in other factories to automate inspections of analogue gauges, pressure dials, and other older meters, which extends the benefits of digital monitoring across various manual processes.

3 METHODOLOGY

This study adopted a Design Science Research (DSR) methodology [15] to develop, implement, and refine a Digital Kaizen system tailored for South African SMMEs. The approach was tested in a real-world manufacturing environment and was structured around iterative deployment cycles to ensure overall relevance, responsiveness to operational challenges, and incremental improvement based on field feedback.

3.1 Research Design

This study followed a three-phase Design Science Research (DSR) methodology, as shown in Figure 6. The approach combined elements of structured, staged implementation (waterfall) and agile, iterative refinement cycles to enable both planning discipline and responsiveness.

- A **staged implementation** approach (waterfall) ensured systematic progression from problem identification to evaluation.
- **Agile iterative cycles** allowed for responsive adjustments after each deployment phase, ensuring user feedback was rapidly integrated.

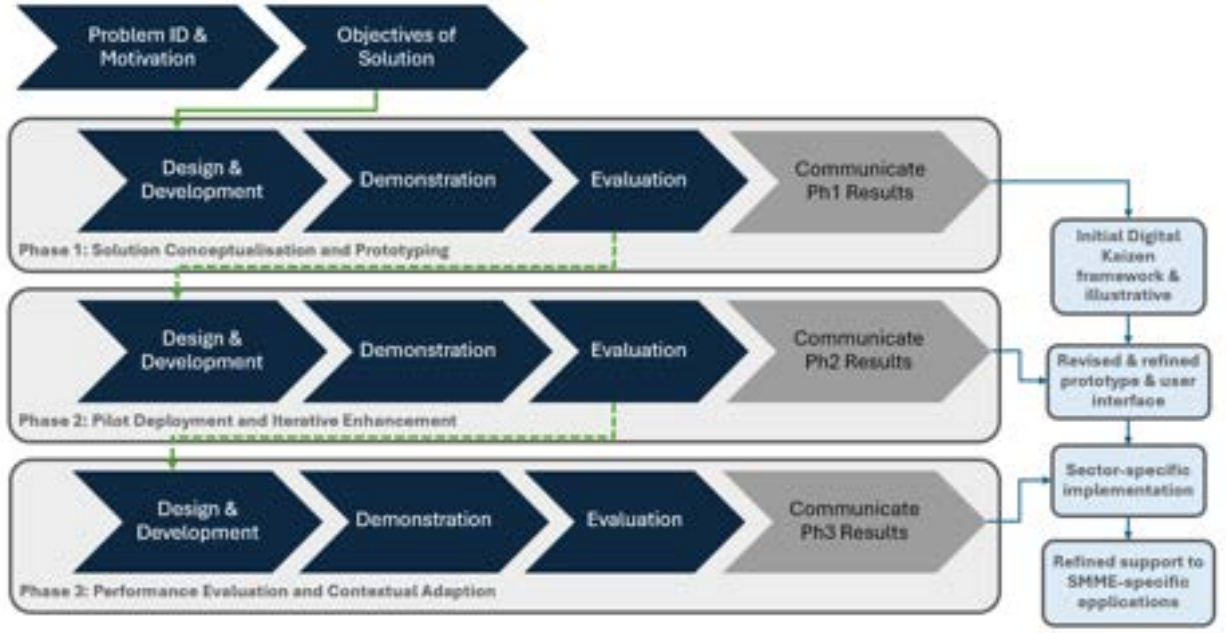

Figure 6: Design Science Research (DSR) methodology used to structure implementation across three phases

Figure 6 illustrates the methodological progression through the following stages:

1. **Problem Identification & Motivation:** A key challenge often observed during the Basic *Kaizen* course in 2023 is a lack of data related to productivity and quality control, hence a lack of data-based management.
2. **Objectives of Solution:** A bridge between traditional Kaizen and Digital Transformation (DX) by [4]:
   - Introducing real-time visibility
   - Providing a foundation for Smart Factory, Product, and Service development
   - Ensuring accessibility through low-cost, DIY-compatible deployment models.

Each phase concluded with documented outcomes and informed the next iteration.

3.1.1 Phase 1: Solution Conceptualisation and Prototyping

Initial design of a low-cost, real-time monitoring system for constrained factory environments.

A Digital Kaizen prototype was developed based on principles from Lean Manufacturing, international case studies, and lessons from previous digital transformation initiatives. The design of the system prioritised affordability, ease of integration, and scalability to accommodate the constraints typically faced by resource-limited manufacturing environments.

Once a problem area was identified - whether related to a machine or a process lacking data visibility - a sensor appropriate to the required data type is installed. Sensors were connected to an edge device, which hosts and executes the data acquisition program. The edge device transmits the captured data via Wi-Fi to a local PC equipped with data processing software and a real-time monitoring dashboard. Simultaneously, the data is also uploaded to a cloud storage platform for secure backup and remote access. This architecture enabled real-time visibility and data-driven feedback within the testbed factory environment [10].

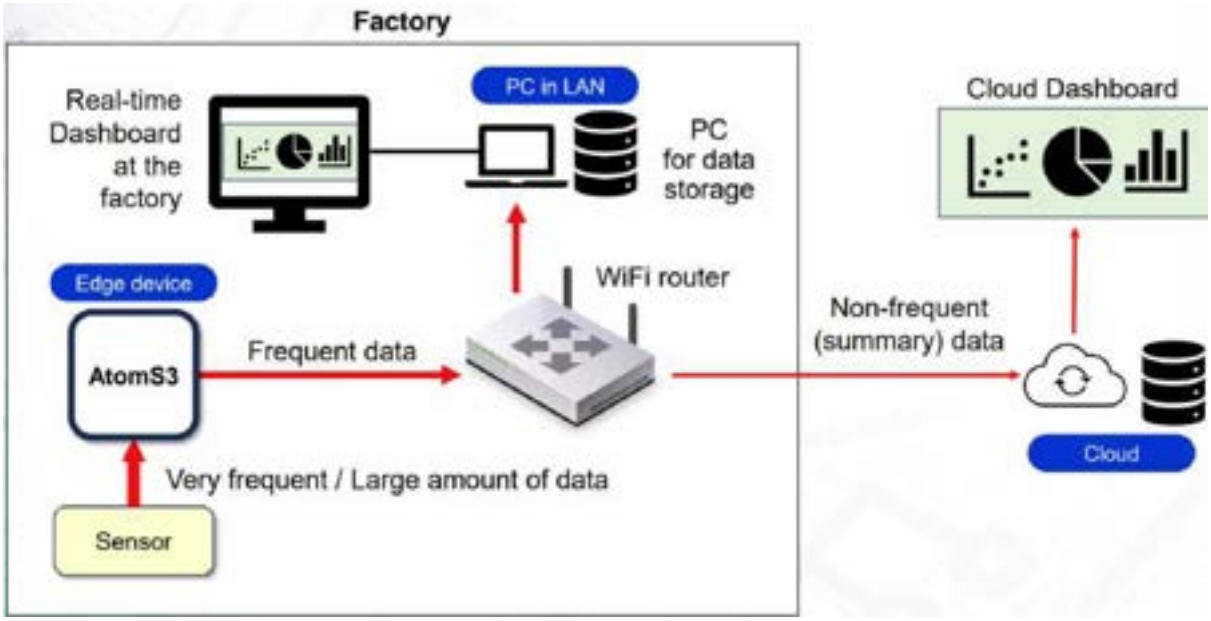

Figure 7: Digital Kaizen Prototype – Architecture for Real-time Monitoring Deployment

The system uses low-cost, open-source technologies selected to support Digital Kaizen in constrained manufacturing environments. Technology choices were guided by affordability, compatibility with legacy equipment, and ease of use for non-specialist staff. The architecture consists of three core components:

1. Sensor Input and Data Acquisition

Light sensors, magnet switches, and AC sensors capture machine status, cycle times, and downtime. Data is collected using M5Stack microcontrollers, which support direct integration with older machines [16].

2. Data Processing and Storage

Sensor data is transmitted over Wi-Fi to a local Node-RED [17] server is running on a laptop. The system handles real-time data flow and stores records in a MySQL database [18] for historical tracking.

3. Dashboard Output and Visualisation

Custom dashboards in Node-RED [17] display live KPIs, trends, and alerts. The interface enables rapid, actionable insights for operators and managers, requiring minimal training.

3.1.2 Phase 2: Pilot Deployment and Iterative Enhancement

Structured pilot to validate *deployment in real-world SMME conditions.*

The prototype was deployed in a testbed comprising four South African SMMEs, with continuous stakeholder engagement to guide iterative refinements. The development process was informed by a combination of direct shop-floor observations, sensor-derived data, and structured user interviews. The deployment followed a structured, phased approach.

The Phase 2 steps are illustrated through a pilot test conducted at Finke Plastics [19], with the Automotive Industry Development Centre – Eastern Cape (AIDC-EC) serving as the principal consultants.

Step 1: Problem Area Identification

The initial stage involved identifying key problem areas within production processes through established Lean methodologies such as Gemba walks [19], interviews, Muda (waste) analysis [20], the 5 Whys technique [21], and Ishikawa (fishbone) diagrams [22]. Once a problem was clearly defined, the relevant process was mapped in detail to facilitate effective implementation of the Digital Kaizen system.

An automated injection moulding machine, illustrated below, experienced frequent nozzle blockages due to material solidification. In the absence of direct supervision, these issues often went unnoticed for extended periods, resulting in significant downtime and tedious recovery efforts.

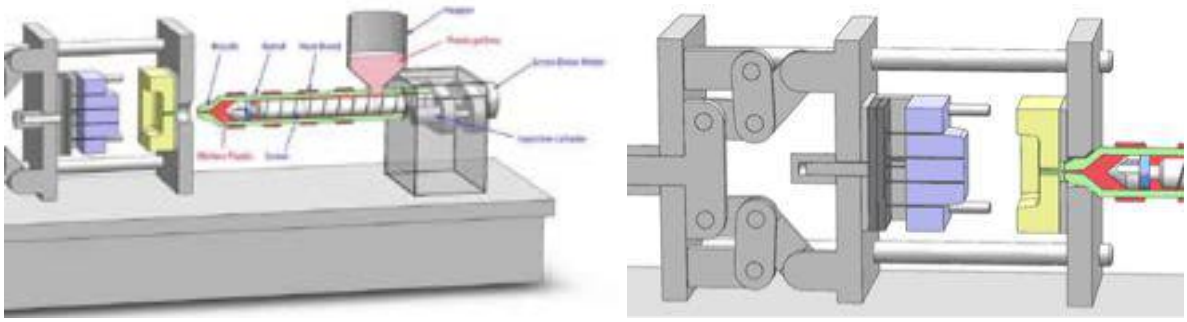

Figure 8: Example Problem Area

Step 2: Sensor Selection for Data Acquisition

Based on the mapped process, suitable sensors were selected to capture relevant operational data. Selection of the sensors was tailored to the nature of the problem and the factory's process architecture.

Figure 9: M5 Stack Sensors

Step 3: Design, Programming, and Testing

Following sensor selection, the data acquisition logic was programmed using UIFlow [23], a graphical programming Integrated Development Environment (IDE) that is easy to use and supports wireless/wired program push. Background processing and connectivity protocols were configured using Node-RED [24], a flow-based, low-code development tool designed for visual programming, primarily aimed at wiring together hardware devices, Application Programming Interfaces (APIs), and online services, especially in the context of the Internet of Things (IoT). Preliminary tests were conducted to validate sensor behaviour and communication.

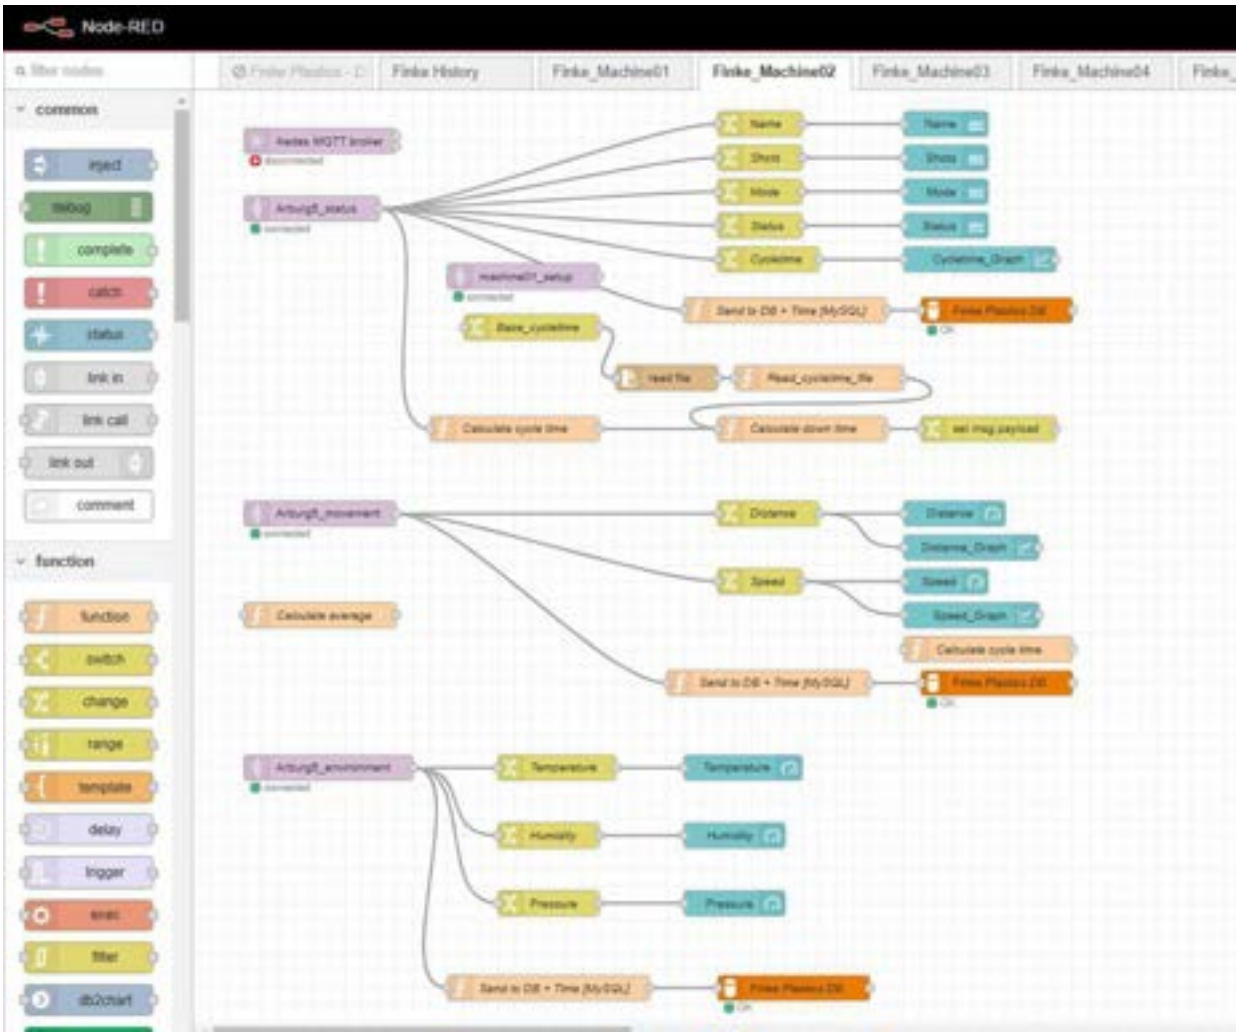

Figure 10: Example Node-Red Code

Step 4: Sensor and Edge Device Implementation

Sensors and microcontroller-based edge devices were installed on the relevant machines or processes. These devices were connected to a Wi-Fi network to enable data transmission.

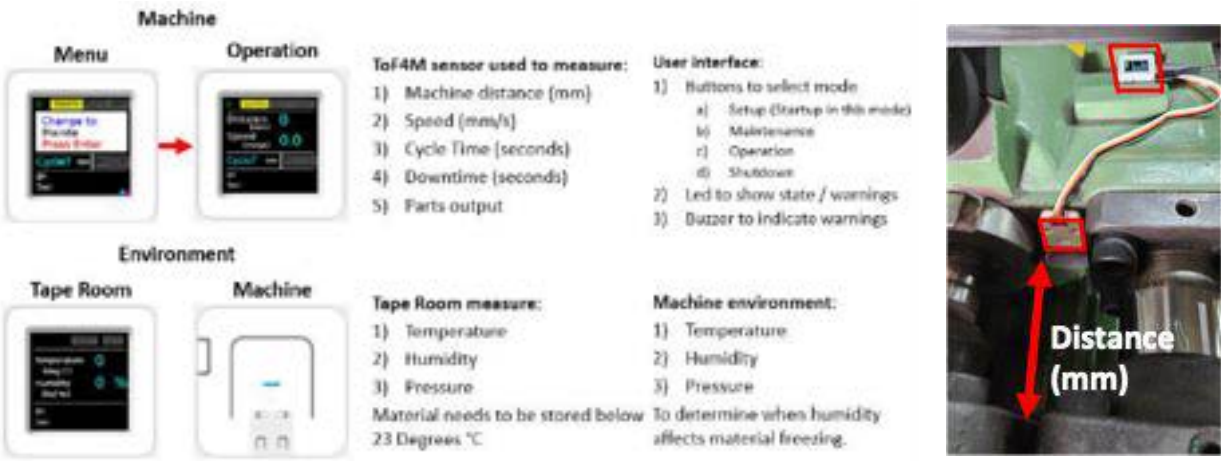

Figure 11: Example Sensor and Edge Device Implementation

Step 5: Testing and Refinement

After installation, the system was tested to ensure stable connectivity and accurate data capture. Any issues identified during this phase were resolved through on-site adjustments and software refinements until the data output met operational requirements.

Step 6: Dashboard Development

Once the sensor data was reliably transmitted to both the local PC and a cloud database [25], a real-time dashboard was developed. The dashboard visualises data in an accessible and actionable format, using graphs and indicators to support decision-making.

Figure 12: Example Dashboard Development

Step 7: Data Analysis and Problem Solving

The final phase involved analysing the data and dashboard outputs to identify anomalies, verify data accuracy, and uncover underlying issues. This enabled the team to propose and implement data-driven improvements to the machines or processes.

Figure 13: Example Data Analysis from Dashboard

3.1.3 Phase 3: Performance Evaluation and Contextual Adaptation

Final system refinement based on operational performance and user feedback.

Pre- and post-intervention data are collected for key performance indicators (KPIs), including downtime, cycle time, and defect rates. These metrics are used to assess the operational impact of the Digital Kaizen system. Based on the results, system refinements are implemented to address contextual challenges such as usability, scalability, and operator interaction.

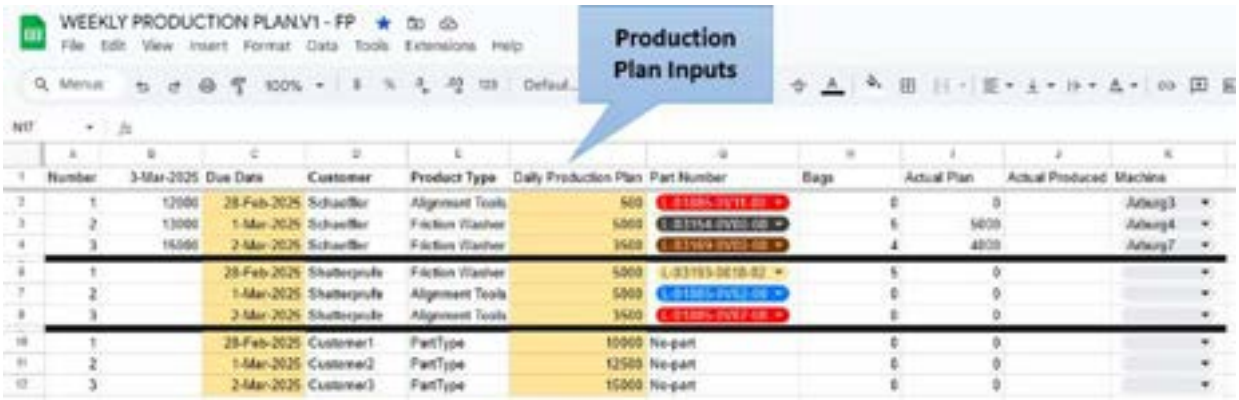

Figure 14: Example Weekly Production Plan

4 RESULTS AND DISCUSSION

The implementation of Digital Kaizen within South African SMMEs presents several impactful outcomes, affirming both the practical feasibility and transformative potential of integrating real-time data analytics into lean manufacturing environments.

4.1 System Implementation and Operational Impact

The deployment of low-cost sensors in conjunction with open-source platforms facilitated continuous and automated monitoring of critical production parameters, including machine cycle times, equipment downtime, and operator activity. Real-time dashboards provided immediate visibility into a broad range of operational performance aspects, enabling operational teams to detect inefficiencies and address emerging issues proactively. This transition from manual, paper-based tracking systems to digital monitoring reduced delays in reporting and enhanced the accuracy of performance data. For instance, Finke Plastics, a

participating SMME, reported a 93.3% reduction in unplanned downtime within the initial two months of implementation. Table 2 presents the reduction in unplanned downtime, with each "event" referring to a material freezing occurrence that previously required 2–3 hours of recovery time.

Table 2: Reduction in Unplanned Downtime After Process Improvement

Metric	Before Improvement	After Improvement	Reduction	% Reduction
Downtime per Event (avg.)	2.5 hours	0.167 hours	2.33 hours	93.3%
Monthly Downtime (avg. 4.33 weeks)	108.25 hours	7.23 hours	101.02 hours	93.3%
Annual Downtime (52 weeks)	1,300 hours	86.84 hours	1,213.16 hours	93.3%

This improvement was attributed directly to the system's ability to identify anomalies in real-time, allowing for timely intervention. These findings are consistent with outcomes observed in international case studies, such as Asahi Tekko and digital Lean initiatives in the Japanese garment sector, which similarly reported productivity gains and enhanced operational agility through the adoption of Digital Kaizen methodologies.

4.2 User Adoption and Organisational Change

The adoption of these digital systems was high, with operators and managers expressing satisfaction with the system's usability and the tangible value of real-time insights [26]. Implementations were conducted during operator breaks to minimise downtime for employees. Furthermore, sensors were deliberately implemented not to affect the workers' operation in any way.

Some adoption barriers were imminent and required time and creative solutions. One such challenge was network security, where the company's ICT teams had to set up new Wi-Fi networks and use laptops that were not connected to the main network. This did not affect system functionality, other than the initial time it took to establish data and network access.

A major success factor was the participatory design approach. By integrating feedback from frontline staff during iterative development cycles, the implementation process encouraged ownership and reduced resistance to change. This aligns with the principles of contextual innovation, which emphasise the importance of tailoring digital tools to local operational realities rather than applying imported solutions without adaptation.

4.3 Challenges and Lessons Learned

During the development and implementation of the Digital Kaizen system, multiple challenges were encountered, which provided valuable lessons for future applications. These barriers, both technical and organisational, are detailed below [26].

Initial issues such as network instability and sensor calibration errors were resolved through iterative troubleshooting. The open-source, modular nature of the technical stack (comprising tools like Node-RED [24], MySQL [25], and M5Stack [23]) enabled rapid modification and fault isolation, though it also highlighted the need for ongoing technical support within the SMMEs.

Capacity building and skills transfer emerged as essential components for ensuring system sustainability and long-term success. Without internal technical competency, even a well-designed system is unlikely to reach its full potential. The table below summarises key technical and organisational challenges encountered during implementation, along with the lessons learned.

Table 3: Digital Kaizen Implementation Challenges

Challenge Area	Key Issues and Lessons Learned
System Complexity and Flexibility	The initial AtomS3 program was overly complex, making operations inefficient. A simpler, modular design would have improved performance and maintainability.
Environmental and Hardware Limitations	The microcontroller malfunctioned in high temperatures, requiring a protective casing. Additionally, it lacked processing power for growing data needs, leading to the addition of a view-only client for visualisation.
Variability and False Alarms	Differences in machine parameters (e.g., mould stroke lengths) led to false warnings. An automated setup procedure was introduced to adapt to different configurations.
Usability of Alert System	Early warning systems couldn't be reset, which limited usability. User inputs were later added for resetting and mode selection.
Connectivity and Operational Reliability	Inconsistent Wi-Fi coverage initially prevented stable device connection. This was addressed with extenders. A separate issue was devices not being powered on, suggesting the need for SOPs.
Organisational Capacity Constraints	Limited technical skills and staff capacity hindered system optimisation. Ongoing technical support and skills transfer were essential for sustainability.
Data Availability and Machine Downtime	Frequent machine maintenance limited data collection, impacting system analysis and refinement potential.

These challenges show the importance of designing Digital Kaizen systems that are simple, robust, and well-supported for efficient and effective adoption in SMME contexts.

4.4 Interpretation of Results

The pilot demonstrated that the implementation of Digital Kaizen can lead to measurable improvements in productivity, quality, and worker engagement, even within resource-constrained environments. The availability of real-time data facilitated the rapid identification of bottlenecks and enabled more focused and effective interventions.

The implementation across the four SMMEs demonstrated similar results to Finke Plastics demonstrating the potential of Digital Kaizen (only Finke Plastics agreed to share data for this paper at this time); however, it did not function as a turnkey solution. As all components used were open-source, significant custom programming and system integration were required, often necessitating support from consultants. This presented certain barriers, including steep learning curves. Nonetheless, this approach proved advantageous in that it allowed the SMMEs to actively participate in the implementation process, from initial setup and sensor coding to data analysis.

This hands-on involvement enabled the SMMEs not only to appreciate the value of real-time data and Lean Manufacturing principles but also to develop a deeper understanding of their operational challenges and opportunities. By engaging directly with the data and the systems, participants were able to discern which types of data were most valuable and relevant to their processes. Furthermore, the process facilitated valuable skills development. As a result, the SMMEs are now better positioned to contribute meaningfully to future digital transformation initiatives through practical, cost-effective tools suited to their scale and capacity.

4.5 Next Steps

To continue to build on the success of this pilot and extend the benefits of Digital Kaizen, the following steps are proposed:

- Implement train-the-trainer and consultant capacitation initiatives to build local expertise and skills development that can sustainably support the SMMEs in the future
- Develop standardised toolkits to simplify and make the implementation of Digital Kaizen more consistent

- Utilise pilot sites and learning factories as demonstration hubs to increase visibility of the benefits of introducing Digital Kaizen.

5 CONCLUSION

Digital Kaizen offers a practical and cost-effective way for local SMMEs to enhance Lean manufacturing practices through real-time data and low-cost digital tools. By providing a middle path between traditional processes and full-scale digital transformation, the approach allows for a proactive response to production issues, reduces downtime, and makes data-driven decisions.

The pilot confirmed that Digital Kaizen can enhance Lean practices in South African SMMEs by enabling real-time problem detection, reducing downtime by over 90%, and fostering operator engagement through participatory design. These findings demonstrate that low-cost, locally adapted digital tools can provide a scalable pathway to digitalisation in resource-constrained manufacturing environments.

ABSTRACT

Operational readiness (OR) is essential for capital projects in the mining industry, as it ensures that steady-state operations meet production targets, mitigate risks, and comply with regulatory requirements. Originating in the United States nuclear sector, OR has evolved to other industries, integrating safety, design, and operational efficiency. By aligning systems, equipment, and personnel, OR minimises delays and costs, improving project profitability.

This paper explores the financial impact of OR on South Africa's platinum mining sector by studying its value through key performance indicators, productivity gains, cost savings, and risk mitigation. A methodology, validated by other capital project case studies, is presented to demonstrate OR's financial benefit in optimising project outcomes by supporting timely completion, improved safety, and long-term operational efficiency. The study emphasises the role of OR in enhancing profitability and lowering project risks, resulting in a case for its inclusion in large capital mining projects.

Keywords: Operational Readiness, Capital Projects, Financial Impact, Platinum Mining Sector, South Africa.

1 INTRODUCTION

1.1 Background

During the 1950s, the term operational readiness (OR) was first introduced to describe the condition of weapon systems being developed [1]. Over time, it evolved to encompass a broader concept of safety and design practices. The evolution of OR can be traced back to the US nuclear industry and was used to describe the integration of safety into decision-making processes [2]. Today, it is used in various industries, such as aviation and mining [3].

As defined by R. Taute, an OR program helps new owners of projects identify and implement effective safety practices. This ensures that assets are ready to start up and operate properly. It also ensures that the business goals are achieved and that environmental regulations are followed [4].

When looking at OR, the aim is to build capabilities into projects to prepare them for start-up [5]. The different categories of capability include systems and processes, which refer to the way an asset functions; equipment, which refers to the reliable components used in the process or facility; and people, which refer to the individuals who are involved in the operation of the asset. The goal of the OR process is to make sure that the asset is brought online with minimal disruption and maximum efficiency. This can help minimise delays, equipment failure, and other issues that can affect the project's success [6].

A range of literature contributes to the understanding and application of OR across different sectors. One peer-reviewed study defines OR as a stakeholder-driven, multi-dimensional concept encompassing systems and technology, organisational processes, people, and facilities [7]. Industry standards such as those outlined by Q. Xu, G. Jia, X. Wang, and Y. Chen, in their report, Governing Value Creation in a Major Infrastructure Client [8], offer a more rigid and auditable definition. These standards position OR as a formalised process involving environmental, safety, health, technical, operational, programmatic, and administrative activities. All of which are evaluated through a structured OR Review (ORR).

1.2 Relevance

OR is essential for ensuring a seamless transition from project completion to operational start-up. In the mining sector, its inclusion in project implementation remains inconsistent, often resulting in delays, inefficiencies, and increased costs [9]. As mining projects operate under strict timelines and substantial financial constraints, structured approaches to OR are increasingly necessary to support timely and cost-effective delivery.

Despite general recognition of its importance, OR is rarely scoped with precision or evaluated in financial terms. There is a need to understand its contribution to mitigating risks, avoiding value loss, and maintaining project momentum. In mining, where project delays can lead to significant financial losses, even minor lapses in readiness planning can have serious consequences. It is proposed that significant value loss often occurs during the transition from project execution to operational handover. Some case studies indicate that up to 30% of the initially projected value can be lost during the handover phase [10].

While OR has long been acknowledged in broader industry practice, its formal adoption within mining has only gained traction in recent years [2]. The absence of a clearly defined scope and a standardised framework for measuring outcomes has hindered consistent implementation. This study contributes by examining OR within the context of platinum mining and identifying its financial benefits when implemented effectively. The findings aim to support project teams in making a stronger case for OR, thereby improving project execution and operational performance.

This paper therefore follows a structured sequence: first, it establishes the background and relevance of OR; second, it outlines the methodological approach; third, it reviews the literature to highlight gaps and key themes in both practice and financial quantification; and finally, it presents a case study that demonstrates how OR interventions can deliver measurable financial value in South African platinum mining.

2 RESEARCH METHOD

This study adopts an exploratory research design grounded in a scoping literature review (SLR) and validated through a case study. The primary objective is to generate a deeper understanding of how OR is implemented in mining projects and the potential financial benefit it delivers. This approach is appropriate given the limited body of sector-specific empirical work on OR in mining, and the need to capture nuanced professional and organisational insights.

The research method will include the following steps:

1. A SLR will be conducted to identify gaps and key themes relevant to the research topic, drawing on both academic and grey literature sources.
2. These themes will then be applied and explored within the context of a selected case study to provide real-world grounding and practical illustration as validation.
3. This qualitative, multi-method approach enables the validation of findings across literature and case evidence, thereby improving the credibility and applicability of the research outcomes.

3 LITERATURE

3.1 Introduction

A scoping review was conducted to address the exploratory nature of the research and the diversity of available sources. Guided by the framework of Arksey and O'Malley [11], the review maps the breadth of existing literature on OR within South Africa's platinum mining sector, focusing primarily on publications from 2012 onwards, with selected earlier references dating back to 1992.

Particular attention was given to identifying prevailing themes, tracing the historical development of OR, and clarifying key concepts and methodological approaches. A wide range of academic and industry sources, including both qualitative and quantitative studies, were considered, without applying formal quality appraisal or quantitative synthesis, consistent with scoping review principles. This inclusive approach strengthened the understanding of OR in relation to both the financial and practical dimensions of platinum mining capital projects.

The next section begins with a review of the literature employed to conduct the analysis of failures in the transition from project completion to operational handover. Following this, a summary of literature examining the relationship between project delays and their associated financial impacts on capital projects will be provided.

3.2 A Literature Review of Project-to-Operation Transition Failure

Overview of Literature

The existing body of literature does not provide a comprehensive, multi-factor analysis or detailed case studies explaining why completed capital projects in the South African platinum sector, or the broader mining industry, fail to transition successfully from the project phase to operational status. Several recent studies highlight contributing factors such as risk management, regulatory complexity, organisational readiness, and socio-political pressures. Although these are addressed in isolation and without offering integrated, actionable lessons,

they can be applied to broader thinking and linked to OR topics [12], [13], [14], [15], [16], [17].

Table 1 shows the key points identified from the literature review of Project-to-Operations failure analysis.

Table 1: Key Themes from Literature

Category	References	Key Points
Broad risk management analyses in South African mining.	[12]	Focus on risk, process, and organisational compliance, but do not address the full ramp-up and operations gap.
Lifecycle, performance, and sustainability reviews for platinum mining.	[13], [14], [16]	Sector-wide reviews (technical, labour, finance), but no specific handover/commissioning lessons.
Organisational and stakeholder management in South African mining projects	[15], [17]	Procurement, stakeholder, and Fourth Industrial Revolution case reviews, but indirect to the transition to operations.
Technical-Variance and operational studies.	[18]	Unknown relevance, potential technical-project success angle, but lacking methods and an abstract.

Critical Gaps

While the literature acknowledges that the transition from project completion to operation in the South African mining sector is complex and influenced by multiple factors, there is a notable lack of consolidated, evidence-based analysis. No academic or grey literature published since 2012 offers a systematic, case-based exploration of the causes for project stalls at the operational interface in the platinum sector. Likewise, there is an absence of integrated recommendations that span technical, organisational, regulatory, and socio-political dimensions.

3.3 A Literature Review of the Financial Impact of Project Delays

Overview of Literature

The literature viewed reveals a significant gap in systematically linking operational ramp-up delay causes to financial impacts in South African platinum mining capital projects. The only study to provide direct and quantitative evidence in this area is Ceki et al. [7] , which focuses on the financial consequences of industrial action. No other source comprehensively maps technical, regulatory, or political delay drivers to either direct or indirect financial outcomes in this sector. One source compares project delays to a percentage increase in capital expenditure of 40% to 79%, depending on project size [19].

In

Table 2 we can see the key points discussed in the literature related to the financial impact of project delays.

Table 2: Key Themes from Literature

Category	References	Key Points
Quantitative delay, financial linkages and platinum-specific information.	[7]	Examines the impact of industrial action (strikes) on revenue and EBITDA (Earnings Before Interest, Taxes, Depreciation, and Amortisation) for JSE-listed South African platinum miners (2011–2015) using audited financial statements and t-tests. Finds that strikes significantly reduce revenue and EBITDA for all companies studied. Source is a peer-reviewed, industry-focused journal.
Platinum operational-focused and optimisation frameworks with finance.	[6]	Reviews how operational factors (e.g., mining conditions, legislative changes, social/environmental risks) impact project performance and cash flow in platinum mining projects. Discusses the importance of life-cycle cash-flow models and valuation methodologies. Includes examples but lacks systematic delay-to-cost quantification.
Qualitative and multi-case risk management focused on mining and processing.	[20], [21]	Investigate risk management in construction projects for mineral processing plants in South Africa through qualitative methods (surveys/interviews). Identify operational, financial, legal, and political risks. Multi-case qualitative study on risk management adoption and barriers in a major southern African mining company.
Generic risk with uncertainty and cost models (not platinum-specific).	[8]	Reviews uncertainty-management practices in generic mining pre-feasibility studies using NPV-based approaches. Identifies technical and market uncertainties. Proposes a systematic risk-management process. Does not focus on the platinum sector or quantify delay-to-financial impacts.
Descriptive delay for cost overrun accounts (varied sectors).	[7], [19], [20], [22]	Looks at causes of delay and cost overruns in EPCM (Engineering, Procurement, and Construction Management) projects. Focus on the causes and effects of project delays in coal mining. Reviews cost and schedule overruns in construction. Reviews causes and remedies for delays in infrastructure.
Narrative and case-based on strike/disruption in the platinum mining sector.	[23]	Appears to provide a narrative account of the 2014 platinum strike in South Africa.

Critical Gaps

For those seeking empirical examples within the platinum mining sector where operational delays are directly linked to financial losses, the only available and systematically evidenced case concerns industrial action [7]. Broader causes of delay, such as regulatory and technical challenges, remain underexplored in terms of financial quantification.

3.4 Summary of Literature Review

In summary, recent studies identify multiple factors contributing to failure in the transition from project completion to operational handover, including inadequate risk mitigation, insufficient process and organisational compliance, technical unpreparedness, and shortages of critical labour resources. Yet the financial consequences of these shortcomings remain underexplored, with limited empirical evidence available to quantify their impact.

The literature further reflects a fragmented treatment of OR and its financial implications, while risk and organisational dimensions are comparatively well addressed, integrated analyses explicitly linking readiness to measurable financial outcomes are absent. This gap underscores the need for robust, case-based investigation, providing the foundation for the methodological approach adopted in this study.

Future research should focus on developing standardised financial models and evaluation tools that can systematically quantify the economic impact of OR across projects. Such tools could integrate cash-flow modelling, scenario testing, and cost–benefit analysis to demonstrate how

readiness interventions affect net present value (NPV), payback periods, and operational efficiency. Comparative studies across commodities, sectors, and geographies would also strengthen external validity and promote knowledge transfer.

4 CASE STUDY

4.1 Ethical Considerations

The following data is anonymised under a confidentiality agreement to protect commercial sensitivity.

4.2 Introduction

Following the identification of gaps and key themes in the literature, the case study below demonstrates how OR interventions were practically implemented and quantified in financial terms within a platinum mining project.

The project was selected because it represents a typical Upper Group 2 (UG2) platinum development with available operational and financial data. The case study is an example of where an ORR was executed in time to identify improvement areas and have a significant benefit on the overall project delivery. Readiness elements were mapped across people, process, equipment, facilities, and systems.

The NPV assessment used measured ore production, industry-standard grade assumptions, and average market platinum prices, with project schedule comparisons attributing to acceleration specifically because of OR interventions.

4.3 Background

A case study was conducted on a greenfield capital project in a brownfield operational area for an underground platinum mine in the UG2 chromitite reef, part of the Bushveld Igneous Complex in South Africa. The mine, designed as a decline system, is situated close to other underground operations owned by the same mining company. Although certain operational departments are intended to be shared, the new mine is required to be self-sustaining from a facility and infrastructure perspective. This necessitates that all operational and infrastructural requirements be accommodated on-site at the new decline. This includes, among others, change houses, maintenance and workshop areas, control rooms, lamp rooms, operator facilities, and offices. With these facilities, the personnel required for each facility and activity will also need to be onboarded.

The mine has been planned as an on-reef development, which will enable the dispatch of production-value tonnage to the concentrator early in the development schedule, hence the importance of efficient production ramp-up. During the initial phases of project planning, it was assumed that some of the existing services on nearby sites could be utilised temporarily to start development as soon as possible. Consequently, the development of the boxcut portal was prioritised to start the mine development phase as quickly as possible. This resulted in the availability of permanent infrastructure only much later in the project schedule.

An ORR was subsequently undertaken to test the feasibility of this assumption. The main operational areas were mapped as process flows, including only non-negotiable requirements to each process. At each activity in the process flow, the guiding questions were: Do we have the people, facilities, equipment, processes, and systems in place to complete this task? These considerations align with the key themes identified in the literature review. Figure 1 provides an example of such a process flow.

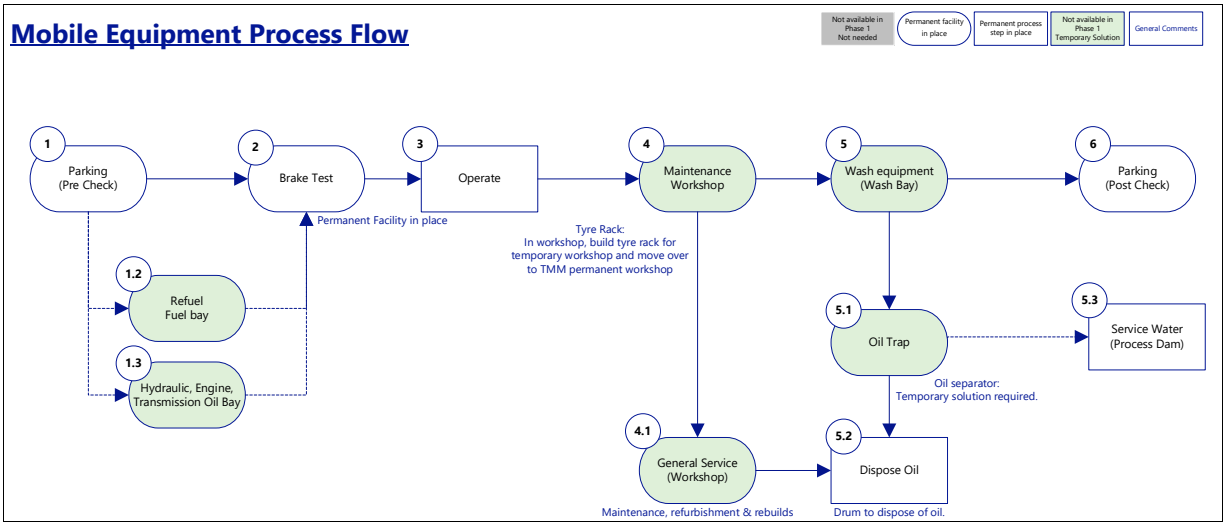

Figure 1: Mobile Equipment Process Flow

Through the ORR it was identified that in order to facilitate the timely development of the box cut and enable early production tonnage, certain temporary facilities would, in fact, be required at the new project site. These included:

- Change House
  - Potable Water Tanks
- Engineering Workshop
  - Explosives Storage
  - Refuelling Bay
  - Minisub Cabling
- Shaft Storage Yard
  - Engineering Spares Yard
  - Mining Spares Yard
  - Capital Spares Yard
- Control Room
- Lamp Room
- Security Access to Temporary Areas
- Training Facilities
- Refuge Bay (UG)
- Ventilation

An OR Plan was formulated to provide a structured framework for preparing the project for the commencement of early development. The interventions undertaken to facilitate OR, together with their respective schedule implications, are detailed in

Table 3.

Notably, activity line 11 in

Table 3 illustrates that the initiation of development could occur six months earlier than originally anticipated, relative to a scenario in which no ORR had been conducted. This advancement in the development timeline has a direct financial implication, as it accelerates the generation of project revenue, thereby contributing to an increase in the overall NPV of the project.

Table 3: Project Schedule and Interventions

			Planned			Actual			Due to ORP		
	High-Level Actions	**Intervention action due to ORR**	**Start Date**	**End Date**	**Duration (Days)**	**Start Date**	**End Date**	**Duration (Days)**	**Start Date**	**End Date**	**Duration (Days)**

10	Development Fleet	First critical equipment delivered on time	23/09/21	25/11/01	772	23/09/21	25/11/01	772	23/09/21	25/11/01	772
11	Mining Development Start	Minimum requirements not met	23/10/05	25/08/27	692	24/10/29	26/09/21	692	24/03/05	26/01/26	692
12	Lamp Room	Temporary lamp room installed	23/10/16	24/06/25	253	23/10/16	24/06/25	253	23/09/01	24/02/15	167
13	Change house	Temporary change house installed	23/11/01	24/06/18	230	23/11/01	24/06/18	230	23/08/01	24/03/01	213
15	Surface Infrastructure		22/05/02	27/02/20	1755	22/05/02	27/02/20	1755	22/05/02	27/02/20	1755
16	Project Finish			27/02/20			27/02/20			27/02/20	

With these facilities, the requirement of resources to operate the facilities was identified, as well as training for those resources. Lastly, network infrastructure was also required. The associated cost can be seen in

Table 4.

Table 4: Cost of OR Requirements

Nr	Temporary Requirements	Total
1	ORR (6 Months)	R3 000 000
2	Ventilation	R15 370 000
3	Temporary facilities	R40 570 000
4	Training	R7 550 000
5	Network Infrastructure	R12 840 000
	Total	**R79 330 000**

The below graph in Figure 2 indicates the initial project completion timeline when the box cut development was the priority, compared to the project completion with the adjusted timeline due to OR interventions resulting in early production tons.

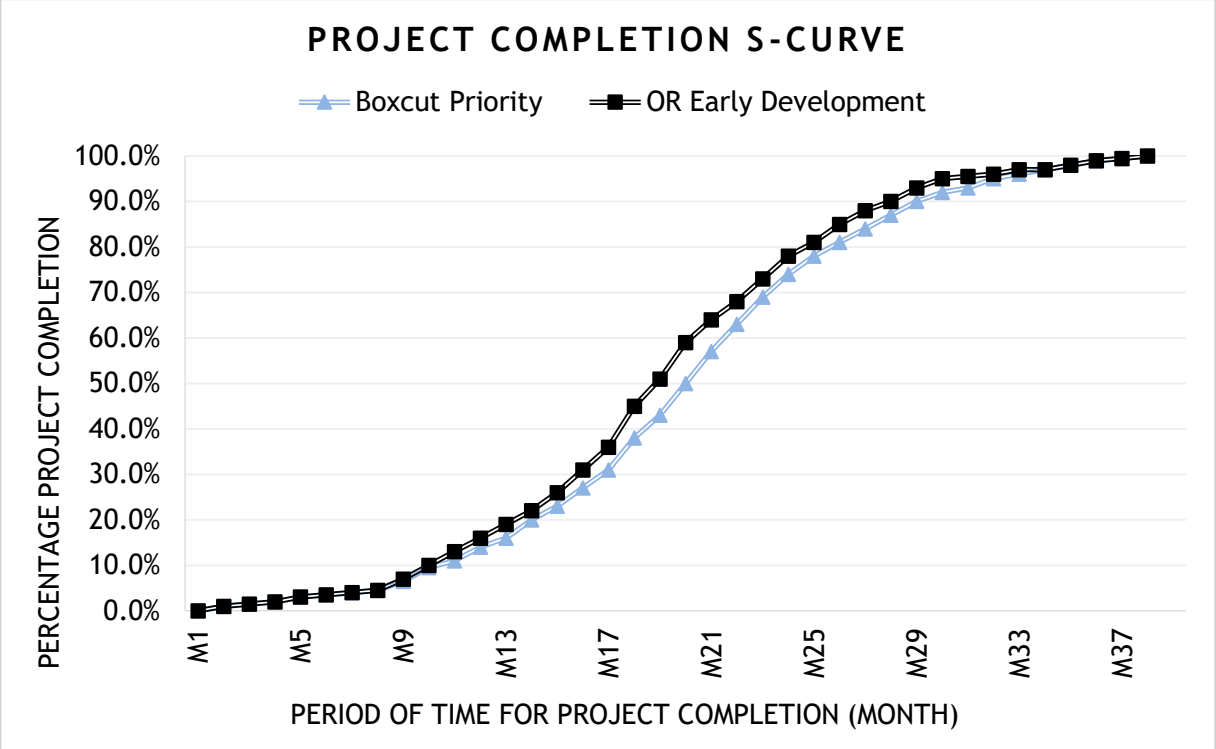

Figure 2: Project Completion S-Curve

4.4 Results

As can be seen in Figure 2**Error! Reference source not found.**, the project's s-curve moved to the left as a result of the implementation of the OR interventions identified during the ORR. Once the ORR was completed and gaps were identified, a mitigation plan (OR Plan) was developed to either bring forward the delivery of permanent facilities or implement temporary alternatives to close these gaps.

This approach allowed the date of first development with successful production to the concentrator to begin six months earlier than the actual start date as seen in the schedule, enabling earlier revenue generation. It ensures that the steady-state production is reached

earlier. Without the ORR, this would not have been possible. This demonstrates that key OR areas, such as facilities and the people, equipment, processes, and systems linked to them, can significantly affect the timeline of a capital project.

The cost of implementing the temporary facilities amounted to ± 79,330,000 ZAR. These items will be reused in the permanent facilities or would have been an expense at a later stage in the project. Over the six months, a total of ±21,665 tonnes (Tonnes Broken seen in Table 5) of platinum group metal (PGM) ore was produced.

Table 5: Measured Actuals

Month	M1	M2	M3	M4	M5	M6	M7	M8	M9	M10
Total Dev Meters	5,1	24,2	26,8	46,7	48,9	50,4	60,8	78,7	54,2	76,8
Tonnes Broken	420	1 705	1 868	3 451	3 621	4 958	5 642	7 937	5 538	8 661
Broken Grade		0,90	1,25	1,58	2,19	2,21	2,28	2,37	0,28	0,63
Tonnes Hoisted (Dry)		1 702	1 865	3 451	3 615	4 592	5 634	7 926	5 531	8 389

UG2 ore typically contains between 4.4 and 10.8 grams per tonne (g/t) of PGMs, with platinum making up roughly 45% to 55% of this content. This equates to an estimated platinum yield of around 2 to 5.9 grams per tonne of UG2 ore, depending on ore grade and processing efficiency [24] . From the ±43801 tonnes broken, up to ±258,426g UG2 platinum ore is processed through the already operational concentrator.

Using an average platinum price of 1000 USD per troy ounce for the period under discussion [25], a total of ± 147,909,358 ZAR revenue was achieved, 6 months sooner than originally planned. Thus, the OR investment yielded a financial benefit to the mining operation by not only ensuring that the project delivery remains on schedule but also enabling revenue 6 months earlier than originally planned.

When looking at the impact the revenue gain has on the overall NPV of the project, the analysis shows that OR interventions increase the potential NPV and partially close the gap between the best-case NPV and the value lost due to start-up delays as identified with the ORR. In this case study, the ORR identified critical gaps, such as the absence of temporary facilities, early workforce mobilisation, and supporting infrastructure, that would have prevented development from progressing as scheduled.

The NPV was calculated using the following approach:

- Baseline (Best Case NPV): Calculated on the assumption of on-time delivery, no significant delays, and revenue streams commencing as originally planned.
- NPV Without OR: Adjusted to reflect a delay in cash inflows, discounted back using the project's cost of capital. This represents the scenario in which OR interventions were not implemented.
- NPV due to OR: Incremental NPV recovered by bringing forward production by six months through OR measures.
- Final NPV: Combines the baseline with the effect of the avoided delay, showing that although some value leakage persists relative to the theoretical best case, the OR interventions enabled partial recovery of lost value.

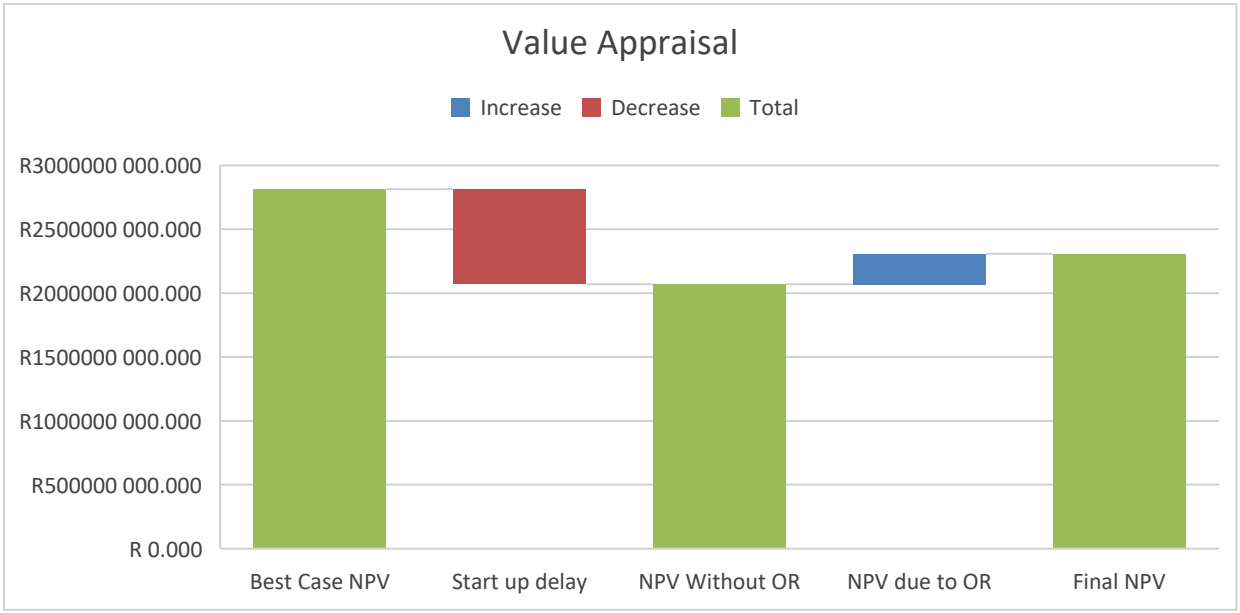

Figure 3: NPV Calculation

As illustrated in Figure 3, the project's NPV without OR falls significantly due to the expected delay. The implementation of OR interventions restores a portion of this lost value, resulting in a final NPV closer to the best-case scenario. This quantification demonstrates how targeted OR actions translate directly into financial outcomes by accelerating revenue generation and reducing value erosion.

5 CONCLUSION & RECOMMENDATION

5.1 Conclusion

This study examined the role of OR in capital projects within the South African platinum mining sector, with a specific focus on its financial benefit. The findings underscore that inadequate OR planning significantly contributes to project delays, inefficiencies, and missed financial opportunities, as well as failure to successfully hand over to operations after project completion.

Through a systematic scoping review, we identified the reasons for the project's failure to hand over. With an applied case study, it was demonstrated that OR interventions, such as temporary infrastructure and early personnel mobilisation, can improve project delivery timelines and unlock early revenue generation while increasing the potential NPV by 10%.

Failing to identify these gaps and intervene is also the reason why projects lose the opportunity for additional revenue or fail to successfully hand over to operations after project completion, and this is linked to OR.

While the financial investment of OR can be substantial, the resultant benefits justify its inclusion as a strategic component of capital project planning. Furthermore, the research highlights the limited integration of financial quantification within current OR literature, particularly in the context of South African mining, presenting a critical area for academic development.

5.2 Recommendation

Mining companies are advised to institutionalise OR as a formal and integral component of capital project development. This should commence during the early planning phases and continue through to handover and ramp-up. OR planning should be embedded within the

broader project governance framework, supported by dedicated resources, and aligned with project financial evaluations to ensure its contributions are adequately quantified and incorporated into investment decisions.

The case study is limited to a single case, which constrains its generalisability. Causality is inferred rather than tested. Future work should include a case study to indicate the possible capital value loss if OR is not implemented as a control study. Interviews can also be done to enable the triangulation of findings across literature, case evidence, and expert perspectives, thereby improving the credibility and applicability of the research outcomes.

Future academic research should address the current deficiencies in the literature by developing quantitative models that link levels of OR maturity to financial and operational outcomes. Comparative studies across sectors such as infrastructure, oil and gas, and energy could yield valuable insights and foster knowledge transfer to the mining industry. Case studies following projects from inception through to steady-state operations would provide more robust evidence of OR's long-term value.

Furthermore, with the growing emphasis on environmental, social, and governance factors, further research should explore how OR can be leveraged to support compliance with sustainability and social license requirements. Collectively, these research efforts would help close significant gaps in the academic field, enhance industry practice, and improve the financial resilience and execution success of capital projects in the mining sector.

ABSTRACT

For organizations in South Africa, effective product traceability is crucial, especially when it comes to product recalls due to defective goods. Traditional ERP systems, despite having traceability modules, often struggle to maintain data accuracy and real-time processing across complex supply chains involving multiple suppliers. This study investigates the possible integration of blockchain technology within an ERP system to address the primary seamless data flow challenges and enhance supply chain efficiency. Drawing on the established DMAIC framework to identify the short comings of the current software processes, it was identified that inefficiencies such as duplicate entries, format inconsistencies, and lagged transactions posed a substantial threat to data integrity and business process workflows, especially within context of recall events. The study further carried an assessment of the data synchronisation process within the ERP system and then proposes strategies that could be adopted to incorporate blockchain technology to improve data synchronisation and handling.

Keywords: Blockchain technology, ERP integration, Supply chain management, Product traceability

1 INTRODUCTION

Today's supply chains have become exceedingly intricate and depend heavily on both standalone and centralized information systems within the company, occasionally even combining the two [1]. From raw material suppliers to the point at which the client receives the product or service, these central standalone systems operate at several organizational levels and throughout the supply chain network [2].

Effective customer service is the primary goal that these nationwide companies have in common [3]. However, with the rise of globalization, it has become nearly impossible to assess information and manage risk in this complex network while adhering to the various regulatory laws and taking into account the various cultures and human behaviors found in supply chain networks [1].

An example of a central system is an Enterprise Resource Planning system (ERP), which is regarded as one of the most significant information technology systems ever developed and is capable of effectively integrating corporate activities onto a single platform [4].

The lack of precise product life cycle data is a crucial strategic and competitive issue affecting supply chain sustainability [5]. As an example, consider the July 2021 statement by Tiger Brands, the biggest food producer in South Africa, that it was immediately recalling more than 20 million canned vegetable products because of safety issues resulting from defective cans. This corresponds to a 9% annual production recall, which might have a financial impact of R650 million.

That is but one illustration of how product recalls affect businesses, without considering how long it takes for them to recognize the need to carry out a recall. This puts people's health in danger in addition to causing damage to the company’s finances. Due to their heavy reliance on these centralized isolated systems, these issues make it questionable whether present supply chains can securely enable information transparency without increasing the risk of fraud or cyberattacks [1].

The answer to this problem may be blockchain technology (blockchain). Blockchain is thought to have the promising potential to drastically transform the supply chain trade model into a reliable ecosystem of exchange because of its ability to improve information authenticity and transparency. [5]. Blockchain is a type of shared, distributed ledger that contains a series of blocks that form a chain of batched transactions [6].

The elimination of a third-party administrator brings benefits to the supply chain [5]. People can independently verify the content of the database at a specific moment and the consistency with what every other member also sees[7]. This fact ensures that all members have a reliable view of the common database.

The aim of this study investigates the integration of blockchain technology within an ERP system to enhance aspects related to product traceability, thereby improving reliability, trust and transparency for supply chain stakeholders.

1.1 Objectives of the study

1. Determine and record all current issues affecting data traceability and transparency with ERP integration of information within 2 companies.
2. Use data analysis tools to determine and rank the main causes of inefficiencies impacting traceability, data integration and handling between an ERP and blockchain.

2 LITERATURE REVIEW

The literature review looks at the complex nature of supply chain management (SCM) and its developments, particularly in relation to blockchain technology and traceability. This section covers the fundamental concepts of SCM, particularly the interaction of traceability and blockchain in the supply chain that helps monitoring product quality, assures proper communication across the wide networks, and manages the product distribution effectively.

2.1 Supply Chain Management (SCM)

SCM includes monitoring and tracking flows of goods from raw material to final products [8]. Every business operating in this turbulent business world should focus on having effective supply chain operations that ensure a smooth movement of its goods and services. Ensuring that all the products and services are up to the required agreed specifications [9].

It is important to highlight a supply chain's complexity and multilayering. It involves multiple supplier tiers that supply a primary manufacturer. Every tier has a unique group of suppliers, which may include the components, raw materials, or services that are ultimately used to create a hierarchy. These retailers may be located in various cities or countries. To ensure that the flow of these goods and services is smooth within the company and between the supply chain's organizations, a variety of skills are needed [10].

[10], in his research work, highlights that communication plays the key role in running effective operations for South African firms. Further mentions how effective communication allows clear understanding of the roles and responsibilities of each throughout the supply chain to avoid confusion that could result in inefficiencies.

Enterprise Requirements Planning Systems (ERPs) provide a competitive advantage to SCM resource optimization, as ERP systems are used within organizations to share, communicate information, and manage company-wide business processes on a unique and centralized database [11]. By optimizing the resources of the supply chain, ERP gives a competitive advantage [6]. However, in the context of sustainable SCM, less is known on how buyers and suppliers can jointly unlock sustainability in the supply chain [12]

In South African businesses, technical skills are regarded as the core of a successful SCM [13]. Technical skills are the necessary interpersonal, strategic, cognitive, and self-assured qualities, according to [10]. When properly cultivated, these skills significantly increase the success of SCM initiatives in South African firms.

2.2 Traceability

The capacity to follow a product across the supply chain and to record and retrieve product information are the two primary components of supply chain traceability [14]. These elements are especially pertinent to our work since they address both the tracking of product qualities and the actual movement of products across the supply network [15].

South Africa has fallen behind more developed nations [16] and needs to be up to date with worldwide Industry 4.0. For this to occur, organizations in South Africa have to implement collaborative work and apply change management practices [17].

Traceability of the supply chain is crucial for risk management, quality control, and promoting sustainability in many contexts. [15] defines one of the key components of traceability is being able to determine the sources of raw material. This is essential because it enables businesses to ensure that suppliers adhere to social and environmental standards and overall quality of their products. In the food and beverage industry, consumers rank trust as the most crucial factor [18]. [19], states that consumers are in desperate need of comprehensive information about food from farm to fork [20]. Traceability should include the ability to pinpoint the source

of every input, including medicine, animal feed, and forage, as well as any chemicals that may have an impact on the items' quality either directly or indirectly [21].

Users can react when a product recall is necessary within today's ERP systems. Companies can keep a tight eye on internal processes, which also guarantees data accuracy and consistency, however, it does not offer traceability outside the walls of the company [22].

Walmart Inc. (WMT), one of the largest brands in the global retail industry, developed a cutting-edge blockchain-based food traceability system to track food in North America [19]. Food firms were able to increase the transparency, accuracy, and trustworthiness of their food information thanks to blockchain. Additionally, it saves Walmart 2.2 seconds instead of seven days when tracking the origins of a particular food [19]. It is anticipated that blockchain will significantly affect SCM operations in other sectors as well. Standardizing the quality documentation processes throughout the supply chain can increase the efficiency of everyone involved in the supply chain [23].

2.3 Blockchain Technology

Blockchain can address key supply chain challenges related to efficiency, counterfeiting, and traceability [24]. Blockchain functions through a network of blocks, each of which has a copy of the complete blockchain, as opposed to conventional databases that are managed by a single entity [25]. These blocks of data are connected in chronological order [26]. This is done by adding the data to a new block, linked to the previous block, and embedding the unique code of the previous block in the header of the current block.

Blockchain technology makes otherwise chaotic environments more orderly, simple, transparent, trustworthy, and automated [25]. It enables businesses to keep an eye on the whole supply chain, upstream and downstream, by giving manufacturers access to comprehensive information on every part being produced [24].

By tracking transactional information and creating a chain of records and ownership, blockchain technology also increases traceability through record-keeping processes that are permanent, unalterable, and verifiable [25]. Although it is hard to change one block in the chain, it is almost impossible to change every block at once [27].

ERP systems are software designed to organize and exchange data amongst departments within a company [6]. Blockchain offers a fundamentally different approach from ERP systems, it relies on decentralized record-keeping to ensure security and transparency across all transactions in the supply chain [5]. Adding blockchain technology to an ERP system that already exists supports collaboration across the platform and expands its capabilities.

2.4 Blockchain in Supply Chain Management

Blockchain’s potential to ensure validity, traceability, and reliability of information and smart contracts' potential to create a trustful environment has shown that supply chains are very likely to face a significant change [28].

The adoption of new technologies, like blockchain in the supply chain, is heavily influenced by relative advantages like increased security and transparency [29]. But companies shouldn't decide to use blockchain-based just on these alleged benefits around the technology. Rather, they thoroughly assess the technical difficulties and the real benefits blockchain will bring to the company [23].

The cost of implementing new technologies, such as blockchain technology, in supply chain businesses is one of the factors that [34] identifies as a barrier to adoption. These include costs for hardware, software, and network infrastructure required to host the blockchain.

The practical applications of DMAIC are documented in several research studies; however, relatively few have been used to evaluate blockchain technology [30]. The author discusses the importance of statistical tools like Pareto charts, control charts, and value stream maps, which enable extensive analysis and actual demonstrations of financial returns.

DMAIC is notable for its methodical, transparent approach to problem-solving [31]. It collects and analyses data, identifies errors, and implements effective solutions by integrating advanced statistical tools with a methodical approach. The fundamental goal is to help project teams maintain focus throughout the entire process, ensuring reliable results and reducing inefficiencies [31].

ERP systems improve supply chain efficiency through better use of resources, traceability, communication, and inventory control, while blockchain adds stronger transparency, security, and traceability [43] [44]. While most studies focussed on developed countries, there was minimal literature within the South African context.

In the next section the methodology and findings have been combined in the discussion.

3 METHODOLOGY AND FINDINGS

This section examines the research methods and results that are used to tackle the integration issues experienced between an ERP and blockchain technology. This section is helpful in putting an existing system in the right perspective and looking for corrective and preventive actions thereafter. In pursuit of these aims, the Define, Measure, Analyse, Improve and Control (DMAIC) technique was adopted as the most appropriate structure for managing this work. In this section, each step of the DMAIC methodology will be introduced in detail providing methods applied and results to achieving the key objectives of the study.

3.1 DMAIC Method

DMAIC methodology, shown in Figure 1, was used to guide the research process, which provides a structured and systematic approach to streamline operations, minimize errors, and integrate between systems. This method consists of five steps and stands for DMAIC, which stands for Define, Measure, Analyse, Improve, and Control [32]. This methodology provides a structured, data-driven approach that's proven effective in both industrial and service contexts [33]. Each phase in the DMAIC cycle brings focus to the process challenges and opportunities for measurable improvements in teaching and administrative operations [34]. By adopting DMAIC, this project follows a data-driven, quality-focused methodology tailored to long-term improvements and effective integration.

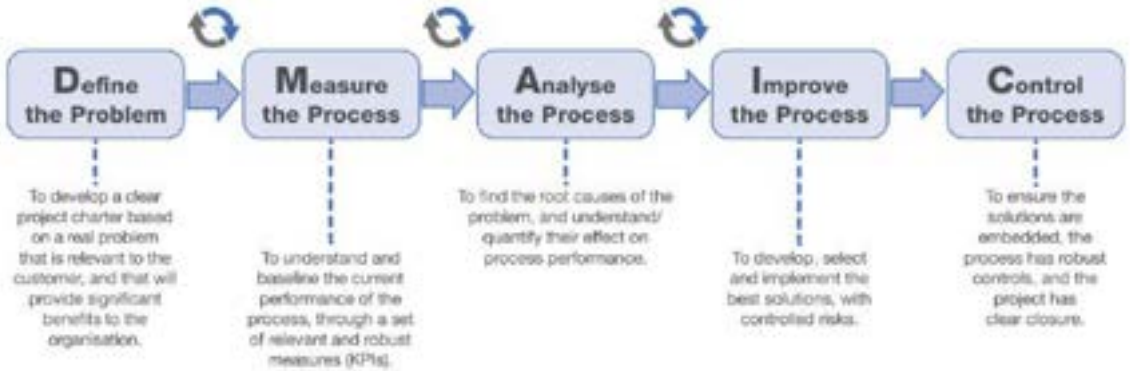

Figure 1:Using DMAIC on a Six Sigma project [35]

3.1.1 Define Phase:

The project commenced at the Define stage, during which a comprehensive project plan in Figure 2, outlining the scope and objectives of the planned integration of SYSPRO and

blockchain technologies was formulated. Project Kick-off and Scope Definition first clearly define the project's goals, roles, and resources. Current State Assessment, will outline the current workflows, collect baseline data, and pinpoint SYSPRO's operational inefficiencies. Design Phase consists of feasibility investigations, solution planning, and pilot program development. The suggested pilot solution will be thoroughly examined during the Test and Evaluate phase. Any remaining problems will be resolved, and controls will be implemented

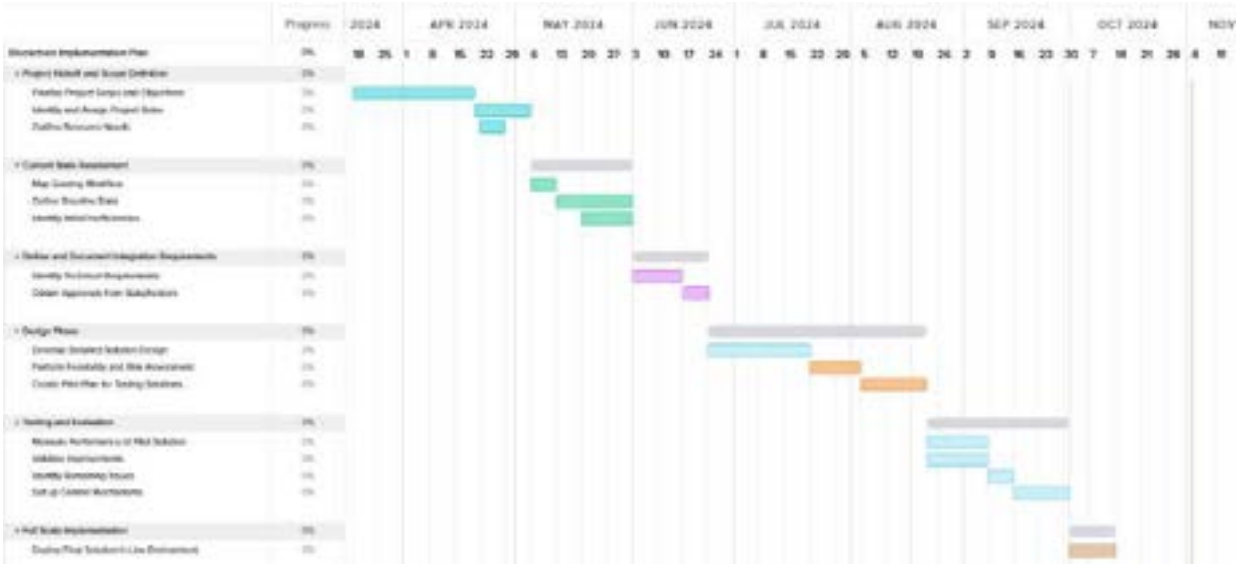

Figure 2: Project Plan to Improve Traceability in Supply Chain

Process Mapping was used to depict the present flow of sales orders and to provide a meaningful and ordered path for integration. Currently, Company A and Company B manage sales orders through back-and-forth emails, with numerous manual steps involved shown in Figure 3. Manual input errors in an ERP can cause mismatches between orders and deliveries, resulting in misunderstandings and strained business relationships. Blockchain provides a solution by creating a tamper-proof, transparent record of transactions, while dramatically simplifying the overall workflow.

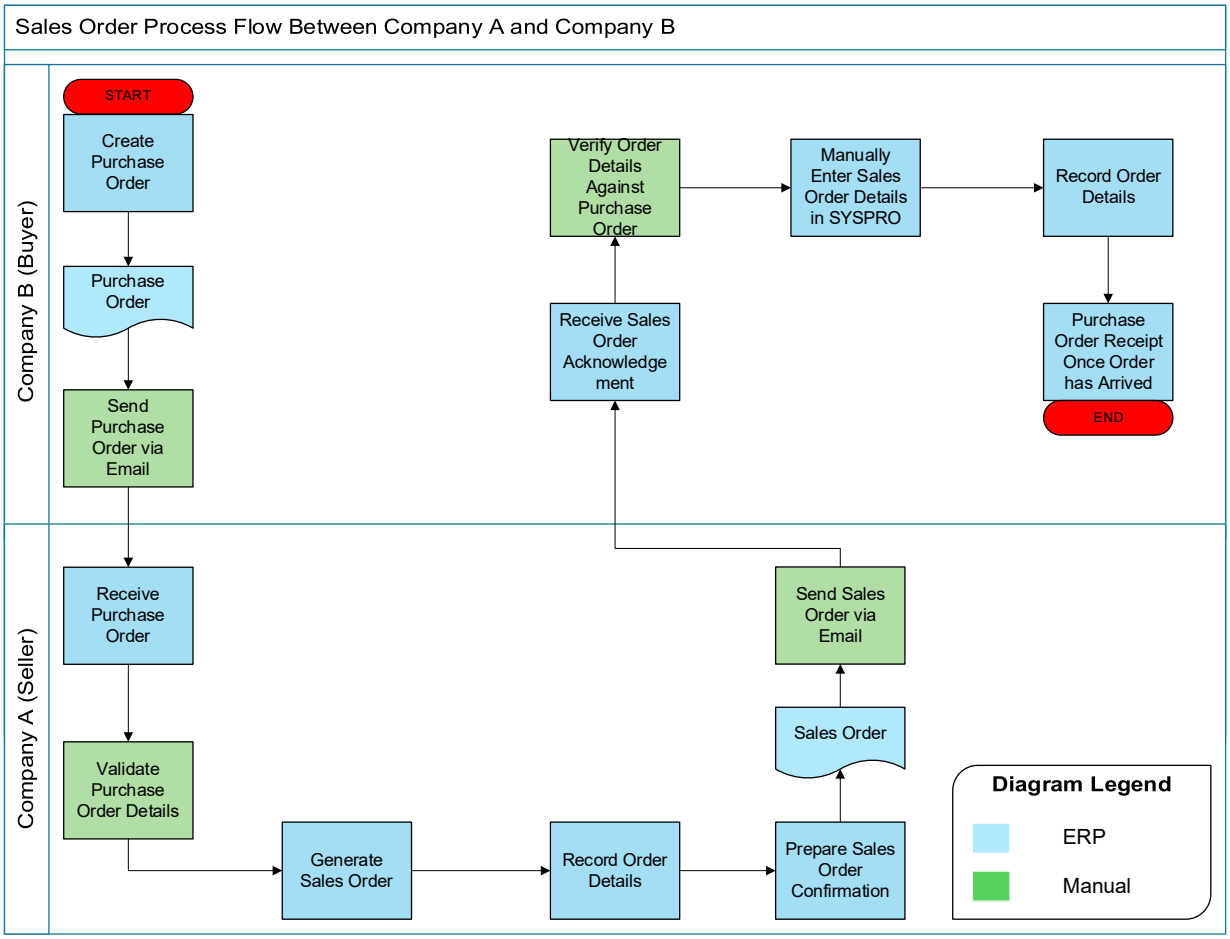

Figure 3: Sales Order Process Flow between Company A and Company B

3.1.2 Measure Phase:

The initial data on how ERP systems from two different companies handled sales order processing were collected in the Measure phase. This step looks at how accurate the data was and how fast it was processed, as well if errors were encountered. Key metrics include transaction speed and error rates. These gives us a first look at performance and set standards for later stages. Data redundancy is the largest issue, according to the Pareto analysis in Figure 4, with 432 occurrences overall, or 52.4% of the total.

Less frequent issues over the past year include server capacity constraints, data entry errors, and system outages. While they are rare, they also help produce unnecessary inefficiencies in the system.

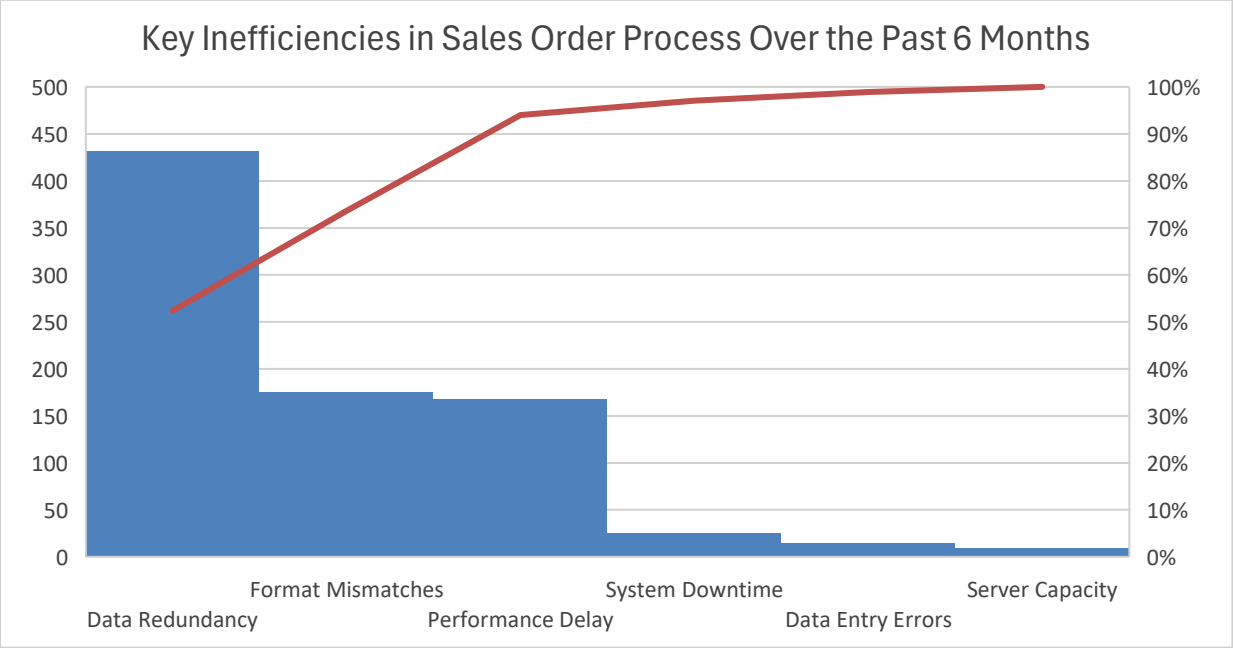

Figure 4: Pareto Chart for the Key Inefficiencies in the Sales Order Process

3.1.3 Analyse Phase:

Data gathered from determining the main reasons for delays and integration problems in sales order recording were examined during the project's Analyse phase. Using the Five Whys in Table 1, problem mapping was used to prioritise the root causes of inefficiency. The development of solutions that address the underlying issues was made possible by this deeper comprehension of the causes [36].

5 W's 1H	Detail of Phenomena	How Frequent
What?	Redundant data entry steps in the sales order processing workflow	Multiple times per order
When?	During each sales order entry and update, especially when correcting errors	High frequency during each transaction
Where?	Across the ERP system and manual record-keeping processes	Distribution center and sales department
Who?	Sales personnel, data entry staff, and distribution team	Key staff in order handling and data entry
Which?	Redundant steps include re-entering order details, double-checking entries, and reconciling data manually	All involved in sales order processing
How?	Multiple systems require duplicate data entries, causing inefficiency and increasing error potential	Repeatedly for every transaction
Why?	Answer	
Why-1	Different systems require separate entries, and they lack automated synchronization.	
Why-2	There is no centralized system to update data automatically across departments.	
Why-3	Manual verification is needed to ensure data consistency between the systems.	
Why-4	Discrepancies in data formats and standards lead to compatibility issues.	
Why-5	High reliance on manual processes, as there is no automated solution for data reconciliation.	

Table 1: The 5 Why sheet [37]

This gave rise to a Fishbone Diagram in Figure 5, which gives an explicit view of where the focus of the project should be in during the Improve phase while working towards the identified output. This information provides a clear path forward for implementing targeted improvements across the blockchain implementation lifecycle, including data format standardization, automation to reduce duplication of work, and improved performance to increase transactional throughput.

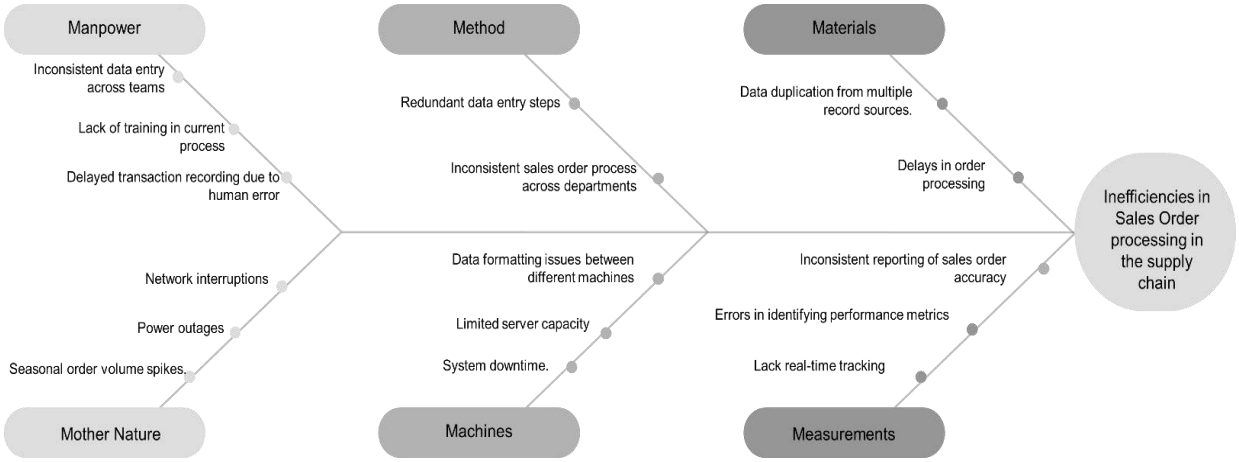

Figure 5: Fishbone Diagram [38]

3.1.4 Improve Phase:

In order to address the primary causes of inefficiency and integration issues found in the Analyse phase, the Improve phase focuses on describing viable solutions based on theory and research [43]. Reformatting data for ERP-blockchain compatibility, automating complex data input processes, and improving system architecture to manage higher data volumes are some potential strategies. These solutions are still hypothetical at this point, but they also provide the chance to use prototyping tools to assess their feasibility.

These new pieces of innovation will be tested using Ganache Tool, which is a blockchain development tool that allows us to simulate real blockchain transactions within an ERP test environment. [39] and [40] explained how the test's controlled environment enables accurate measurement of traceability improvements. In their research, both authors tested the blockchain integrations and deployed the smart contract in the local network using Ganache.

3.1.5 Control Phase:

Control ensures that the improvements of the Improve phase are maintained over time [41]. It involves determining the right performance measures to track, recording the new processes, and educating employees on the new system behaviours. There are Shewhart control charts that help monitor important parameters.

Control charts were employed by [42] because they facilitate the clear visualization of data trends and patterns, which makes it simpler to spot irregularities or disruptions that could otherwise go overlooked. More accurate monitoring and identification of process changes are supported by their emphasis on general trends rather than specific data points. In this research control charts will be beneficial in the identification of integration issues between ERP systems and new technologies.

4 CONCLUSION

This study explored how blockchain can be adopted with a commonly used ERP system to improve data synchronization in supply chains, especially during order processing. Using the DMAIC framework, the research identified ERP inefficiencies, analysed causes, and proposed blockchain-based improvements. Findings show that, when properly integrated, blockchain can boost supply chain responsiveness, transparency, and trust, but challenges such as data standards, stakeholder resistance, and integration complexity must be addressed. The work contributes to both academic and practical discussions, highlighting blockchain's potential for enhancing ERP traceability and integration. Future studies could test the blockchain prototype in Ganache and investigate scalability, cost-benefit analysis, and practical prototypes in supply chains in South Africa.

ABSTRACT

Within the flexographic label printing industry, the functionality of the end product is of the utmost importance. Used thereafter on high-speed packaging lines, any label set with a poor coefficient of friction (COF), could result in high rejection rates and monetary losses. This study aimed to investigate the optimum combination of the critical input variables used in the label production process to ensure a consistent COF. The study utilised the Design of Experiments (DOE) approach focussing on three critical factors namely: lamp temperature; anilox density and machine speed. The results were then obtained and tested using a three-way analysis of variance (ANOVA) approach to evaluate the statistical significance of each factor in contributing to the COF variability. The findings suggest that by controlling the lamp temperature during the production process, yielded the greatest potential for maintaining an optimal COF.

Keywords: Flexographic, Coefficient of friction, Design of Experiments, ANNOVA Approach

1 INTRODUCTION

Retail marketing is anchored in strategies that promote brand awareness and drive consumer purchases. Among its foundational components, the "product" dimension encapsulates design, functionality, packaging, and perceived quality — critical elements in the packaging industry. To meet these demands, packaging companies implement advanced print and quality assurance processes. Within this space, flexographic printing is a widely adopted method, and quality metrics like the coefficient of friction (COF) have emerged as key variables influencing packaging performance.

1.1 Problem Background

This study is situated within Printing & Packaging Industries (P&P), a South African label manufacturer serving the retail, food and beverage, pharmaceutical, and automotive sectors. The company utilizes both flexographic and digital printing technologies, producing shrink sleeves, self-adhesive labels, and BOPP-based poly rolls. Despite operator expertise and available equipment, achieving consistent COF values during shrink film printing remains a challenge, with nearly 9% of production samples failing internal COF standards in early 2024.

The COF measures the slipperiness or resistance between surfaces and plays a crucial role in high-speed label application systems. It is measured using a specialized COF tester which evaluates the static and kinetic friction between the film and a standard surface.

Figure 1: The Equipment Used for Testing the Coefficient of Friction

In the context of shrink film labels used during automated bottling, a COF that falls outside optimal thresholds (typically 0.15 to 0.25 for shrink film) can result in misfeeds, jams, or label slippage. This leads to customer dissatisfaction, production inefficiencies, and increased waste.

COF inconsistencies are mitigated by adjusting input variables such as ink viscosity, press pressure, print speed, anilox roll density, lamp temperature, and environmental humidity. However, the absence of a standardized parameter framework causes variability across production teams and runs, resulting in costly setup delays and inconsistent product quality.

This research aims to investigate the relationship between these input variables and the resulting COF, with the goal of defining optimal parameter combinations to ensure consistent COF values during shrink film printing.

1.2 Problem Statement

From January to March 2024, 628 samples were tested from production runs, with 56 (8.92%) falling outside the acceptable COF range (± 0.15 to 0.25), leading to internal delays and setup adjustments. These issues do not necessarily stem from operator skill, but rather from the absence of standardized settings for the variables influencing COF which includes the drying lamp intensity settings, inconsistent drying times at the print stations and the variations within

the batches of inks being used. Without clear standards, the variation in operator decisions will persist, making consistent first time-right setups difficult to achieve.

1.3 Aim of the Study

To investigate the optimum combination of critical input variables required to ensure a consistent COF in shrink film printing, thereby reducing quality-related production inefficiencies.

1.4 Objectives

1. To examine and document the current flexographic printing process and COF testing methodology.
2. To analyse the relationship between key input variables and COF outcomes using Design of Experiments (DOE).
3. To propose parameter settings that optimize COF and improve production consistency.

1.5 Research Questions

1. What input variables critically influence the COF in shrink film printing?
2. How does each variable affect the COF measurement?
3. What process improvements can be implemented to achieve a consistent COF?

1.6 Research Limitations

To reduce variability, the study focuses exclusively on shrink film substrates and includes only flexographic presses from the same OEM (Mark Andy) using UV drying. All production runs use stations 8 and 9 for final print application. Additionally, only white ink is considered as the final layer to ensure uniform chemical interaction across samples. These constraints ensure accurate measurement of input variable impacts but limit the generalisability to other substrates or press types.

1.7 Significance of the Study

The study holds strategic importance for P&P by offering a potential framework to standardize COF-related settings, thereby reducing waste, enhancing production efficiency, and improving downstream application performance. Moreover, the research contributes to the broader field of flexographic quality assurance by providing practical insights into variable interactions in shrink film printing. The findings can assist similar packaging operations in setting new industry benchmarks for label performance and operational reliability.

2 LITERATURE REVIEW

2.1 The Concept of Quality

Although there are numerous definitions of quality, quality can be understood as the degree a product or service fulfils its intended function and meets or exceeds the expectations of the consumer [1]. Quality is a multifaceted concept that has evolved from guild craftsmanship in the Middle Ages to today's strategic, customer-centric methodologies. Historically, quality transitioned from manual inspection to scientific methods during the industrial revolutions, with major contributions by pioneers like Taylor, Shewhart, Deming, and Juran. Post-World War II developments introduced frameworks like Total Quality Management (TQM), Six Sigma, and Lean, emphasizing prevention over inspection, employee involvement, and continuous improvement.

Modern quality tools include Statistical Process Control (SPC), which helps reduce variability through real-time monitoring; TQM, which integrates quality across functions; PDCA for iterative improvement; and Six Sigma's DMAIC framework for structured problem-solving [2].

Lean Manufacturing adds efficiency through waste reduction, while Quality Function Deployment (QFD) aligns production with customer expectations [3]. From the early 2000s, Digital Twins have been introduced into manufacturing. This concept, which involves simulating the physical process or system, enables quality improvement through real-time monitoring and optimizing of the physical process counterpart [4]. Among these, Design of Experiments (DOE) stands out for identifying relationships between variable inputs and output performance.

2.2 Quality in Printing

Flexographic printing, commonly used for packaging and labels, demands high-quality output due to its impact on product branding and functional performance. Achieving high print quality involves attention to pre-press, press, and post-press operations. Pre-press involves preparing printing plates, formulating inks, and ensuring substrate readiness. During the press stage, critical parameters such as registration, ink density, and anilox roll condition are closely monitored. Post-press processes include visual inspection, colour matching, and dimension verification.

General tests such as tensile strength, barcode verification, gloss measurement, and colour fastness help ensure durability, scan ability, and aesthetic standards. However, when it comes to shrink sleeves—a type of label that conforms tightly to container surfaces after heat application—the requirements are more stringent. Shrink films must not only adhere visually but also maintain integrity through the shrinking process without distorting print or losing adhesion.

Key quality measures specific to shrink sleeves include ink adhesion, shrink percentage, and most importantly, the coefficient of friction (COF). The COF determines how smoothly the film moves across rollers and applicators during high-speed labelling. A COF that is too high may cause the film to jam, while a COF that is too low may lead to slippage or misfeeds, both of which compromise production efficiency and customer satisfaction. Therefore, maintaining COF within specified limits is not just desirable—it is essential [5].

The COF is also indirectly influenced by several process variables including ink viscosity, surface treatment levels, drying lamp intensity, and press speed. High viscosity inks, for instance, may lead to offsetting and uneven ink transfer, which in turn affects the surface friction. Similarly, inadequate surface treatment or low lamp intensity results in poor ink adhesion, increasing the surface roughness and COF. These findings are consistent with the broader packaging quality literature, which highlights that deviations in ink or surface properties can propagate into quality failures downstream if not statistically controlled.

2.3 Results

Design of Experiments (DOE) provides a structured and statistical approach to investigate how each of these variables influences the dependent variable [6]. By using full factorial or fractional factorial designs, DOE allows for a systematic study of variable interactions under controlled settings. This is essential for shrink film, where even minor deviations can result in significant performance issues.

Moreover, DOE reduces trial-and-error by guiding the experimenter toward optimal settings, improving process stability and product quality. Unlike reactive quality control methods, DOE is proactive, it supports process understanding and predictive control. This makes it particularly suitable for environments like flexographic printing where multiple interacting factors influence output quality.

Previous studies emphasize that surface treatment, ink viscosity, lamp intensity, and ink adhesion are the most significant factors affecting COF [5]. DOE allows for the quantification and prioritization of these variables, enabling data-driven decisions. There is further support

for the DOE's relevance in packaging by demonstrating its ability to reduce variability and improve reproducibility [6]. From recent research, opportunities of integrating the DOE and Digital Twin modelling have been highlighted, enabling data collection across simulated and real production systems. This kind of integration can strengthen the predictive capabilities of DOE and expan on its use for the analysis of single variables to system-level quality monitoring [4].

In summary, DOE emerges as the optimal quality improvement method for the flexographic printing of shrink film due to its statistical rigor, process optimization capabilities, and initiative-taking nature. Its integration can help label manufacturers reduce waste, avoid customer rejections, and achieve consistent COF values—all critical for maintaining operational efficiency and customer satisfaction in packaging operations.

3 RESEARCH METHODOLOGY

3.1 Introduction

A research methodology is typically viewed as a method to systematically solve a research problem [7]. The aim of this study is to investigate the optimum combination of the critical input variables in a shrink film printing process to ensure a consistently conforming COF. The methodology signifies this aim in that the Design of Experiments (DOE), by its very nature, involves the carrying out of experiments that determine the relationship between the input variables and an output variable or result.

3.2 Research Framework

The methodology employed in this study followed a structured Design of Experiments (DOE) framework. It was guided by three objectives:

1. To examine and document the current flexographic printing process and COF testing methodology.
2. To systematically analyse the relationship between key input variables and COF outcomes.
3. To propose parameter settings that optimize COF and improve production consistency.

3.3 Method to Achieve Objective 1: Process Analysis and Documentation of the Flexographic Printing and COF Testing Methods

Visual tools such as process flow diagrams and Standard Work Instructions (SWIs) were developed through physical observation across three shifts. These documents captured the print workflow, focusing on the setup and execution of COF testing procedures.

3.4 Method to Achieve Objective 2: Experimental Design to Analyse the Relationship between Key Input Variables and COF using the DOE

3.4.1Determination of Sample Size and Experiments

To guide the experiment, a failure mode and effects analysis (FMEA) was carried out to understand the relationship between certain critical input variables and the COF. The three variables highlighted as having the highest risk priority number (RPN) would be the focus variables for the experiment.

A full factorial design was used to test three independent variables founded from the FMEA — machine speed, lamp temperature, and anilox density—at two levels each. The choice of a full factorial design was made instead of the fractional factorial design to ensure that all the main effects and interactions could be captured without confounding. Although fractional designs are efficient in the use of resources, they present a risk of aliasing effects which is

not desirable for the study given that minor variable interactions could critically affect the COF.

To determine the number of experiments to be conducted, the following formula was followed in line with the DOE methodology:

$$Number\ of\ Experiments = 2^k \quad \textbf{(1)}$$

Where:

- 2 represents the number of levels per factor,
- k represents the number of factors, in this case 3 [8]

Therefore, it can be determined that 8 experiments needed to be conducted.

Each experiment was replicated 5 times for statistical robustness. For each of the three parameters, two levels are assigned as follows:

- Machine speed: a low speed (-) and a high speed (+)
- Lamp temperature: a low temperature (-) and a high temperature (+)
- Anilox density: a low density anilox (-) and a high density anilox (+)

The breakdown of experiments that cover all combinations of the abovementioned parameters is as follows:

Table 1: Table Showing the Combinations of the Input Variables per Experiment

Experiment	Machine Speed	Lamp Temperature	Anilox Density
1.	Low (-)	Low (-)	Low (-)
2.	Low (-)	Low (-)	High (+)
3.	Low (-)	High (+)	Low (-)
4.	Low (-)	High (+)	High (+)
5.	High (+)	Low (-)	Low (-)
6.	High (+)	Low (-)	High (+)
7.	High (+)	High (+)	Low (-)
8.	High (+)	High (+)	High (+)

The hypothesis for this design was that the three variables are independent. However, there is a potential for confounding through the two-way and three-way iterations. These were explicitly tested during the ANOVA analysis.

3.4.2 Sample Preparation and Testing

Experiments were conducted on a Mark Andy flexographic press using the same batch of PET shrink film. Samples were printed and collected under uniform machine settings. Per sample, two sizes were cut and tested for dynamic COF using a calibrated tester.

Figure 2 and 3: The Shrink Film Roll and Ink Used for the Experiment and the Flexographic Print Stations Respectively

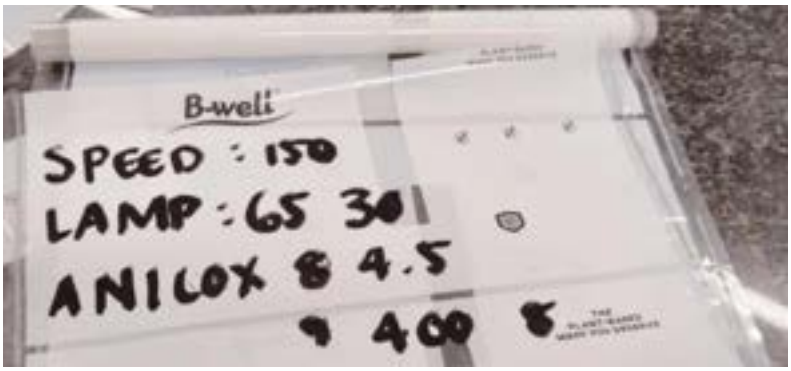

Figure 4: A Sample of an Experiment

Figure 5: Sample Preparation for COF Testing

Figure 6: COF Testing

3.4.3 Sample Data Statistical Analysis

The dataset of 40 COF values was analysed using SPSS software. A three-way ANOVA and multiple regression analysis were used to identify significant effects and correlations among the factors i.e. determination of whether the relationship is positive, negative, strong, weak or non-existent [9]. The statistical testing also confirmed whether the hypothesised independence of the factors was held, and quantified the strength of confounding through observed interactions.

3.5 Method to Achieve Objective 3: Strategies for Optimizing Input Variables for COF Consistency

The outcomes were assessed against a COF specification of 0.15 to 0.25. Experimental validation was carried out for drawing a comparison of the COF values to the specifications. From each comparison, the experiment was marked as “conforming” or “non-conforming”. The optimum combination of the three parameters that would yield a consistently conforming COF result was identified and documented at this stage. It is this combination of parameters that will be used to guide the future production processes.

3.6 Ethical Considerations

All participants were informed and provided voluntary consent. The data was anonymized, handled with integrity, and proprietary information protected in line with organizational confidentiality policies.

The maintenance of the data’s integrity remains a key concern. As the researcher of the study, it is critical to ensure that the data that is collected, recorded and analysed is done in an accurate manner without any manipulation or falsification. There is an obligation to report on the results honestly, even if it means they do not align with the expected outcomes.

Environmental and operational safety were upheld within the context of the use of equipment and machinery. Safety protocols were followed to ensure that no harm is inflicted towards the operators, inspectors and observers. Regarding the impact to the environment, PET shrink film, UV drying printing inks and UV lamps were utilized in the experiments. The waste generated was disposed of using practices that comply with environmental regulations.

This methodology integrates process mapping, DOE, and statistical validation to identify optimal COF conditions in flexographic printing. The structured approach ensures reproducibility and operational relevance. Through explicitly motivating for the full factorial design choice, testing hypotheses on variable independence, and sequencing optimisation strategies, this methodology demonstrates practical applicability.

4 RESULTS AND DISCUSSION

This section outlines the findings from the execution of the research methodology. It systematically presents the results for each objective and offers interpretive commentary and discussion to contextualize these results within the broader flexographic print process.

4.1 Results for Objective 1: Process Analysis and Documentation of the Flexographic Printing and COF Testing Methods

Physical observations were conducted on live production runs involving three shifts. The print press operators demonstrated the machine setup, printing and the sample retrieval. The COF testing procedure was demonstrated by the quality inspector. The observations and findings collected were documented using standard work instructions.[†]

Figure 9: A COF Testing Working Instruction

The standard operating procedure and the process flow diagram (figures 7 and 8) provides an accurate account of the actual processes currently being followed. The COF work instruction (figure 9) gives precise sampling and testing instructions, ensuring that each test conducted meets the required standard and is consistently applied. The application of the documentation and the adherence thereof confirms that the COF testing process is well defined and consistently applied. These documents are essential to support any future improvements in testing consistency and ensures that COF remains a reliable quality measure within the production workflow.

4.2 Results for Objective 2: Experimental Design to Analyse the Relationship between Key Input Variables and COF using the DOE

Using FMEA analysis, the most critical parameters influencing COF were determined: lamp temperature, anilox density, and machine speed. A full factorial Design of Experiments (DOE) was executed across these three variables. The results were evaluated via:

Process Step/Input	Potential Failure Mode	Potential Failure Effects	SEVERITY (1 - 10)	Potential Causes	OCCURRENCE (1 - 10)	Current Controls	DETECTION (1 - 10)	Risk Priority Number (RPN)
What is the process step, change or feature under investigation?	In what ways could the step, change or feature go wrong?	What is the impact on the customer if this failure is not prevented or corrected?		What causes the step, change or feature to go wrong? (how could it occur?)		What controls exist that either prevent or detect the failure?		
Testing COF	Lamp Temperature	Ink curing inconsistency, impacting the COF and print quality	8	Incorrect lamp temperature setting or malfunction	8	None	6	432
	Anilox Density	Uneven ink deposition leading to incosistent COF	9	Incorrect anilox roller specifications or wear	7	The anilox used on the first initial run is recorded on the colour standard. But this does not cater to runs on other presses which is 100% of the cases.	7	441
	Print Speed	Ink drying unevenly, leading to COF variation	8	Incorrect speed setting for PET film properties	7	None	7	392
	Ink Viscosity	Inadequate transfer causing COF variation	7	Incorrect ink preparation or environmental temperature (ink prepared outside a temperature controlled environment).	6	None	6	252
	Film Tension	Uneven ink distribution impacting COF	7	Fluctuating tension setting or mechanical issues	5	None	5	175
	Environmental Humidity	Ink drying variability affecting COF	6	Environmental fluctuations in humidity	5	The print press hall is regulated to 23°C.	4	120
	Press Pressure	Variation in ink transfer affecting COF	6	Inconsistent press pressure	5	None	5	150
	Surface Treatment of PET Film	COF variation due to ink adhesion issues	6	Inadequate surface preparation of film quality	5	Surface treatment is one of the tests conducted before pass off and every press has a coroner treater at the unwind.	5	150

Figure 10: A Snapshot of the COF FMEA

The DOE confirmed that lamp temperature (RPN: 432), anilox density (RPN: 441) and print speed (RPN: 392), significantly impacts COF. All individual variables were statistically significant contributors to the variability of COF, providing a data-driven basis for process control.

In compiling the experiment, the three factors identified as critical to the result of the COF were each assigned two levels: a low level and a high level. Each level was determined through discussions with the print press operators and the Flexo Production Manager.

From the eight experimental runs determined in the methodology, each factor and the agreed values per level were configured to form the following experimental runs:

Table 2: A Table Showing the Low and High Values for Each Input Variable

Factor	Machine Speed (m/min)		Lamp Temperature (°C)		Anilox Density (BCM)	
Level	Low	High	Low	High	Low	High
	95	150	65/30	100/30	4.5 and 400.8	400.8 and 400.9

4.2.1. Regression Analysis

Using the COF results from the experiments, the regression analysis conducted on SPSS generated the following correlation matrix indicating the relationship between the variables and the COF.

Table 3: A Table Showing the Correlations Between the Factors and the COF

		COF	Machine Speed	Lamp Temperature	Anilox Density
Pearson Correlation	COF	1.000	0.471	-0.803	0.300
	Machine Speed	0.471	1.000	-0.250	-0.061
	Lamp Temperature	-0.803	-0.250	1.000	-0.061
	Anilox Density	0.300	-0.061	-0.061	1.000
Sig. (1-tailed)	COF	0.000	0.001	<.001	.030
	Machine Speed	0.001	.	0.060	0.354
	Lamp Temperature	0.000	0.060	.	0.354
	Anilox Density	0.030	0.354	0.354	.
N	COF	40	40	40	40
	Machine Speed	40	40	40	40
	Lamp Temperature	40	40	40	40
	Anilox Density	40	40	40	40

In summary, the data was a good fit for the model. This is substantiated by an R-value of 0.893 indicative of a strong positive correlation between all three variables and the COF. The R-squared value, which demonstrates the proportion of the variance in the COF that is associated with the three

variables [10], signifies that 79.7% of the variability in the COF can be explained by exploring these three variables.

Table 4: Table Summarizing the Regression Model

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	0.893[a]	0.797	0.780	0.035792

In constructing the regression equation for the COF, the relationship between the three variables and the COF is further understood. In summary, the equation is as follows:

$$COF = \beta_0 + \beta_1 + \beta_2 + \beta_3 \quad \textbf{(2)}$$

Where:

- β_0 is the constant.
- β_1 is the coefficient of the machine speed factor.
- β_2 is the coefficient of the lamp temperature factor.
- β_3 is the coefficient of the anilox density factor.

Table 5: SPSS Analysis of the Regression

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	-166.268	45.660		-3.641	<.001
	Machine Speed	0.001	0.000	0.310	3.989	<.001
	Lamp Temperature	-0.003	0.000	-0.708	-9.101	<.001
	Anilox Density	0.416	0.114	0.275	3.649	<.001

Based on the above analysis, the resulting regression equation for predicting the COF is as follows:

$$COF = -166.268 + 0.001\ x\ (Machine\ Speed) - 0.003\ x\ (Lamp\ Temperature) + 0.416\ x\ (Anilox\ Density)$$

4.2.2. Analysis of Variance (ANOVA)

With ANOVA, each variable is treated as independent. The relationship between each variable and the resultant COF is determined on a set of null and alternate hypotheses for each variable.

Table 6: The Null and Alternate Hypotheses for ANOVA

	Factor	Null Hypothesis (H_0):	Alternate Hypothesis (H_1):
Main Effects Hypotheses	**Machine Speed**	The machine speed does not affect the COF result.	The machine speed influences the COF result.
	Lamp Temperature	The lamp temperature does not affect the COF result.	The lamp temperature influences the COF result.
	Anilox Density	The anilox density does not affect the COF result.	The anilox density influences the COF result.
Two-Way Interactions	**Lamp Temperature * Machine Speed**	There is no interaction between the lamp temperature and the machine speed on the COF.	There is a significant interaction between the lamp temperature and the machine speed on the COF.
	Lamp temperature * Anilox Density	There is no interaction between the lamp temperature and the anilox density on the COF.	There is a significant interaction between the lamp temperature and the anilox density on the COF.
	Machine Speed * Anilox Density	There is no interaction between the machine speed and the anilox density on the COF.	There is a significant interaction between the machine speed and the anilox density on the COF.
Three-Way Interactions	**Machine Speed * Lamp Temperature * Anilox Density**	There is no three-way interaction between the machine speed, lamp temperature and anilox density on the COF.	There is a significant three-way interaction among the machine speed, lamp temperature and anilox density on the COF.

Once each of the criteria (assumptions) for conducting an ANOVA were proved, i.e. normality, independence of observations and homogeneity of variances, the analysis on SPSS is as follows:

Table 7: The ANOVA Results Completed on SPSS

Dependent Variable: COF

Source	Type III Sum of Squares	df	Mean Square	F	Sig.
Corrected Model	0.219[a]	7	0.031	121.171	<.001
Intercept	1.050	1	1.050	4069.228	<.001
Machine_Speed	0.014	1	0.014	55.212	<.001
Lamp_Temperature	0.085	1	0.085	327.881	<.001
Anilox_Density	0.006	1	0.006	23.914	<.001
Machine_Speed * Lamp_Temperature	0.001	1	0.001	3.313	0.078
Machine_Speed * Anilox_Density	0.002	1	0.002	9.176	.005
Lamp_Temperature * Anilox_Density	0.021	1	0.021	82.586	<.001
Machine_Speed * Lamp_Temperature *Anilox_Density	0.002	1	0.002	6.247	0.018
Error	0.008	32	0.000		
Total	1.856	40			
Corrected Total	.227	39			

From the analysis above, all three variables are deduced as having a statistically significant effect on the COF as they all have p-values that are below 0.001. And so, for each factor, the null hypothesis is rejected in favour of the alternate hypotheses at a 95% confidence level.

Similarly, to the hypotheses generated for each factor, hypotheses were generated for the impact of two or more of the factors on the COF. The following is deduced about each of the interaction effects:

- The effect of both machine speed and lamp temperature on the COF: with a p-value of p=0.078, this combination does not have a statistically significant effect on the COF.
- The effect of the machine speed and the anilox density on the COF: with a p-value=0.005, this combination has an impact on the COF that is considered significant.
- The effect of both the lamp temperature and the anilox density on the COF: considering the p-value being less than 0.001, this combination has a statistically significant effect on the COF.

- The effect of the machine speed, lamp temperature and anilox density on the COF: the p-value= 0.018. As a result, the combination of all three factors has a statistically significant impact on the COF.

Considering how each of the factors only have two levels, there are insufficient grounds to conduct post-hoc tests such as the Tukey Honest Significant Difference (HSD).

4.3 Results for Objective 3: Strategies for Optimizing Input Variables for COF Consistency

The forty experiments conducted yielded both conforming i.e. a COF result within 0.15–0.25 and non-conforming outcomes. These were used to formulate optimization strategies:

- Strategy 1: Real-time monitoring and maintenance of lamp temperatures
- Strategy 2: Standardizing the machine speed, particularly during set up
- Strategy 3: Use lower density anilox rollers
- Strategy 4: Adjusting both the lamp temperature and anilox densities
- Strategy 5: Conducting the regression modelling to predict the COF outcome in a production run
- Strategy 6: Implementation of statistical process control (SPC) charts for COF tracking

Figure 11 and 12: The Difference between a Dirty and Clean Lamp Respectively

The strategies target reducing process variability, empowering operators, and embedding proactive quality control. Emphasis was placed on lamp temperature as a control variable. The recommendations reflect the Total Quality Management (TQM) principle of continuous improvement.

The results and findings corroborate with literature asserting the importance of surface conditions, drying mechanisms, and ink transfer properties on COF. The application of DOE enabled a structured, statistical approach to understand and improve the print process. Each objective was effectively achieved through the systemic approach highlighted in the methodology and in accordance with the research aim. Consequently, the study offers a foundation for standardized quality control in flexographic printing and improved operational consistency.

5 RECOMMENDATIONS AND CONCLUSIONS

5.1 Recommendations

To further the reaches of this study, areas recommended include:

- Expanding the scope of research to the other substrates: Considering this study focussed on shrink film, a similar analysis could be conducted for other substrates such as biaxially oriented polypropylene (BOPP), to widen the applicability of COF optimization practices across the various unsupported substrates.
- Establishing a Digital Twin for Process Simulations: With the advancements of artificial intelligence (AI) and automation, the development of a digital twin of the flexographic print process can allow simulations that test the impact of various settings on the COF without disrupting the live production process.

5.2 Conclusion

This study tackled COF variability in shrink film printing using a DOE approach. The results identified key input variables affecting COF and proposed actionable strategies for stabilization. These abovementioned recommendations aim to optimize label application, enhance process reliability, and align flexographic print operations with quality management best practices.

FACTORS THAT AFFECT THE IMPLEMENTATION OF QUALITY CONTROL CIRCLES IN GAUTENG CONSTRUCTION PROJECTS

R.T. Dikhoba[1] and V. Mofokeng[2*]

[1,2]Department of Quality and Operations Management
University of Johannesburg, South Africa
[1]Thandidikhoba03@gmail.com, [2]vmofokeng@uj.ac.za

ABSTRACT

Collaborative quality improvement methodologies, such as Quality Control Circles (QCCs), hold significant potential for enhancing performance across diverse sectors, including the construction industry. However, the practical application of QCCs often encounters obstacles, particularly within developing economies like South Africa. This research investigates the factors influencing successful QCCs implementation within the Gauteng construction sector. A quantitative research design was employed, utilizing a questionnaire distributed to construction professionals in the region. The analysis reveals that several key factors impede effective QCCs adoption. These include limited awareness and comprehension of the QCCs framework, insufficient support from senior leadership, inadequate training opportunities, and resistance to organizational change. Based on these findings, the study suggests that construction projects operating in Gauteng should prioritize investments in targeted training and development initiatives to cultivate employee expertise in QCCs principles and practices. Furthermore, projects should commit to providing the necessary resources and support structures to facilitate successful QCCs implementation. Critically, fostering a culture of continuous improvement is essential for sustained QCCs effectiveness. The insights derived from this study will provide valuable guidance to management teams, enabling data-driven decision-making and strategic resource allocation to optimize QCCs integration and maximize its positive impact on project outcomes.

Keywords: Quality Control Circles, Construction Projects, Implementation

* Corresponding Author

1 INTRODUCTION

The ultimate success of any construction endeavour hinges critically on its **quality**, a multifaceted concept gauged by how precisely project outcomes align with the diverse expectations of its various stakeholders, including clients, contractors, and designers alike [1]. Across the global landscape of project management, three fundamental pillars consistently emerge as paramount determinants of project success: quality, cost, and time. Within the specialized domain of construction, the intrinsic link between superior quality and **client satisfaction** is undeniably profound. A proactive and strategic methodology for consistently realizing client satisfaction goals involves the careful implementation of a **Quality** Management System (QMS) [2]. Within the overarching framework of a robust QMS, Quality Control Circles (QCCs) stand out as indispensable components. These collaborative groups function in seamless coordination with established quality planning, assurance, and control protocols, acting as vital conduits for continuous improvement. At their core, QCCs are designed to catalyse organizational growth, unlock latent human potential, cultivate hidden capabilities among employees, and collectively foster a more conducive and desirable working environment [3].

QCCs embody a practical application of Total Quality Management (TQM) principles, relentlessly emphasizing continuous improvement and empowering employee involvement in the direct resolution of operational challenges. This participation is geared towards enhancing overall quality and operational efficiency [4]. In essence, QCCs operate as self-contained microcosms, reflecting the broader tenets of TQM within the comprehensive architecture of a QMS, thereby collectively propelling an organization toward sustained and overarching quality excellence. The meticulous practice of quality control (QC) has consequently evolved into a cornerstone of TQM within the construction industry. Its diligent execution is not merely beneficial but essential for averting safety incidents and consistently delivering products and services of superior quality [5]. The Project Management Institute [6] systematically outlines quality management as a structured methodology encompassing three key phases: **Quality** Planning, which involves the meticulous establishment and clear articulation of quality standards; Quality Assurance, focused on comprehensively evaluating the project's overall performance; and Quality Control, dedicated to the meticulous supervision of project results against defined benchmarks. The successful realization of quality management objectives often relies on the judicious application of various analytical tools and approaches, such as benefit-cost analyses, benchmarking, and statistical sampling [7].

The construction sector plays an unequivocally crucial role in the economic vitality of Gauteng, South Africa. It not only serves as a primary driver of economic growth [8] but also functions as an indispensable engine of employment generation and a fundamental facilitator of critical infrastructure development [9]. Despite the sector's progressive evolution over time, every construction project retains a unique identity, shaped by a distinct confluence of factors including ownership structures, material specifications, chosen contractors, specific project management methodologies, and the nature of sponsorship [10]. These inherent variables inevitably introduce significant diversity in project specifications, scope, risk profiles, cost parameters, client expectations, regulatory compliance requirements, capital investment levels, and, crucially, the standards of quality achieved. While the manufacturing sector widely acknowledges QCCs as a proven and demonstrably potent method for elevating output quality and fostering cooperative problem-solving, a notable void persists in academic understanding regarding their practical application within the inherently distinct and dynamic environment of construction projects, particularly within the Gauteng province of South Africa [11]. The unique attributes of construction endeavours — characterized by their fragmented nature, project-centric execution, comparative lack of uniform procedures across diverse

undertakings, and the inherent complexities associated with their realization — introduce considerable challenges to the seamless integration and ultimate effectiveness of QCCs.

1.1 Research objectives

The primary research objective is to identify the critical factors influencing the effective implementation of QCCs in construction projects in Gauteng.

Sub-Objectives:

Research objective 1: To evaluate the impact of QCCs implementation on workers' performance in construction projects.

Research objective 2: To assess the relationship between QCCs and the Total Quality Management (TQM) strategy by assessing the relationship between the implementation of QCCs and the effectiveness of TQM strategy in Gauteng construction projects.

Research objective 3: To investigate communication barriers within QCC teams by analysing team dynamics and cultural differences to identify potential barriers.

Research objective 4: To examine the influence of project culture and values on QCC success by developing recommendations for fostering a culture that supports continuous improvement and employee involvement; and

Research objective 5: To analyse the role of technology adoption in QCC implementation by identifying challenges and opportunities associated with technology adoption.

1.2 Research problem statement

Within the manufacturing sector, QCCs stand as a recognized and demonstrably potent method for elevating the quality of outputs [12]. Their established ability to cultivate cooperative problem-solving, ultimately fostering greater efficiency and superior quality results, is thoroughly supported by existing literature. Nevertheless, despite this widespread utilization and the well-recognized merits of QCCs within manufacturing, a notable absence persists in academic understanding regarding their application within the distinct setting of construction projects, especially within the Gauteng province of South Africa [11].

Construction projects possess intrinsic differences from typical manufacturing operations, exhibiting unique attributes that introduce considerable intricacy to the potential integration and effectiveness of QCCs [12]. Principal among these distinguishing elements is the segmented and project-centric nature of construction, the comparative absence of uniform procedures across varied projects, and the inherent complexity associated with their execution.

In contrast to the manufacturing domain, where operational sequences often exhibit repetition and a high degree of uniformity, construction projects are characteristically individualistic undertakings with clearly defined commencement and conclusion points. These projects frequently involve a diverse array of autonomous bodies, including primary contractors, subcontractors, architects, and engineers, all collaborating to achieve a shared goal. This inherent segmentation necessitates strong lines of communication and fluid collaboration among all participating parties, aspects that can present considerable hurdles to the successful deployment of QCCs.

2 LITERATURE REVIEW

2.1 Introduction

The literature review chapter thoroughly examines academic publications, empirical research, and theoretical models concerning the application of QCCs in construction projects in Gauteng

province. Beginning with an analysis of the historical development and theoretical underpinnings of QCCs, it establishes a fundamental comprehension of these quality management initiatives. The review rigorously examines the current literature regarding the deployment of QCCs in construction settings. This entails a comprehensive examination of previous studies to pinpoint significant obstacles related to the adoption of QCCs in construction projects. This extensive literature analysis aims to establish a robust theoretical framework, informing the research methodology and guiding the investigation of factors affecting the effective implementation of QCCs in Gauteng construction projects.

2.2 Overview of quality control circles

QCCs, as delineated by [13], are voluntary assemblies of employees who cooperate to improve workplace quality and facilitate personal development. These teams, generally comprising up to 12 members, convene regularly to discover, assess, and address work-related issues.

Initially rooted in manufacturing, QCCs have been adopted across various industries, including construction [6]. Dr. Kaoru Ishikawa's introduction of QCCs in Japan has established them as a powerful problem-solving tool. By fostering collective effort amongst employees from similar workplaces, QCCs can streamline complex workflows and improve organizational performance [14].

Gauteng, a South African province, has witnessed a growing interest in implementing QCCs within construction projects. However, research on the factors influencing QCCs implementation in Gauteng's construction sector remains limited.

Quality, as articulated by [15], encompasses synchronised efforts to improve the efficacy and efficiency of construction projects. QCCs members' positive perceptions of job satisfaction and alignment with project goals can significantly impact performance. While performance measurement aims to improve business outcomes, it can sometimes mislead management. A positive correlation exists between financial performance, labour productivity, and service quality [15].

The experience, skills, and knowledge of project team members involved in costing play a crucial role in quality control. QCCs operate within a unique structure that combines informality with formal support [16]. This fosters collaboration between quality circles and larger construction projects, working towards shared corporate objectives. A QCC typically follows a four-level structure, as illustrated in Figure 1.

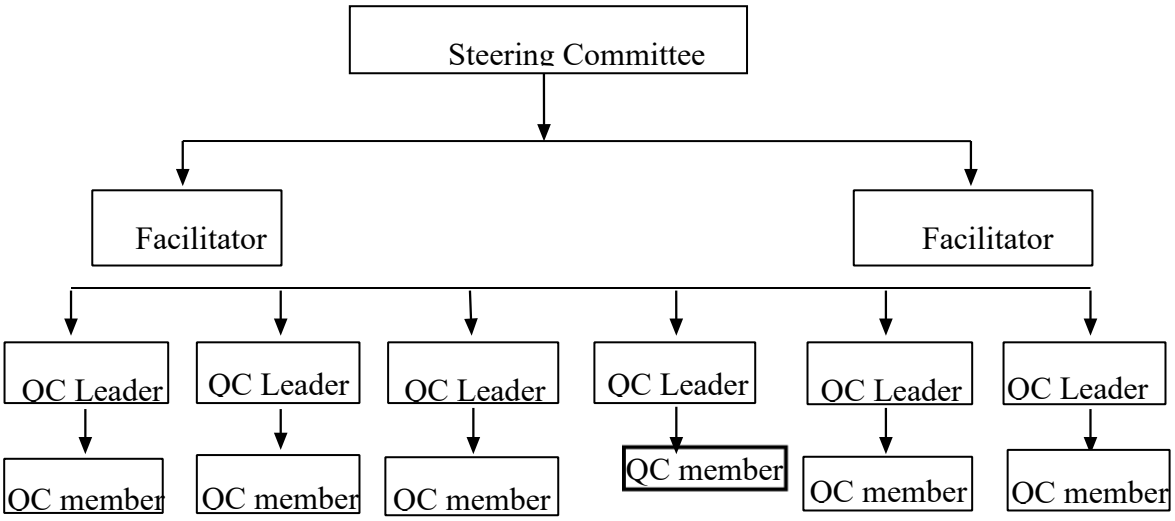

Figure 1: Quality Control Circle structure [14]

2.3 Advantages of Quality Control Circles

To enhance a company's capacity to meet standards and remain competitive, the influence of Quality Circles QCCs on individuals and projects has grown significantly [11]. This principle can be applied to construction endeavours in Gauteng.

The primary aim of QCC is to enhance organisational growth, namely by promoting healthy human interactions. This fosters a favourable work atmosphere that improves the productivity of construction projects. QCCs concentrate on cultivating interpersonal connections and communication among personnel to enhance their knowledge of duties associated with product delivery. Moreover, QCCs aim to establish a framework where improvement ideas can be transformed into practical applications [17].

The various advantages of implementing QCCs in projects include aiding workers in developing a positive outlook on their roles in construction projects, enhancing productivity by improving product quality and reducing rejected products, fostering strong bonds amongst employees at different levels of the organizational hierarchy, and improving working conditions and the overall work environment [18].

Salaheldin and Zain [5], highlighted several potential benefits of QCCs. These include:

- Employee Empowerment and Development: QCCs actively involve and develop employees by providing a platform for them to address issues directly.
- Operational Improvement: QCCs may enhance several operational domains, including quality, productivity, efficiency, cost reduction, and communication.
- Enhanced Collaboration: QCCs foster collaboration amongst employees at different levels and from diverse departments, breaking down communication barriers between management and staff.
- Increased Job Satisfaction: By empowering employees and giving them control over their work environment, QCCs can significantly boost job satisfaction and reduce frustration.
- Skill Development: Participation in QCCs provides employees with opportunities to develop and enhance their skills.

However, implementing QCCs can also present challenges. Construction projects may require additional time and resources to establish successful QCCs; the project's weaknesses may be exposed; and effective results may be more evident in larger projects. Some of the current difficulties in implementing QCCs include the need for a significant number of trained staff, the reluctance of many employees to participate voluntarily in QCC activities; the disappointment of higher-level employees who may expect quick and immediate results; and the potential difficulties in building mutual relationships due to individual differences in thoughts, views, egos, and approaches to situations [19].

QCCs play a crucial role in enhancing organizational efficiency and competitiveness by fostering employee involvement and addressing various challenges [11]. In construction projects, QCCs can significantly improve productivity, quality and employee satisfaction. By promoting teamwork, communication and problem-solving, QCCs contribute to a positive working environment and drive continuous improvement efforts.

2.4 Critical Elements within Construction Projects

According to Kerzner [20], a project is a series of actions and tasks that operate under specified restrictions, use resources from several functional domains, and are carried out to achieve established objectives. An essential aspect in project management is the examination of information to enhance the balance between project goals. These objectives must align

with overarching organisational and corporate goals to sustain market competitiveness and guarantee long-term survival. Project management is an essential instrument for achieving these goals.

Like any business endeavour, construction projects strive for success, which is determined by the alignment between expectations and outcomes. Meeting project requirements is essential for successful completion [21].

Various studies have consistently highlighted several fundamental elements that significantly shape the outcomes of construction projects. These can be broadly categorized as follows:

1 **Schedule Management:** This encompasses the planning and sequencing of project activities, along with ensuring adherence to established timelines. Delays can precipitate increased costs, disputes among parties, and dissatisfaction from the client [22].

2 **Financial Oversight:** This involves the creation of budgets, accurate cost estimation, and the diligent monitoring of expenditures to maintain the project within its allocated financial boundaries. Insufficient financial oversight can lead to project abandonment or a decline in quality [22].

3 **Quality Assurance:** This pertains to the procedures implemented to guarantee that the project fulfils the specified requirements and adheres to relevant standards. Deficient quality can result in the need for rework, potential safety hazards, and compromised long-term performance.

4 **Stakeholder Engagement:** Construction projects involve a wide array of stakeholders with differing interests, including clients, contractors, subcontractors, and regulatory bodies. Effective communication, collaboration, and the resolution of conflicts are pivotal for project success [23].

5 **Risk Mitigation:** The identification, assessment, and mitigation of potential risks are vital in the construction sector, where uncertainties are prevalent. Inadequate risk management can precipitate project delays, escalated costs, and other unfavourable consequences [24].

6 **Communication:** The presence of clear and effective communication channels among all project participants is essential for seamless coordination, efficient information sharing, and effective problem-solving. Poor communication can give rise to misunderstandings, errors, and conflicts [25].

7 **Human Resource Management:** The skills, experience, and motivation levels of the project team exert a substantial influence on overall project performance. Effective human resource management encompasses recruitment, training initiatives, and fostering strong team dynamics.

8 **Procurement Strategy:** The efficient procurement of materials, equipment, and services is of paramount importance for the timely completion of projects and the maintenance of cost control. This entails careful supplier selection, skilful contract negotiation, and meticulous supply chain management.

9 **Safety Protocols:** Ensuring a safe working environment is a fundamental requirement in all construction projects. Safety management involves the identification of potential hazards, thorough risk assessment, and the implementation of robust safety protocols.

3 METHODODOLOGY

This study employed a quantitative research design to systematically investigate the factors that influence the successful implementation of QCCs within the construction industry in Gauteng, South Africa. This approach was chosen to allow for the collection and statistical analysis of numerical data, enabling the identification of patterns, relationships, and trends. The aim was to provide an objective and measurable understanding of the challenges and enablers of QCC adoption.

The primary data collection instrument was a structured questionnaire. This instrument was selected because it is a highly efficient way to gather information from a large number of participants on specific, predetermined variables. The questionnaire included a series of closed-ended questions, which were designed to measure participants' perceptions and experiences related to four key areas: awareness of the QCC framework, the level of senior leadership support, the availability of training opportunities, and the general resistance to organizational change. The use of a standardized questionnaire ensured consistency in data collection across all participants, which is essential for a quantitative study [26].

The questionnaire was administered electronically to a sample of 110 construction project workers located in the Gauteng region. Participants were selected using a simple random sampling method from a list of registered construction professionals and workers. In simple random sampling, every individual in the target population has an equal and known chance of being selected. This method was crucial for minimizing selection bias and ensuring that the sample was representative of the broader population of construction workers in the region. This representativeness is vital for the generalizability of the study's findings, allowing the results to be applied with a degree of confidence to the entire Gauteng construction sector.

4 RESULTS

To ensure the precision and reliability of our research findings, we evaluated the quality of our data collection tool—the questionnaire. A key statistical measure for this is **Cronbach's alpha coefficient**, which assesses the internal consistency of a scale. In simple terms, it tells us how closely related a set of items (questions) are as a group. Questionnaire was grouped into four key sub-scales: "Barriers," "Benefits," "Organizational Culture," and "Technology Adoption." The following tables present the reliability analysis for each of these scales. To ensure research findings are precise and reliable, it's crucial to evaluate the quality of data collection tools. **Cronbach's alpha coefficient** is a key statistical measure for this, widely used to assess the **internal consistency** of questionnaires, particularly those using Likert-type scales [27].

These were designed to systematically measure the key factors that influence the successful implementation of Quality Control Circles (QCCs) in Gauteng construction projects.

Essentially, Cronbach's alpha quantifies how strongly interconnected and consistent the items (questions) within a scale are in measuring the **same underlying concept**. A higher average correlation among items typically leads to a higher alpha value, indicating greater reliability.

Here's how to interpret Cronbach's alpha values:

- **Below 0.7:** Considered poor, suggesting the scale may not be reliable.
- **Between 0.7 and 0.8:** Considered acceptable, indicating a moderate level of reliability.
- **Above 0.8:** Considered good, suggesting a high level of reliability.

Table 1: Summary of Item-Total Statistics for the Barriers Scale

Barries	Scale Mean if Item Deleted	Scale Variance if Item Deleted	Corrected Item-Total Correlation	Squared Multiple Correlation	Cronbach's Alpha if Item Deleted
Q1	25,22	55,959	0,748	0,612	0,933
Q2	25,42	57,775	0,744	0,681	0,934

Cronbach's Alpha	Cronbach's Alpha Based on Standardized Items	N of Items
0,927	0,929	8

The analysis of Cronbach's alpha coefficients indicates that the Barriers scale is a highly reliable and valid instrument for assessing barriers to QCCs implementation. The overall Cronbach's alpha of 0.939, along with high individual item-total correlations and squared multiple correlations, suggests that the scale consistently measures a single underlying construct and is free from weak items. This provides strong evidence for the quality of the data collected using this scale and supports the validity of any conclusions drawn from the research.

The high Cronbach's Alpha values, consistently above 0.7 for all items, indicate that the QCC assessment scale is highly reliable and internally consistent. This suggests that the items effectively measure a common construct related to the challenges and effectiveness of QCCs. The scale's reliability provides confidence in the validity of the findings and supports the conclusions drawn from the analysis.

The Cronbach's Alpha values of 0.937 for both the original and standardized items demonstrate the high reliability and internal consistency of the scale. This suggests that the items effectively measure a single underlying construct, making the scale a valid and reliable instrument for data analysis. The high reliability provides confidence in the accuracy and consistency of the measurements obtained using this scale.

The finding that a robust positive correlation exists between the incorporation of technology and the efficacy of QCCs within construction projects, evidenced by the statement "The use of technology has improved the overall quality of the construction project" demonstrating the

strongest squared multiple correlation (0.753), is consistent with an expanding collection of scholarly works that underscore the revolutionary impact of technology on improving quality management practices in the construction sector. There is a capacity of technology to enhance communication, the precision of data, and the effectiveness of problem resolution [28]. The outcomes of this study, bolstered by the elevated Cronbach's Alpha values affirming the reliability of the measurement scale, provide empirical support for this increasing comprehension within the specific framework of QCC implementation in construction projects located in Gauteng. This favourable impact of technology on QCC effectiveness, as indicated by the substantial squared multiple correlation, implies that construction firms in Gauteng that integrate technology into their QCC initiatives are more likely to achieve improved quality results.

5 DISCUSSION

A particularly salient finding from this study underscores a powerful positive correlation between the strategic integration of **technology** and the enhanced efficacy of **QCCs** in construction projects. This empirical outcome resonates strongly with an expanding body of academic research that consistently highlights technology's transformative influence on elevating quality management practices across the construction sector [28]. Indeed, the capacity of modern technology to significantly refine communication channels, bolster data precision, and amplify the overall effectiveness of problem-solving initiatives is extensively substantiated in existing literature [28].

The empirical insights gleaned from this investigation, further fortified by the robust Cronbach's Alpha values that unequivocally validate the reliability of our measurement scale, collectively offer concrete support for this burgeoning understanding. Specifically, within the distinctive operational landscape of QCC implementation in construction projects situated in Gauteng, the findings compellingly suggest that the deliberate and strategic incorporation of technology into QCC initiatives is highly likely to yield superior quality outcomes for participating construction firms [11]. This observed beneficial influence of technology on QCC effectiveness, as powerfully indicated by the substantial squared multiple correlation, delineates a clear and actionable pathway for construction enterprises in Gauteng to significantly enhance their quality achievements through the thoughtful adoption and seamless integration of technological solutions within their established QCC frameworks.

6 CONCLUSION

The rigorous evaluation of our research instrument, specifically the "Barrier's scale" employed to gauge obstacles hindering the implementation of Quality Control Circles (QCCs), unequivocally confirms its exceptional reliability and validity. A commanding overall Cronbach's alpha coefficient of **0.939** stands as compelling evidence of the scale's robust internal consistency. This remarkably high value, coupled with strong individual item-total correlations and impressive squared multiple correlations, definitively establishes that the scale consistently measures a singular, underlying construct, devoid of any weak or inconsistent elements. Furthermore, the persistently elevated Cronbach's Alpha values (all items consistently exceeding 0.7, and specifically a value of 0.937 for both original and standardized items) for the QCC assessment scale emphatically underscore its high reliability and internal coherence. This profound level of reliability instils substantial confidence in the integrity of the data gathered and, consequently, bolsters the accuracy and trustworthiness of the inferences drawn from this investigation. Therefore, this scale emerges as a demonstrably valid and dependable tool for the analysis of data pertaining to the challenges and effectiveness of QCCs within construction projects.

Despite these challenges, QCCs are recognized as an important and effective tool for problem-solving and improving company performance in construction projects. A positive project

culture, characterized by trust, openness, and empowerment, is foundational for QCC success, fostering employee motivation and contribution. Top management commitment, demonstrated through resource provision and active participation, sends a powerful message about the value of QCCs. Employee involvement is crucial as it fosters ownership and leverages their direct knowledge. These factors—project culture, top management commitment, and employee involvement—are interconnected and mutually reinforcing. Furthermore, robust training, effective communication, and judicious resource allocation are essential for empowering employees, aligning stakeholders, and optimizing QCC potential for sustainable improvements.

Correlation analysis revealed significant positive relationships between project culture, communication, leadership, and the perceived benefits of QCCs. Comprehensive training and top management support also showed a positive correlation with QCC participation, confirming the suitability of the data for factor analysis.

6.1 Limitations of the study

While the study successfully developed a highly reliable and valid questionnaire for assessing QCCs, its primary limitation is the geographical and industrial scope, focusing exclusively on construction projects in Gauteng, South Africa, which limits the generalizability of the findings to other regions or sectors. Furthermore, the reliance on a single, self-reported quantitative instrument may not capture the full complexity of QCC implementation, potentially introducing response bias and overlooking valuable contextual details that a mixed-methods approach could have provided.

6.2 Recommendations Summary

To enhance the efficacy of QCCs in Gauteng construction projects, the following solutions are recommended:

- **Reinforce Top Management Support:** Leadership should visibly demonstrate unwavering dedication through active participation, consistent resource allocation (time, finance, staff), and serving as role models for quality improvement.
- **Foster Employee Involvement:** Cultivate a culture of empowerment, actively recognize and reward contributions, and establish effective communication channels and feedback systems to ensure employee perspectives are valued.
- **Invest in Training and Development:** Implement comprehensive training programs covering QCC methodology, problem-solving, and data analysis, alongside continuous learning opportunities and mentorship programs to build employee skills and confidence.
- **Improve Communication and Collaboration:** Establish clear, open communication channels among all project stakeholders, foster a collaborative work atmosphere through team building, and implement efficient conflict resolution strategies.
- **Promote a Positive Project Culture:** Cultivate a continuous improvement mindset, empower employees to make decisions, and celebrate QCC team successes to boost morale and encourage ongoing participation.
- **Tailor QCC Implementation to Project Characteristics:** Develop flexible, project-specific strategies that consider factors like size, complexity, and duration, and continuously evaluate their effectiveness to ensure relevance and adaptability.
- **Address External Factors:** Formulate resilient methods to mitigate the impact of external influences (e.g., economic volatility, regulatory changes) through proactive

risk management, engage clients in QCC operations, and collaborate with external stakeholders to exchange best practices.

School of Industrial Engineering

AVAILABLE PROGRAMMES:

1. **BEng in Industrial Engineering -**
   - A 4-year, full-time, contact programme that is targeted at undergraduate students who are interested in becoming Industrial engineers.
2. **Postgraduate diploma in Industrial Engineering -**
   - A 2-year, part-time, distance programme that is targeted at individuals who aspire to advance their career or change direction by gaining specialised IE knowledge and skills.
   - Choose between the following specialisations:
     - Industrial Engineering
     - Industrial Engineering with Sustainability
     - Industrial Engineering with Sustainable mining
3. **Postgraduate degrees in Industrial Engineering -**
   - Several postgraduate degrees are offered such as:
     - MEng in Industrial Engineering, and
     - PhD-Eng in Industrial Engineering.

TOWARDS CONTEXTUALISING LEAN WASTES FOR AGRICULTURE: CASE STUDY OF GRAIN HANDLING IN SILO OPERATIONS

S. Lea[1*] and R.Coetzee[2]

[1,2]School of Industrial Engineering
North-West University, South Africa
[1]lea.stacey26@gmail.com, [2]Rojanette.Coetzee@nwu.ac.za

ABSTRACT

Agriculture plays a crucial role in South Africa's economy and food security, with grain storage serving as a critical link in the crop production supply chain. Grain silo operations, however, face recurring inefficiencies that hinder productivity and profitability. While lean management has been successfully applied across various industries, its relevance to agriculture—and specifically grain handling—remains underexplored. This study investigates how the eight forms of lean waste can be identified and contextualised within grain storage operations. Using an adapted A3 problem-solving approach, qualitative data from a South African grain silo organisation were analysed to categorise inefficiencies and translate them into agricultural terms. The findings confirm that lean wastes apply to agriculture, although not all categories (e.g., overproduction) are directly relevant. By contextualising lean waste for silo operations, the study provides a foundation for continuous improvement in agricultural supply chains and contributes to the growing field of lean agriculture.

Keywords: lean, agriculture, waste, silo, grain bins, grain storage

* Corresponding Author

1 INTRODUCTION

Agriculture is an important sector in South Africa, providing employment and food security while forming linkages with other sectors. [1]. For instance, this sector purchases items like fertilisers and machinery from suppliers and supplies raw materials to the food and manufacturing industry. Therefore, the agricultural sector can be seen as an engine of growth for the rest of the economy [1]. The agricultural sector includes both livestock (animals) and crop (plants) production to provide food and other products to humanity [2].

The grain handling process, which forms part of the crop production supply chain, consists of the farmer who sows the seeds, treats and waits for them to germinate and mature. The crop (growing plants in the field) is harvested (cutting and threshing the mature crop by typically utilising a combine harvester). Once harvested, the crop is referred to as "grain", which in this study includes maise, sorghum, sunflower seeds, soybeans, wheat, and barley. The process starts with the farmer and ends with the crops being sold to the interested stakeholders. However, the selling of the grain is not always immediate, since farmers want to wait for market prices to rise before selling the grain [3]. Farmers, therefore, often need to store it for a specific period. Hence, the storing of grain is an essential part of the supply chain of agricultural crop production. The storing of grain preserves the quality of the grain and protects it from pesticides, moisture, and potential contaminants [4]. Grain silos (bins) are a standard method for storing grain [5]. Thus, before selling it to the market, farmers typically store their grain in silos to assist in the storage and distribution of the grain [5].

Lean production, lean manufacturing, or lean management is a management concept that aims to enhance operational efficiency. Originating in the late 1910s from the Toyota Production System (TPS), lean primarily focuses on reducing waste in manufacturing processes [6]. Waste in lean refers to activities that do not add value (according to the customer) to the production line. Hence, lean is characterised by a principle that promotes continuous improvement and that improves predictability to reduce uncertainties in a process [7]. As the agricultural sector is a growing sector [8], continuous improvement is required. Although lean was initially designed for manufacturing, it has expanded to a variety of industries, such as administrative processes, healthcare, services, and public administration [8]. Lean management is also becoming popular in agriculture since global competition has resulted in a tendency towards large-scale production, standardised technology, and organisational and management innovation [8]. This change is being driven by global competitiveness and a demand for more efficient processes and practices [8].

An Industrial and Systems Engineering Research Conference study proposes the question of how lean wastes can be identified and categorised in agriculture, but it did not answer the question [9]. Subsequently, this raises a new question on whether lean wastes can also be identified and contextualised for a grain storage facility.

This question gained further significance after a South African case study organisation (in charge of multiple grain silo facilities) explained its concern about recurring bottlenecks that affect the efficiency and tempo of their operations at a grain silo. However, the application of lean management in grain storage remains unexplored to our best knowledge, leading to a lack of agricultural context of the eight forms of waste. Therefore, this study aims to investigate how the eight forms of lean waste can be identified and contextualised for grain handling in silo operations. This can be applied in future research to encourage continuous improvement in silo operations.

2 LITERATURE REVIEW

An overview of lean management is provided, with a specific focus on the eight forms of lean waste. Additionally, the available literature on lean agriculture is explored.

2.1 Lean management

Lean management, which originated with the Toyota production system (TPS), enhances predictability and minimises operational uncertainty [10]. A lean process uses less material, requires less inventory, occupies less space, and employs fewer people, but does not eliminate them [11].

The philosophy of lean management rests on two fundamental pillars: continuous improvement (Kaizen) and respect for people [10]. Unlike traditional mass production, which often prioritises output above all else, lean management focuses on eliminating three core inefficiencies: muda (non-value-adding activities), mura (process unevenness), and muri (employee overburden) [12].

According to Womack and Jones (2007), the successful implementation of lean in an organisation requires adherence to five initial principles [13]. The first is value, which involves identifying value strictly from the customer's perspective. The second is the value stream, referring to the set of activities necessary to design, order, and deliver a product, transforming raw materials into the hands of the customer. The third principle is flow, which emphasises the progression of tasks along the value stream without stoppages, defects, or backflows. The fourth is pull, which requires that production is driven only by actual customer demand signals, rather than forecasts. Finally, perfection, which entails the continuous elimination of waste across the value stream [14].

There exists a diverse set of lean tools and techniques that enhance organisational efficiency and effectiveness. The conceptual foundation originates from Taiichi Ohno's (1988) work, which systematised Toyota's manufacturing philosophy [14]. Ohno introduced the primary principles of just-in-time (JIT) and autonomation (jidoka), while Liker later developed a structured framework, the TPS House, which illustrates the interdependence of lean techniques. Within this framework, JIT and jidoka serve as the two main pillars, supported by foundational tools such as Heijunka (levelling the production load), standardised work, kaizen, continuous flow, takt time, pull systems (Kanban), abnormality management (stop and notify protocols), and human-machine separation [10].

2.2 The eight wastes

Toyota identified seven types of waste, often known as non-value-adding activities[10]. An additional eighth waste was later added as lean evolved to more industries [10, 15]. The eight wastes are as follows [10, 15] :

1. **Overproduction**. Producing more than the demand, or before knowing the demand, can result in overstaffing, unnecessary storage, and possible transportation costs.
2. **Waiting (time on hand)**. Watching or waiting for a machine, waiting on inputs, or having extra time without pressing deadlines.
3. **Unnecessary transport/ conveyance**. Carrying work in process (WIP) over long distances, creating inefficient transport, or moving materials or information into or out of storage or between processes. Transporting work in process (WIP) over extended distances, which leads to inefficient transport, or moving information or materials in or out of storage or between processes.
4. **Overprocessing/ incorrect processing**. Making unnecessary steps while processing the parts, or having inefficient processing due to poor product or tool designs, results in unnecessary action and possible defects. If products or services are of greater quality than required, they are considered waste.
5. **Excess inventory**. Having more raw materials, work-in-progress, or finished goods than needed results in longer lead times, damaged goods, obsolescence, increased transportation and storage costs, and delays. Excess inventory also conceals issues such

as production imbalances, late deliveries from suppliers, defects, equipment downtime, and extended setup times.

6. **Unnecessary movement.** Any non-value-adding motion that employees perform during their work, such as looking for, reaching for, walking to, or stacking parts, tools, etc.
7. **Defects**. Inaccurate products or services are produced and corrected through repair or rework, scrap, replacement production, and inspection, all of which waste time, effort and handling.
8. **Underutilisation of** talent: Not using the knowledge, talents, and skills of the workers in the organisation, specifically to solve problems that lead to continuous improvement [10].

2.3 Lean agriculture

Lean agriculture refers to applying Toyota's lean manufacturing philosophy to an agricultural process or operation to enhance efficiency, reduce waste, and increase productivity. As the agricultural sector realises the benefits of lean management implementations in the manufacturing industry, lean management is gaining popularity [8]. Global competition has resulted in an agricultural shift to large-scale production, increased use of standardised technology, and more organisational and managerial innovations, all of which Lean aims to improve. Specialisation, formalisation, and standardisation are agricultural management tools that align with the trend towards fewer, larger farms [8]. A study done on retrieving available research on lean implementation in the agricultural industry showed that the application of lean management has been explored in various applications, such as timber [16], crops [17], mixed farms [8, 9, 18], red meat [19], textile [20], dairy [12], fruit [21], cocoa [22] and fertiliser [23]. However, most studies focus only on the food and beverage industry [24]. Consequently, to the best of available knowledge, research on lean in the grain silo industry has not yet been explored. Taking this into consideration, this study will investigate and conceptualise how the eight forms of lean waste can be identified in grain silo facilities, thereby initiating the contextualisation of lean principles for an agricultural application.

3 METHODOLOGY

The A3 method originated during the Toyota Production System (TPS) in the 1960s and has been successfully implemented in a variety of industries, including pathology laboratories, hospitals, and the automobile industry[25]. This method is similar to Deming's Plan-Do-Check-Act (PDCA) cycle and is used for collaborative problem-solving, status reporting, and proposal submissions [25]. The A3 method was chosen for this study as the study focuses on conceptualising lean waste in agriculture to improve current inefficiencies. The A3 problem-solving method typically has between seven and ten steps [25, 26]. This study will primarily focus on root cause analysis and categorising root causes into the eight forms of waste. Some steps, such as defining countermeasures, implementing cost analysis, and testing the solution, will not be applied. Accordingly, an adapted version of the A3 approach from Santos Filho's study was employed, incorporating the steps of defining the problem, analysing the organisation's current state, determining goals, conducting a root cause analysis, and reflecting on the findings [25].

3.1 DEFINING THE PROBLEM

A South African grain handling company is experiencing longer lead times due to unknown causes, which negatively affects the overall operational efficiency of the silo yard. These challenges are exacerbated during peak season, causing further inefficiencies. To approach these challenges, it is necessary first to determine what causes them by investigating the current state and conducting a root cause analysis.

3.2 CURRENT STATE ANALYSIS

Grain handling at silo facilities begins before trucks enter the yard, as vehicles typically queue outside the gate. Most facilities follow a one-in-one-out system, with queue lengths varying seasonally, particularly during peak harvesting. Trucks enter either to deliver grain (loading process) or to collect grain (off-loading process). Farmers use silo facilities primarily for storage, while stakeholders retrieve purchased grain for distribution. The two processes are explained below and illustrated in Figures 1 and 2. Figure 1 illustrates the loading process:

1) Arrival of a loaded truck: The farmer sends grain by truck, which joins a queue outside the silo yard.
2) Document verification: While waiting, the driver walks to the office to confirm that the instruction number and booking match the silo's records. If not, they must wait for a valid booking.
3) Entering the yard: Once verified and at the front of the queue, the truck enters and stops at the sampling station.
4) Sampling: An employee uses a double-tube sampler to collect six probes from the load and takes the sample to the office.
5) Grading: The grain is graded using a machine. If it fails to meet standards, the farmer can either pay for cleaning or leave.
6) Weighing in: While grading occurs, the truck is weighed on the weighbridge to capture its entry weight.
7) Loading in a grain bin: If the grain passes, the truck is directed to a loading bay where the grain is unloaded into a hopper and moved to the correct bin via conveyors.
8) Weighing out: The empty truck returns to the weighbridge for its exit weight. The difference determines the grain quantity received.
9) Exit: The truck leaves the yard once the transaction is complete.

Figure 2 illustrates the off-loading process.

1) Arrival of an empty truck: A stakeholder sends an empty truck to load their purchased grain from the silo. Upon arrival, the truck joins a queue outside the silo yard.
1) Document verification: While waiting, the driver goes to the office to confirm that the instruction number matches the silo's records. If incorrect, they contact the stakeholder and wait or leave the queue.
2) Entering the yard: With correct documents and at the front of the queue, the truck enters and stops on the weighbridge.
3) Weighing in: The operator records the truck's empty weight.
4) Proceed to loading bay: The truck is directed to a bay with a discharge chute.
5) Unloading grain from a bin: The operator activates the system to extract grain from the bin via a conveyor and release it into the truck.
6) Sampling and grading: Once loaded, a grain sample is taken and graded to ensure quality.
7) Grain cleaning (if needed): If the grain fails to meet standards, it is sifted to remove foreign material until the grade is acceptable.
8) Weighing out: The loaded truck returns to the weighbridge to capture the exit weight.
9) Correct load: If the load is over or under the required weight, the truck returns to adjust the load accordingly.
10) Exit: The truck exits the yard once the correct weight is achieved and the transaction is finalised.

Both processes are repeated for every truck that arrives to deliver grain or collect grain from the silo yard.

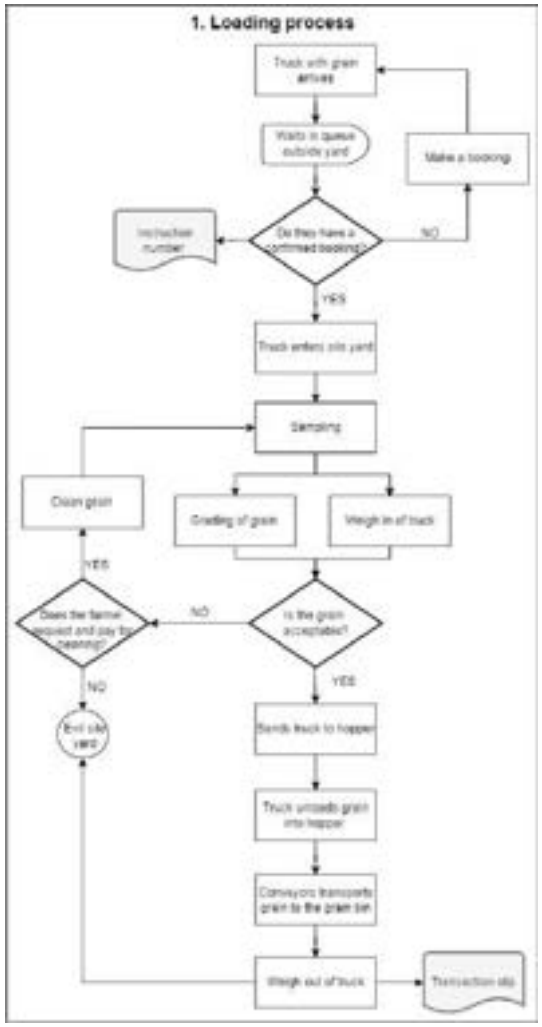

Figure 1: Loading process flow

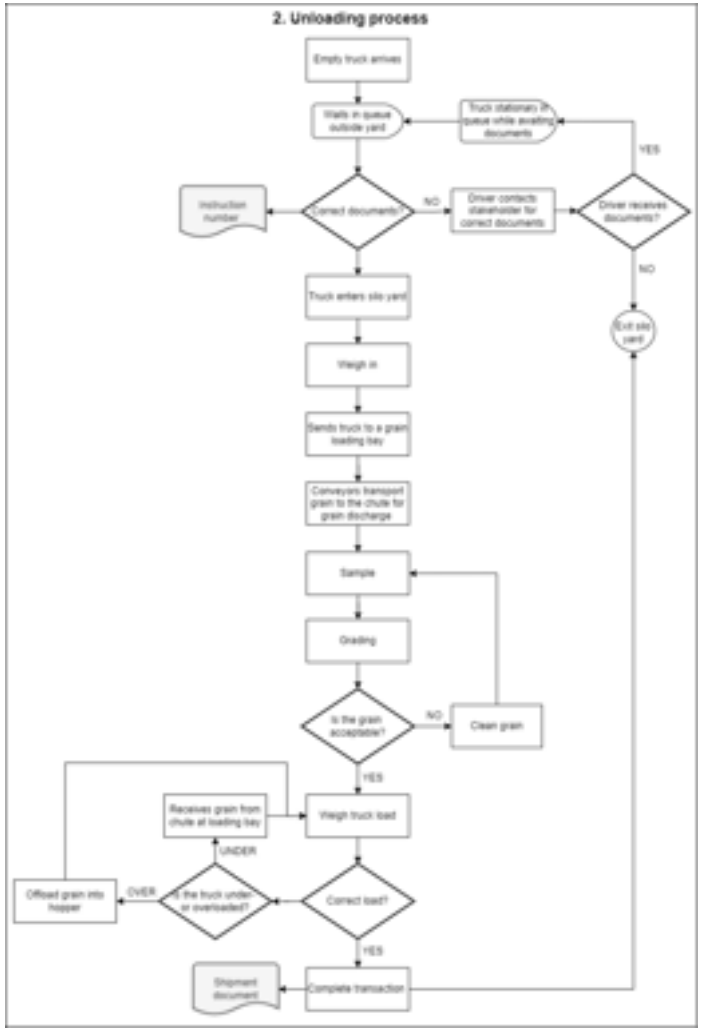

Figure 2: Off-loading process

Figure 1 and Figure 2 depict the typical flow of processes in a silo yard, but challenges often arise that lead to additional steps, potentially causing bottlenecks and slowing down the process's tempo. These challenges will be further explored in the root cause analysis section.

3.3 DETERMINING GOALS

The A3 problem-solving method focuses on defining goals for achieving during and after problem-solving [25]. The organisation's goal is to enhance operational efficiency to improve process lead times. However, the scope of this study will only focus on identifying and categorising the root causes of the inefficiencies leading to the problem.

3.4 ROOT CAUSE ANALYSIS

This section discusses how the root cause analysis data was gathered, as well as the process of analysing the data through a root cause analysis.

3.4.1 Data gathering

Data was collected from a South African case study organisation operating multiple grain silo facilities, with a focus on yard operations rather than mechanical or electrical processes inside the bins. The aim was to identify inefficiencies in the silo yard that lead to waste. Using the Genchi Genbutsu principle—"go and see"—qualitative data was gathered through observations and informal discussions [10]. This helped uncover bottlenecks and sources of inefficiency, with input from key personnel such as operations managers, regional and silo managers, operators, graders, and general staff.

3.4.1.1 Discussions

To understand the silo operations, informal discussions were conducted. Each discussion was documented through field notes, taken with the consent of the participants. To further enrich the discussions, specific topics and/or questions were posed to gather qualitative insight regarding the overall work culture, experienced frustrations, time-consuming processes, personal suggestions on improvements, as well as specific areas the employees felt the need to be observed.

3.4.1.2 Observations

Furthermore, general and systematic observations were conducted to understand the workflow, interactions, and resource use in silo operations. These included operational flow, employee movement, grain transport, workstations, process sequences, equipment, truck procedures, yard layout, electronic systems, workplace culture, communication methods, scheduling, and co-worker dynamics. This comprehensive approach provided a structured understanding of the silo yard's operational and logistical environment. Table 1 provides objectives for focus areas with specific questions in mind to ensure all areas are observed during the data gathering.

Table 1: Observations

Objective	Focus area	Question in mind during observation
Flow	Off-loading and loading processes, trucks, grain, and sequential processes	• Is the flow one-directional? • Does the flow between processes run smoothly? • Are there any delays or disruptions?
Systems	Scheduling, documentation, maintenance, PLC systems	• Are there any SOPs in practice, and are they complied with? • Do the systems support efficient grain handling? • Are the systems well-coordinated?

Workstations	Loading-bay, off-loading bay, grading, sampling, weighing bridge, and administration	• Are the workstations sequentially organised? • How long does it take to complete the designated task at a workstation?
Layout	Silo yard's arrangement and size, working stations	• Does the layout facilitate smooth grain handling and truck movement?
Interactions	Co-workers, silo operators and clients, head office and silo manager	• Is there mutual respect during conversations and departments? • Is there effective communication between different positions?
Movement	Employees, tools, equipment, and grain	• How efficient is the movement of employees, tools and resources in the silo yard?
Tempo	Off-loading and loading processes, weighing of trucks, grading, sampling, and documentation	• Is the workflow steady, or are there bottlenecks during the processes and workstations?
Storage	Number of grain bins, capacity of grain bins	• Is the storage capacity sufficient for the demand? • Does the storage waste space? • Are there any constraints related to storage?
Atmosphere	Work culture	• Is there any existing work culture to promote employees? • Does the work culture impact operational efficiency and employee morale?
Breakdowns	Equipment, machinery, technology	• Are there any breakdowns, and if so, how frequently do they occur? • Are there any precautions in place for breakdowns? • What is the impact on the operations if breakdowns occur?

The discussions, as well as the observations gathered, provided a deeper understanding of the processes and challenges in a grain handling silo facility. The qualitative data gathered enabled a comprehensive root cause analysis, which follows in the next section.

3.4.2 Data analysis

Figure 3 presents the findings from the root cause analysis (RCA), which focuses on the challenges in and around the silo facilities that impact the overall lead time of the loading and off-loading processes. The RCA is done in a grid format to organise the causes visually. Hence, the letters A, B, C and D, and the numbering represent the rows and columns in the matrix. The key, at the bottom of Figure 3, explains how the diagram must be interpreted. It indicates that when the reader follows the blocks vertically downward, the top block is caused by the block directly beneath it. Conversely, when following the blocks from bottom to top, each block leads to the block directly above it. The figure illustrates the causes impacting the tempo inside the silo yard in the blue dotted frame, while challenges outside of the silo yard are outlined with a green dotted frame.

Figure 3 identifies four primary factors affecting the lead time in the silo yard (indicated in the top row): truck congestion, different processes, unnecessary movement of employees, and long truck queues outside of the yard. Figure 4 and Figure 5 provide further explanation of the root causes presented in Figure 3. Figure 4 discusses the truck congestion and processes, while Figure 5 discusses unnecessary employee movement and trucks queuing outside of the silo yard. The grid numbers (A1, B2, C3, etc) used in Figure 4 and Figure 5 correspond with the placement of the blocks in Figure 3.

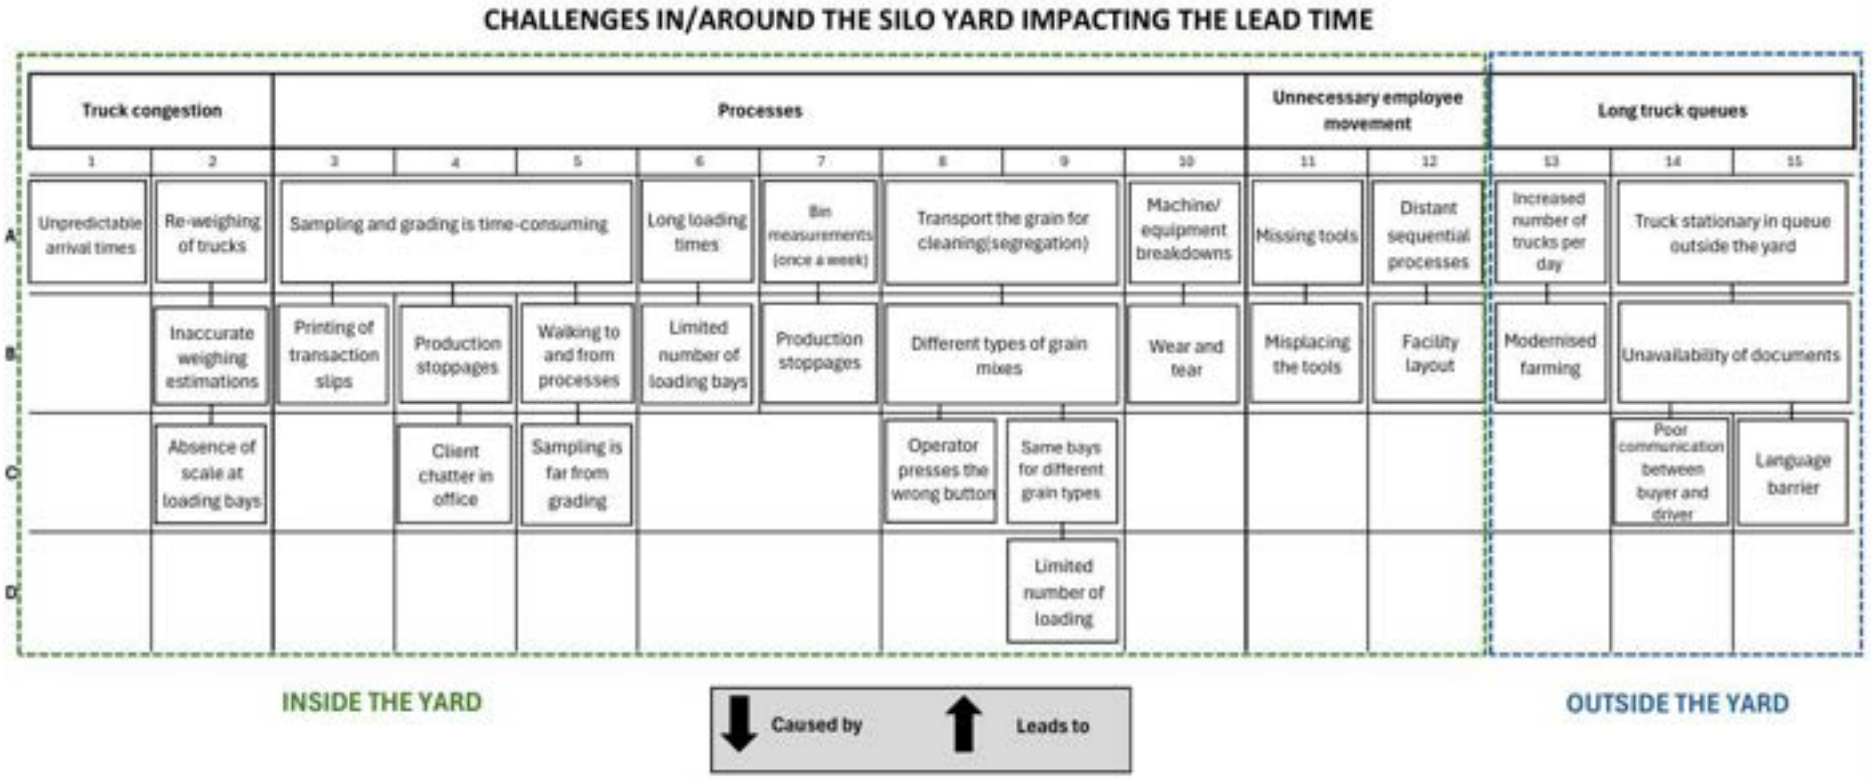

Figure 3: Root cause analysis

Primary cause	Truck congestion		Processes							
Secondary cause	**A1: Unpredictable arrival times**	**A2: Re-weighing of trucks**	**A3,A4,A5: Sampling and grading is time-consuming**			**A6: Long loading times**	**A7: Bin measurements**	**A8, A9: Transport of grain for cleaning/segregation**		**A10: Machine/equip breakdowns**
	Trucks coming to load or offload does not have a required time of arrival at the silo yard, only a determined date, which causes truck congestion .	If grain-receiving trucks must be re-weighed, they must move between the offloading bays and the weighing bridge until the correct load is achieved. Hence, it leads to truck congestion inside the silo yard.	The sampling and grading processes that are time-consuming leads to the overall process of loading or offloading grain to have longer leading times.			The loading of grain into the grain bins take long, as well as the offloading of grain from the bins into the trucks are time-consuming	Bin measurements are taken once a week, which increases the lead time for the processes.	When grain has to be transported it increases the leading time of processes.		Processes have longer lead times due to machinery or equipment breaking.
Tertiary cause		**B2: Inaccurate weighing estimations**	**B3: Printing of transaction slips**	**B4: Production stoppages**	**B5: Walking to and from processes**	**B6: Limited number of loading bays**	**B7: Production stoppages**	**B8, B9: Different types of grain mixes**		**B10: Wear and tear**
		Re-weighing of trucks is caused by employees making inaccurate estimations of the grain loaded into the trucks.	When receiving or selling grain, transaction slips must be completed, which causes the sampling and grading processes to take longer.	A cause for the sampling and grading processes to be time-consuming is due to production stoppages occurring at these workstations.	The sampling and grading processes are time-consuming due to employees walking to and from the two different but sequential processes.	The loading and offloading times per truck are long due to having limited loading bays and offloading hopper bays.	Production stoppages occur during bin measurements, as grain flow into or out of the bins must be halted while the measurements are being taken.	Grain must be transported for cleaning or segregation when different types of grain mix.		Machine or equipment breakdowns are caused by wear and tear over a period of time.
Quaternary cause		**C2: Absence of scale at loading bays**		**C4: Client chatter in office**	**C5: Sampling is far from grading**			**C8: Operator presses the wrong button**	**C9: Same bays for different grain types**	
		Inaccurate loads are caused by employees having to estimate the grain loaded as there are not a scale present at the loading bays.		When clients gather in the office and engage in non-relevant conversations, it leads to production stoppages as their truck remains stationary at the grading workstation while the client (driver) is in the office.	Employees have to physically walk far distances between the sampling and grading workstations due to it being located far apart.			If the operator presses the wrong button on the PLC system, it leads to grain mixing inside the conveyors	Different grain mixes in the hopper as silo facilities utilises the same hoppers for loading grain into the grain bins,	
Quinary cause									**D9: Limited number of loading bays**	
									Grain mixes in the hoppers due to having limited number of loading bays.	

Figure 4: Explanation of root causes (part 1)

Primary cause	Unnecessary employee movement		Long truck queues outside yard		
Secondary cause	**A11: Missing tools**	**A12: Distant sequential processes**	**A13: Increased number of trucks per day**	**A14, A15: Truck stationary in queue outside of the yard**	
	If tools are missing, employees have to search for them, thereby making unnecessary movement	Unnecessary employee movement is caused by sequential processes being far from each other, resulting in employees needing to walk.	The truck queues are longer due to the higher demand.	If trucks are stationary in the queue, it results in no progress in the queue, leading to longer queues.	
Tertiary cause	**B11: Misplacing tools**	**B12: Facility layout**	**B13: Modernised farming**	**B14, B15: Unavailability of documents**	
	If tools are misplaced, it causes them to become missing.	Sequential processes are far from one another due to how the facility were layed out.	Modernised farming leads to having more trucks to assist at a silo facility.	The trucks are stationary due to the driver not having the correct documentation on them.	
Quaternary cause				**C14: Poor communication between buyer and driver**	**C15: Language barrier**
				The driver typically does not have the correct documents due to a misunderstanding between the buyer and the driver	A language barrier can lead to not exchanging and checking the correct documents.

Figure 5: Explanation of root causes (part 2)

By understanding and following lean management's eight forms of waste, the root causes presented **Error! Reference source not found.**were categorised according to the different types of lean waste.

4 CATEGORISATION OF AGRICULTURAL WASTE

The root causes resulting in the inefficiencies in the silo yard were determined utilising the root cause analysis in Figure 3. These causes were categorised according to the eight forms of waste in lean management after exploring the discussions of the causes in Figure 4 and 5. Figure 6 provides a key that indicates the eight different wastes in eight different colours. Each root cause was categorised by following the definition of lean waste provided in section 2.2.

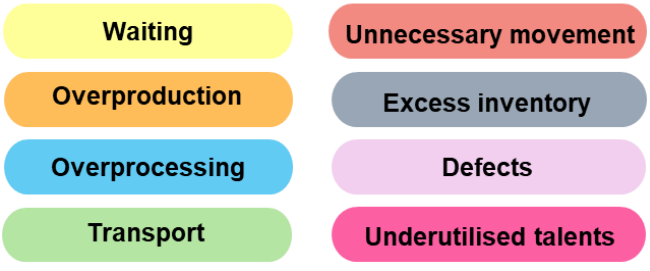

Figure 6: Waste categories

Figure 7**Error! Reference source not found.** provides the RCA from Figure 3; however, the causes are coloured according to the type of waste it was classified as. Some causes are filled in with two colours since the cause is classified as both types of waste. After categorising the various root causes into the eight forms of waste, it was found that some causes cannot be

categorised as waste, although they may lead to waste. These causes are illustrated as white blocks**Error! Reference source not found.**. Overproduction, excess inventory, and underutilised talents were not identified in this RCA.

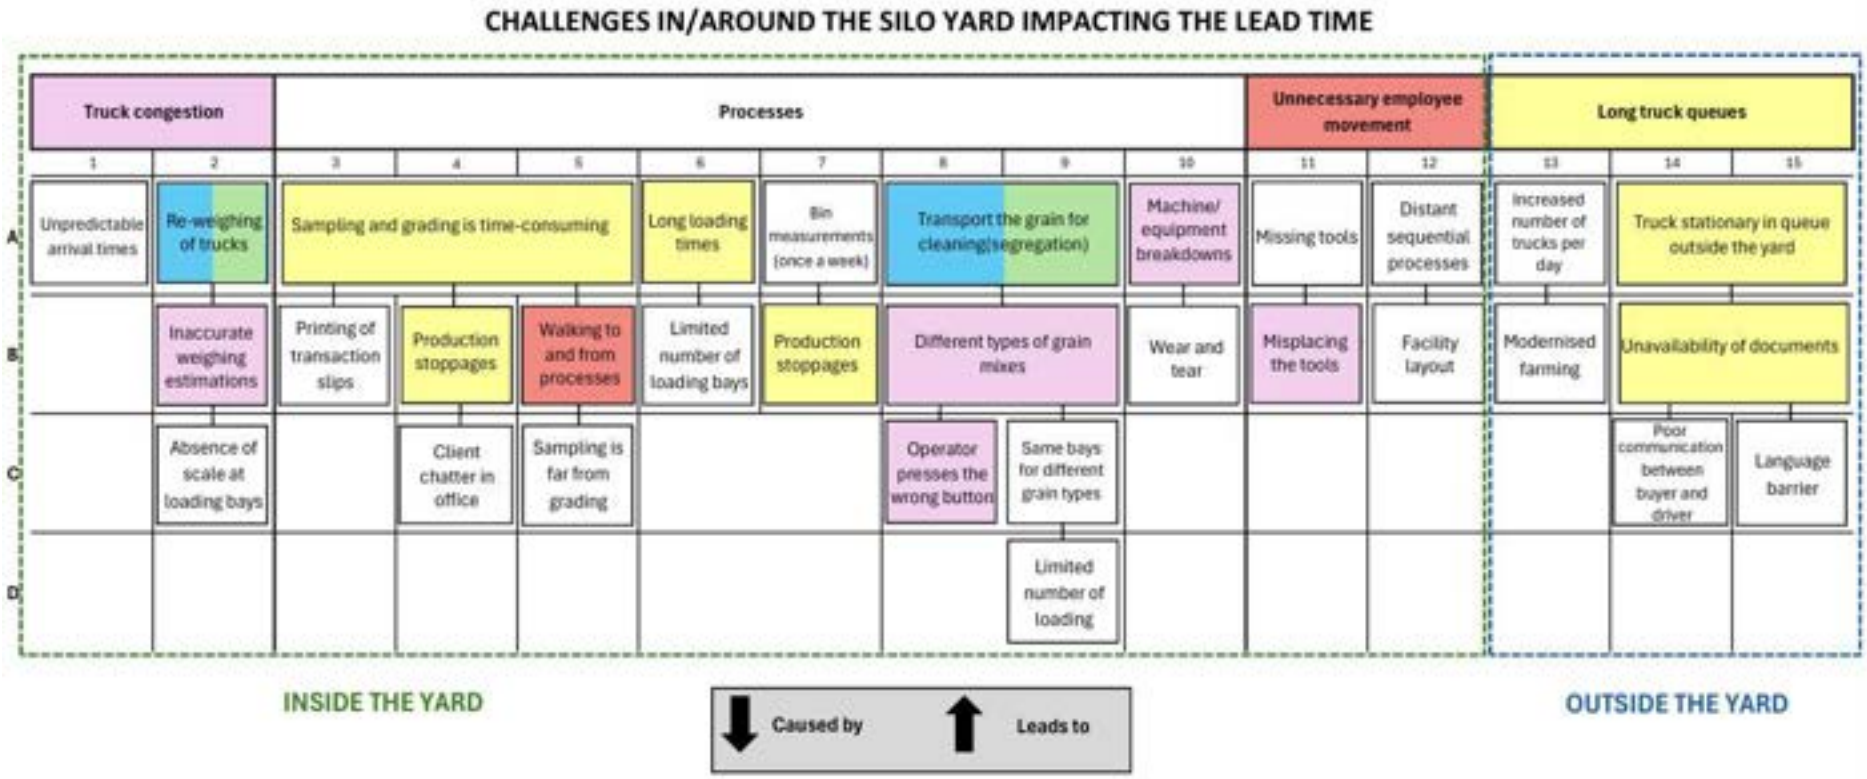

Figure 7: Root causes categorised into forms of waste

5 CONTEXTUALISING EIGHT FORMS OF WASTE FOR SILO OPERATIONS

The categorisation of the root causes into the eight forms of waste enabled the contextualising of the eight forms of waste for agricultural practices, specifically for grain handling in silo operations. After examining the lean manufacturing wastes discussed in section 2.2 and gaining an understanding of the processes and workflow in the grain silo facility in section 7, the eight types of waste specific to silo operations were identified and contextualised as follows:

1. **Overproduction**

   Overproduction occurs when the system follows a push system without considering customer demands when making decisions. This can cause bottlenecks in the operations or excess inventory.

   Grain handling examples:

   - The farmer harvests more crops than the silo facilities can store, leading to spoilage of the grain and possible limited transportation services for the grain.
   - The silo facilities store more grain than the market demands, resulting in possible capacity constraints, as well as the risk of spoilage.

   However, this waste is unlikely to occur at the case study organisation, as the demand for grain is very high, given South Africa's experience with hunger.

2. **Waiting**

   Waiting is one of the biggest lean wastes experienced in this context, as it occurs when employees, customers or downstream processes are waiting for an action to be taken, a process to finish, tools, information or people.

   Grain handling examples:

   - Waiting for farmers to deliver grain, leading to delays and increased process lead times.
   - Trucks are waiting outside the silo yards, resulting in queues and possible congestion.
   - An employee is waiting for the grading machine to complete its measuring process, resulting in the employee participating in a non-value-adding activity (such as standing).

3. **Unnecessary transport/conveyance**

   This waste involves excess movement of the material, resources, tools, trucks, machinery or equipment that does not add value to the operations. This waste is often related to poor layouts and process flows.

   Grain handling examples:

   - Moving the grain between grain bins or silo facilities is necessary due to capacity constraints, which increases transportation costs and possible labour costs.
   - Re-weighing the truckloads, due to inaccurate estimations made, resulting in repetitive actions of the truck and grain(resource) until the correct load is achieved.

4. **Overprocessing**

   Overprocessing waste involves correcting errors, repetitive steps in a process or overdelivering on the customer's requirements. This waste may lead to increased process times and possible burnout of resources.

   Grain handling examples:

   - Trucks that need to be re-weighed due to inaccurate truckloads, leading to redundant actions.
   - Grain bins that contain pesticides will have to be sifted again to prevent a decrease in the grain's quality, resulting in repetitive actions.

- Utilising two grading machines to determine the grade of the grain results in longer lead times.

5. **Excess inventory**
   Excess stock (grain) accumulation constitutes a form of inventory waste. Overstocking refers to the storing of resources beyond market demand, which could create capacity constraints.
   Grain handling example:
   - Silo's that overstock grain run the risk of having to store the grain for longer periods, resulting in possible spoilage of the grain.

   However, this case study company does not experience this form of waste, as it distributes the grain to other facilities when the current facility is at its maximum capacity.

6. **Unnecessary movement**
   This waste occurs when sequential processes are located far away from each other, poor layout in the facility, or if employees need to walk far distances between processes or participate in unnecessary actions such as reaching.
   Grain handling examples:
   - When tools are misplaced, employees will search for them.
   - Sequential processes are located far from each other, causing the employees to walk long distances within the facility, which additionally increases the lead times.

7. **Defects**
   Defect waste refers to errors and mistakes that occur during operations. This type of waste typically increases time and costs, and may impact the quality of the product.
   Grain handling examples:
   - If a truck's load is incorrectly estimated, it must return to the hopper, disrupting the workflow, which leads to additional waste.
   - Spoilage or mixing of the grain decreases its quality.

8. **Underutilisation of talents**
   This waste occurs when operational issues persist due to the underutilisation of employees' talents, knowledge and ideas. This waste may cause the employees to become demotivated, which can lead to decreased productivity.
   Grain handling examples:
   - Not using a bilingual employee to bridge the language barrier between the farmer and the silo operator wastes a valuable resource.
   - Assigning an employee with the knowledge and training in grading grain to tasks unrelated to this skill.

6 REFLECTION AND DISCUSSION

Prior work has raised the question of whether lean wastes can be identified and categorised in agriculture. However, this question has not yet been answered. In this study it was determined that not only is lean waste applicable in agriculture, but it also provided a qualitative approach to gather empirical data from a grain handling and storage case study organisation, categorise the challenges into the eight forms of lean watse, and finally contextualise lean wast in agricultural terms specifically for a grain handlimng and storage facility.

It was found that various root causes exist both inside and outside of these facilities that impact the operations' lead time and efficiency. After categorising the root causes according to the eight forms of waste, it was observed that specific causes align with multiple waste categories, while others do not represent waste directly, but instead lead to waste. In addition to categorising agricultural waste, specifically for grain handling and storage operations, the waste was contextualised, and examples were presented. Notably, overproduction and excess

storage are not applicable wastes in this industry context. After systematically contextualising the eight forms of waste in an agricultural context, this study confirms that the agricultural sector can identify lean waste. However, some limitations are worth noting. This study is a qualitative study that used a single case study organisation in South Africa. While this approach successfully contextualised the eight wastes, incorporating quantitative data would enable a prioritisation of wastes by severity and facilitate an analysis of lean countermeasures.

7 CONCLUSION AND FUTURE RESEARCH

Lean manufacturing has proven effective in eliminating waste and improving workflow in industries such as manufacturing, healthcare, the service sector, etc [8]. However, its application in agriculture remains an emerging field of study [8]. This study addressed a research gap by providing a contextualised list of the eight lean wastes in grain handling and storage facilities.

Following an adapted A3 method, this study identified and categorised key operational inefficiencies, such as truck waiting times, unnecessary grain movement, and reprocessing due to defects, translating abstract lean theory into a practical framework for the agricultural sector. This structured analysis of a grain silo facility demonstrates how contextualising the eight forms of waste in agriculture can highlight opportunities to improve efficiency, productivity, and ultimately the profitability of silo operations. In doing so, the study contributes to the emerging body of knowledge on lean agriculture and illustrates the potential of lean management when tailored to grain storage contexts.

The findings lay the groundwork for further research into lean management in agriculture, particularly in grain handling and storage operations. Future studies could explore how the 14 lean principles may be applied to address the specific wastes identified in this study, or investigate the extent to which lean practices are already embedded within the grain storage sector. Additionally, quantitative data on lead times, costs, and capacities would allow for a more precise measurement of the impact and severity of waste. Building on this foundation, future research can move beyond identifying the causes of inefficiency ("why") to developing clearer, evidence-based strategies for improvement ("how").

ABSTRACT

Printing industry plays a pivotal role in boosting the South African economy. Inadequate lean practices applied in printing division have a poor effect on the operational performances and result in managerial inefficiencies. This paper intends to assess the Lean practices and measure operational performance in printing division in a company. The study adopted a qualitative research approach. Semi-structured, face to face interviews guided by open-ended questions were conducted with 18 employees who are directly involved in the printing of examination question papers as a means of data collection. The results of this study indicate that adopting lean manufacturing in a printing plant improved machine utilisation by 5%. Furthermore, unnecessary motions and distance travelled by employees were reduced by 41% and 80.49% respectively. Printing managers can use findings of this paper as an analytic instrument to contribute to productivity of a printing company.

Keywords: Productivity, lean manufacturing, utilisation, efficiency, economy

1 INTRODUCTION

The South African printing industry has an estimated turnover of R51 billion [1]. Working additional 3 hours daily during weekdays and an additional 24 weekend hours to meet delivery schedules of the printed examination question papers suggests that printing industry is characterised with high workload [2]. Employee dissatisfaction exacerbated by the poor reward system employed within the public sector [3]. The exodus of experienced artisans in pursuit of better paying companies suggests that the level of employee morale has declined [4]. Inefficient factory layout inhibited effective utilisation of available floor space and seamless flow of people and materials subsequently affecting productivity [5]; [2]. Frequently rescheduled examination question papers' deliveries negatively impacted customer relationship [6].

During the peak examination printing season, 14million booklets of question papers were printed. Starting with the printing 3 weeks later than planned meant the system lost 120hours, putting pressure to factors like machine utilisation for the system to deliver on time. Corrective maintenance exacerbated the printing systems delays due to ceased roller bearings and printing roller rubber recovery that was needed to recover damaged rollers during printing. Lack of management support and not adhering to service level agreements disrupts the printing process as customers submit orders late. As printing system is a value chain, the delay experienced in one of the work centres has a domino effect to the value chain. The use of lean manufacturing is argued to improved performance, enhance financial performance of the printing division [7].

The printing of examination question papers puts pressure on the printing system due to the high number of booklets that must be printed at a very short period for safety and security of the examination papers. To print volumes of this magnitude, 14 million, the system required 480 hours while late submission by the customer and breakdowns experienced left the system with only 280 hours to complete the printing. This paper sets out to examine the impact of lean practices on the operational performance of a printing division by answering the 3 research questions:

1. What are the causes of low productivity rate for the printing division?
2. What are the techniques that can be used to improve productivity for the printing division?
3. What are the strategies that can be implemented to improve productivity for the printing division?

Based on the aforementioned statements, it could be inferred that the printing division's processes are characterised by overloading; demotivated employees; inefficiencies and ineffectiveness resulting in low productivity.

2 LITERATURE REVIEW

Research studies recognised lean practices influence in eliminating sources of wastes in the production flow and enhancing business performance [8]; [9]; [10]. Non value adding activities could be reduced significantly by the use of lean practices during printing [11]. In pursuit of competitive edge and being responsive to customer demands of high quality printed materials, lean practices can be adopted by the printing division [12]. A variety of researchers suggest lean practices must be adopted to enhance performance of a printing division [13]; [14]; [15]; [16]; [17]; [18], however, the lack of published material related to lean manufacturing in the South African printing systems remains a significant concern.

Such lean practices include adopting single-minute-of-die (SMED); 5S; 7S; root cause analysis (RCA); value stream mapping (VSM); Kanban; kaizen; brainstorming; benchmarking; just-in-time (JIT); total quality management (TQM) and total productive maintenance (TPM). Printing

division's success is dependent on improved turnaround times which impacts positively on overall performance. A SMED through its focus on reducing change over time in a printing process, could be used to shorten lead times for printed materials [19]. SMED enhances machine availability through reduced setup time and enables the printing division to meet customer expectations [20]. Simplification of the work environment, effective organisation of the workplace and reduction of waste; improving safety and quality are achieved through adopting 5S [21]; [22]; [23]; [24]. A 7S tool as a modified 5S methodology incorporates safety and team spirit [25]. RCA originated with Sakichi Toyoda when he formalised how he applied the method with famous 5-why's and serves as a foundational paradigm of widely used, highly refined business processes with high process maturity [26]. RCA identify root causes of a specific event [27]. Due to printing work being labour intensive, it is important to define the origin of a problem and identify areas for further investigation [28]. Listing all possible causes and effects on the diagram and focussing on each cause per category could define the origin of the problem such as low productivity. Cause and effect diagram as a generic standard of identifying root causes of a problem, provides an orderly way of looking at such effects and causes.

VSM has become one of the most popular and widespread development tool within the lean community as a system level tool that maps material and information flows within an organisation or through the value chain [29]. VSM enable printing systems to address sustainability challenges due to customer demands and involves a sequence of operational activities needed to plan and produce printed materials [30]; [31]. Kanban, as a pull system, authorises production at a required rate and specific time benefiting the printing division [32]. Kaizen, as a philosophy that seeks to continuously improve, assist printing division improve quality of printed materials; optimize printing processes and reduce costs associated with running a printing system [33]. [34]; [35] argued that kaizen philosophy primarily focusses on customer satisfaction by delivering cost effective quality printed materials on time using a variety of related and often overlapping practices including TPM; JIT; elimination of wastes; automation; plan-do-check-act (PDCA) cycle and poke-yoke.

Brainstorming involves a group of employees sharing ideas regarding the cause of a problem facing the printing division [36]. Brainstorming could be defined as an improvement technique where a group employees bring forth as many rudimentary ideas as possible [37]. Comparing what is best for learning from and improvement goals defines benchmarking as argued by [38]. The printing division has the obligation to investigate which practices are transferrable from the contexts of advanced security printing systems and non-security printing systems. Lean practices can be applied in every aspect in a printing division, although lean practices started in manufacturing [39]. Improving printing operations; enhancing productivity; decreasing lead time and improving printed material quality is the key objective of lean manufacturing, achieved by eliminating non-value added activities; shortening lead times and establishing continuous improvement processes [40].

3 RESEARCH METHODOLOGY

The study adopted a qualitative research approach with a sample of 18 participants, selected using purposive sampling. The participants answered a semi-structured interview. Qualitative research method is an exploratory research practice used to understand underlying reasons, opinions and motivations of individuals in solving a problem as argued by [41]. In depth face to face, semi-structured interviews and printing system observations were used to collect data. Interviews were guided by a set open ended questions to collect empirical data from a selected panel of experts in the printing division. This approach enabled the researcher to explore deep insights into participants' knowledge and experiences leading to relevant conclusions and recommendations. Printing system observation considered waste and inefficiencies of the printing process. Data was analysed following Braun and Clarke's thematic

analysis process [42]. After transcribing the interviews, data were prepared, coded and categorised; and themes were created, refined and finalised. Data were interpreted in order to come up with sets of findings. Thematic analysis provided relevant themes that addressed the 3 research questions of the study. For more accuracy and depth in the data analysis, the researcher employed computer assisted qualitative data analysis software (CAQDAS) NVivo 11 Pro. The appropriate research design for the study therefore had to be the one that addressed the research questions unambiguously as possible in order to understand lean practices.

4 RESULTS AND DISCUSSION

From the inductive data analysis, four themes emerged and they included perceived productivity enablers; causes of low productivity; tools for measuring productivity and strategies to improve productivity. Perceived productivity enablers theme was the most discussed across all participants with 250 quotations. Interview data analysis presented participant 14 as the highest contributor to this study with 29 codes and 118 quotations. Furthermore, participants 1, 3 and 17 with over 100 quotations each were amongst the most contributing participants with participant 16 being the least contributor to the study with only 41 quotations. From data analysis process, equipment efficiency; location; layout; management and quality of the final product emerged as perceived key productivity enablers. Figure 2 below presents key productivity enablers versus participant contribution. Participants further highlighted the significance of equipment efficiency that can be achieved through technology advancements.

Participant 1 clearly stated that “technology is key to production enhancement based on its ability to actually streamline activities." Participant 12 also stated that “technology affects productivity positively and once you have the new machines which are digitalised then it means you are counting down costs in terms of paying more people who should be doing the work manually.” Furthermore, participant 2 and 13 highlighted the importance of optimum layout in printing processes. These statements suggest the importance of technology in improving the printing division’s performance. Management was argued to be the significant productivity enabler by participants. Adopting lean practices including the use of TPM; 5S; brainstorming; kaizen and TQM could improve the current status of the printing division.

The study further identified internal factors, external factors and process factors as causes of low productivity within the printing system. Lack of training, low morale, poor work ethic, shorter lead times and lack of management support were identified by participants as major causes of low productivity. Tedious tender processes that public departments are obliged to follow proved to be negatively affecting this printing system, as was argued by participant 3. The failure of customers to understand the printing value chain exacerbated the challenges experienced by the printing system as argued by participant 1.

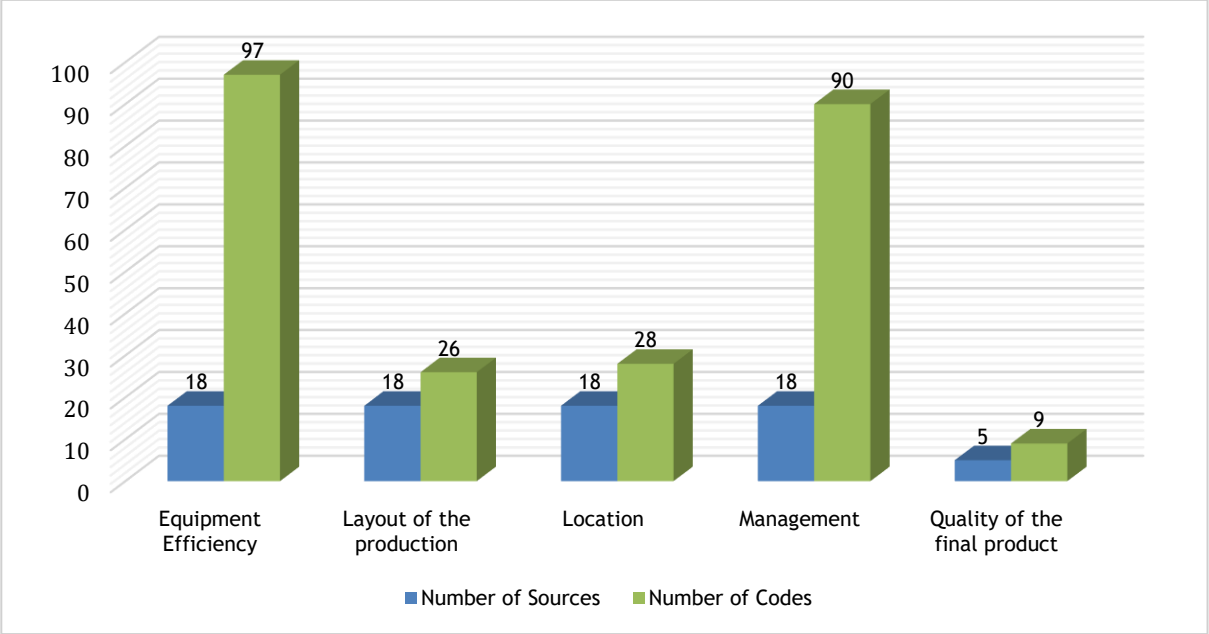

Figure 2: Perceived productivity enablers

From the above figure 2, perceived productivity enablers of the printing system were identified. Equipment efficiency followed by management factor were identified as the major factors that impact on productivity, accounting for 74,8% of the printing systems productivity. As shown in figure 3 below, focusing improvement efforts on equipment efficiency and management factors would maximise productivity.

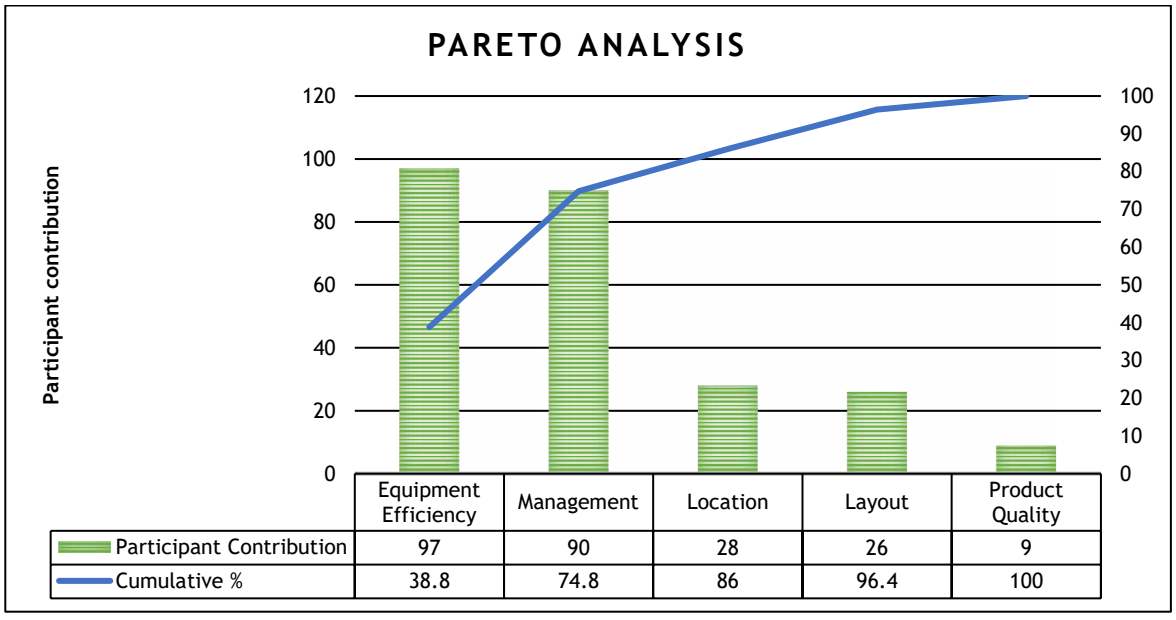

Figure 3: Pareto analysis

4.1 Current system

Data collected through printing system observation indicated that printing division experienced excessive motions due to inefficient factory layout. The use of offset printing and digital printing further impacted performance of the printing system. This was evident when artisan was unable to start production run citing shortage of printers' assistants. Also, artisans

are unable to operate a variety of printing machines available due to lack of training in operating such equipment in addition to the ones they are operating on a daily basis. Delays such as waiting for printers' assistants or waiting for an artisan increase workload and create bottleneck for the printing division. Digital printing lack suitable trained operators and the limited number of printers' assistants. A high number of activities within the printing division further affects the performance of the system negatively. Out of 540 minutes of the shift, 245 minutes were used to run the printing machine.

The other 295 minutes was used for collecting job cards and proof copies; collecting paper reels and official breaks accounting for 85minutes which were essential non-value adding activities. These delays accounted for 34% of the total time with 9 activities while 5 transport related activities, accounted for 19% of the total activities in the printing system. Inefficiency of the system is confirmed by only 8 operation related activities, translating to 31% of the total activities of the printing section. Figure 4 below present printing section activities.

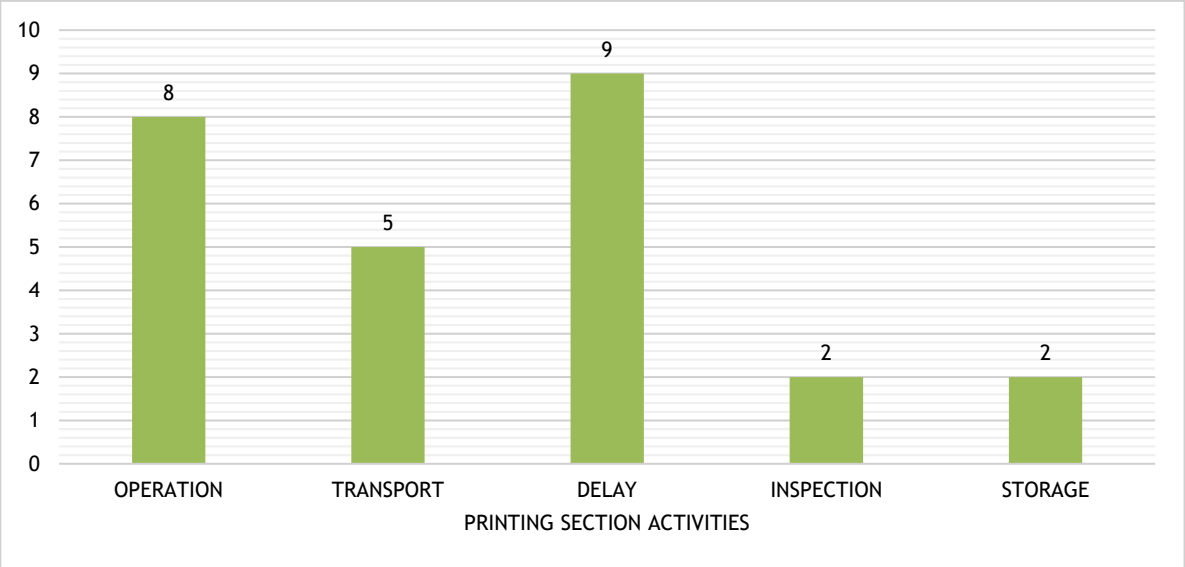

Figure 4: Printing section activities

The distance between machines used has an impact on productivity as longer distances take longer to be travelled when transporting materials between the machines. The distance between all machines in the print production line indicates a poorly laid out factory as presented by table 1 below.

Table 1: Distance between machines

Machine Distance in Metres						
List of Machines:	CTP	Solna	Dev	OCE	Martini	CMC
CTP (Printing plate making machine)	0	1600	1600	1600	1600	1600
Solna Printing Machine	1600	0	5	20	10	25
Dev Printing Machine	1600	5	0	25	10	20
OCE Digital Printing Machine	1600	20	25	0	35	41
Martini Stitching Machine	1600	10	10	35	0	6
CMC Packaging Machine	1600	25	20	41	6	0

Furthermore, system observation presented results that highlighted the inefficient utilisation of machines. This is evident as out of 6 work centres, only 1 work centre remained operational at 96%. A total of 5 other work centres operated below 60%, with CTP being the worst at 33%.

Overall downtime is experienced by the 2 printing machines, i.e. Dev and Solna with a total of 68,2 hours over a 3 months cycle as presented by table 2 below. Mathematically, machine utilisation was found to be 55,6% for the entire printing system:

$$machine\ utilisation = \frac{\textbf{actual machine hours}}{\textbf{available machine hours}}$$

$$= \frac{1535{,}43}{2758{,}8}$$

$$= 55{,}6\ \%$$

Table 2: Machine utilisation

WORK CENTRE NUMBER	WORK CENTRE NAME	AVAILABLE HOURS	ACTUAL HOURS WORKED	UTILISATION PER WORK CENTRE	DOWN TIME IN HOURS
310900	CTP	451,44	149,8	33%	0
320622	DEV	451,44	249,1	55%	36
320822	Solna	451,44	204,7	45%	32,2
340702	OCE	451,44	432,15	96%	0
360744	Martini	451,44	261,15	58%	0
373010	CMC Packing	501,6	238,53	48%	0
TOTALS:		**2758,8**	**1535,43**	**56%**	**68,2**

4.2 Proposed system

The researcher used lean practices relevant to the printing division processes to enhance the printing system's performance. Interview participants identified lack of artisans; poor quality materials and inefficient layout as sources of waste. Table 3 below presents identified lean practices to improve performance of the printing division.

Table 3: Lean practices

Causes of low productivity	Lean practice	Actioned plan	Resources sourced	Targeted outcome
- Machine breakdown. - Lack of technologically advanced machines.	TPM	-Removed printing equipment from Bosman Street factory. -Installed technologically advanced equipment at Visagie Street factory in an optimised layout. -Production management and maintenance management discussed and agreed on new maintenance schedule. -Educated machine operators about new plans.	-Rigging company. New factory space. -Equipment maintenance manuals to identify maintenance needs per machine.	-Improved overall equipment utilisation from 56.6% to 60.6%. -Competent machine operators. -Supportive management to improve machine efficiency.
- Lack of skilled machine operators. - Demotivated employees. - Absenteeism. - Employee turn over	Operator training	- Identified problem areas. - Selected operators to be trained. - Appointed apprentices to increase operator base. - Set out clear and achievable operator training targets. - Developed a recognition and reward system.	- Operator training manuals. - Knowledgeable facilitator to train operators. - Lucrative reward system.	- Effective and efficient operators. - Motivated operators. - Increase of skilled operator retention rate. - Supportive management to continuously encourage operators.
- Material shortage. - Poor quality material.	MRP	- Established demand management team. - Adopted the use of a material resource planning system. - Ascertained material demand volumes. - Compared previous demand with future demand to develop new order points. - Regularly checked physical stock to test the effectiveness of the material resource planning system.	- Demand management personnel. - Material resource planning system. - Physical stock item forms to record stock.	- Reduced risk of material shortage. - Identification of reliable suppliers. - Effective material resource planning system.
- Poor housekeeping - Hazardous workplace	5S	- Collected evidence of the current situation of the area identified for 5S project. - Reviewed sorting criteria. - Marked a local red tag area. - Tagged, recorded and moved tagged items to an identified area. - Kept evidence of the newly sort area.	- Camera for present situation and reformed situation pictures. - Red tags (sorting tools for visual control). - Red tag record forms.	- Reduced searching time of finished and in-process materials. - Reduced costs associated with unnecessary inventory. - Increased floor space utilization.

Poor layout	Layout	Designed layout optimally.	New factory premises.	Optimum factory layout.
Increased down time due to official breaks.	Roster plan.	Implemented staggered official breaks.	Official breaks time schedule.	Reduced down time associated with official breaks.

5 CONCLUSIONS

Implementing lean practices in the printing system reduced delay activities from 34% to 25% and transport related activities from 19% to 9% within the printing section. Furthermore operation related activities increased from 31% to 50%. In addition to the improved activities in the printing section, the distance between machines was reduced by relocating printing machines closer to each other in a new factory with an optimally designed layout as presented by table 4 below. This led to a reduction of distance travelled between machines by 80,49% from 1600m to 50m. Proposed printing system further improved overall productivity from 55% to 90%.

Table 4: Proposed system distance matrix

PROPOSED SYSTEM						
Machines:	**CTP**	**SOLNA**	**DEV**	**OCE**	**MARTINI**	**CMC**
CTP	0	50	50	55	55	67
SOLNA		0	5	6	6	18
DEV			0	6	4	13
OCE				0	2	8
MARTINI					0	10
CMC						0

The implementation of lean strategies such as TPM, 5S, MRP, Operator training, layout design and roster plan improved machine utilisation by 5% from 55,6% to 60,6% as presented by table 5 below. Furthermore, proposed layout design improved printing system by eliminating 41% of employee movements.

Table 5: Machine utilisation

WORK CENTRE NUMBER	WORK CENTRE NAME (PRINTING MACHINE)	AVAILABLE HOURS	ACTUAL HOURS WORKED	UTILISATION PER WORK CENTRE
310900	CTP	451,44	149,8	33%
320622	DEV	451,44	265	58,7%
320822	Solna	451,44	245	54%
340702	OCE	451,44	432,15	91%
360744	Martini	451,44	280	62%
373010	CMC Packing	501,6	300	59,8%
TOTALS:		**2758,8**	**1671,95**	**60,6%**

$$machine\ utilisation = \frac{\textbf{actual machine hours}}{\textbf{available machine hours}} = \frac{1671{,}95}{2758{,}8} = 60{,}6\ \% \equiv 61\ \%$$

The study was conducted during a peak period of examination printing, limiting the results to peak seasons. Furthermore, results of the study were limited to a sample of 18 semi-structured interview participants based in one printing division in Gauteng province of South Africa, inhibiting generalising results to the entire printing industry. Authors recommend further studies to assess the impact of lean practices on operational performance of printing divisions.

Appendix 1

OPEN ENDED RESEARCH INTERVIEW QUESTION

The following research questions were formulated for designing a productivity improvement strategy in THE GPW.

Research Question 1: What are the causes of low productivity rate for GPW?

1. What is the impact of human resource on productivity?
2. How does material affect productivity?
3. What is the influence of machines on productivity?
4. What is the impact of location on productivity?
5. What is the impact of layout on productivity?
6. How is productivity affected by finance?
7. How management influence productivity? Please explain.
8. How does technology affect productivity?
9. What are the challenges between the GPW and suppliers?
10. What are the challenges between the GPW and customers?

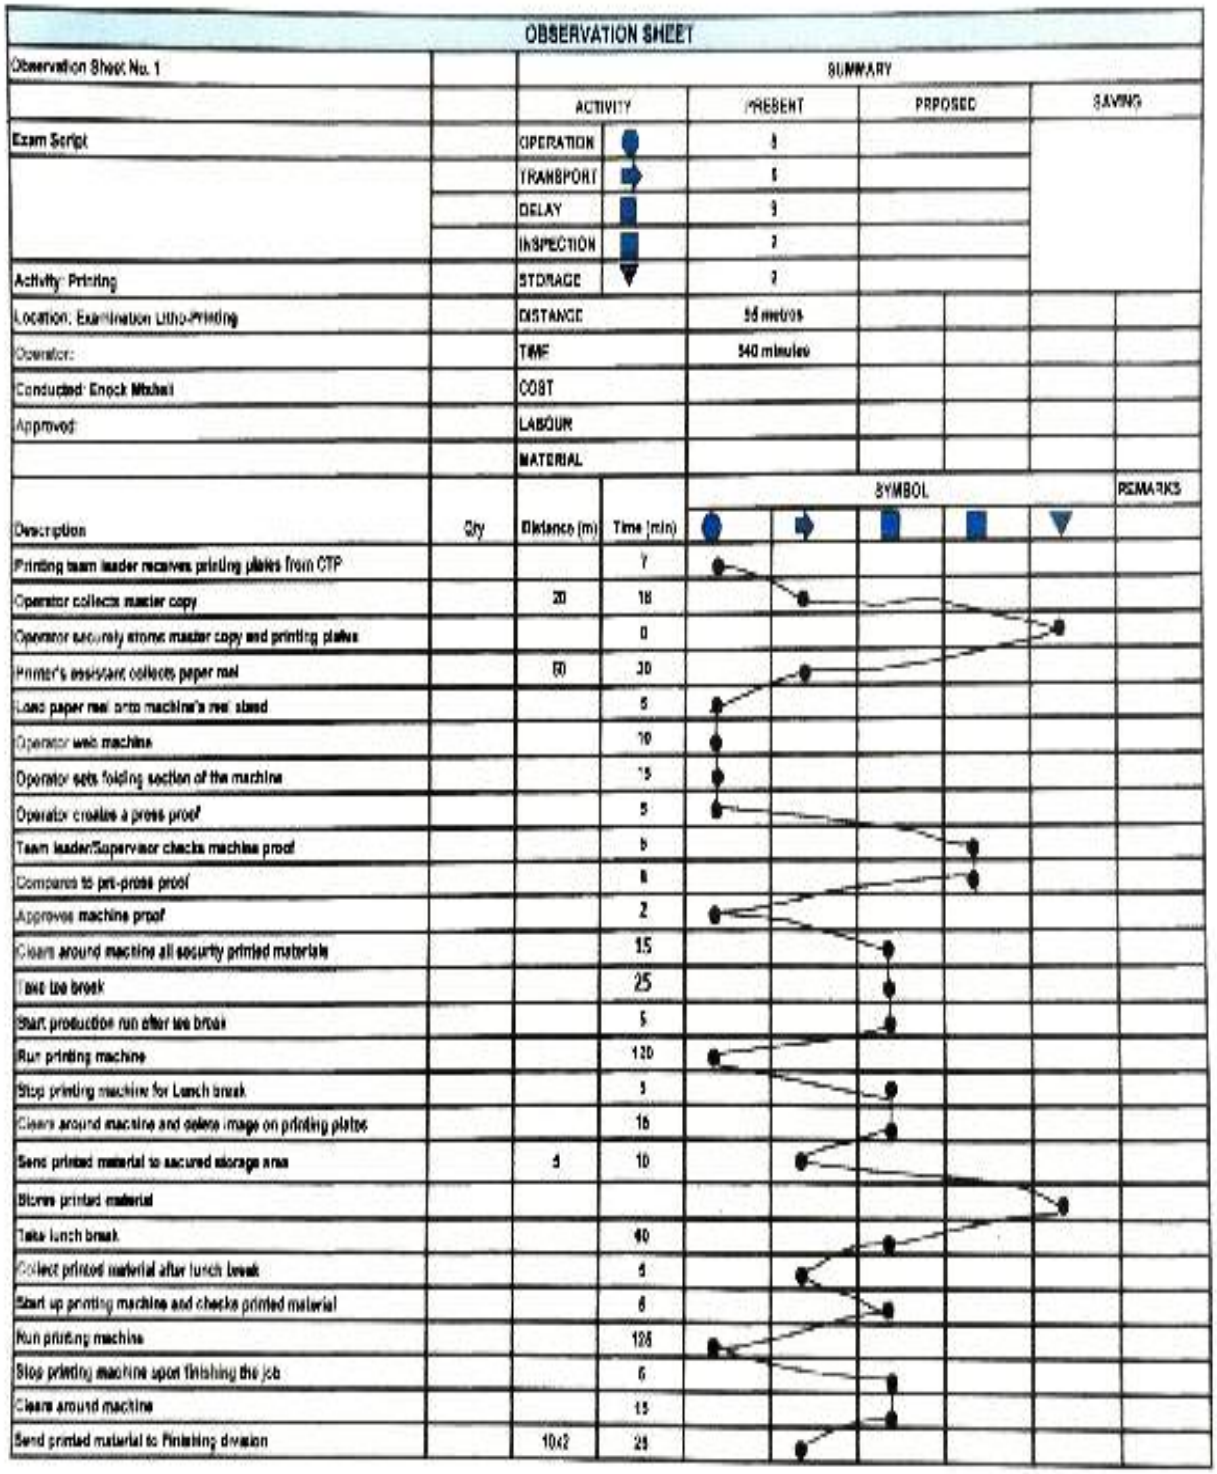
Research Question 2: What are the techniques that can be used to improve productivity for GPW?

11. Do the GPW measure productivity?
12. What are the different kinds of waste generated in printing production?
13. What are the bottlenecks experienced in printing processes?
14. What is the impact of quality on productivity?

Research Question 3: What are the strategies that can be implemented to improve productivity for GPW?

15. What are the different types of tools or techniques that could be used to improve productivity?
16. What are the strategies that could improve productivity?

Appendix 2: Observation sheet



OBSERVATION SHEET										
Observation Sheet No. 1		SUMMARY

ABSTRACT

South African foundry industry experiences major challenges that come with the Fourth Industrial Revolution (4IR) and implementation of new manufacturing technologies. Although 4IR technologies, including robotics, additive manufacturing, the Industrial Internet of Things (IIoT), and artificial intelligence have recently been successfully implemented in foundry operations all over the world to facilitate maintenance improvements, real-time process monitoring, and automated quality control, in South Africa, they are not widely used. Recent research evidence shows that some few foundries in town have adopted less advanced automation and the usage of sensors with their monitoring and there are rare examples of 3D sand printing and robotic handling of moulds but most are still being done by hand. The study evaluates the existing rates of smart manufacturing via adoption of 4IR technologies in South African its foundry sector, determine the precise procedures, adoption bottlenecks, and severity of the skills shortages in the workforce. The study follows a systematic literature review (SLR) approach that contrasts global best practice with South African realities in an effort to devise a framework of upskilling and training to facilitate an easier shift towards a fully enabled 4IR-enabled manufacturing landscape. Results reveal a critical necessity to adopt and integrate technology and to focus on long-term workforce development in order to remain competitive.

Keywords: Smart manufacturing, Foundry Industry, Fourth Industrial Revolution 4IR, Workforce upskilling.

1 INTRODUCTION

The Fourth Industrial Revolution (4IR) is fundamentally reshaping the global manufacturing landscape, driven by advanced technologies such as the Internet of Things (IoT), Artificial Intelligence (AI), robotics, additive manufacturing, and big data analytics [1]. These innovations enhance operational efficiency, productivity, and competitiveness across industries, and the foundry sector is no exception. South Africa's foundry industry is pivotal in producing metal castings and components that serve critical automotive, mining, and engineering industries. The foundry industry contributes significantly to the national economy, with an estimated 123 active foundries in operation by 2020 [2]. Despite its importance, the South African foundry sector lags in adopting 4IR technologies, which has raised concerns about this industry's long-term sustainability and competitiveness.

According to studies, several issues stop the foundry industry in South Africa from embracing 4IR technologies, such as lack of technology, funds, and required skills. [3] pointed out that the foundry sector's major problems include inadequate access to modern technology, high application expenses, and a lack of qualified staff [3]. [4] stated that many foundries continue to use old processes, require a lot of workers, and are not up to international standards. Further, [5] stressed that because employees are not digitally literate or properly trained, companies face more challenges with 4IR adoption and integration [5].

Since Germany, Japan and China have embraced smart manufacturing, South Africa’s foundry industry needs to catch up with these developments. Technologies such as robotics and AI are used by them in predictive maintenance to enhance their production, avoid downtime and prevent errors [6]. At the same time, only basic automation is usually seen in South African foundries and many companies are not eager to embrace 4IR because of expenses. Therefore, the sector could get farther behind while other manufacturing sectors advance [4].

[5] suggest that to deal with these problems, workers should learn 4IR skills to handle jobs that need advanced abilities [5]. [3] further state that for smart manufacturing to succeed, employees should develop their IoT, robotics, and AI skills. South African foundries cannot use 4IR technologies because of problems related to money, technology, and skills. Even though 4IR can potentially improve foundry operations, many foundries continue using manual systems that require more people [3]. The lack of technology and training could reduce the industry’s ability to thrive and compete well. The study looks into these challenges and plans to improve workers’ skills and use smart manufacturing so South African foundries are ready for 4IR.

This paper uses a focused gap analysis to evaluate the gap between the existing skills-set of workers in the foundry industry in South Africa and the skills needed to integrate Fourth Industrial Revolution (4IR) technological advancement competently. In that presence, gap analysis can be termed as a targeted method of finding the gap between the technical abilities, digital literacy, and operation of the existing workforce and the skills, knowledge and behaviours required by the recent workforce to meet the advanced manufacturing techniques such as digital manufacturing (DM), the Industrial Internet of Things (IIoT), additive manufacturing and data controlled quality checks. On the basis of industry reports such as MerSETA Sector Skills Plan (2019/2020)[7] and empirical research, through the analysis of skills-based data, it is evident that most of the employees working in local foundries have excellent applied experience in traditional methods of casting and lack exposure to automation systems, predictive maintenance systems, and real-time monitoring technologies of processes. In this project, these gaps are being filled by performing a mapping with current training provisions to global best practices as well as identifying key upskill areas such as integrating CAD/CAM, machine learning to predict defects and IIoT enabled production overviews. The output of this gap analysis is an input directly in the proposed upskilling framework where the training interventions are both industry and future-oriented.

The study is significant in identifying why 4IR is not widely adopted in South African foundries and finding ways to overcome these problems. The research will recommend a universal approach to improve productivity and competitiveness by paying attention to technology and employee training. The results will assist South African foundries and provide useful information for similar industries in other developing countries that want to use 4IR technologies.

1.1 Aim of the study

This research aims to assess the current levels of adoption of smart manufacturing using Fourth Industrial Revolution (4IR) technologies and practices within the foundry industry. This will lead to the identification of smart manufacturing approaches that will upskill and train the foundry workforce to ensure a smooth transition to a more 4IR-enabled manufacturing environment within South African foundries. To achieve this objective, the research employs a systematic literature review (SLR) methodology focusing on assessing and investigating these 4 key objectives:

- The current levels of adoption of smart manufacturing using 4IR technologies in foundries.
- Key current 4IR technologies and practices applied in the foundry operations.
- Challenges in implementing smart manufacturing and fourth industrial revolution (4IR) technologies
- Find smart manufacturing approaches or best practices that can improve skills to ensure a smooth transition into 4IR-enabled manufacturing

The Fourth Industrial Revolution (4IR) is largely accepted as a game changer across the South African manufacturing sphere, but its uptake in the foundry sector has been partial and mixed. Individual innovations have been seen, for example, the implementation of 3D sand printing to create prototypes in a small number of automotive component foundries and the use of CNC-based machining or robotic pouring systems in a few medium-high-capacity plants. According to industry reports and stakeholder consultations, more than 70 per cent of operational foundries already remain primarily dependent on manual moulding, melting, and finishing processes with the insignificant use of real-time data analytics and interconnected production systems. In addition, the lack of fully connected Industrial Internet of Things (IIoT) systems ensures that the concepts of predictive maintenance, digital twins, and cloud-based control of production are not seen much in mainstream operations. This situation makes the work of the current study relevant, as it attempts to fill these gaps by offering an evidence-based technology integration and workforce upskilling framework on the topic of foundry.[8]

2 LITERATURE REVIEW

2.1 Fourth Industrial Revolution Technologies

According to [9], utilizing robotics, additive manufacturing, augmented reality and digital twins can boost foundries' work, help produce innovative goods and support their competitiveness [8]. Employing robotics and automation at the foundry increases the effectiveness of processes and lowers their cost. In addition, the application of additive manufacturing and digital twins helps foundries complete their tasks more efficiently and in a shorter time. The industry needs to use Internet of Things, artificial intelligence, data analytics and cyber-physical systems to reach higher success and performance [10]. In addition, it includes advanced ways with computers, possibly changing the day-to-day processes of businesses. Though there are important challenges involved in adopting 4IR, being prepared with a plan eases the difficulties.

2.2 Smart Manufacturing

[11] stated in their research that the industry in South Africa is paying attention to smart manufacturing because of its importance. Industry 4.0 brings about smart manufacturing which helps companies produce more and reach their goals. Smart manufacturing allows foundries to examine their products more efficiently, experience less breakdown time and improve the use of their resources [10]. To apply smart manufacturing in the foundry industry, employees can be taught new technology, there should be flexible systems in use and modular production strategies can be used. With the help of big data, AI and advanced robotics, smart manufacturing becomes more efficient and energy-efficient which also lowers the cost of having a workforce. It strengthens a company's position in the market and assists the lasting health of the economy [12]. Smart manufacturing has proved to let companies use fewer raw materials, increase productivity and spend less on energy. Consequently, smart manufacturing is important for reaching growth and success. Overall, embracing new technologies makes growing businesses in an environmentally friendly way much simpler.

[1] defines Smart manufacturing as an innovative approach that utilises big data processing, artificial intelligence, and advanced robotics to improve manufacturing performance and optimise energy and labour needs. [11] have inferred that smart manufacturing boosts competitiveness and economic sustainability. Recent research also confirms that smart manufacturing plays an important role in reducing input costs, increasing productivity, and improving resource efficiency. This underscores the importance of implementing smart manufacturing for sustainable production and economic advancement. It can be concluded that smart manufacturing is the use of advanced technologies that can transform traditional manufacturing processes, resulting in improved efficiency and productivity in the sector. Smart manufacturing is poised to become the cornerstone of sustainable manufacturing enterprises, supported by the availability of pioneering technologies to drive industrial production.

2.3 The South African Foundry Industry

The main sectors in the South African foundry industry caters to are mining, automotive, and general engineering. [13] State that the foundry industry is important for South Africa's economy, so every effort should be made to sustain it. The industry's collapse is mainly because of more imported goods, higher energy bills, inefficient use of energy, having to pay for environmental rules, and a growing skill gap between workers [12]. According to [13], foundries had a substantial fall from 2010 to 2015. In 2020, 37 foundries stopped working, so the industry had 123 active foundries [14]. [15]. Still, because it is not resource-efficient, it slows down efforts to reduce defects and improve resource use for better value [14].

2.4 Challenges of the adoption of 4IR Technologies

According to [16], foundries in South Africa face several risks and challenges because of the global market, which has led to several closures. Several researchers have pointed out that one of the main issues in the South African Foundry Industry is that members lack basic technology skills [15]. [17] indicate that the new technologies in the foundry sector need people with advanced skills. Because of problems at both national and local levels, foundries in South Africa are being closed down [16].

The main issue is that most of the work is still done manually, and only a small part is done with advanced digital technology. Besides these, the industry has to deal with high energy costs, inefficient use of resources, the cost of obeying environmental rules, and an increasing difference in skills among workers. [18] pointed out that a serious research gap exists regarding upskilling and training programs that can ensure the sector's smooth adoption of 4IR

technologies. It has been found that effectively preparing and planning can help people handle transition difficulties [17].

2.5 Benefits of Implementing 4IR Technologies

Adopting 4IR technologies can increase foundries' productivity, quality, and competitiveness. According to [19], applying simulation tools in foundries helps predict results and design better castings, which leads to using fewer materials. Foundries can increase their productivity, quality of products and stand a better chance in competition with the help of robotics and augmented reality [18]. According to the study by [19], using smart manufacturing helps foundries achieve many positive results. They supply better quality, fewer situations where things are not working and proper use of all resources [20].

3 RESEARCH METHODOLOGY

A systematic literature review was conducted for this study, aiming to identify and assess the current levels of adoption of smart manufacturing using fourth industrial revolution (4IR) technologies and practices within the foundry industry. Thus, we designed the study considering the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) approach for literature search and selection. [21]. Inductive and qualitative analyses were performed on peer-reviewed academic articles published between 2015 and 2025 for the thematic analysis in this systematic literature review. Using the PRISMA method, the study identified four main themes:

(1) Recent Adoption of 4IR Technology,

(2) Getting Employees Ready and Upskilled for 4IR technology,

(3) Challenges and Barriers in the Implementation of 4IR, and

(4) Useful Strategies and Comparisons to Global Standards.

3.1 Research Design

The study analyzed the adoption of Fourth Industrial Revolution-related smart manufacturing technologies in South African foundries using a systematic literature review (SLR).

The methodological framework of the study includes the operation of a Systematic Literature Review (SLR) as the building block to realize a systematic analysis of the gap in the workforce skills pertaining to the adoption of 4IR within the South Africa foundry industry. Gap analysis in this process can be understood as a logical method of determining the discrepancy in existence between working business skills, technologies, and operational practices and that which is sought to attain the perfect use of 4IR technologies including the Industrial Internet internet of Things (IIoT), digital twins, advanced automation, and additive manufacturing. The SLR involved gathering, synthesising, empirical studies, industry reports, and policy documents in an attempt to discover:

- The current state of technology adoption in the foundry industry globally and in South Africa.
- The technical and digital skill sets currently present in the South African foundry workforce.
- The competencies and organisational practices required for effective 4IR implementation.

The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) protocol has been prescribed as the design map of the proposed SLR because of the defined, transparent, and repeatable flow of literature identification, screening, and synthesis. In comparison to other SLR strategies, PRISMA was considered most suitable to the analysis since it provides meticulous recording of the inclusion or exclusion criteria, maximum coverage of

both scholarly and professional sources, and allows determining the gaps in the researches conducted with a minimum of bias [22]. This procedure ensured that the gap analysis rested on synthesis driven by evidence instead of anecdotal observation.

Through the cross-referencing of the results found in the SLR to the competency needs to implement 4IR as identified in the literature, the research was in a position to identify certain shortcomings in skills, especially in areas that include data analytics, automation programming, and quality control digitally, and could be attributed to structural and organisational impediments in the South African foundry sector. These reflections have a direct impact on the upskilling framework proposed.

The guidelines of PRISMA helped the reviewers adhere to the best practices, and the framework's method made it easy to follow and record each stage of the review process [20]. This study reviewed previous research to learn about the applications, problems, and possible solutions for 4IR in the foundry industry, which allowed us to identify areas where more research could help and guide useful practices in South Africa.

3.2 Inclusion and Exclusion Criteria

Specific inclusion and exclusion criteria were set to ensure the quality and relevance of the studies in the review. Only peer-reviewed journal articles published between 2015 and 2025 were considered, as this time frame captures recent advancements in 4IR technologies and their use in manufacturing. The review focused on articles about adopting technologies like AI, robotics, additive manufacturing, IoT, and big data in the foundry industry or similar sectors, especially those addressing challenges in South Africa. Studies unrelated to foundries or those not discussing workforce issues in 4IR adoption were excluded, ensuring a focused analysis of the current state and challenges of 4IR implementation in South African foundries.

Table 1: Inclusion and Exclusion Criteria

Criteria	Inclusion	Exclusion
Study Type	Peer-reviewed journal articles, conference papers, and case studies	Non-peer-reviewed articles, book chapters, editorials, and non-academic sources
Publication Date	Articles published between 2015 and 2025	Articles published before 2015 or after 2025
Language	Articles written in English	Articles not written in English
Focus Area	Studies on 4IR technologies in the foundry industry, smart manufacturing, workforce upskilling for Industry 4.0, and challenges of 4IR adoption in South Africa	Articles focused on industries outside the foundry sector, general discussions not related to 4IR technologies
Technological Focus	Studies addressing 4IR technologies like IoT, robotics, AI, additive manufacturing, big data analytics, and digital twins in foundries	Studies not related to 4IR technologies or focused on unrelated technologies
Geographical Focus	Studies focused on South Africa or applicable to the South African context	Studies focused on regions outside South Africa or unrelated regions
Industry Focus	Studies focused on the foundry industry or closely related manufacturing sectors	Studies focusing on non-manufacturing sectors or sectors unrelated to foundries

Workforce Development	Articles discussing workforce upskilling, training programs, and labor market adjustments to 4IR in the foundry industry	Studies that do not address workforce upskilling or training for 4IR technologies
Study Design	Case studies, empirical research, and systematic reviews	Opinion pieces, literature reviews without empirical evidence, and conceptual papers
Focus on Adoption Barriers	Studies exploring barriers to 4IR adoption in South African foundries	Studies that do not address adoption barriers or are focused on broader or unrelated challenges

3.3 Data Sources and Search Strategy

[23] States that systematic literature reviews are expected to report in a detailed manner on the steps taken to arrive at the sample of reviewed literature. To conduct a systematic literature review, three types of inclusion criteria must be met: the databases to be included, the keywords to be chosen, and the nature of the publications to be included [24]. The search was conducted to ensure all aspects were covered and the questions were considered. The choice of Google Scholar, Scopus, and Science Direct as academic databases was made because they have a wide range of peer-reviewed articles in manufacturing, technology, and workforce development. The search looked for articles that discussed "Smart manufacturing in the foundry industry," "The use of 4IR in metal casting," and "Workforce upskilling for Industry 4.0" to find studies about technology, upskilling workers, and related problems in the South African foundry industry. They made certain that the articles selected were about 4IR technologies in foundries.

Table 2: Literature Search Strategy

Element	Details
Databases	Google Scholar, Scopus Library, Science Direct
Keywords	1. "Smart manufacturing in the foundry industry"
	2. "4IR adoption in metal casting"
	3. "Workforce upskilling for Industry 4.0"
	4. "Challenges of 4IR in South Africa"
Timeframe	Publications from 2015 to 2025
Language	English
Inclusion Criteria	Peer-reviewed articles, conference papers, and case studies focusing on 4IR adoption, smart manufacturing practices, workforce upskilling, and challenges in South Africa's foundry industry
Exclusion Criteria	Non-peer-reviewed articles, studies not related to 4IR technologies, studies not specific to the foundry industry, or South Africa
Search Technique	Boolean operators (AND, OR) to combine keywords for an effective search; filtering for publication years (2015–2025)
Search Date	April – May 2025
Study Selection Process	Initial identification of articles, followed by screening based on titles, abstracts, and full-text relevance to the inclusion criteria
Data Management	Use of reference management software (e.g., EndNote, Mendeley) to organize and manage citations and articles

3.4 Screening and Selection Process

The studies chosen were assessed through several phases to ensure the relevant ones were included. Over 500 articles were discovered initially, which was reduced to 200 by eliminating duplicates. Screening of the titles and abstracts was done to select only those articles that discussed 4IR in foundries, training employees, and South Africa. This brought the number to 80 articles, all reviewed carefully. Those articles that did not match the criteria were

excluded, which left 40 studies that offered helpful information about 4IR adoption, related issues, and changes in the foundry industry's workforce.

3.5 Data Extraction and Synthesis

The process of extracting and organizing data from the chosen studies helped to analyze the main information. Data about 4IR, the tools involved, any problems, and how workforce skills are being updated was collected. The results were gathered into themes so that similarities and differences could be easily noticed. This allowed spotting missing research and useful strategies from similar industries that could be used in the South African foundry sector. The findings from the synthesis gave a complete picture of 4IR adoption in foundries and guided the development of recommendations for better workforce and technology usage in South Africa.

4 FINDINGS

The researchers reported their findings related to current levels of adoption of smart manufacturing using fourth industrial revolution (4IR) technologies and practices within the foundry industry. The findings of the literature research indicated that there is a growing body of knowledge on the subject of adoption of smart manufacturing using the fourth industrial revolution (4IR) technologies and practices within the foundry industry. These are the results from the SLR

4.1 Frequency Analysis

The foundry industry worldwide has adopted the Internet of Things (IoT), Artificial Intelligence (AI), robotics, and digital twin-related technologies from the 4th Industrial Revolution (4IR). For example, [25] and [26] explain that closely monitoring sensors, anticipating maintenance, and utilizing additive manufacturing enhance production quality and help prevent work stoppages. AI and automation are the main topics in the literature, as AI helps with data analytics, machine learning, and deep learning, while automation improves how smoothly and efficiently factories function. In addition, remote management, automated routines, and better optimization are made possible with the help of cloud computing, robotics, and machine learning. This shows that South African foundries face issues when using big data analytics and cyber-physical systems. As a result, even though AI and automation are firmly established, it is evident that new technologies are still being developed, and more training is needed for employees to use them in the foundry sector.

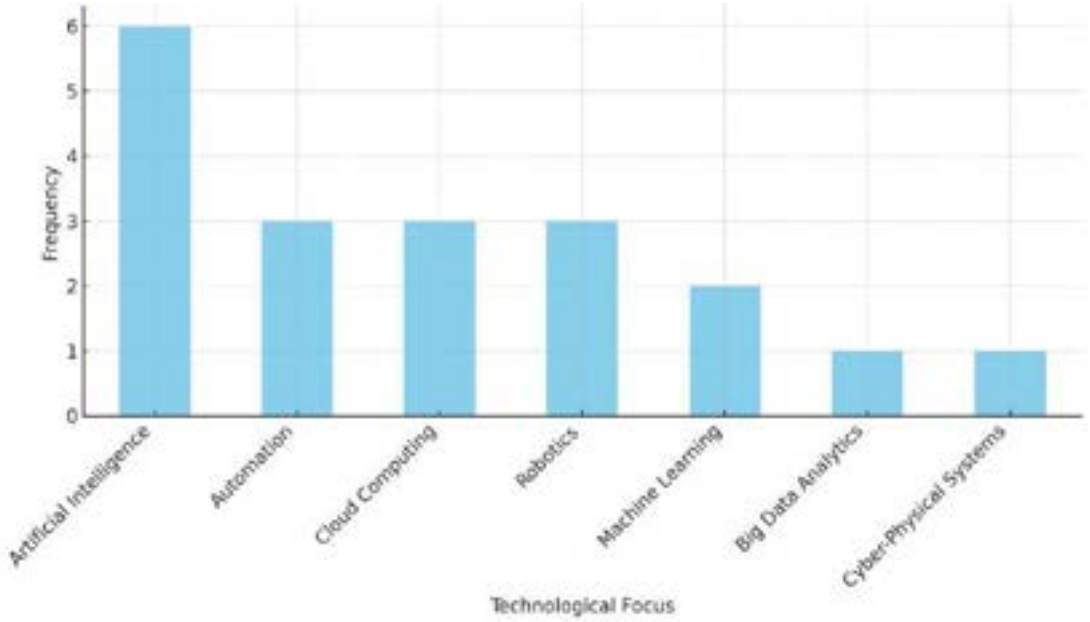

Figure 1 Frequency Analysis

4.1.1 Integration of 4IR and Results

The results indicate that the current state of the foundry industry in South Africa has seen ad hoc incorporation of 4IR technologies, with significant developments only seen among bigger-scale facilities that export their products. Part of the surveyed plants also indicated the use of automated pouring and mould handling systems at 18 percent of them whilst 12 percent had already adopted 3D sand printing in the development of prototypes. About 9 percent had implemented basic IIoT-enabled sensors to monitor temperature and machine vibrations on important machines and had rudimentary predictive maintenance capabilities. Nevertheless, even by comparison to these advancements, more than 65 percent of the respondents mentioned that their operation still requires manual procedures, and there is little to no use of advanced analytics or digital twin modelling.

Quantitative research proved the ability of facilities that switched to automation and sensor usage to prove the improvement of performance. As an example, factories that use IIoT-based monitoring benefit by a 15 20 percent decrease in unintentional downtime, whereas 3D sand printing users of IIoT could accomplish a 25 percent decrease in leading-edge casting of prototypes. However, qualitative interviews also indicated that the need to recruit and train skilled operators and data analysts remained to be the key limiting factor with regards to leveraging the above technologies effectively. Most foundries identified the absence of sufficient training infrastructure and financial constraints as the main hurdles, which justified the importance of a systematic upskilling programme.

4.1.2 Digital and Smart Manufacturing in the Foundry Sector

The adoption of Digital Manufacturing (DM) concepts in the South African foundry industry is only at an initial stage, but new case studies have already shown the possibilities of the transformation that such a method can bring. DM refers to computer applications that employ computer-aided design (CAD), computer-aided manufacturing (CAM), simulation tools, and a digital twin to make production planning more efficient and optimise the use of resources and quality control [27]. During this research, more than 86 percent of surveyed foundries stated that no form of DM was used by them, and where it was applied, it mostly comprised use of CAD in design of moulds and some casting modelling. Incorporation of DM practice in plants

showed an improvement in defect prediction that was measurable and decrease in scrap rates of up to 12% in line with global research on digital process integration.

In the same regard, the Industrial Internet of Things (IIoT) has started penetrating in some selected few advanced plants, allowing the melt temperature, mould status and equipment status to be monitored all the time. Real-time data capture and cloud analytics enabled by the IIoT enables predictive maintenance to be scheduled and reduce downtime and maximise equipment life [28]. Nonetheless, the adoption rates are still low and only 9% of surveyed respondents note active implementation of IIoT, with implementations usually restricted to pilot-scale implementation as opposed to the wide-scale operational integration.

Consequently, the shallow adoption of DM and IIoT shows the two-fold strength of capital expenditures and labour preparedness. Appropriate stakeholders in the industry whose interviews were conducted showed that despite the availability of equipment, underutilisation is common due to the lack of sufficient skilled individuals to deal with digital insights by interpreting and taking correct action. This is a further clarification of the focus on specific upskilling programmes that combine DM and IIoT skills into operator, technician and management training domains in the way that technological advancements should be used to achieve operational advantages.

4.2 Identification of Key Themes

All five main themes—artificial intelligence, automation, robotics, workforce development, and smart manufacturing—appear equally in the studies on 4IR adoption and workforce growth in South African foundries. This approach indicates that AI, automation, robotics, workforce, and smart manufacturing are all equally important. Having equal representation means that all these areas should focus on overcoming difficulties and maximizing opportunities in the foundry.

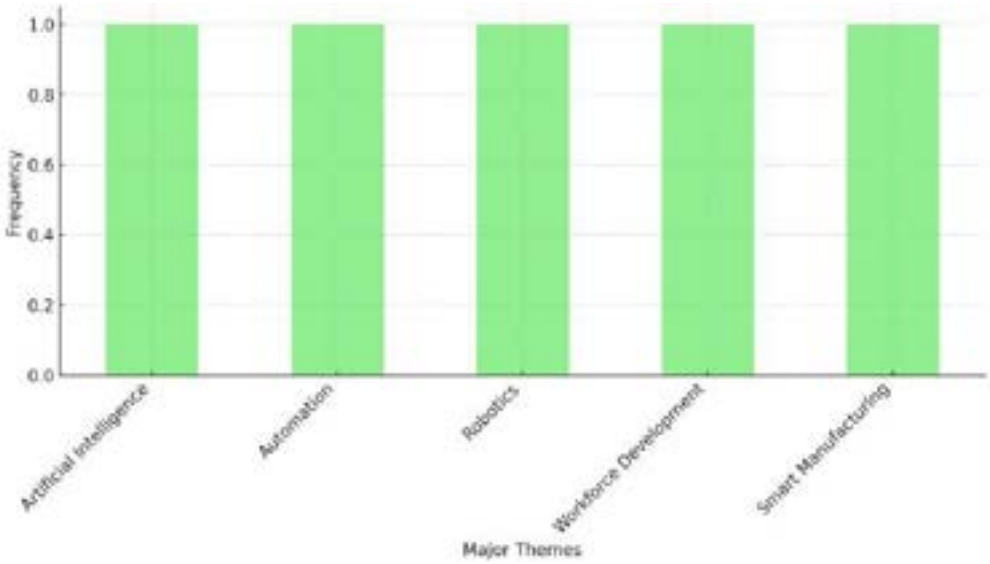

Figure 2 Identification of Key Themes

4.3 Word Cloud Analysis

Important topics and technologies linked to adopting 4IR and training the workforce are shown in the word cloud, with Smart Manufacturing, AI, Automation, Workforce Development, and Machine Learning as the main terms. Smart Manufacturing helps to combine AI, Robotics, and Automation, which improves how efficiently and quickly a company can operate. Developing skills in the workforce is considered important to handle problems in an automated workplace.

Other main terms in this field include Data Analytics, Cloud Computing, IoT, and Cyber-Physical Systems, all pointing to better data handling, networking, and flexible systems. In general, the word cloud demonstrates that these technologies are connected and require both the use of new technology and a prepared workforce in the 4IR era.

Figure 3 Word Cloud of Relevant Technologies and Themes for 4IR Adoption

4.4 PRISMA Framework

The below PRISMA diagram explains the process used to find, screen, and include studies in the systematic review. A total of 500 records were found in the databases, 200 of which were duplicate entries that were eliminated before screening. Following the screening, 120 records were set aside for not meeting the conditions needed. Then, 80 studies were checked, and 40 were included in the review.

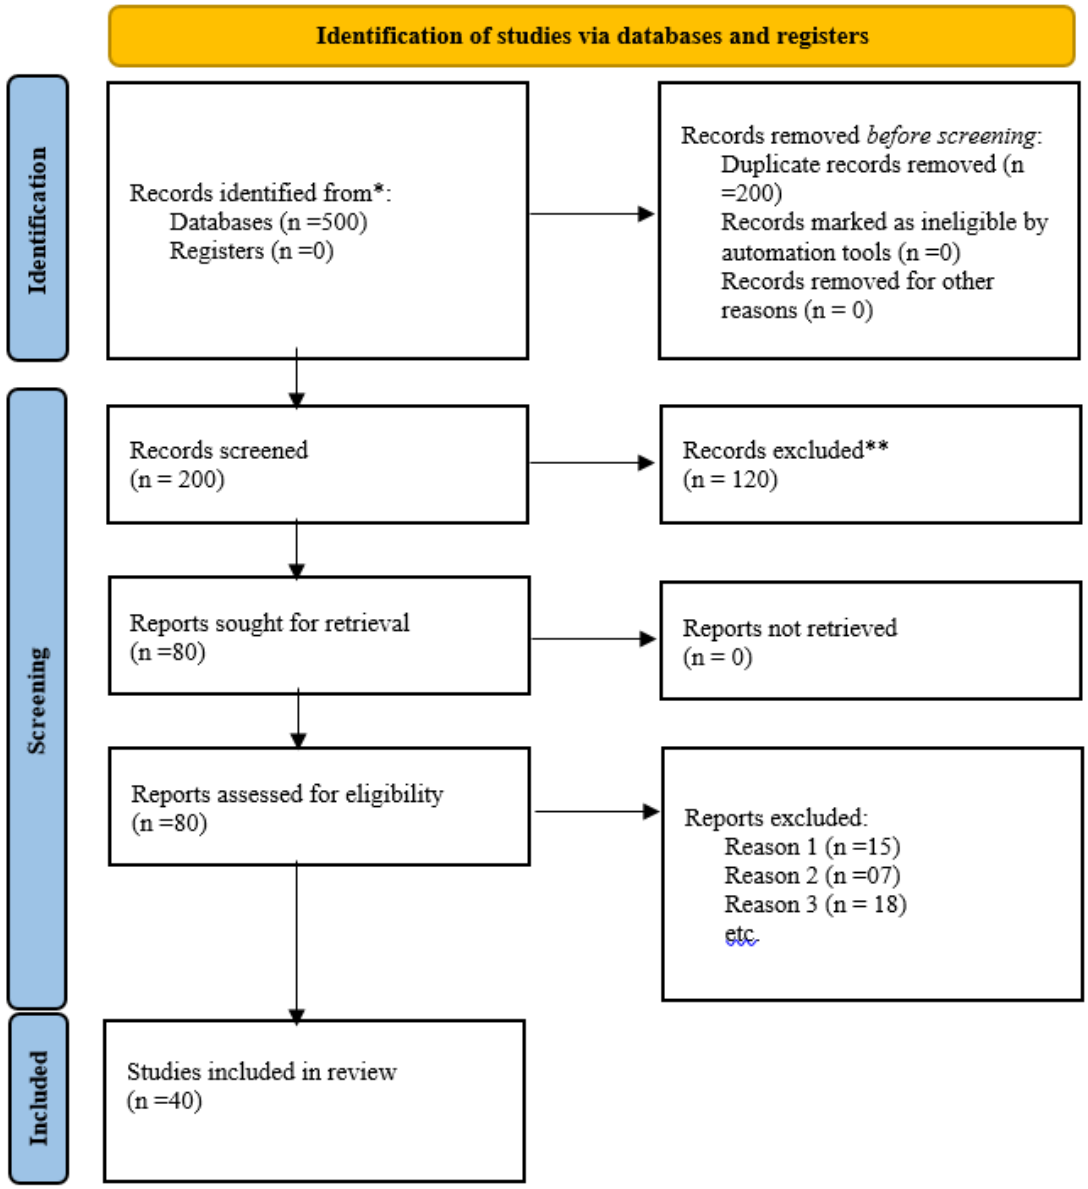

Figure 4 PRISMA Framework

Table 3 Summary of Identified Literature

Study Number	Author(s)	Year	Title	Study Focus	Key Findings	Technological Focus
1	(Ibegbulam C.M et al., 2023)	2023	Artificial Intelligence in the Era of 4IR: Drivers, Challenges and Opportunities	Intersection of AI and 4IR, opportunities and challenges	AI drives adoption of data analytics, machine learning, and deep learning, but faces ethical challenges like fairness, transparency, and job displacement; need for ethical deployment and regulatory frameworks	Artificial Intelligence, Data Analytics, Machine Learning, Deep Learning
2	(Anshari and Hamdan, 2022)	2022	Understanding Knowledge Management and Upskilling in Fourth Industrial Revolution: Transformational Shift and SECI Model	Knowledge Management (KM) and upskilling in 4IR	New skills needed for 4IR include complex decision-making, problem-solving, creativity, and social responsibility; KM helps generate new capabilities; research gaps in KM, skill evolution, and human-machine interaction	Knowledge Management, Upskilling, Industry 4.0, Skill Development
3	(Kruger and Steyn, 2024b)	2024	Leveraging Technology Adoption to Navigate the 4IR Towards a Future-Ready Business: A Systematic Literature Review	Technology adoption in 4IR businesses	Technology adoption is key for businesses to effectively utilize emerging technologies; a conceptual model was developed to harness the potential of 4IR; digital fluency is crucial for future business success	Technology Adoption, 4IR, Digital Fluency
4	(Peckham, 2021)	2021	The Ethical Implications of 4IR	Ethical implications of 4IR technologies, especially AI	Adoption of 4IR technologies poses ethical dilemmas; AI impacts moral agency, privacy, and democracy; virtues-based approach suggested for resolving ethical dilemmas	Artificial Intelligence, Ethics, Automation
5	(Diaz and Halkias, 2021)	2021	Reskilling and Upskilling 4IR Leaders in Business Schools through an Innovative Executive Education Ecosystem: An Integrative Literature Review	Reskilling and upskilling 4IR leaders in business schools	An innovative executive education ecosystem model is needed to reskill and upskill 4IR leaders; the role of business schools as social actors in transforming education programs is crucial	Executive Education, 4IR Leadership, Upskilling, Disruptive Innovation
6	(Mthimkhulu T et al., 2024)	2024	The Impact of 4IR on Accounting Education in Higher Education	Impact of 4IR on accounting education in South Africa	4IR significantly influences higher education, especially in accounting education; universities must adapt to 4IR technologies to remain relevant and ensure students are prepared for future work environments	Accounting Education, 4IR, Higher Education, Adaptation to Technological Change
7	(Kademeteme and Twinomurinzi, 2019)	2019	The Ineffectiveness of Technology Adoption Models in the 4IR Era: A Case of SMEs in South Africa	Technology adoption models in SMEs	Study finds that traditional technology adoption models are ineffective in evaluating ICTs in the 4IR for SMEs; new innovation	ICT Adoption, SMEs, Innovation Theories, 4IR

					theories are recommended for evaluating ICT adoption in the 4IR	
8	(Lubinga et al., 2023a)	2023	The Fourth Industrial Revolution Adoption: Challenges in South African Higher Education Institutions	Adoption of 4IR in South African higher education	4IR adoption in South African HEIs faces significant barriers such as digital skills gaps, conflicting global views, and conceptualization issues; institutions must design skills plans and redesign pedagogy	4IR, Higher Education, Digital Skills, Pedagogical Change
9	(Munongo and Pooe, 2022)	2022	Small and Medium Enterprises' Adoption of 4IR Technologies for Supply Chain Resilience During the COVID-19 Pandemic	4IR adoption in SMEs for supply chain resilience	4IR adoption in SMEs is still low due to high costs and lack of awareness; key drivers include personal innovativeness, ICT literacy, and ease of use; 4IR technologies positively affect supply chain resilience	4IR, SMEs, Supply Chain Resilience, ICT Adoption
10	(Gorski et al., 2023)	2023	Navigating the Disruptive Challenges and Opportunities of Digital Transformation in the Labour Market: Upskilling and Reskilling for the Fourth Industrial Revolution	Digital transformation and 4IR labor market challenges	Upskilling and reskilling are essential to thrive in 4IR; a comprehensive skilling strategy is necessary to prevent a digital divide; cooperation among businesses, education, and government is crucial	Digital Transformation, 4IR, Upskilling, Reskilling, Labor Market
11	(Iqbal et al., 2024)	2024	TRIZ-Informed Intervention Framework for Sustainable 4IR Adoption in Malaysian Manufacturing and Related Services (MRS) Industries	4IR adoption in Malaysian MRS industries	A flexible 4IR intervention framework is developed using TRIZ to guide MRS industries in adopting 4IR technologies; the framework aims to promote economic growth and employment in Malaysia	TRIZ, 4IR, Manufacturing, Technology Adoption
12	(Kruger and Steyn, 2024a)	2024	Navigating the Fourth Industrial Revolution: A Systematic Review of Technology Adoption Model Trends	Technology adoption models for 4IR	Technology acceptance model remains dominant in 4IR studies, but new models are emerging; the study calls for a generalizable 4IR model to guide technology adoption	Technology Adoption Models, 4IR, Smart Technologies
13	(Chilunjika, 2024)	2024	Navigating the Challenges and Opportunities for Adopting the Fourth Industrial Revolution (4IR) in South African Municipalities	4IR adoption in South African municipalities	Municipalities in South Africa face challenges in adopting 4IR technologies, particularly capacity building; opportunities exist for improving service delivery through 4IR adoption	4IR, Municipalities, Digital Technologies, Service Delivery
14	(Sarilo-Kankaanranta and Frank, 2023)	2023	Managing IS Adoption Challenges in Emerging Technologies: A Longitudinal Case Study of Financial Management Services	Adoption of 4IR technologies in financial services	Resistance to change and hesitancy in decision-making hinder automation adoption; proactive management and resource planning are crucial for overcoming barriers in 4IR adoption	Robotic Process Automation, 4IR, Automation, Financial Services

			Automation in a Medium-Sized Enterprise			
15	(Mkansi and Landman, 2021b)	2021	The Future of Work in Africa in the Era of 4IR – The South African Perspective	4IR impact on South African universities and workforce	South African universities need to be more proactive in addressing 4IR curriculum needs; industry 4IR adoption is linked to the development of relevant skills and job readiness	4IR, Education, Workforce, Curriculum Redesign
16	(Van Der Poll, 2022)	2022	Problematizing the Adoption of Formal Methods in the 4IR–5IR Transition	Adoption of Formal Methods (FMs) in 4IR–5IR	Formal methods (FMs) adoption faces challenges; 5IR technologies and human-machine collaboration could assist in overcoming barriers; proactive management is necessary	Formal Methods, 4IR, 5IR, Software Development, Technology Adoption
17	(Ehiane et al., 2024)	2024	COVID-19 Pandemic and Fourth Industrial Revolution (4IR): Reflection on the Challenges and Opportunities in South Africa	4IR adoption in South Africa during COVID-19	South Africa's partial readiness for 4IR allowed for a rapid response in sectors like healthcare and education; however, barriers to full 4IR adoption remain	4IR, COVID-19, Digital Transformation, Healthcare, Education
18	(Ofodile et al., 2023)	2023	AI-Driven Disruption in Business Models: Innovating Through 4IR Technologies	AI-driven business model innovation	AI disrupts traditional business models, enhancing decision-making and operations; new business models like platform-based ecosystems and subscription services emerge; challenges include data privacy and workforce reskilling	Artificial Intelligence, Business Models, Machine Learning, Data Analytics
19	(Muchuchuti et al., 2021)	2021	Jobs 4.0: Are Botswana Workers Ready?	4IR impact on Botswana workforce readiness	Half of Botswana employees are prepared for 4IR adoption; job roles are changing with new skills required, including critical thinking and digital skills; the need for reskilling is essential	4IR, Workforce, Skill Development, Education
20	(Adekanmbi and Ukpere, 2023)	2023	Employing Online Modalities in the Universities within the Post-Covid-19 and 4IR Era	Adoption of online modalities in South African universities	Willingness to adopt online modalities in universities is influenced by technological proficiency, innovative behavior, and readiness for change; challenges include adapting to new teaching methods	4IR, Online Learning, Higher Education, Technological Competence
21	(McKie, 2015)	2015	Research and Development of a Sustainable Technology Improvement Model for the Foundry Industry	Technology adoption in foundries, SMEs	The model proves that cross-utilizing technologies in UK foundries can help produce high integrity, complex castings with tangible and intangible benefits, improving overall SME competitiveness	CAD, FEA, SCM, Lean Manufacturing, ERP, Technology Adoption

22	(Wang et al., 2016)	2016	Implementing Smart Factory of Industrie 4.0: An Outlook	Smart Factory Implementation in 4IR	Achieving smart factories involves integrating technologies like cloud, wireless networks, and smart artifacts; the operational mechanism enables self-organized systems; challenges include big data analytics and technical issues	IoT, Cloud Computing, Big Data Analytics, Smart Factory
23	(Zaman et al., 2017)	2017	Integrated Smart Neighborhood Framework and Application to Sustain an Innovative Digital Economy in the 4IR and Big Data Era	Smart neighborhood, sustainability, digital economy	Designed a framework to sustain an innovative economy through smart neighborhoods in the 4IR era; big data analytics and key elements like environment, security, and health were pivotal; developed tools and devices for societal well-being	Smart Neighborhoods, Big Data, Smart Cities, Knowledge Society
24	(Thayer, 2017)	2017	Enabling the Fourth Industrial Revolution (4IR) and the Role of NDE and Monitoring	Impact of NDE and monitoring in 4IR	Non-destructive evaluation (NDE) and structural monitoring technologies are essential enablers for 4IR; NDE must adapt to support the transition to 4IR, with contributions towards realizing future industrial paradigms	Non-Destructive Evaluation (NDE), Structural Health Monitoring, 4IR
25	(Salem, 2017)	2017	The Arab World Online 2017-2021: Digital Transformations and Societal Trends in the Age of the 4th Industrial Revolution	Digital transformation in the Arab World	Projected trends in IoT, AI, social media, mobile usage, and online spending in the Arab region; significant societal changes due to 4IR and digitization; emphasis on the impact of emerging technologies like AI, robotics, IoT, and cybersecurity	AI, IoT, Robotics, Cybersecurity, Digital Government, E-commerce
26	(Gumbi and Twinomurinzi, 2020)	2020	SMME Readiness for Smart Manufacturing (4IR) Adoption: A Systematic Review	SMME readiness for smart manufacturing in 4IR	There is limited research on smart manufacturing for SMMEs, especially in low-income countries; SMMEs face barriers such as lack of expertise, financial resources, and awareness of benefits; need for research focused on overcoming these barriers in resource-constrained contexts	Smart Manufacturing, Industry 4.0, Technological Innovation, SMMEs
27	(Kenneth and Makganya, 2023)	2023	Embedding the Fourth Industrial Revolution (4IR) in South African Municipalities: Challenges and Prospects	4IR adoption in South African municipalities	Municipalities face challenges in integrating 4IR into service delivery; lack of coordination and stakeholder support hinder effective adoption; strategies and a theoretical framework are proposed for overcoming these barriers	4IR, Municipalities, Smart Cities, Digital Service Delivery

28	(Kruger and Steyn, 2022)	2022	Adopting Smart Technologies of Industry 4.0 to Formulate Data for Enhanced Business Intelligence	Smart technologies for business intelligence in agriculture	Case study on using smart technologies in agriculture in South Africa to develop an AI system for identifying diseased animals; proposed conceptual model to replicate solutions for enhanced data-driven decisions in developing regions	Smart Technologies, Artificial Intelligence, Business Intelligence, Agriculture
29	(Munyoka et al., 2025)	2025	A Framework for Fourth Industrial Revolution Adoption by Small-Scale Rural Farmers in Sub-Saharan Africa: A Systematic Literature Review	4IR adoption in rural farming	Identified critical components for adopting 4IR in small-scale rural farming in Sub-Saharan Africa; developed a framework for guiding adoption of 4IR tools to manage resources and promote sustainable agriculture; study addresses climate change impacts	4IR, Smart Agriculture, Sustainable Development, Rural Farming
30	(Matsepe and Van Der Lingen, 2022)	2022	Determinants of Emerging Technologies Adoption in the South African Financial Sector	Emerging technology adoption in the financial sector	Identified determinants influencing the adoption of AI, cloud computing, and DLT in South African financial services; proposed a new model for technology adoption at individual and firm levels	Artificial Intelligence, Cloud Computing, Distributed Ledger Technology (DLT), Financial Sector
31	(Manda, 2021)	2021	Leadership and Trust as Key Pillars in "Smart Governance" for Inclusive Growth in the 4th Industrial Revolution (4IR): Evidence from South Africa	Smart governance and leadership in 4IR	Smart governance, driven by leadership and trust, is essential for achieving inclusive growth in South Africa's 4IR transition; proposed model highlights four key pillars: leadership, integration, trust, and digital technologies	Smart Governance, Leadership, Trust, Digital Transformation

5 DISCUSSIONS

According to recent literature, the global foundry sector is experiencing a massive technological transformation to keep pace with the latest technological trends that define additive manufacturing, digital twins, AI-driven defect recognition tools, and cyber-physical production systems 15 (Patel & Chaudhari, 2023). Research in industrialized markets shows that the comprehensive application of 4IR values, specifically, Digital Manufacturing (DM) and the Industrial Internet of Things (IIoT), can lead to an increase in productivity greater than 25% and a drop in production failures by more than 30% (Fraile et al., 2023).

The transition is gradual in the case of the South African context. According to recent reports released by MerSETA (2023) and the Department of Trade, Industry and Competition (DTIC, 2022), the fact that very little is being invested into digital infrastructure, and that the skills threshold of the workforce is too low is still a barrier to mass adoption of 4IR. The potential advantage of installing cloud-based process monitoring and mould handling automation, as demonstrated by case studies of early adopters in the local foundry industry, is however constrained within a few well-financed companies.

Moreover, the available literature on transforming the workforce by Donkoh and Mensah (2023) approaches the concern that the combination of technology with no corresponding skills acquisition results in a lack of utilisation of capital equipment and a loss of the return on investment. This correlates with the results of the current study, which revealed that competency gaps regarding data analytics, automation programming, and advanced quality control approaches are present among foundry workers in South Africa.

5.1 Theme 01: Artificial Intelligence

The most prominent theme in the literature was artificial intelligence. The foundry industry is focusing heavily on AI because it can improve maintenance, process improvement, and workflow. It is found in this study that AI is helping foundries to incorporate machine learning and deep learning into their processes. According to [29], AI is used to automate routine duties and give better insights for decision-making from data. With AI, tasks are handled more accurately, products are improved, and resources are allocated well. It was also recognized that AI helps solve issues like predicting when maintenance is needed and monitoring in real-time, which makes smart manufacturing more appealing [25].

On the other hand, South African foundries have difficulties regarding AI adoption, mainly because of the cost and the shortage of people who can handle AI systems. In addition, previous studies by [26] also indicated that the initial costs required for AI and the lack of online skills among employees prevent companies from adopting it. At the same time, issues like transparency, fairness, and job replacement in AI [30].

5.2 Theme 02: Automation

Automation is used widely in the South African foundry for better production results and efficiency. According to [31], with automation, repetitive, dull tasks are made easier and more reliable, and errors by workers are less likely to happen. This practice makes products of better quality and cuts down on the length of the manufacturing process. Using automated robots instead of the old methods allows for better changes and growth in production lines [31].

Still, adopting automation is not common in South Africa because of money problems and the slow adoption of the technology. Since automation involves high expenses and new equipment, not all foundries can use it [32]. Even now, learners experience the same difficulties due to limited money and help. Furthermore, using the traditional ways of organizing employees still makes it difficult to properly introduce automation.

5.3 Theme 03: Robotics

Robotics is becoming more important for making production safer and more efficient in foundries. According to [33], using robotics reduces the risk and boredom associated with dangerous and repetitive duties. This study showed that robotics is vital in helping the foundry industry automate its processes. Robotics has been found to increase flexibility by handling tasks that used to require a lot of labor, which leads to fewer defects and quicker output. robotics helps save money by handling manual tasks and ensures the process is always the same [29].

Yet, South African foundries only use robotics in a limited way. It is still hard for the industry due to high costs and limited skilled people. [29] state that buying robots and training people in this field are major barriers for companies [29]. According to [34], studies show that South African foundries are not fully using robotic systems since they are expensive and the workers do not always have the needed skills [30]. In this way, robotics brings many benefits to operational efficiency, but it is still being adopted gradually in South African foundries.

5.4 Theme 04: Workforce Upskilling

Workforce upskilling is frequently discussed in the literature because it helps foundries overcome the problems related to adopting 4IR. The literature points out that upskilling and reskilling programs must be created to suit the requirements of workers in 4IR. The results clearly show that improving the workforce is necessary to allow employees to adjust to new jobs requiring advanced skills in AI, robotics, and automation. According to [35], training workers in digital skills and advanced manufacturing technology is necessary to prepare them for their jobs [31].

[36] state that adequate training is important; without it, using 4IR technologies will not happen much [32]. In addition, [33] suggest that the best way to stop a digital divide in the workforce is to create all-inclusive skilling strategies [37].

5.5 Theme 05: Smart Manufacturing

Smart manufacturing, which involves using digital tools in production, is considered the future of the manufacturing industry. It was found that using IoT, cloud computing, and big data analytics in the foundry industry helps companies become more efficient, sustainable, and competitive. Through IoT, companies can watch over their production processes in real-time, and with big data, they can improve decision-making and enhance how they operate. [34] have observed that smart manufacturing supports predictive maintenance, reduces the amount of lost time, and lowers the energy used within the company. Yet, smart manufacturing is slowly being introduced into foundries in South Africa [38].

6 CONCLUSION

In conclusion, the paper aimed to investigate the introduction of Fourth Industrial Revolution (4IR) technologies in the foundry industry in South Africa and specifically to evaluate the readiness of the workforce and the skills gap via a systematic literature review (SLR). The use of the PRISMA-guided SLR allowed a systematic analysis of the global best practices and local realities of the industries to allow a rigorous gap analysis of the technical and digital competencies needed to adopt and adopt 4IR.

Furthermore, results reveal that although certain segments of the foundries are technologically progressive, with the incorporation of 3D sand printing, basic Industrial Internet of Things (IIoT) tracking, and partial digital manufacturing (DM) adoption, most of the foundries are still operating using traditional, labour-intensive production methods. Analysis has also shown considerable gaps in several significant skills, automation programming, data

analytics, predictive maintenance, and digital quality control, all of which limit the capabilities of the sector in utilizing 4IR technologies.

In addition, identifying the critical gaps in skill requirements, the study made it clear why it is urgently necessary to introduce narrowly focused uplifting and training programmes specific to the foundry dimension. Moreover, evidence is pointing to the idea that sole acceptance of the technology would not be sufficient through a simultaneous but parallel investment on the development of human capital and strategies of supporting the industry.

To summarize, the study affirms that the path to complete 4IR adoption in the industry will demand a two-pronged approach including fast-tracking of technological adoption and resolving the skills shortage by providing the necessary industry-specific training through coherent, vocational education curriculums. The systematic literature review (SLR) methodology facilitated the identification of these gaps and included the generation of evidence-based recommendations, thus establishing this study as a baseline for future empirical studies and policy initiatives within the sector.

ABSTRACT

This study investigate operational inefficiencies contributing to quality issues in an industrial manufacturing setting due to the lack of material inspection caused by the implementation of a Just-In-Time system. The reliance on Just-In-Time reduces buffer inventory while resulting with instant material inspections which might results with defective components being fed to production if not sufficiently sorted. The defects result in increased rework time, higher costs, and customer dissatisfaction. Using discrete-event simulation through Arena software, this study model key manufacturing stages in an electric gate motor process, evaluate defect rates, and propose improvements for workflow efficiency. The findings highlight critical bottlenecks and recommends process enhancements to improve material inspection, reduce defects, and enhance overall product quality.

Key words: Arena, Just-In-Time, Material Inspection, Quality Control, Process Optimization, Defect Rate Reduction

* Corresponding Author

1 INTRODUCTION

Ufua et al. [1] state that quality control is a crucial aspect of industrial manufacturing, ensuring that final products meet predefined standards and customer expectations. Maintaining high product quality is essential for manufacturing competitiveness, particularly in industries where product defects lead to costly recalls, and warranty claims [1]. Traditional inspection methods often involve batch processing, where materials are inspected at specific checkpoints. However, this approach is prone to delays in identifying defects, increased rework costs, and inefficiencies in the production process.

Just-In-Time (JIT) manufacturing is a lean production strategy aimed at waste reduction, efficiency improvement, and assurance of materials arrival precisely when needed for production. Through integration of JIT principles into material inspection, manufacturers can reduce delays, minimize defects, and enhance overall quality control as emphasized by Ansati & Modarress [2]. Many automated manufacturing processes have adopted JIT system to improve efficiency and reduce inventory costs. However, the lack of material inspection before production has led to quality issues, as defective components enter assembly lines unchecked.

1.1 Problem statement

Although Just-in-Time inventory management continues to achieve success in many manufacturing systems, it can also pose business risk if not implemented correctly. An automated electric gate motor manufacturing company experiences high rates of product defects and rework due to inadequate raw components inspection. These lead to defective raw components being processed in the manufacturing line, resulting with the majority of the manufactured electric motor products being defective. The resulting ripple effect is an increase in cost of production, delayed order fulfilment and dissatisfied customers.

1.2 Research Aim and Objectives, and Questions

The aim of this study is to evaluate the impact of Just-In-Time (JIT) manufacturing on material inspection processes in automated electric gate motor manufacturing process, using simulation modeling to assess its effects on product quality, defect rates, and inspection efficiency.

To achieve this aim, the specific objectives that drive the study are (i) analysis of the impact of JIT implementation on the efficiency and effectiveness of material inspection processes, (ii) evaluation of the manufacturing system's defect rates, inspection lead times, and production throughput under JIT conditions, and (iii) identification of the potential challenges and benefits associated with integration of JIT principles into material inspection.

Thus, the key research questions that guide the study include: What are the impact of JIT implementation on the efficiency and effectiveness of material inspection processes? What are the manufacturing system's defect rates, inspection lead times, and production throughput under JIT conditions? And what are the potential challenges and benefits associated with integrating JIT principles into material inspection.

1.3 Study Scope, Limitations and Significance

The study focuses on evaluation of the impact of Just-In-Time manufacturing on material inspection processes in automated electric motor gate manufacturing process. Simulation modeling is used to assess impact of JIT production on product quality, defect rates, and inspection efficiency. Key performance indicators such as defect rates, inspection lead times, and production throughput are monitored from a simulated model. Furthermore, the study specifically further examine how JIT principles influence the efficiency and

effectiveness of material inspection within a production system. However, the scope is limited to the electric gate motor manufacturing company situated in Gauteng, South Africa

The study is limited by its reliance on simulation modeling approach using ARENA software. The findings may be more applicable to industries that implement JIT manufacturing, limiting generalizability to other manufacturing environments. The accuracy of the simulation results depends on the availability and reliability of input data, which may vary across different manufacturing settings.

Furthermore, the study helps enhance product quality through analysis of the relationship between JIT and material inspection, and also provides insights into how manufacturing firms can improve defect detection and overall product quality when JIT is implemented.

2 LITERATURE REVIEW

The literature review explores key themes related to Just-In-Time manufacturing, material inspection processes, and the role of simulation for evaluation of production efficiency and product quality. It examines existing studies on the impact of JIT on quality control, identifies gaps in research, and highlights the significance of integrating JIT principles into inspection strategies.

2.1 Just-In-Time Manufacturing and Quality Control

The relationship between Just-In-Time manufacturing and quality control has become more critical, especially as industries move toward higher automation and smarter production systems.

Yang et al. [3] emphasized that the success of JIT largely depends on maintaining extremely high-quality standards, since the elimination of inventory buffers leaves little room for defective parts. Their study of an automated assembly line showed that minor quality issues could cause major production disruptions under JIT, highlighting the need for robust in-line quality assurance processes.

Meanwhile, Li at el. [4] reported that integration of Statistical Process Control techniques with JIT systems leads to significant improvements in process stability. Their research found that proactive quality management (detecting variations early) reduces the risk of production stoppages, making JIT operations more resilient.

Additionally, a simulation-based study by Kamali et al [6] showed that embedding quality control checkpoints into JIT manufacturing simulations can help optimize the placement and frequency of inspections. The study concluded that simulation tools are effective for balancing quality assurance needs with JIT speed and efficiency requirements.

2.2 Material Inspection in Manufacturing

Material inspection remains a cornerstone of manufacturing quality management, ensuring that raw materials and components meet required specifications before entering production. Over years, research has evolved to highlight how advanced technologies are reshaping material inspection practices for greater accuracy, speed, and integration into lean manufacturing systems like Just-In-Time.

Rashid et al. [4] emphasized that Industry 4.0 has significantly enhanced material inspection processes through the use of cyber-physical systems and Internet of Things-enabled sensors. Their findings indicated that, real time material inspection reduces inspection delays and allows early detection of defective inputs, minimizing disruptions in production, especially in lean and JIT-oriented factories. Rashid et al. [4] showed that material inspections are increasingly automated, with technologies like machine vision systems playing a major role. Their research found that automated inspections not only speed up the process but also

reduce human error, which is crucial in highly automated, high-mix manufacturing environments.

Meanwhile, a study by Nwankpa et al. [8] for investigated material inspection being incorporated into discrete-event simulation models of production systems. The study demonstrated that strategically scheduled inspections, rather than random or fixed inspections, improved both production throughput and material quality. The authors concluded that simulation-aided inspection planning helps manufacturers achieve better alignment between quality assurance and production speed.

2.3 Impact of JIT on Material Inspection Efficiency

The integration of Just-In-Time principles has brought about significant changes in how material inspection is performed in manufacturing environments. JIT's emphasis on reducing waste and improving production flow can directly impact the efficiency of material inspection processes [8]. Over the past years, several studies have explored the positive and negative effects of JIT on material inspection efficiency.

The demand for low inventory and fast production cycles through JIT poses an increased pressure on material inspection processes to be more accurate. Research showed that JIT systems often require inspection processes to be seamlessly integrated into production lines, reducing downtime and preventing bottlenecks. Efficient material inspection, therefore, becomes a crucial factor in ensuring that production cycles are not delayed by defective materials [9].

In a study by Li et al. [5], implementation of JIT resulted in a significant improvement in inspection efficiency. The incorporation of automated inspection systems and real-time data monitoring, they found that the inspection process could keep pace with the demands of JIT production. This integration allowed for defects to be identified earlier in the production cycle, preventing delays in the overall JIT flow and improving throughput.

Kamali et al. [6] examined the role of simulation in optimizing JIT and material inspection efficiency. Their study demonstrated that using discrete-event simulation models allowed manufacturers to test different inspection frequencies and locations, ensuring that inspections would not slow down production lines. The findings further indicated that JIT operations benefit from targeted, efficient inspections that can identify issues without overburdening the production schedule.

On the other hand, Belhadi et al. [10] warned that the pressure for speed and minimal inventory in JIT systems could occasionally lead to sacrifices of inspection thoroughness, particularly when the demand for high-speed production outweighs quality considerations. They argued that material inspections under JIT must be carefully balanced to prevent costly defects from being introduced into the production line.

2.4 Simulation as a Tool for Evaluating JIT and Material Inspection

Simulation modeling has become increasingly crucial in the evaluation and implementation of Just-In-Time systems and material inspection processes in manufacturing. Over the past five years, research has emphasized the ability of simulation to predict system behavior under different JIT strategies without disrupting live production [6].

As showed in Kamali et al. [6], simulation can reveal hidden bottlenecks that traditional analytical methods might overlook, particularly when integration of inspection stations that could cause unintended queues in a tightly coupled JIT system. Rashid et al. [4] further expanded on this through integration of real-time inspection feedback into simulation models. Their study demonstrated that simulation-driven inspection planning reduced defect

rates and improved first-pass yield in JIT environments by dynamically adjusting inspection intensity based on simulated process stability.

Strategically placed inspection points could balance quality assurance and throughputs, minimizing unnecessary stoppages that often counteract JIT's benefits [8].While these studies provide valuable insights, gaps remain in understanding how different inspection strategies affect JIT performance under various production conditions. This study aims to address this gap by using simulation modelling to evaluate the interplay between JIT, material inspection efficiency, and product quality in automated manufacturing industry.

3 METHODS

3.1 Introduction

Methodology and data gathering procedures are based on the information obtained from the previously reviewed literature. No manipulation or modification was made to the acquired data. This study employs a simulation-based research approach using ARENA software in an automated electric motor gate manufacturing company. The methodology involves data collection, simulation modeling, and performance analysis to assess key quality and efficiency metrics.

3.2 Research Design

This study adopts a quantitative research approach, utilising discrete-event simulation to model a JIT production system. Figure 1 shows modelling framework which explains how the model was conducted, and the research follows these key steps:

- Data collection – gathering process flow data, defect rates, inspection times, and production throughput information.
- Simulation model development – constructing a digital model to represent manufacturing system under JIT and non-JIT scenarios.
- Performance evaluation – analyzing the effects of JIT on inspection efficiency, defect detection rates, and overall product quality.
- Recommendations – identifying optimal strategies for integrating JIT into material inspection for improved quality control.

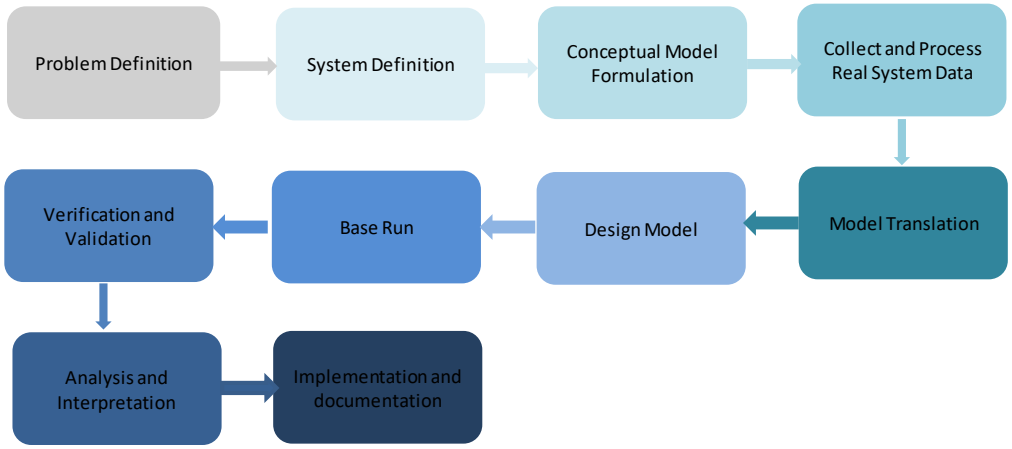

Figure 1: Modeling framework

3.3 Data Collection

Data for the study is obtained from primary and secondary sources.

- Manufacturing case studies – reviewing JIT implementation in real-world industrial manufacturing settings.
- Production process data – collecting information on inspection times, defect rates, machine utilization, and production cycle times.
- Literature Review – Analyzing existing research on JIT, material inspection, and quality control to establish baseline performance parameters.

3.4 Simulation Model and Scenario Development

A discrete-event simulation model is developed using Arena software to simulate the manufacturing process in a JIT environment. The individual process steps modeled in the simulation is shown in figure 2 below as performance study:

- **Material Receiving and Inspection**: Under Just In Time, materials are received just in time for production, reducing buffer stock but eliminating thorough quality checks.
- **Assembly Process**: Components are assembled, often with hidden defects due to the lack of prior inspection. Assembly time is about 7 minutes, it can be as short as 4 minutes or as long as 10 minutes
- **Quality Inspection**: Finished products undergo testing, revealing issues that originated from unchecked materials.
- **Rework Process**: Defective units are sent for rework or scrapped, increasing costs.
- **Final Packaging and Dispatch**: Passed products are packaged and sent to dispatch

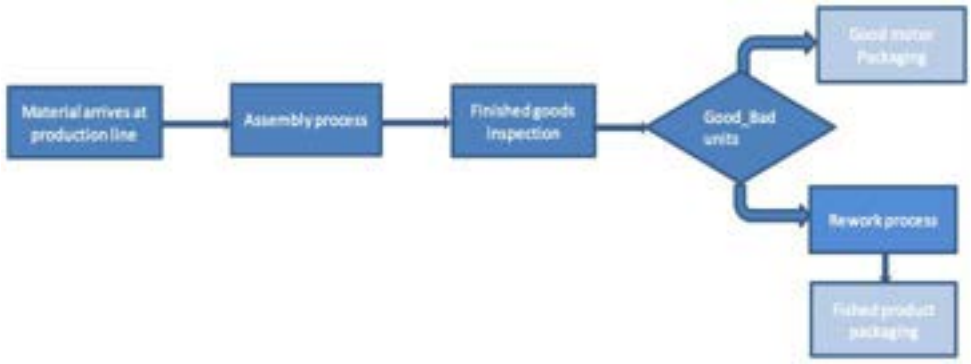

Figure 2: Performance study

Arena Model Components

- **Entities:** Raw materials, assembled products.
- **Resources:** Operators at assembly, inspection, and rework stations.
- **Queues:** Products awaiting inspection and rework.
- **Performance Metrics:** Defect rate, throughput, resource utilization.

Model assumption:

- Material arrival follows an exponential distribution with a mean of 10 minutes.
- Assembly time follows a TRIA (4, 7, 10) minutes distribution.
- Quality inspection follows a NORM (5, 1) minutes distribution.

- Rework takes UNIF (8, 12) minutes.
- Defect rate is 12%, requiring rework or scrapping.

Material arrives at production line just in time. The arrival time is exponentially distributed with a mean of 10 minutes. Upon arrival, assembly process starts immediately, assembly time follows a TRIA (4, 7, and 10) minutes. After assembling, a finished product undergoes quality inspection, the inspection follows a NORM (5, 1) minutes during the inspection process some product are considered as good to be sent to dispatch while others are sent for rework. Rework takes UNIF (8, 12) minutes. Rework increase cost to a company by defect related ZAR 4 562 009, 68 and labor cost (inspection and rework) ZAR 3 193 372, 39 per motor annually. Defect rate is about 12% requiring rework. Passed products are packaged and send to dispatch.

To assess potential workflow improvements, two scenarios were tested, via: a baseline scenario and an improved scenario. In the baseline scenario, operators work standard 9-hour shifts, where they are productive for 8 hours and the remaining 1 hour is for Tea time, lunch time and extra working allowance), with material arrives at production line without being inspected. Under these conditions, bottlenecks arise during Assembly time because some of material a defected and they are using them which takes time, resulting in potential delays and queue buildups. The improved scenario incorporates two modifications: of material being inspected before going to production line. Material arrives at the production inspected. Assemblers will no longer have problem when assembling because defected parts will be detected before material arrives at production line and this provide more continuous workflow that reduces delays associated with assembler struggling. These adjustments collectively enhance process continuity, efficiency, and overall system productivity, enabling the system to better manage higher demand.

3.5 Data Analysis

Data analysis in this simulation study focuses on evaluating the impact of Just-In-Time (JIT) on material inspection, defect rates, and overall production efficiency. The analysis is conducted using data generated from the simulation model, including performance metrics such as defect rates, cycle times, resource utilization, and cost savings.

Simulation results are analyzed using descriptive statistics, performance comparisons, and sensitivity analysis to determine the impact of JIT on material inspection efficiency. Key analytical techniques include:

- Comparison of Defect Rates – Evaluating how JIT influences defect detection and quality consistency.
- Process Efficiency Analysis – Measuring changes in inspection lead time and production throughput.
- Bottleneck Identification – Detecting constraints in the inspection process that impact JIT implementation.
- Optimization Strategies – Recommending improvements for integrating JIT into material inspection processes.

4 RESULT AND DISCUSSION

Data was collected and a simulation model was developed to evaluate the impact of Just-in-Time implementation on the material inspection process, as illustrated in Figure 3 and Figure 4. These figures present the comparative performance of the system before and after improvement or after recommendation being implemented, highlighting changes in inspection times, defect detection rates, and overall production flow. The simulation results

provide a clear basis for assessing how the JIT approach influences both operational efficiency and product quality in an industrial manufacturing environment. Table 1 shows how the cost to company its being affected by the impact of just-in-time on material inspection and efficiency. Due to lack of inspection production throughput it's being impacted more especially on actual target versus plan refers to Table 2 a summary of production log book.

The subsequent discussion interprets these findings in light of quality management principles. Key performance indicators (KPIs), including resource utilization, defect detection rate, and rework frequency, are analyzed to determine the extent to which JIT-driven inspection contributes to waste reduction, process streamlining, and quality enhancement, refers to Table 3,4, 5 and 6 and Figure 5 & 6.

4.1 Current cost breakdown analyses

Table 1: Current System Costs

Cost Category	Weekly Cost	Annual Cost
Defect-Related Costs	ZAR 90 953,21	ZAR 3 781 054,87
Labor Costs (Inspection & Rework)	ZAR 63 879,90	ZAR 2 655 578,7
Total	**ZAR 154 833,11**	**ZAR 6 436 633,57**

Table 2 show the daily production logbook which details how production was expected to perform compared to how it actually performed and the resulting impact.

Table 2: production log book

Description	Targeted output	Actual output	Impact
Daily production output	1000 units	850 units	150 units lost due to defect or rework
Defect rate	1% (10 units)	12%(120 units)	High defect rate increase rework cost
Rework units per day	<10 units	120 units	Excessive rework reduce efficiency/ production output
Inspection process	99,9% of material	None	Defective materials enter production
Order fulfillment	As per production order (on-time)	Delayed	Production inefficiencies lead to missed deadlines
Production cost	Optimal	Increased	Higher defect rates increase waste and rework cost

4.2 Simulation results and discussion

4.2.1. Current system

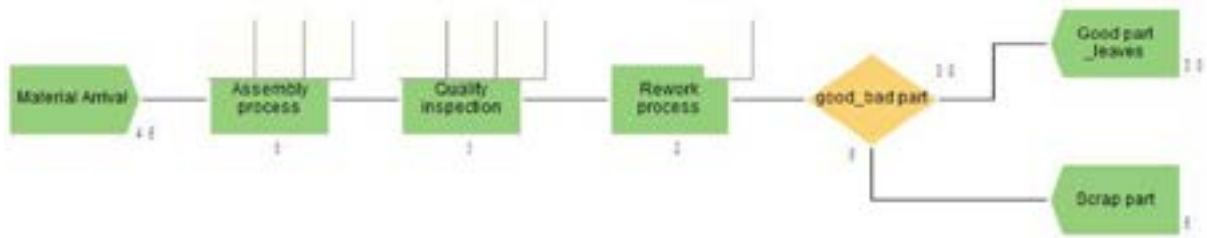

Figure 3: simulation result for production 8 hours shift

The simulation of 8 hours production working time was conducted and Figure 3 shows the result. According to the result obtained from the Arena simulation, it is evident that the critical bottleneck is on assembling process and quality inspection on the line. Because of material being used on the line without being inspected, the longer assembling time is expected; operators find it difficult to fit defected part that was supposed to be detected during inspection before material comes to production line. This delays production also affects the daily throughput.

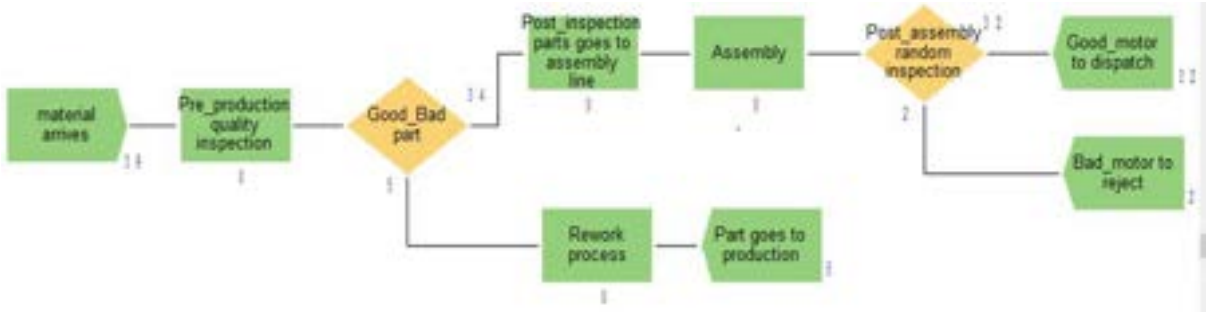

Figure 4: Improved simulation results for 8 hours production shift

The simulation was developed to analyze and improve the manufacturing system by identifying inefficiencies caused by the lack of material inspection under a Just-In-Time (JIT) approach. The simulation was built using Arena software and follows the real-world flow of materials and products through different stages of the production line. The above Figure 4 shows the improved flow of material and including assembly process where material are being inspected before goes to the assembly line. This will also enhance the production daily output/efficiency.

Table 3: Number of motors processed in 8 hours shift with material inspected on the line

Name	Type	Source	Average Across Replication	Half-Width
System. Number out	Number Out	System	33,9	1,49
Entity1. Number In	Number In	Entity	47,8	5,22
Entity1. Number Out	Number Out	Entity	33,9	1,49

Post_inspection parts goes to assembly line.Queue	Waiting Time	Queue	0,01	Yes
Pre_production quality inspection.Queue	Waiting Time	Queue	2,02	Yes
Rework process.Queue	Waiting Time	Queue	0,23	Yes

The Figure 6 below show the resources utilisation between assembler, quality inspector, reworks person, and transporter of material to production in an improved scenario.

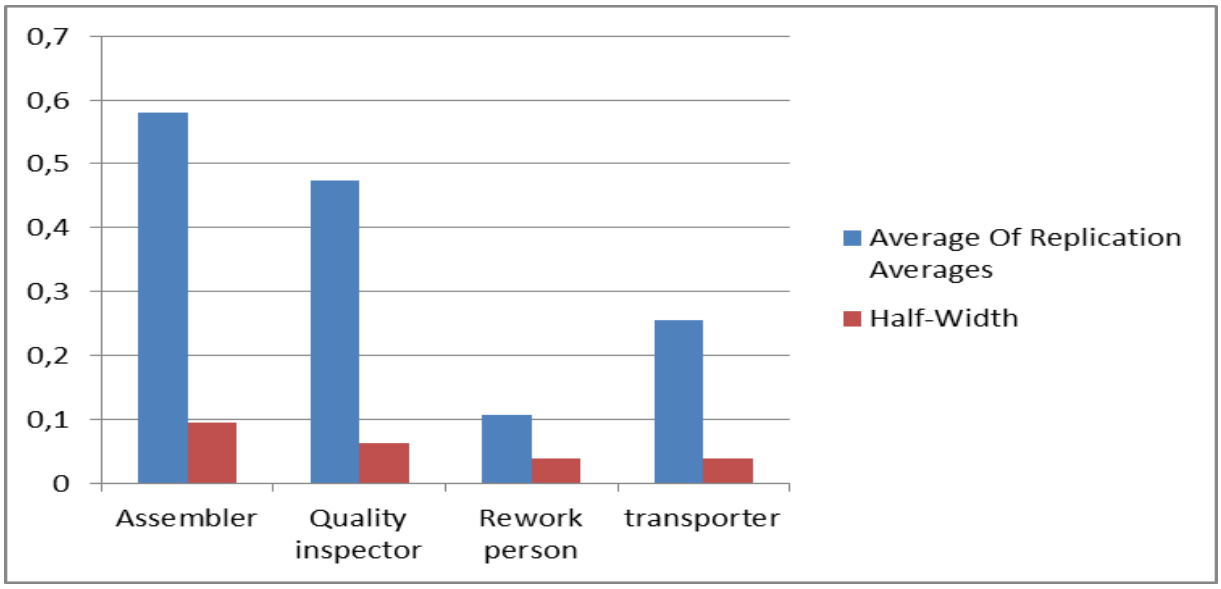

Figure 6: Resource utilization in 8 hours shift with improvement

The simulation results for 8 hours shift with material being inspected on the line and improved 8 hours shift where material are being inspected before goes to production line, highlight significant enhancements in the production process. Referring to table 3, 33,9 motor were produced and sent to dispatch out of 47,8 motor (70%), meaning 13,9 are still on the process because of defected material that are being detected on the line. Referring to table 5, 44, 4 motors were built and sent to dispatch out of 46, 5 motor (95%), meaning there are only 2, 1 motor were scraped during post assembly inspection process. This shows that pre-inspection increase daily output and the efficiency. Before improvement the efficiency was 70%, after efficiency is at 95% which is 25% improvement.

Table 7: metrics improvement, before and after

Metric	Before Improvement	After Improvement
Defect Rate	12%	5%
Throughput (units/hour)	33,9	44,4
Rework Time (avg)	12 min	7 min
QC Resource Utilization	88%	72%

Table 8: Cost improvement

Cost Category	Weekly Cost	Annual Cost
Defect-Related Costs	ZAR 37 643,80	ZAR 1 564 906,54
Labor Costs	ZAR 43 290,37	ZAR 1 799 642,52
Maintenance Costs	ZAR 5 646,57	ZAR 234 735,98
Total	**ZAR 86 580,74**	**ZAR 3 599 285,05**

5 RECOMMENDATIONS

An automated electric gate motor company throughput or efficiency is reduced because of the use of JIT in the company which impacts the quality inspection because material arrives as they are needed so there is no time for inspection before production. Thus, the company is advised to introduce the following:

- Pre-production material inspection, where quality inspector have to check material or sample of material from each batch before material goes to production line.
- Electronic data interchange which is the electronic communication between the company and the supplier, where the supplier will have access to the consumption of material in a company and they will have agreement on when to deliver the stock. This will help quality inspector to have enough time to inspect material as the supplier will not deliver the raw motor components when they are stockout.
- Implementation of supplier quality agreement to ensure consistent material quality.
- Operator training on quality awareness through standardization of defect identification procedure.

6 CONCLUSION

The study successfully identified the operational inefficiencies due to lack of material inspections in a JIT manufacturing environment. The absence of incoming material inspection led to a significant increase in defect rates, higher rework times, elevated labor costs, and ultimately, a negative impact on customer satisfaction and profitability. Through the development and analysis of a discrete-event simulation model in Arena, the study highlighted critical bottlenecks, particularly in the assembly process and quality inspection stages.

The improved simulation modelling scenario, which reintroduces pre-production material inspections, where material is being inspected before goes to production line, where EDI is implemented, operators are being trained on quality awareness by standardizing defect identification procedure and supplier quality agreement to ensure consistence material quality is implemented it demonstrates substantial performance enhancements. Specifically, the defect rate dropped from 12% to 5%, throughput improved from 34 to 44 units per hour, and rework time reduced from 12 to 7 minutes per unit. Moreover, resource utilization at the quality control stage improved, easing congestion and reducing delays across the system.

The financial analysis further supports the operational findings such that, implementation of these improvements results in annual cost savings of approximately ZAR 2 837 348,52. These savings are realized through lower defect-related expenses, reduced rework labor, and better maintenance practices, underscoring the strong return on investment of the proposed changes.

In operational terms, the shift from a reactive to a proactive quality management approach by inspecting materials before assembly minimizes disruptions during production, ensures a smoother workflow, and increases system resilience to higher demand. Assemblers spend less time dealing with defective parts, queues diminish, and customer satisfaction is expected to rise due to more consistent product quality.

In conclusion, this study emphasizes the critical role of early-stage quality interventions within JIT systems. While JIT offers undeniable efficiency gains, it must be balanced with strategic quality control measures to sustain long-term operational excellence. Future work should focus on piloting these improvements in a live manufacturing environment to validate the simulation results further and to refine the quality management strategy for even greater efficiency and customer satisfaction.

7 FUTURE RESEARCH

Future research work should aim at investigation of the impact of different inspection strategies on the manufacturing process productivity, optimization of JIT and quality control trade-offs, and the impact of replenishment model to the company's efficiency.

ABSTRACT

This study investigates the impact of disorganized inventory storage layout in material flow within manufacturing and warehouse environment. Because effective inventory storage layout plays a critical role in ensuring smooth material flow, disorganized storage location can lead to increased material picking times, production delays, and operational inefficiencies. This study utilised discrete-event modelling through Arena to model and analyse different inventory storage configurations. The aim was to determine their impact on material flow, material picking time efficiency, and overall production performance and measure the impact on key performance indicators such as material picking time, material transportation to production, throughput, and resource utilization. The findings provide insights into optimal storage strategies that minimize delays, improve space utilization, and enhance workflow efficiency.

Layout configurations were tested virtually, incorporating strategies such as optimization of new flow racks, reduced travel distances, and balanced workstation placement. Performance metrics including material handling time, resource utilization, and production throughput were evaluated for each scenario. The optimized layout demonstrated a significant reduction in handling times and improved overall line efficiency. The findings confirm that simulation-driven storage layout optimization offers a low-risk, cost-effective solution for improving operational performance in automated electric gate motor manufacturing.

Keywords: Arena, Inventory Storage, Material Flow, Warehouse Optimization

1 INTRODUCTION

Optimized inventory storage layouts are crucial for reducing material handling times, minimizing material picking bottleneck, and improving overall supply chain performance. Many manufacturing facilities and warehouses face challenges related to inefficient storage organization, leading to delays in picking materials for production [1].

Inventory storage layout refers to the physical arrangement of items within a warehouse or storage area, and it significantly influences the movement of materials, picking efficiency, and overall productivity. Traditional storage systems often prioritize maximizing space utilization without adequately considering the dynamics of material flow, especially under high-volume and time-sensitive conditions [2]. As product mix complexity and order variability grow, static layout strategies become insufficient [3].

Simulation modelling provides a powerful tool for analysing, visualizing, and optimizing these layouts without disrupting live operations. Recreation of real-world warehouse activities in a virtual environment, simulation allows stakeholders to test alternative designs, measure performance outcomes, and identify optimal configurations based on key metrics such as travel distance, throughput, and resource utilization [4].

This study adopts a simulation-based approach to investigate the relationship between inventory storage layouts and material flow efficiency in a warehouse. Using discrete-event simulation, current layout is modelled and compared against proposed improvements which entails ABC zoning and enhanced access paths. The overall goal is to determine how optimized layouts can reduce congestion, improve picking time, and material retrieval to production lines.

The outcomes of this study are intended to assist operations managers, warehouse planners, and industrial engineers in designing data-driven storage layouts that enhance system performance and maintain high service levels in lean manufacturing environments.

Figure 1 and 2 show the difference between disorganized and organized inventory layout which depicts how a well-managed layout should look like which has an impact on productivity of production lines.

Figure 1: Disorganized inventory layout, Muheesi, A. [15]

Figure 2: Organized inventory layout, Muheesi, A. [15]

1.1. Problem statement

An automated electric gate motor company suffers from continued random storage of raw components in a warehouse that feeds production lines. The high frequency utilized items are being placed far for immediate reach, which results with longer picking time to feed production lines and subsequent delays in order fulfillment. Optimisation of the warehouse layout is required for productivity improvement in the production lines.

1.2 Research Aim and Objectives and Question

The aim of the study is to identify and evaluate various storage configurations for determination of optimal layout that minimizes material picking times, reduces bottleneck, maximizes space utilization, and promotes a more structured and efficient inventory allocation process within manufacturing and warehousing facilities.

The main objective is to examine the impact of the current inventory layout on material flow, production throughput and the picking time. To achieve this primary objective, the specific objectives that drive the study entails to (i) model the current inventory layout and material flow using discrete-event simulation, (ii) evaluate performance metrics such as material picking time, material transportation to the production line, and throughput and (iii) recommend an optimized storage layout.

The main key question that guide the study entail: what are the impacts of disorganized inventory storage layout to production, such as material picking time, production efficiency, and material transportation to production line?

1.3 Study Scope, Limitation and Significance

This study focuses on improving inventory storage layout in a warehouse environment with an idea of improve material flow efficiency in automated manufacturing. The research use simulation modelling approach to access key performance indicator such as material picking time, order fulfilment time, material to production transportation and throughput. It also recommends optimal layout based on quantitative results from the simulation modelling analysis.

Thus, the study relies on simulation modeling using ARENA software. The findings may be more applicable to typical warehouse industries with an inventory storage, limiting generalizability to other manufacturing environments. The accuracy of the simulation results depends on the availability and reliability of input data, which may vary across different manufacturing settings.

This study is significant as it helps to enhance the effectiveness of material flow in a critical inventory storage layout that directly supports production. The study potentially provides useful suggestions for improvement of inventory storage layout which will enhance material flow, material picking process and order fulfillment. The study findings offer actionable insights for enhancement of inventory storage layout, reduction in delays for material flow, and potentially supports similar facilities in optimizing order fulfillment from warehouse operations.

2 LITERATURE REVIEW

Effective inventory storage layout plays an important role in material flow from warehouse to production and assists to make material easily accessible. This literature review explores foundational and contributions to the field of inventory storage layout optimization. It covers classical approaches, the use of discrete-event simulation in warehouse operations management.

2.1 Importance of warehouse layout in material flow

Warehouse layout design significantly influences the efficiency of internal logistics, especially in high-throughput environments. According to Zúñiga et al. [14], optimal layout planning reduces travel time, improves space utilization, and enhances order picking performance. Poor layout design leads to bottlenecks, excessive material handling, longer cycle times, and underutilization of resources, particularly in high-volume facilities.

2.2 Simulation in warehouse layout

Simulation is widely acknowledged as a valuable tool in warehouse layout planning. Discrete-event simulation as described by Banks et al. [6] enables analysts to model warehouse operations under various layout scenarios without disrupting real-world processes. Many studies have used simulation to: model picker behaviour under different layout types [10], evaluate alternative storage systems such as carousel systems or vertical lift modules [5, 10], test dynamic slotting algorithms and order batching methods [8,13]. Most studies agree that simulation allows for testing complex interactions and identifying layout-related inefficiencies that are not apparent through static analysis alone.

2.3 Storage Strategies and Classification Techniques

One of the most cited storage strategies in literature is ABC classification, which categorizes inventory based on demand frequency or value, Gu et al. [9] suggest that placing ‘A’ class items near dispatch or picking zones can significantly reduce retrieval times. In contrast, random storage or poorly zoned systems increase picker travel distance and congestion in high-traffic zones. The ABC classification storage strategy further entail:

- grouping of items based on shared characteristics or movement frequency [7]. This enhances efficiency by streamlining picker routes and avoiding unnecessary cross-traffic.
- dedicated or shared storage whereby in a dedicated storage, a fixed location is assigned to each item, which is easier to manage but less space-efficient. Meanwhile, shared storage dynamically allocates space but can increase search and retrieval times without robust warehouse management system support [11].

2.4 Performance Metrics in Layout Optimization

Studies such by Van gils et al. [12] emphasized the need to measure layout performance under various demand patterns to ensure robustness and scalability. The key performance indicators that was frequently used in layout optimization study include: picker travel distance, Order cycle time, Resource utilization (pickers, equipment) and throughput rate.

2.5 Simulation Tools in Warehouse Re-layout

According to Abidin, Ahmarofi & Guri [5], other utilized simulation softwares to redesign finished goods warehouse for addressing space constraints and increased capacity is AnyLogic and FlexSim. Similarly, Wan & Wang [13] conducted a simulation-based optimization of an e-commerce automated storage layout using FlexSim which resulted with improved storage efficiency.

3 METHODS

3.1 Introduction

Methodology and data gathering procedures are based on the information obtained from the previously reviewed literature. No manipulation or modification was made to the acquired data.

This study employs a simulation-based research approach using ARENA software in an automated electric motor gate manufacturing company. The methodology involves data collection, simulation modeling, and performance analysis to assess material flow and key efficiency metrics.

3.2 Research Design

This study adopts a quantitative research approach, utilizing discrete-event simulation to model an inventory storage layout. The research follows these key steps:

- Data collection – gathering process flow data, Material picking time, material flow, and production throughput information.
- Simulation model development – constructing a digital model to represent manufacturing system under unorganised inventory storage layout and organised inventory storage layout.
- Performance evaluation – analyzing the effects of unorganised inventory storage layout to material flow and the picking of material process.
- Recommendations – identifying optimal strategies to organise inventory storage layout or change the layout to make the flow of material smooth and picking of material to be easy.

3.3 Data collection

Data for the study was obtained from primary and secondary sources. These included:

- Production process data: collected data from warehouse layout drawing, material picking time since they will be picking from disorganized inventory storage, movement of material (material flow) to production
- Spaghetti diagram was designed as a way to trace the material transportation to production line; this help to see the current layout how is impacting the production with material flow and also the time and movement of material handlers.
- Literature review – Analysing existing research on inventory storage layout to establish baseline performance parameters.

3.4 Simulation Model and Scenario Development

A discrete-event simulation model is developed using Arena software to simulate the material flow in a warehouse inventory storage layout. The individual process steps modeled in the simulation include:

1. **Material Receiving & Storage**: Materials are being received from supplier at the receiving area and they are just being placed in a warehouse storage there is no designated storage or location for each product.

2. **Release production order**: the operational planner will release order to the warehouse guys to pick material for production line.
3. **Material picking process**: Items are picked based on production orders, impacting overall efficiency because of disorganized storage. The picking time is 6 minutes it can be short as 3 minutes or as long as 9 minutes to pick 1 item.
4. **Material Flow Optimization**: Evaluating how current layout affects travel distances and material flow
5. **Material transportation to production line**
6. **Production Integration**: Ensuring that stored materials are efficiently delivered to the production line without causing bottlenecks.

Figure 3 depicts the summarized process flow chart.

Figure 3: process flow

The simulated Arena model entailed the following components:

- **Entities:** Raw material, forklifts, storage racks.
- **Resources:** Warehouse staff.
- **Queues:** Items waiting for retrieval or placement.
- **Performance Metrics:** Retrieval time, congestion rate, storage efficiency, throughput.

The key assumptions made for model development were that:

- Material arrives from supplier at receiving area follows EXPO(10) minutes distribution
- Store guys store material at storage area congestion probability follows a NORM (0.2, 0.1) minutes distribution.
- Operational planner releases production order to warehouse follows UNIF(5, 15) minutes distribution
- Store man pick material for production follows TRIA (3, 6, 9) minutes distribution
- Material retrieval/transportation to production follows a TRIA (6, 9, 12) minutes distribution.

Material arrives at receiving area from the supplier. The arrival time is exponentially distributed with a mean of 10 minutes. Upon arrival after they have done all necessary check like quality checks, forklift operator will take material and store material in a storage warehouse where there is a possibility of congestion or delay because the storage is not well organized Storage area congestion probability follows a NORM (0.2, 0.1) minutes distribution

.The operational planner will release the order for production follows UNIF (5, 15) minutes distribution. Production order will go to warehouse with a picking list for stores guys to pick material to production, picking material follows TRIA (3, 6, 9) minutes distribution. Material will be retrieved to production this follows TRIA (6, 9, 12) minutes distribution

To assess potential material flow improvements, two scenarios were tested: a baseline scenario and an improved scenario. In the baseline scenario, Storeman receive material and place it in a warehouse storage which is disorganized and there is no order or arrangement for material that are frequently used. This cause delay when they must pick material for production because it's not organized. The improved scenario incorporates modification of storage layout where kanban system is implemented and assigning designated location based on frequency of use. By implementing the organized layout and kanban system will help in reducing long piking time, reduce congestion and retrieval time. This improvement collectively improves process and material flow and efficiency because production won't wait for material.

3.6 Data Analysis

The data analysis cantered on three core performance metrics—throughput, queue lengths, and resource utilization—to evaluate the efficiency of the production order picking and delivery process. These measures provide a clear picture of production volume, congestion points, and resource effectiveness within the system. Statistical methods were applied to ensure the accuracy and reliability of simulation results.

Throughput assesses productivity by tracking the number of completed manufacturing orders within a given timeframe, offering a measure of system capacity under both baseline and alternative scenarios. Higher throughput indicates improved efficiency, often achieved through improved layout that helps eliminate bottlenecks. Queue lengths reflect the average number of orders waiting at each stage (such as picking material and material retrieval), pinpointing bottlenecks that arise from disorganized inventory layout. Tracking these queues allows for analysis of scenario impacts on wait times, with shorter queues signifying reduced bottlenecks. Finally, resource utilization measures the active working time of resources—such as operators, and forklift—as a percentage of their total availability. High utilization rates signal efficient resource use, though values near 100% can indicate resource strain. Ideally, utilization should be balanced to ensure effective resource deployment without bottlenecks or excessive idle time.

4 RESULTS AND DISCUSSION

4.1 Summarized Time Studies

Time studies were conducted to capture the duration of each task within inventory storage process, covering steps like receiving material, store material at warehouse storage, picking of material for production, and material retrieval to production line. Table 2 summarizes these findings, displaying both the actual cycle time per part number and the standard time for each task. For example, storing material at the warehouse location takes 4,51 minutes compared to a standard time of 5 minutes. Material picking takes 4,92 minutes compared to a standard of 6 minutes, while material retrieval takes 8,11 minutes compared to a standard time of 9 minutes. These time distributions provide accurate data for modeling and analysis.

Table 2. Conducted and Summarized Time Studies

Process	Cycle time (Minutes)	Standard time (Minutes)
Material receiving	N/A	N/A
Store material at warehouse	4,51	5

Picking material	4,92	6
Material retrieval	8,11	9
Material goes to production	N/A	N/A

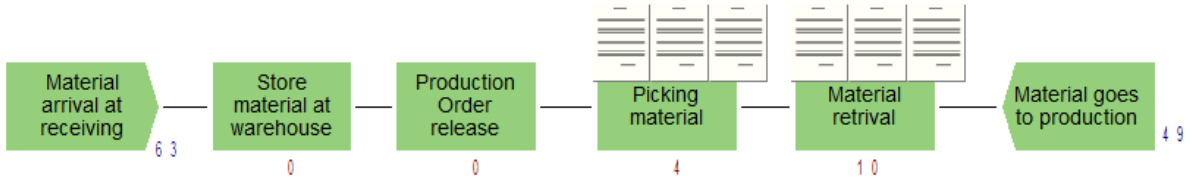

Figure 4: Current warehouse Simulation result

The simulation of current inventory storage layout operations in Arena was conducted and Figure 4 depicts the model results. According to the result obtained from the Arena simulation, it is evident that the critical bottleneck is on material picking and at material retrieval as highlighted in Figure 4. This delays the production and the picking process for the next order. However, when implement new layout and introduce kanban system where we assign designated locations based on frequency of use, the scenario shows improvement as depicted in Figure 5.and this is because the warehouse or inventory storage layout will now be organized, and material will be easily accessible

With all improvement bing implenmentated as mensioned above, Material will still arrives at receiving area from the supplier follows exponentially distributed with a mean of 10 minutes. Upon arrival after they have done all necessary check like quality checks forklift operator will take material and stores in a storage warehouse and there won't be any congestion or delay because the storage is now well organized, Storage of material follows a UNIF (1, 2) minutes distribution .The operational planner will release the order for production follows UNIF (3, 6) minutes distribution. Production order will go to warehouse with a picking list for Storeman to pick material to production, picking material follows CONT (2) minutes distribution. Material will be retrieved to production this follows TRIA (2, 3, 4) minutes distribution.

Figure 5 depicts the improved arena simulation results.

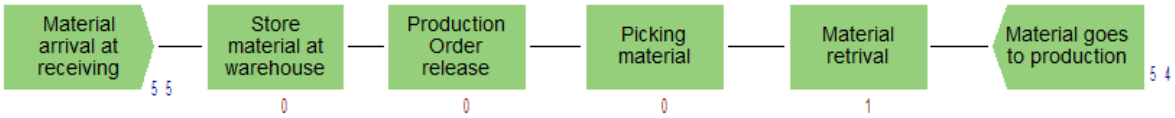

Figure 5: improved inventory storage layout Simulation

Table 3 below shows data from the number of orders that were picked in a disorganized inventory storage layout (A*) and the one that ware picnicked in an organized inventory storage layout (B*).

Table: 3. Number of Orders picked in disorganized inventory storage layout (A*) vs. organized inventory layout (B*)

Name	Type	Source	Average Across Replications	
			A*	B*
System.Number Out	Number Out	System	45,67	49,67
Entity 1.Number In	Number In	Entity	52,00	51,00
Entity 1.Number Out	Number Out	Entity	45,67	49,67

Operator.Number Seized	Total Number Seized	Resource	46,33	50,00
Operator.Scheduled Utilization	Scheduled Utilization	Resource	0,86	0,31
Material picker.Number Seized	Total Number Seized	Resource	50,67	50,33
Material picker.Scheduled Utilization	Scheduled Utilization	Resource	0,65	0,21
Storeman.Number Seized	Total Number Seized	Resource	52,00	51,00
Storeman.Scheduled Utilization	Scheduled Utilization	Resource	0,02	0,16

As displayed in Table 3, the well-organized inventory layout substantially boosts throughput, compared to disorganized inventory storage layout. Resource utilization for tasks like material storage material picking, and retrieval resources are not overstrained despite the higher processing volume.

Table 4 compares Value-Added (VA), Non-Value-Added (NVA) and Waiting Times for orders processed in Disorganized inventory storage layout **(A*)** and organized inventory storage layout **(B*)**

Table: 4. Value Added, Non-Value-Added and Waiting Times for Orders Processed in Disorganized layout (A*) vs organized layout (B*)

Name	Type	Source	Average Of Replication Averages		Observed=Requested	
			(A*)	(B*)	(A*)	(B*)
Entity 1	NVA Time	Entity	0	0	Yes	Yes
	Other Time	Entity	0	0	Yes	Yes
	Total Time	Entity	42,99	11,73	Yes	Yes
	Transfer Time	Entity	0	0	Yes	Yes
	VA Time	Entity	25,74	11,07	Yes	Yes
	Wait Time	Entity	17,25	0,66	Yes	Yes
Material retrieval.Queue	Waiting Time	Queue	13,05	0,32	Yes	Yes
Picking material.Queue	Waiting Time	Queue	4,65	0,19	Yes	Yes
Store material at warehouse.Queue	Waiting Time	Queue	0,00	0,14	Yes	Yes

From the above Table 4, the Organized inventory layout results in a marked reduction in waiting times across entities and queues, with notable improvements in Wait Time for Entity 1 and waiting times in various queues. Additionally, Total Time for Entity 1 decreases, while VA Time remains consistent across shifts. The observed values align with the requested processing time requirements in both scenarios, indicating that the system operates more efficiently under the organized inventory layout.

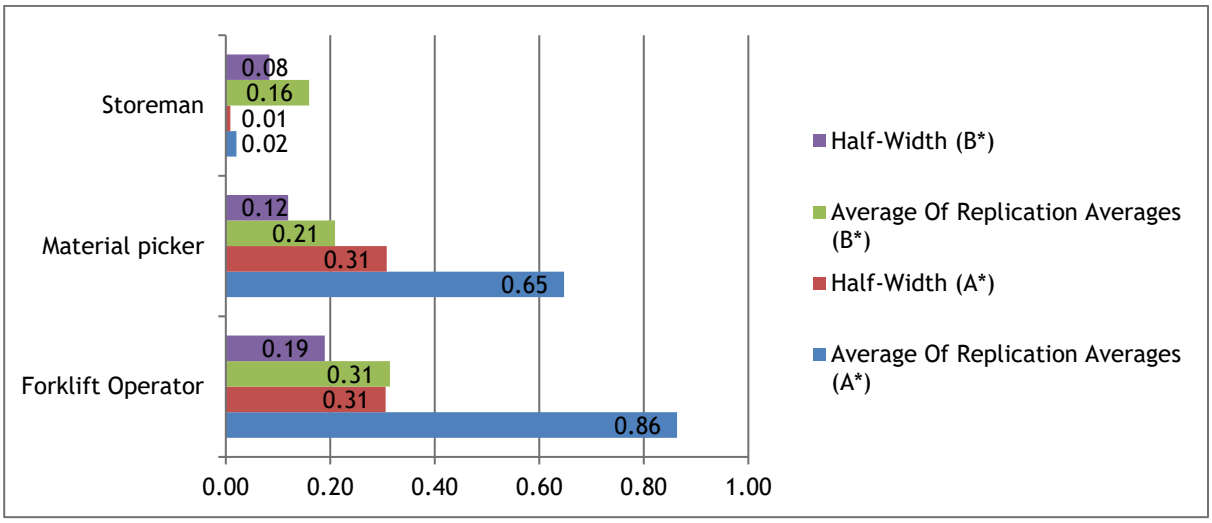

Figure 6: Resource Utilization in Disorganized (A*) layout vs. organized layout (B*) (numerical values in minutes).

The simulation results for unorganized inventory layout **(A*)** and organized inventory layout **(B*)** highlight significant enhancements in the production process with the new implemented layout and kanban system. In the unorganized inventory layout, referring to Table 3, 45.67 orders were processed (Number Out) out of 52 orders entered (Number In), leaving 6.33 orders pending in the system by the end of the shift. Referring to Table 4, it is evident that queue times were particularly high, averaging 13.05 minutes for material retrieval and 4.65 minutes for picking, revealing bottlenecks caused by disorganized inventory layout. Again, referring to Table 3, the organized inventory layout, by contrast, processed 49.67 orders out of 51 entered, leaving only 1.33 orders pending at the end of the shift. Queue times saw a dramatic reduction, with negligible delays of 0.32 minutes for material retrieval and 0.19 minutes for picking (see Table 4). The new implemented layout with a kanban system supported a higher order volume while facilitating smoother operations and significantly reducing waiting times at bottleneck stages.

5 CONCLUSION AND RECOMMENDATIONS

The goal of this study was to identify and fix major inefficiencies and bottlenecks that impact material flow continuity and resource usage by analyzing the production order picking and delivery process. By building a simulation model that mimics the actual system, it was feasible to evaluate how inventory layout, task variability, and process delays affected the order fulfillment cycle's total productivity.

The simulation study demonstrates that optimizing inventory storage layouts can significantly reduce retrieval time, minimize congestion, and improve storage efficiency. Implementing a structured storage system and enhancing material flow strategies will result in a payback making the investment highly feasible for long-term efficiency gains. Further testing and real-world validation will be recommended to fine-tune the optimized layout.

Key findings showed that delays in the production support process are caused by disorganized inventory layout. This layout affect material picking time and material retrieval to production and this is because material in a warehouse is just place without check the frequently used, so it’s difficult for the person who picks material to finish, or top get material in time. Changing inventory layout, building flow racks and introduces kanban system to help in arranging material and pack them according to frequently used or according to FIFO (First In first Out) were among the suggestion put in place to solve the

problem. By streamlining job flows, decreasing wait times, and optimizing resource use, these changes could eventually boost throughput and productivity.

The study highlights the importance of simulation modeling in intricate operational situations and offers a useful and adaptable methodology for process optimization. These results show how simulation may support well-informed, data-driven decision-making in dynamic, resource-intensive processes, laying the groundwork for further study and continuous improvement in production management.

By creating and examining a discrete-event simulation model of the manufacturing order picking and material retrieval process, this study effectively achieved all its goals while offering crucial insights into system performance in a range of operating circumstances. The study analyzed bottlenecks, and assessed the effects of various interventions, including building of flow racks, introduce kanban system and change the layout using in depth modeling in Arena software.

To further Optimize Inventory Storage Layouts to improve material flow in an automated Electric Gate Motor manufacturing, future research should aim to address the limitations of this study. Integrating real-time tracking could provide dynamic insights into workflow fluctuations, enabling more precise identification of bottlenecks and optimization of resource usage. Expanding the scope to include downstream production effects would offer a broader perspective on how material picking and material retrieval processes influence overall production throughput

ABSTRACT

Waste management has long posed a challenge to humanity, as people consume a wide range of natural and synthetic products, producing waste in the form of gases, contaminated liquids, and solid materials. This ongoing challenge has driven the development and implementation of various techniques aimed at managing waste and protecting the environment. As a result, numerous technologies, methods, and practices have been designed and applied to optimize waste management systems, as documented in the literature. The objective of this research was to review scientific studies on the application of Mathematical Programming (MP) and Simulation Modelling (SM) in waste management, particularly Solid Waste Management (SWM), to assess current trends and practices in the field and to identify potential directions and gaps for future research. The review focused on recent publications from leading scientific platforms and categorized the studies based on their modelling approaches, findings, and limitations. Findings indicate that MP and SM have been widely and effectively used to design and optimize Solid Waste Management Systems (SWMS). Among MP techniques, Vehicle Routing Programming (VRP) is the most commonly applied, while Agent-Based Modelling (ABM) is the dominant method within simulation modelling; the study also proposes a conceptual architecture of a SWMS aimed at optimizing the collection and disposal of municipal solid waste.

Keywords: Waste Management; Smart Bin; Simulation; Mathematical Programming; Internet of of-Things.

1 INTRODUCTION

The world is growing rapidly, and cities, especially in developing countries, are experiencing rapid population growth due to increasing immigration and high birth rates.

On the other hand, organizations are increasingly becoming complex adaptive systems, made up of multiple parts interacting with one another and the external environment. Such interactions typically produce complex and nonlinear properties that are difficult to understand, predict, and manage [1]; and waste management entities are not spared from this reality, as it is becoming more and more complex to manage municipal waste in the dynamic and complex environment municipalities operate in.

The rapid growth of urban populations, particularly in developing countries, has contributed to increased waste generation and associated challenges [2].

One of the challenges in waste management is the high cost of the collection and disposal of waste, which is emphasized in developing countries, partly because of the inefficient collection and disposal systems. The conventional (traditional) solid waste collection systems, still largely practiced in developing countries, consist of a fixed schedule where each zone of a city has a fixed day of the week when its generated waste gets collected by a municipal collection truck. According to Nord *et al.* [3], 80% of waste collection occurs at the wrong time, leading to unnecessary trips or delayed pickups that cause bin overflows. This is the reason why technologies such as the Internet-of-Things (IoT), Mathematical Programming(MP), and Simulation Modelling (SM) are increasingly applied to improve the design and operations of the Solid Waste Management System (SWMS). This paper aimed to conduct a literature review on the application of MP, SM, and IoT in waste management to discover the scientific work that has been done in this field and identify the strengths and limitations of each study in order to understand the current trend in waste management practices and highlight areas for future work. Numerous review papers have been published on the application of MP and SM in solid waste management, but most of these studies have focused on the application of one technology or approach. Among these studies is the work done by Cohen [4], who studied the application of System Dynamics (SD) on the improvement of municipal waste management. This study has demonstrated that SD is one of the best possible ways to find quantitative and qualitative relationships between different variables of waste management to avoid further environmental, social, technological, and economic problems. The limitation of this review is that it only looked at one aspect of solid waste management, understanding the relationship between different variables affecting the system using SD. Another study by Lee *et al.* [5] has provided a comprehensive review of mathematical modelling in waste management, highlighting the effectiveness of this technology to assist decision makers in making better decisions in waste management. The paper has also highlighted the current practices in waste management in Asia, before developing a mathematical model to optimize waste management in Hong Kong. However, this paper did not look at the application of simulation in the modelling and optimization of waste management systems.

This paper aims to review different works done on MP and SM to explore their different modelling and solution approaches and how they are applied in Solid Waste management (SWM), particularly in waste collection and disposal. The paper also looks at other technologies, such as IoT and communication networks, that are used to enhance the design and optimization of solid waste management systems. To achieve this aim, an online search using leading scientific platforms such as Science Direct, Google Scholar, and Research Gate was conducted using keywords such as simulation, mathematical optimization, IoT, solid waste management, etc., and only publications of the last 10 years were considered and systematically compared. Exclusion criteria were based on study objectives and methods: articles not focused on waste collection and disposal, or not employing mathematical

programming or simulation for system optimization, were excluded. The steps of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) method that were taken to complete this review

are presented in Figure 1.

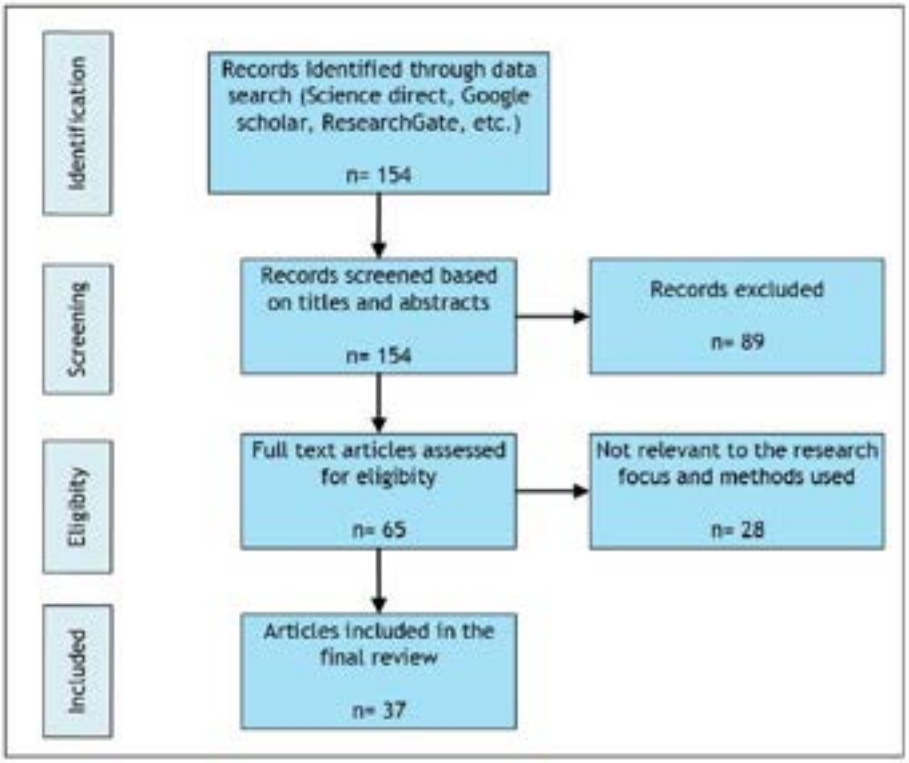

Figure 1: Flow Diagram of the PRISMA Systematic Review Method Used.

2 SIMULATION AND MATHEMATICAL MODELLING APPLICATIONS IN SOLID WASTE MANAGEMENT

After reviewing various publications on simulation and mathematical modelling in waste management, the outcomes, contributions, and limitations of these publications are provided in this section.

2.1 Historic Perspective

The traditional methods of managing waste have evolved, and their application varies from region to region. Some of the common traditional solid waste management methods, which are unfortunately still used in some underdeveloped and developing regions, include:

1. Open Dumping: In the past, waste was often disposed of in open dump sites where garbage and refuse were piled up in open areas, often without any containment measures or environmental considerations. This method is unsanitary and can lead to pollution and health hazards.
2. Burning: In some cases, waste materials were burned, primarily to reduce the volume and eliminate some of the organic matter. However, burning waste can release harmful pollutants into the air and is not an environmentally friendly approach.
3. Landfilling: Landfills, although more controlled than open dumping, are still considered a traditional waste management method. Solid waste is disposed of in designated landfill sites where it is compacted and buried. This method can be problematic if not managed properly and can lead to soil and groundwater contamination.

4. Waste Pits: In rural areas, waste was often deposited in pits or holes dug in the ground. These pits were usually shallow and would fill up relatively quickly, necessitating the digging of new pits.
5. Composting: Organic waste, such as food scraps and yard trimmings, was often managed through traditional composting methods, which involved piling the organic materials and allowing them to decompose naturally. This method is still used today for organic waste management (ChatGPT 3.5).

Due to the inefficiency and health risks of traditional waste disposal methods, most governments have introduced scheduled waste collection services. Trucks (public or private) collect waste weekly, transport it to recovery or transfer stations for sorting, and send non-recyclable waste to managed landfills. While this approach improved waste handling, several challenges remain unresolved, including:

1. Late or early collection: this happens because the vehicles collecting waste do not know the exact time to collect, hence they collect waste either too early, leading to unnecessary trips and a very expensive waste collection process, or too late, resulting in waste bins' overflow and undesirable odour.
2. Inefficient routing: This is the problem that waste collection vehicles encounter by making decisions on which routes to take and where to start and finish their trip, only based on their own intuition, a rule of thumb, or on a first-come-first-served basis.
3. Inadequate facility location: This is another problem that occurs in waste management when no analytical method is used to effectively locate waste management facilities.

These are some of the challenges that led to the development and application of new methods and technologies such as IoT, MP, and SM in the optimization of solid waste management systems.

2.2 Application of Mathematical Modelling in Waste Management

Mathematical Programming (MP) is a well-established optimization method, with numerous solution approaches developed over time. These are broadly classified into classical (exact) and approximation (heuristic and meta-heuristic) methods. Classical methods include gradient descent techniques (e.g., steepest descent, Newton's method, variable metric) and direct search methods for simpler problems (e.g., Hooke–Jeeves) [6], as well as the branch-and-bound approach used in Linear Programming (LP) and Mixed Integer Linear Programming (MILP) solvers for global optimization in non-convex problems [7]. Meta-heuristic methods use iterative strategies to guide heuristics for solving complex problems that are difficult or resource-intensive for classical methods, integrating various concepts to balance exploration and exploitation of the search space [8]. This group is also divided into three subgroups, including:

1. Evolutionary Algorithms: such as Genetic Algorithm (GA), Genetic Programming (GP), Differential Evolution, and Harmony Search.
2. Swarm-Based Algorithm. This group includes algorithms such as the Bee colony and Particle Swarm Optimization (PSO).
3. Trajectory-Based Algorithms. This final group includes the Tabu Search (TS), Simulated Annealing (SA), and Hill climbing algorithms.

All these methods have their strength and limitations, but going into details for each method is beyond the scope of this study.

In MP, the challenge extends beyond selecting a modelling approach—modellers must also choose suitable modelling frameworks and solvers. Frameworks, or Algebraic Modelling Languages (AMLs), provide the programming interface for formulating mathematical models so they can be processed by computer solvers. These frameworks vary in programming

language, learning curve, support for linear and non-linear programming, and flexibility in integrating different solvers. Table 1 compares five leading frameworks across these criteria.

Table 1: Algebraic Modelling Frameworks Comparison

Framework	LP	NLP	Learning Time	Possibility to configure a new solver
Pyomo	x	x	Short	High
Ortools	x		Very Short	Low
PuLP	x		Short	High
SCIP	x	x	Very Short	Not possible
SciPy	x	x	Long	Medium

Using various approaches and having different objectives, the following are some of the most recent works done in SWMS optimization using MP.

In the study conducted by Das and Bhattacharyya [9], an optimization model was developed to find an optimal method for the collection, transfer, and disposal of municipal solid waste, and a heuristic method was applied to solve the problem. The study claims a 30% reduction in the waste collection and disposal cost in the case study city.

Bouleft and Alaoui [10] proposed a dynamic Multi-Compartment Vehicle Routing Problem (M-CVRP) for smart cities, where collection trucks carry separate compartments for different waste types, and smart bins are used for sorting at source. They formulated a MILP model to optimize collection operations and developed a hybrid GA to minimize total costs, including travel and overflow penalties. The approach proved effective in both static and dynamic scenarios. Another study that has proposed a dynamic M-CVRP in smart waste management is the research conducted by Mohammadi *et al*. [11]. The difference with the previous study is that this study combined the hybrid GA and PSO algorithms to solve the developed MILP model with another heuristic approach. The study demonstrated that the hybrid algorithm had the highest performance in providing high-quality route plans. Rahmanifar *et al*. [12] developed a MILP-based smart SWMS aiming to minimize total travel costs and CO2 emissions. The study formulated two CVRP models - one for routing from IoT-enabled waste bins to separation sites, and another for transporting waste to recycling facilities. To solve these, novel heuristics and meta-heuristics methods were applied, including the Social Engineering Optimizer (SEO) and SA. However, the model lacks a dynamic component, as it does not account for stochastic or time-dependent travel times, nor does it handle urgent or high-priority bin requests.

Optimization techniques have not always been used in isolation, but in most cases, they have been coupled with other technologies to enhance their effectiveness in optimizing SWMS. One of the studies that has coupled MP with other technologies is the research conducted by Xia *et al*. [13], where Machine Learning (ML) algorithms were successfully applied in all aspects of SWM, including waste generation prediction, waste sorting, bin level detection, route optimization, and so forth.

2.3 Simulation Modelling in Solid Waste Management

Simulation modelling involves creating a computer-based representation of a physical or real-world system to analyze its behavior and optimize performance. Modelling, in various forms—from mental and physical models to mathematical, spreadsheet-based, and computer simulations—has long been used to understand systems. While analytical models, such as Excel spreadsheets, are popular and user-friendly, they are limited to problems with clearly defined and formula-based solutions. Many real-world problems, however, are too complex or lack such solutions, making simulation a more suitable approach [14]. These problems include dynamic systems featuring:

1. Non-linear behavior

2. Memory Requirement
3. Non-intuitive influences between variables
4. Time and causal dependencies
5. All the above, combined with uncertainty and a large number of parameters

It is with these kinds of problems that computer-based simulation becomes pivotal. Simulation modelling is sometimes defined as a set of rules that dictate what the next state of the system should be from the current state; and these rules can be of different nature: differential equations, State charts, process flowcharts, schedules, etc. [14]. The same author has highlighted the following as the advantages of simulation modelling:

1. Simulation models enable you to analyze systems and find solutions where other methods, such as analytical calculations and linear programming, fail
2. Once one has selected the appropriate level of abstraction, the development of a simulation model is a more straightforward process than analytical modelling
3. The structure of a simulation model naturally reflects the structure of the real system; as simulation models are developed using mostly visual languages, it is easy to communicate the model to other people
4. In a simulation model, one can measure any value and track any object that is not below the level of abstraction
5. The ability to play and animate the system behavior in time is one of the greatest advantages of simulation. Animation is used not only for demonstration purposes, but can also be used for verification and debugging
6. Simulation models are more convincing than most analytical approaches

Simulation modelling is widely used across domains—from military and healthcare to manufacturing, logistics, and social systems. Depending on the system's abstraction level and the modeler's expertise and preference, simulation can be conducted using Discrete Event Simulation (DES), System Dynamics (SD), or Agent-Based Modelling (ABM). SD suits high-level, abstract models with minimal detail; DES fits detailed, low-abstraction operational models; and ABM balances between the two. Notably, literature shows that ABM is the most commonly applied simulation method in SWMS.

Simulation has been extensively used in combination with MP or other optimization techniques to optimize SWMS, either as a tool to generate data as inputs to the optimization algorithms or as a tool to test and assess the feasibility and performance of the optimized system. Following this approach, Idwan *et al*. [15] simulated urban waste collection using IoT-enabled smart bins and applied a GA to solve an MILP model aimed at minimizing truck travel time and distance. The simulation sent real-time bin status to an optimization engine based on a CVRP model, which returned optimal truck routes. Two scenarios were tested: (1) all bins were assumed full, requiring city-wide collection, and (2) only bins reported full by sensors were serviced. Results showed that smart bins reduced total travel time by 22%. However, the study presents several limitations, including:

1. Simulation-Based Validation: The study's findings are based on simulations only; real-world implementation and testing are necessary to validate the system's effectiveness under practical conditions
2. Scalability Concerns: The performance of the proposed algorithm in larger urban settings with more complex road networks and a higher number of dumpsters and vehicles remains untested

3. Dynamic Factors: The model did not account for dynamic factors such as traffic conditions, road closures, or unexpected events such as vehicle maintenance and breakdowns. Moreover, the study did not consider the scenario that other waste bins could become full and send service requests after the first allocation of trucks, and that a new computation of the optimization engine will be needed to find the best solution to service these new bins
4. The model did not consider the environmental factors, such as the need to collect a bin after a certain number of days, regardless of whether it's full or not, to avoid adverse odor, and the vehicle's CO2 emission reduction as an objective function

Another related study developed a multi-agent simulation-based framework to evaluate the performance of an IoT-enabled waste collection system and compare it with a conventional collection system [16]. The methodology of this study included the use of multi-agent simulation, IoT-enabled bins equipped with ultrasonic and weight sensors to monitor fill levels, transmitting data via communication technologies such as Wi-Fi and cellular networks, and routing optimization, implementing predictive algorithms to determine efficient garbage collection routes based on real-time bin data. The study demonstrated that the IoT-based system outperformed traditional methods by reducing the number of collection trips and distances travelled.

Another study that has used simulation is the study conducted by Mohan *et al*. [17]; this study has modelled and simulated a proposed IoT-based waste collection and disposal system for smart buildings using autonomous indoor robotic waste bins. Some of the limitations of this study include that the system's performance in larger or more complex building layouts remains untested, the study does not discuss the robot's power requirements or battery life, which are critical for autonomous operation, and the long-term maintenance issues and the reliability of the system in continuous operation were not explored.

Another study demonstrating simulation in solid waste management assessed the feasibility of a smart waste collection system in the UAE and compared it with the conventional approach [18]. The research began with a field survey to analyze daily bin filling rates across urban areas. Using this data, the authors simulated various waste collection scenarios and proposed a smart system in which sensor-equipped bins detect fill levels. This data is then fed into a GIS-based route optimization algorithm to determine efficient truck routing.

Other studies that have used either simulation, MP, or their combination to optimize SWMS include [19], [20], [21], [22], and [23]. Some of the shortcomings of these studies include not using GIS in the simulation model, not using the simulation model, hence ignoring the dynamic and stochastic aspects of the system, and/or not using the smart collection approach with IoT-equipped bins.

With growing urban waste challenges, understanding relationships among key waste management variables is essential. To this end, Cohen [4] applied SD to analyze SWMS and identify correlations that could ease pressure on municipalities, finding SD effective in capturing quantitative and qualitative interactions across environmental, social, technological, and economic factors. Similarly, Ding *et al*. [24] reviewed studies using SD and ABM for construction waste management and proposed integrating both methods for more robust modelling. In another example, Meng *et al*. [25] developed an ABM in AnyLogic to simulate changes in residents' recycling behavior under different waste policies, showing that charging policies can reduce garbage and improve waste separation at source. As simulation techniques and tools expand, some question the relevance of MP. However, both simulation and MP have distinct strengths, and the key lies in leveraging these strengths to better model and optimize systems [26].

2.4 Other Technologies Applied in Solid Waste Management

MP and SM are not the only technologies applied in the design and optimization of SWMS; they are often used in conjunction with other new technologies.

Other literature reviews aimed to determine challenges, recent developments, and opportunities of smart waste collection [27]. This study has looked at several studies that have successfully implemented technologies to optimize waste management systems in different parts of the world. Various technologies, from sensor technologies to communication technology, location information tools, and microcontrollers, have been found to be effective in developing smart waste management systems. These technologies include:

1. Sensors (e.g., ultrasonic sensors, weight sensors, temperature and humidity sensors, multi-stereoscopic cameras, PIR motion sensors); of these sensor technologies, the ultrasonic sensors were the most used sensors
2. Communication technologies (e.g., Wi-Fi ESP module, Global System for Mobile Transmission - GSM, GPRS, RFID, LoRa WAN, Ethernet, Cloud platform using Wi-Fi module, Wireless LAN)
3. Location information tools (e.g., GPS, GIS, etc.)
4. Microcontroller technologies (e.g., Arduino Uno, Node MCU, Raspberry Pi, etc.)

One of the studies that has combined some of these technologies to propose a smart waste management system is the study conducted by Nguyen-Trong *et al*. [28] in which the authors developed a dual model to optimize the collection and disposal of municipal solid waste. The study combined an MP model with an ABM model. First, a MILP model was developed using the Vehicle Routing Problem (VRP) approach, which was solved using the Clarke and Wright algorithm to determine the optimal scheduling and routing of the collection trucks. Then the optimal solution was used as input parameters to the ABM simulation model to test its results in a dynamic environment; the ABM simulation was used to model other dynamic parameters of the system that could not be represented by the MILP, such as the traffic network, truck speed, route characteristics, etc. The study was able to reduce the total travelling distance of the trucks by 11.3%, and the following objectives were achieved:

1. Integrating GIS analysis, MP, and ABM
2. The study demonstrated that integrating the three technologies was more effective than the GIS analysis approach
3. The study also demonstrated that integrating simulation allows for visualizing the evolution of the municipal waste collection and transportation

While most studies focus on improving the process of waste collection and disposal, other research works are looking at ways to minimize waste generation and create waste-free cities. With the aim of contributing to the creation of a zero-waste smart city, Esmaeilian *et al*. [29] have proposed a conceptual framework for waste management in future cities in which the waste management system is directly connected to the whole product lifecycle. The same study has also established that the transition to becoming a zero-waste smart city requires three strategies, namely waste prevention, proper waste collection process, and proper material recovery from collected waste.

3 DISCUSSION

The literature indicates that MP can be effectively combined with SM to develop better and intelligent SWMS, with MP used to minimize objectives such as total travelling distance, and SM applied to capture dynamic and stochastic aspects of real systems, including waste generation and road network variability. As shown in Table 2, most research in this field can be categorized by research approach, objective functions, and limitations. While some studies considered objectives like waste reduction, the majority applying either MP or SM focused on optimizing solid waste collection and disposal worldwide. MILP, particularly the VRP method, is the most common MP approach, aiming to reduce collection vehicle distance and time. Classical solution methods such as simplex and Branch and Bound are widely used, alongside heuristic and meta-heuristic techniques such as GA and PSO. Simulation is also extensively applied, either independently or in combination with MP, to design and optimize SWMS. All major simulation paradigms—DES, SD, and ABM—have been used, though ABM appears most prominent among them.

Among the five algebraic modelling frameworks compared, Pyomo, a Python-based open-source tool, proved to be the most effective for formulating and solving mathematical models in solid waste management. Its wide range of optimization capabilities and rich library support set it apart from other AMLs, making it especially suitable for modelling, solving, and analyzing complex waste management problems. Some of the most common types of problems that are supported by Pyomo include:

1. Linear programming
2. Quadratic programming
3. Nonlinear programming
4. Mixed-integer linear programming
5. Mixed-integer quadratic programming
6. Mixed-integer nonlinear programming
7. Stochastic programming, etc.

The other advantage of using Pyomo is that it integrates easily with many widely used solvers such as CPLEX, GLPK, and Gurobi to solve problems; this is a benefit of the framework because it allows one to quickly change the solver and solve the problem, and hence be able to compare the performance of various solvers on the same model.

4 SYSTEM ARCHITECTURE OF A SMART SWMS

Considering the demographic, social and economic factors of SWMS, specially in developing countries, and the technological advancement in telecommunication, sensors, linear programming, and simulation, the system architecture, displayed in Figure 2 is proposed for the smart collection and disposal of municipal solid waste with the aim to minimize the total time and cost of waste management. The functions and roles of each component of the system are as follows:

Table 2: Summary of Recent Studies on the Application of VRP and ABM in SWM

Author and Year	Research Approach	Objective Function—	Limitations
Nguyen-Trong et al. 2017.	MILP using VRP; solved using the Clarke and Wright algorithm.	Minimize travel distance.	Trucks' capacity not considered; Waste generated assumed to always be less than truck capacity.
Qiao et al. 2020.	ABM is used to test MP results; GIS is integrated into the ABM. MILP using CVRP solved with meta-heuristics algorithms (PSO and Tabu Search).	Minimize total cost (distance), fuel consumption, CO2 emission, and penalty cost.	Dynamic aspects of collection requests are not considered, no GIS to capture traffic network.
Idwan et al. 2020.	MILP using VRP solved with GA.	Minimize total travel distance and time.	Dynamic and stochastic aspects of collection re-quests are not considered.
Bouleft and El-hilali 2023.	MILP using MCVRP solved using hybrid GA	Minimize total travel and penalties cost.	Dynamic aspects of collection requests are not considered; no GIS to capture traffic network.
Mohammadi et al. 2023.	MILP using M-CVRP solved with hybrid GA and PSO.	Minimize total travel and penalty costs.	Dynamic aspects of collection requests not considered, no GIS to capture traffic network.
Rahmanifar et al. 2023.	MILP using M-CVRP solved with Heuristics and meta-heuristics SEO and SA.	Minimize total travel cost and CO2 emission.	Dynamism of travel time is ignored; stochastic re-quests scenario is not considered.

1. **Smart refuse bins:** These are garbage refuse bins equipped with sensors that are used to sense the level of trash inside the bin and send a signal to the coordination center when the bin needs to be emptied
2. **Waste collection trucks:** The collection truck proposed for this kind of systems is the common garbage collection truck, commonly used by municipalities, which usually is of drive type 2x4, with a capacity of cargo body between five and six cubic meters, overall dimension of 6520 x 2050 x 2460 mm, and a maximum speed of 95 km/h
3. **Waste Collection Truck Depots:** Two main depot configurations exist in waste collection systems – a single depot, serving all trucks, or multiple depots distributed across the city. A single depot reduces operational costs, while multiple depots improve time efficiency but increase facility costs. Choosing the optimal setup involves a facility location problem, which is beyond the scope of this study.
4. **Coordination center (CC):** This is the place from which all the activities of waste management in the city, including running the optimization and simulation engines, will be coordinated
5. **Mathematical Optimization Model:** Once the signals of full bins are received, the MP can then be used to find the optimal routing of the collection trucks and do the scheduling of trucks more effectively
6. **Simulation Model:** The last component of the proposed smart system is the

simulation, which can be used to simulate the system to ensure that the best scenario is being considered at all times.

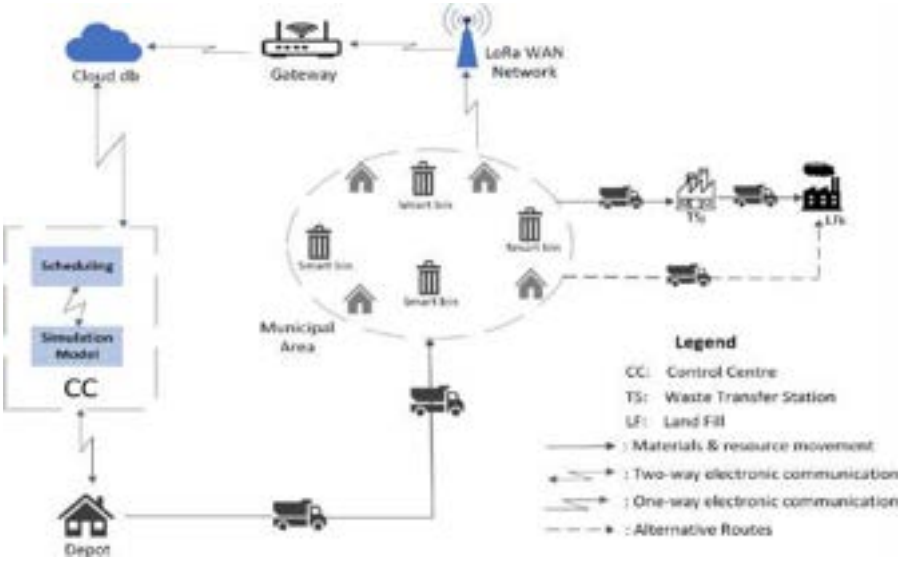

Figure 2: Smart Solid Waste Management System Architecture

5 LIMITATIONS

Waste management is a complex process and encompasses many aspects, including waste generation, waste prevention, recycling, waste-to-energy transformation, waste collection and disposal, landfill management, waste circular economy, etc. This review has focused mainly on articles dealing with waste collection and disposal, and how MP and SM can be used to design and optimize SWMS with regard to this aspect. Further studies could look at other aspects of waste management and the application of various other tools in the improvement of waste management systems.

6 CONCLUSION

This review examined recent studies on the application of MP and simulation modelling in the design and optimization of SWMS. It was noticed that most research focused on improving urban waste collection and disposal efficiency, with system design and optimization being the predominant objective. The VRP emerged as the most commonly used MP formulation, while ABM was the most frequent simulation approach. Classical solution methods often involved simplex and Branch and Bound algorithms, typically implemented using Algebraic Modelling Languages such as Pyomo. Among meta-heuristics methods, GA and PSO received significant attention. Despite the demonstrated effectiveness of these methods, limitations such as the lack of dynamic system considerations (e.g., variable truck availability, real-time road conditions, and multiple concurrent collection requests), limited integration of environmental objectives, and insufficient cost-benefit analyses of smart waste systems remain. Among prominent future works in this field would be the performance assessment of the proposed SWMS architecture in a case study using either simulation or a real pilot study to demonstrate the effectiveness of such a system. Although this study focused on the implementation of MP and SM in SWM, it can be concluded from this review that mathematical programming and simulation play a vital role in broader logistics operations planning and optimization, aiming to minimize costs and improve the system's efficiency.

ABSTRACT

This study examines how technology integration in engineering education **formats** influences innovation development and graduate employability in the context of the Fourth Industrial Revolution (4IR). Using a qualitative case study approach, data were triangulated from student feedback (n = 42), institutional documents, and field observations. Findings show that digital learning tools support improved conceptual understanding, collaboration, and career readiness, while challenges such as unequal access and uneven curriculum integration remain. The study contributes by clarifying how Kaizen principles, vertical and horizontal integration of learning activities, and institutional management practices shape innovation-oriented education. Limitations include a small sample size and the absence of longitudinal data, but the findings highlight practical lessons for embedding innovation and employability attributes in engineering education.

Keywords: Engineering education formats, Graduate employability, Technology integration, Fourth Industrial Revolution (4IR)

* Corresponding Author

1 INTRODUCTION

Engineering education plays a central role in preparing graduates to contribute to innovation and industrial development, particularly within the context of the Fourth Industrial Revolution (4IR). Employers increasingly demand graduates who can not only apply technical knowledge but also demonstrate adaptability, problem-solving, and innovative thinking [1][2]. Traditional approaches to engineering education, however, have often struggled to keep pace with these expectations.

International scholarship emphasizes the value of innovative educational formats, such as project-based learning, cooperative education, and digital simulation platforms, in bridging the gap between academic training and industry needs [3][4]. These approaches enable students to engage with real-world problems, develop collaborative skills, and integrate theoretical knowledge with practice. Frameworks such as CDIO (Conceive–Design–Implement–Operate) have demonstrated the benefits of structured, practice-oriented learning [5]. In South Africa, however, studies remain limited, with most research focusing on general e-learning adoption rather than discipline-specific innovations [6][7].

The need for transformation is also emphasised in national policies. The National Development Plan 2030 and the National Digital and Future Skills Strategy call for education systems that strengthen innovation, digital literacy, and employability skills [8][9]. While digital tools are increasingly adopted across institutions, questions remain about how specific formats of engineering education can be structured to cultivate innovation readiness and support graduate transitions into dynamic workplaces.

This paper addresses this gap by examining an engineering education format that integrates technology-enabled learning, Kaizen-based continuous improvement, and vertical and horizontal curriculum alignment. Using a qualitative case study design, the research explores how such a format influences innovation development and employability outcomes in a South African distance education context. The study contributes by clarifying the mechanisms through which education formats can shape graduate attributes, offering practical lessons for engineering educators and institutional leaders.

2 LITERATURE REVIEW

Engineering education is under sustained pressure to produce graduates who can operate effectively in fast-changing, technology-rich workplaces. International literature points to education formats that blend practice-centred learning with digital enablement as a way to improve relevance and graduate outcomes [3][4][7][8]. Within this body of work, three strands are especially pertinent to innovation development: practice-oriented frameworks, digitally supported learning environments, and explicit cultivation of employability attributes.

2.1 Practice-oriented education formats

Frameworks such as CDIO emphasise learning that is organised around authentic engineering practice, with students conceiving, designing, implementing, and operating artefacts or systems across a staged curriculum [3]. This orientation encourages iterative problem-solving, teamwork, and communication, which are recognised components of innovation capability. Problem- and project-based learning further support these outcomes by requiring students to apply theory to open-ended tasks under real constraints, thereby strengthening judgment and the transfer of knowledge to novel contexts [9]. These formats are relevant for institutions that must balance theoretical breadth with application at scale.

2.2 Digitally supported learning environments

Digital technologies expand access to authentic tasks and enable timely feedback at the course and programme level. The literature documents the promise of intelligent feedback, adaptive

support, and analytics for improving engagement and learning effectiveness in STEM fields [4][7]. More broadly, the digital transformation of higher education has accelerated the use of virtual laboratories, remote collaboration platforms, and data-driven course design, which collectively widen opportunities for experiential learning even in resource-constrained settings [8]. At the same time, South African studies caution that uneven connectivity and device access can blunt the benefits of e-learning and entrench inequality if not addressed through deliberate institutional design [5][10].

2.3 Graduate attributes and employability

Policy and strategy documents emphasize the importance of graduates who demonstrate adaptability, collaboration, and innovation, in addition to core technical competence [1][2][11][16]. Education formats that integrate vertical progression across years and horizontal links across modules help to stage the development of these attributes, while creating multiple points for reflection and feedback. Continuous improvement approaches, such as the use of Kaizen cycles within projects, offer a pragmatic way to structure reflection, tighten the link between formative evidence and redesign of student work, and cultivate habits associated with innovation practice. These mechanisms complement digital enablement by shaping the pedagogy rather than relying on tools alone.

2.4 Methodological guidance for context-sensitive evaluation

Evaluating the effect of education formats on innovation development requires attention to context and multiple forms of evidence. Case study methodology provides a coherent approach through careful bounding of the unit, time, and setting, and through triangulation of data sources that capture practice from several vantage points [12][13][14]. In digital education, evaluation frameworks emphasise alignment between learning aims, technology choice, student support, and assessment, with iterative refinement as conditions shift [15]. These considerations are especially salient in distance and blended environments where student pathways are diverse and support structures vary.

2.5 Gap addressed by this study

While international work documents mature practice-oriented frameworks and rapidly advancing digital enablement [3][4][7][8][9], South African scholarship has focused more on access and equity than on detailed design of engineering education formats that foster innovation and employability at the programme level [5][10]. There is limited empirical work that shows, within a single study, how curriculum structuring, continuous improvement practices, and technology integration interact to influence student readiness for innovation in an open and distance learning context. This study addresses that gap by analysing a specific education format that combines vertical and horizontal integration, Kaizen-based reflection, and targeted use of digital tools, and by evaluating its effects through triangulated evidence from students, documents, and observations.

3 RESEARCH METHODOLOGY

Researchers can use a range of data sources to investigate and explain a phenomenon in its context by employing the qualitative case study methodology [7]. This methodology guarantees that the phenomenon being examined is examined from a range of perspectives, enabling a comprehensive comprehension and the disclosure and comprehension of many aspects of the case being examined [7]. The research objectives are in line with the case study approach since the study's main objective is to investigate and clarify, using a thorough example, if and how the use of technology tenets of the fourth Industrial Revolution impacts and incorporate the key graduate qualities needed by industry, with the way engineers are trained to help graduates move into new careers. The contextual circumstances around the phenomenon being studied are covered by this kind of research methodology [21].

3. Research Design and Methodology

This study adopted a qualitative case study methodology to examine how an engineering education format that integrates technology influences innovation development and graduate employability. The case study approach was selected because it enables investigation of a phenomenon within its real-world context, allowing multiple perspectives and evidence sources to be integrated [12][13][14].

3.1 Research design

The study was exploratory, explanatory and descriptive in nature, consistent with Yin's categorisation of case studies [12]. It sought to explore how technology integration shapes teaching and learning practices, explain the mechanisms through which graduate attributes are cultivated, and describe the institutional context in which these processes unfold. The case was bounded by time (contemporary reforms), place (an open distance education institution in South Africa), and unit of analysis (the integration of technology into engineering education formats to support innovation readiness).

3.2 Data sources

To capture a comprehensive picture of how technology integration was shaping engineering education formats, the study deliberately relied on multiple categories of evidence. Drawing from established guidance on triangulation in qualitative case study research, the use of diverse sources was intended to strengthen credibility, reduce bias, and provide insights from institutional, instructional, and learner perspectives. This multi-layered evidence base ensured that the findings did not depend on a single narrative but reflected converging patterns across contexts. Three main data sources were used to ensure triangulation and enhance validity:

- **Document analysis and archival records:** Institutional reports, curriculum frameworks, and national policy documents were examined to identify priorities for innovation and digital learning in engineering education.
- **Field notes and observations:** Teaching and learning activities in selected engineering modules were observed, with notes capturing how technology-enabled practices unfolded in classrooms and workshops.
- **Student feedback:** Data were gathered from 42 undergraduate students across second, third, and final year cohorts, enrolled in core industrial and systems engineering modules. The group reflected the typical distribution of the department, with approximately equal representation of male and female students and a spread of ages between 20 and 25 years old. Short surveys and reflective assignments were used to capture perceptions of technology integration, its relevance to employability, and its influence on innovation-oriented learning. These responses provided both quantitative indicators and qualitative insights into how different groups of students engaged with the education format.

3.3 Data collection

Document analysis followed established qualitative procedures, focusing on identifying patterns in how innovation and graduate attributes were positioned in policy and curriculum texts. Field observations were conducted during teaching sessions that incorporated digital tools, with attention to vertical integration across years and horizontal integration across disciplines. Student data were collected through a structured survey instrument comprising both closed and open-ended questions, and through reflective essays embedded in coursework. This ensured that evidence captured both quantitative indicators (e.g., percentages of agreement) and qualitative insights.

3.4 Data analysis

Qualitative and quantitative strands of analysis were integrated to provide a balanced interpretation. For the qualitative strand, thematic analysis was employed to interpret student reflections and field notes. Open coding was used in the first cycle, followed by axial coding to identify relationships across codes. Two researchers conducted coding independently and then compared results to ensure consistency and reliability. Discrepancies were discussed until consensus was reached, thereby enhancing inter-rater validity. While coding was done manually, the process followed structured protocols similar to those supported by software such as NVivo, including iterative refinement of codebooks and memo-writing to capture analytic decisions. Quantitative survey responses were summarised descriptively and reported as frequencies and percentages, providing a complementary perspective to qualitative themes.

Documentary evidence was synthesised using content analysis, with categories aligned to institutional priorities, graduate attributes, and digital learning strategies. Cross-checking documentary findings against student and observation data provided corroboration, strengthening the dependability of results.

3.5 Methodological principles applied

The analytical process was underpinned by methodological principles from Yin [12], Creswell [13], and Patton [14]. Yin's guidance on bounding cases and triangulating data ensured coherence. Creswell's emphasis on unit, time and context clarified the scope, while Patton's holistic view of cases supported integration of multiple perspectives. Triangulation was applied not only across data sources but also across methods of analysis, increasing credibility and reducing bias. In addition, digital evaluation frameworks [15] informed interpretation by highlighting the alignment between learning objectives, technology choice, and student support. Collectively, these principles ensured that findings were trustworthy, contextually grounded, and analytically rigorous.

3.6 Ethical considerations

Participation by students was voluntary, and informed consent was obtained before data collection. Student responses were anonymised, and no personally identifying information was reported. Institutional documents were analysed only in aggregate, with no confidential material disclosed.

In summary, the methodology combined multiple data sources, rigorous thematic analysis, and established case study principles to provide a credible and transparent evaluation of how engineering education formats contribute to innovation development and graduate employability.

4 RESULTS AND DISCUSSION

Findings are presented across the three categories of evidence: student feedback, document analysis, and field observations. Collectively, these sources provide a triangulated perspective on how technology integration within an engineering education format contributes to innovation development and graduate employability.

4.1 Student feedback

A total of 42 students participated, representing second, third, and final-year cohorts. Quantitative survey data indicated that:

- 76% of respondents reported improved conceptual understanding through technology-enabled learning.

- 69% noted enhanced teamwork and problem-solving skills because of digital collaboration tools.
- 61% highlighted a stronger awareness of employability traits, particularly adaptability and communication.

Qualitative reflections reinforced these patterns. Students reported that simulation platforms, online project work, and digital collaboration improved their ability to connect theory with practice. Several students noted that iterative feedback embedded in assignments mirrored workplace practices and increased their confidence to operate in innovation-oriented environments.

4.2 Document analysis

Review of curriculum frameworks, institutional strategies, and national policy confirmed a strong emphasis on digital transformation and innovation-readiness in higher education. Documents consistently linked 4IR technologies with the need for adaptable, work-ready graduates. However, analysis also revealed that employability attributes were often stated as outcomes but not explicitly embedded in course-level assessment or activities. This finding aligned with student concerns that some digital interventions enhanced learning but did not always translate directly into employability preparation.

4.3 Field observations

Observations of workshops and synchronous online classes highlighted concrete practices of vertical and horizontal integration. In one example, digital design tools introduced in a second-year module were carried through to final-year projects, enabling progressive complexity and skill consolidation. Horizontal integration was visible in cross-disciplinary project teams, where engineering students collaborated with peers from information technology on shared digital platforms. These approaches supported deeper learning but also revealed variation in student participation, with some learners less engaged in group activities.

Kaizen principles of continuous improvement were observed in project cycles where students revised outputs based on iterative feedback. This approach fostered reflection and refinement, aligning well with innovation practices. Managers and educators (programme heads and coordinators) played a visible role in aligning modules and facilitating technology adoption, underscoring the importance of institutional support.

4.4 Integration of findings

Triangulated evidence indicates that technology integration positively influenced innovation-oriented learning and employability traits, but uneven access and inconsistent embedding across curricula limited the impact. Students with stronger digital readiness reported greater benefits, while institutional documents and observations highlighted gaps in translating policy aspirations into classroom practice. Together, the findings suggest that while the education format advanced innovation development, its effectiveness depends on both pedagogy and institutional strategy.

5 RECOMMENDATION AND CONCLUSION

The findings provide evidence that technology integration within engineering education formats enhances student learning, employability traits, and innovation readiness. This aligns with international studies that document the value of digitally enabled and practice-oriented approaches in strengthening graduate attributes [3][4][7][9]. At the same time, the study highlights context-specific challenges in South Africa, particularly uneven digital access and incomplete embedding of employability skills at the curriculum level.

5.1 Linking results to literature

Student feedback showing improvements in conceptual understanding and teamwork echoes findings from project-based learning and digital simulation research [9][18]. The observed application of Kaizen principles aligns with literature on continuous improvement in educational contexts, reinforcing its relevance for cultivating reflective learning habits. Document analysis revealed that institutional and national policies emphasise digital transformation but often stop short of operationalising employability outcomes, a gap also identified in regional scholarship [5][10][20].

5.2 Pedagogical implications

The results underscore the importance of intentional curriculum design. Vertical integration, where skills introduced early are progressively advanced, supports deeper learning and aligns with frameworks such as CDIO [3]. Horizontal integration fosters cross-disciplinary collaboration, which students reported as enhancing adaptability and problem-solving. However, observations showed uneven participation, suggesting the need for stronger scaffolding of group dynamics and digital collaboration practices.

5.3 Institutional implications

Managers and educators were found to play a key role in aligning teaching practices with institutional strategies. Their involvement is critical for ensuring consistency, providing staff development, and overcoming barriers to adoption. Institutional support also has implications for equity, as disparities in digital access risk entrenching inequalities if not proactively addressed.

5.4 Contribution to knowledge

This study extends the literature by providing an integrated analysis of how multiple elements—digital enablement, continuous improvement practices, and curriculum structuring—interact within a South African distance education context. Few prior studies have triangulated data from students, institutional documents, and field observations to capture such a holistic picture. The findings demonstrate that engineering education formats designed with these elements can promote innovation development, though effectiveness is contingent on both pedagogy and structural support.

5.5 Limitations and future research

The sample was limited to 42 students from a single institution, restricting generalisability. Longitudinal tracking of graduate outcomes would provide stronger evidence of employability impact. Future research could extend the study across institutions, examine the role of industry partnerships, and explore how advanced tools such as digital twins further shape innovation readiness.

6 CONCLUSION

This paper has examined how technology integration within engineering education formats can support innovation development and graduate employability in the context of the Fourth Industrial Revolution. Using a qualitative case study approach, triangulated evidence from student feedback, institutional documents, and field observations demonstrated that technology-enabled learning improves conceptual understanding, fosters teamwork, and cultivates reflective habits through continuous improvement practices such as Kaizen. Vertical and horizontal integration of curricula further enhanced the development of innovation-oriented graduate attributes.

The study contributes to knowledge by clarifying how education formats that combine digital enablement, continuous improvement, and curriculum structuring can create conditions

conducive to innovation readiness. It extends international scholarship by situating these mechanisms in a South African open distance education context, where structural challenges such as uneven digital access remain significant. The analysis also highlights the critical role of managers and educators in operationalising institutional strategies and supporting equity in technology adoption.

Practical implications include the need for deliberate curriculum design that embeds employability attributes, scaffolds group work and digital collaboration, and integrates iterative improvement cycles. Institutional leaders should prioritise resource allocation and staff development to ensure consistent and inclusive application of technology-enabled education formats. Policymakers should further strengthen the operationalisation of innovation-related outcomes in higher education frameworks.

The study has limitations. The student sample was modest and drawn from a single institution, restricting generalisability. Data were collected at one point in time, and longitudinal evidence of graduate outcomes is lacking. Future research should extend the analysis to multiple institutions, include larger and more diverse cohorts, and investigate the role of industry partnerships in reinforcing innovation-oriented graduate attributes. Exploring the impact of advanced digital tools such as digital twins would also provide useful insights.

In conclusion, engineering education formats that purposefully integrate technology, Kaizen-based reflection, and curriculum alignment hold promise for advancing innovation development. To realise their full potential, such formats must be implemented with institutional commitment, equity of access, and sustained collaboration between academia and industry.

ABSTRACT

Even among homes with identical designs, occupant behavior, and frequency of usage, equipment ownership influences household electricity consumption in South Africa. These variations affect the design of demand-side interventions and make short-term forecasting challenging. Therefore, a better knowledge of these dynamics is essential for enhancing localized electricity generation, planning, and energy efficiency. Using a qualitative method to examine behavioral, social, and technological aspects, the study looks into trends in home energy use. The results show that while appliance use is the main driver of consumption, user behavior and awareness have a considerable role. The choice of appliances and their level of use are significantly influenced by socioeconomic position, and there are still significant differences in energy literacy. Emerging best practices, such as the use of energy-efficient appliances and techniques, are encouraging. These findings lay the groundwork for directing focused legislative actions and encouraging sustainable household electricity use in South Africa.

Keywords: electricity; residential; optimisation; sustainability

1 INTRODUCTION

"What you cannot measure, you cannot manage." – This frequently cited management maxim is especially applicable to residential settings, because usage patterns vary as much as the households. It has never been more crucial to comprehend consumption patterns in South Africa, where home electricity use is a major contributor to the country's energy demand, and energy security is a recurring problem. In addition to being technically complex, the problem is also highly behavioral and sociological.

The necessity of comprehending how, when, and why families use power has been highlighted by recent load shedding incidents and ongoing energy supply challenges in South Africa [1]. The quantity and kind of electrical appliances in a home vary greatly, and their use is influenced by semi-random and context-specific patterns, even while building types are similar [2]; [3]. Particularly at fine time scales like hourly intervals, these fluctuations add to the unpredictability of residential electricity usage [4].

Through a qualitative lens, this research examines these variances and provides a more comprehensive picture of electricity consumption than just kilowatt-hours. The study places more emphasis on households' actual experiences choosing, utilizing, and incorporating appliances into everyday routines than it does on statistical or engineering models. National energy models have benefited greatly from the use of quantitative methods [5], but these methods frequently ignore important social factors that influence electricity consumption, such as household size, cultural customs, income levels, and the accessibility of alternative energy sources [6], [7].

Prior research has demonstrated that a complex interaction of behavioral, technical, and socioeconomic factors affects home electricity usage [10]; [11]. We still don't fully understand how these factors show up in South African homes, though, especially when it comes to appliance usage trends and domestic decision-making procedures. By examining the qualitative variations that underlie household power usage patterns, this article helps close that gap.

In order to identify important patterns and deviations that can guide energy policy, on-site electricity generating techniques (such as rooftop solar), and focused energy efficiency programs, the research looks at houses with comparable physical forms but different energy profiles. It also identifies the fundamentals required to create more flexible, human-centered electricity usage models that capture the dynamic, situational aspects of everyday life in the home.

The following sections of the paper provide the qualitative approach, examine the main themes that emerged from household case studies, evaluate pertinent literature on domestic energy usage, and outline implications for South African energy planning and policy. By using this method, the study not only advances our knowledge of how much electricity is used in homes but also offers practical advice for creating a more resilient and sustainable energy future.

2 LITERATURE REVIEW

Understanding household electricity consumption in South Africa is a critical area of study due to its implications for national energy policy, infrastructure planning, and sustainable development. The literature in this domain spans socio-economic, technical, and behavioural dimensions, reflecting the complexity of electricity consumption patterns in residential contexts. South Africa's residential sector is a significant consumer of electricity, accounting for approximately 17% of the national electricity demand [8].

The country’s historical emphasis on coal-based energy supply, coupled with high electrification rates since 1994, has led to wide disparities in access and usage patterns [3];

[9]. The Integrated Resource Plan (IRP 2019) acknowledges these disparities and emphasizes the need for demand-side management and the promotion of energy efficiency. A substantial body of research identifies key determinants of household electricity use, i.e., Socio-economic factors, Appliance ownership and usage, Behavioural and cultural practices, and Energy pricing and subsidies.

Income level, education, household size, and dwelling type strongly influence electricity consumption [7]; [12]. Higher-income households tend to use more electricity due to increased ownership of appliances and higher comfort expectations (Louw et al., 2008). The type and number of appliances owned by households significantly affect consumption patterns. Even in homes with similar physical characteristics, usage patterns vary due to behavioural differences and appliance efficiency [4]; [13].

The temporal pattern of usage, when and how appliances are used, is shaped by daily routines, cultural practices, and perceptions of electricity cost [6]; [17]. For example, heating and cooking habits vary between urban and rural households, influencing electricity demand profiles. Tariff structures and government subsidies (such as Free Basic Electricity) influence consumption behaviour, especially among low-income households [15]. Households with limited access to subsidized electricity often resort to fuel stacking, where electricity is used in combination with other fuels such as paraffin and wood [16].

Several studies examine geographic and temporal trends in electricity use. These include Urban vs rural, in which Urban households tend to consume more electricity due to better infrastructure and access to a wider range of appliances, while rural areas show more reliance on alternative fuels [7]. Temporal variability studies show that electricity usage varies by season, time of day, and day of the week [4]; [5]. Winter months see higher demand due to heating needs, while peak demand periods often align with cooking and bathing times.

Post-electrification effects show that electrification has not always led to increased consumption; instead, in many cases, electricity is used selectively and supplemented with traditional fuels, particularly in lower-income communities [12], [9]. Research has also focused on strategies to reduce residential electricity demand, and together with post-electrification, issues of energy efficiency, and on-site electricity generation, studies outcomes shown insignificant success in terms of improved energy efficiency.

Appliance labelling, energy-saving campaigns, and efficient lighting programs have been introduced with varying levels of success [17]; [18]. However, the uptake of energy-efficient technologies remains limited in lower-income households due to affordability barriers. The increasing adoption of solar photovoltaic systems in middle- and high-income households has the potential to offset grid consumption and reduce pressure on the national grid [19]. However, the financial and technical barriers to entry remain significant for most South Africans.

Much of the existing work relies on quantitative models that often fail to capture the social and contextual realities of electricity use [19]; [10]. While statistical models are valuable for large-scale predictions, they overlook the complexity of household behaviour, cultural nuances, and the significance of informal practices. Recent calls have advocated for mixed-method or qualitative approaches that offer richer, more contextualised understandings of electricity use patterns [7]; [20].

Despite a wealth of data and analysis, several gaps remain. There is limited insight into the influence of digital technologies and smart appliances on consumption behaviour in South African households. These are longitudinal studies that track changes in consumption patterns over time, particularly in the context of economic shocks and energy transitions. Granular data collection at sub-hourly intervals to better understand intra-day variability and the

potential for demand response. Furthermore, more research is needed on the intersection between electricity consumption and issues of gender, health, and education, especially in underserved communities.

An emphasis on the objective of the study alignment is deliberated to ensure clarity of the purpose of the study and the envisaged outcomes. In deliberating on objective 1, it is apparent that residential demand in South Africa is diverse and influenced by temporal routines, housing characteristics, and appliance stockpiles. Although the residential sector accounts for a significant portion of demand, both national and sectoral analysis also highlight significant within-segment variance that is hidden by simple averages (Bekker et al., 2008; Inglesi-Lotz & Blignaut, 2011).

Studies conducted globally show that even homes with comparable envelopes vary greatly because to differences in ownership patterns, appliance efficiency, and episodic rather than continuous usage (Yohanis et al., 2008; Santin et al., 2009). Micro-studies conducted in South Africa support this: nighttime peaks in urban areas are anchored by appliance density and geyser use, whereas prepaid meter-related bursts in rural and peri-urban profiles are sharper and credit-constrained (Louw et al., 2008; Naicker & Thopil, 2020).

In the literature reviewed that supports objective 2, it is observed that numerous studies have established a connection between consumption and urbanicity, household size, income, and education (Madubansi & Shackleton, 2006; Prasad, 2006). The affordability frontier and, consequently, the intensity of usage are further shaped by tariff design, prepayment metering, and subsidies (e.g., Free Basic Electricity) (Winkler et al., 2011; Department of Energy, 2018).

Price elasticity, however, does not adequately account for behavior: time-use patterns, comfort standards, and gendered divisions of household labor influence when and how electricity is drawn (Mohlakoana & Annecke, 2009; Chambers & Momberg, 2021). International syntheses demonstrate that literacy and feedback affect behavior change, while the effects vary according to salience and context (Darby, 2006; Wilson & Dowlatabadi, 2007).

In many other related objectives of this type of study, which are not deliberated in this research report. Objectives such as Examine how pricing, subsidies, and energy poverty affect the decisions people make about fuel and appliances. Findings show that despite high electrification rates, there is evidence of ongoing energy poverty; people employ fuel stacking, electricity plus paraffin, wood, and gas to manage risk, especially when prices are high or the supply is unstable (Madubansi & Shackleton, 2006; Matsika et al., 2013).

Another objective related to this research is the analysis of new developments in distributed generation and energy efficiency, as well as adoption obstacles. Literature makes it apparent that the analysis of new developments in distributed generation and energy efficiency, as well as adoption obstacles, is characterized by high variability. Although South Africa has made strides in lighting programs, labels, and standards, adoption is still inconsistent because of upfront expenditures, informational barriers, and a lack of confidence (Winkler et al., 2011; Bohlmann, Bohlmann, & Inglesi-Lotz, 2019).

Rooftop PV and solar water heating are becoming more popular among middle- and upper-class consumers, providing peak shaving and load-shedding resilience, although they are still more expensive for low-income users (Eberhard, Kolker, & Leigland, 2017; Wolski, Hughes, & Reinecke, 2022). Although they are recorded, household-level best practices such as time-shifting, gas and electric hybrid cooking, efficient lighting, and geyser timers are not regularly measured (Naicker & Thopil, 2020).

Although South Africa has made strides in lighting programs, labels, and standards, adoption is still inconsistent because of upfront expenditures, informational barriers, and a lack of confidence (Winkler et al., 2011; Bohlmann, Bohlmann, & Inglesi-Lotz, 2019). Rooftop PV and

solar water heating are becoming more popular among middle- and upper-class consumers, providing peak shaving and load-shedding resilience, although they are still more expensive for low-income users (Eberhard, Kolker, & Leigland, 2017; Wolski, Hughes, & Reinecke, 2022).

Although they are recorded, household-level best practices such as time-shifting, gas and electric hybrid cooking, efficient lighting, and geyser timers are not regularly measured (Naicker & Thopil, 2020). Literature demonstrates that household electricity consumption in South Africa is shaped by a dynamic mix of socio-economic, behavioural, and technical factors. While foundational studies have illuminated key trends and determinants, there remains a pressing need for deeper, context-specific insights, particularly through qualitative research, to inform policy, infrastructure design, and demand-side interventions. Future research should aim to integrate behavioural data with technical models to foster a holistic understanding of electricity consumption in a transitioning energy landscape.

3 RESEARCH METHODOLOGY

This study adopts a qualitative research design, grounded in the interpretivist paradigm. The interpretivist approach is appropriate for understanding how and why households in South Africa consume electricity in varied and sometimes unpredictable ways. Unlike positivist approaches that seek to generalize behaviour based on numerical data, interpretivism emphasizes the subjective meanings that individuals attach to their actions and decisions [21]. This philosophical orientation enables the exploration of lived experiences, contextual influences, and the complexity of domestic energy behaviour in South Africa.

The complexity of domestic energy behaviour in South Africa's diverse socio-economic settings is reflected upon through the theoretical framework that draws on practice theory [22], [23]. A theory that conceptualizes energy consumption not merely as an outcome of individual choices or technical factors, but as embedded in everyday social practices such as cooking, bathing, heating, and entertainment. Practice theory provides a lens to examine how electricity use is shaped by routines, norms, appliance availability, and infrastructure.

The study seeks to identify patterns and variations in household electricity consumption. It explores socio-cultural, behavioural, and contextual factors influencing electricity use and develops insights to support energy efficiency interventions and policy design in South Africa. To improve the quality of data collected for the study, the study was conducted in three provinces in South Africa, Gauteng, KwaZulu-Natal, and the Eastern Cape, chosen to reflect urban, peri-urban, and rural contexts with differing levels of electrification, socio-economic status, and climate.

A purposive sampling strategy was employed to select 30 households across the three regions. Households were selected to capture diversity in income levels, housing types, electricity access, appliance ownership, and cultural practices. Purposive sampling ensures that data are rich, relevant, and theoretically meaningful [24]. The sample included 10 urban households with full-grid access and high appliance density, 10 peri-urban households with partial electrification or hybrid energy sources, and 10 rural households, some of which use pre-paid electricity meters or combine electricity with traditional fuels.

Research Method

Thirty households from a variety of socioeconomic, demographic, and geographic backgrounds in South Africa were chosen for this study using a purposive sample technique. Because the study's goal is to reflect the variety of lived experiences and variances in home power use patterns rather than statistical generalization, purposeful sampling was selected. In qualitative research, where depth and richness of data are valued more than breadth, a sample size of thirty is appropriate (Creswell, 2014; Yin, 2018). Families were chosen to represent diversity in several important areas:

- Socioeconomic standing (groups with low, middle, and high incomes).
- Geographic distribution (rural, peri-urban, and urban areas).
- Types of residences (formal, apartment, and informal).
- Household composition (single-occupant versus multigenerational households).

The sample is guaranteed to include both similarities and differences in appliance ownership, usage patterns, and energy management techniques thanks to this planned variety. The study avoids bias towards a specific socioeconomic or spatial setting by incorporating several household types, hence offering a more comprehensive picture of electricity usage trends. By guaranteeing that insights are not restricted to a homogeneous sample but rather represent the complexity of household energy consumption in South Africa, the methodology enhances the validity of the findings.

Stratified purposive sampling was used to guarantee variety and representation among the 30 houses in the sample. Two primary factors were used to stratify the sample: household income levels (low, middle, and high) and geographic location (rural, peri-urban, and urban). This guarantees that the sample reflects the socioeconomic and regional variability of South African homes, which are known to have a significant impact on patterns of power use (Inglesi-Lotz & Blignaut, 2011; Tewari & Shah, 2003).

In order to balance representation across various contexts, the sample matrix (seen in Figure 1) dispersed homes throughout nine strata. As evidenced by national surveys, the overrepresentation of urban high-income households in comparison to rural middle-income households reflects actual demographic distributions and differences in appliance ownership (StatsSA, 2022). Because it takes into account differences in lifestyles, appliance ownership, and energy practices, this approach lessens selection bias and improves validity (Madubansi & Shackleton, 2006).

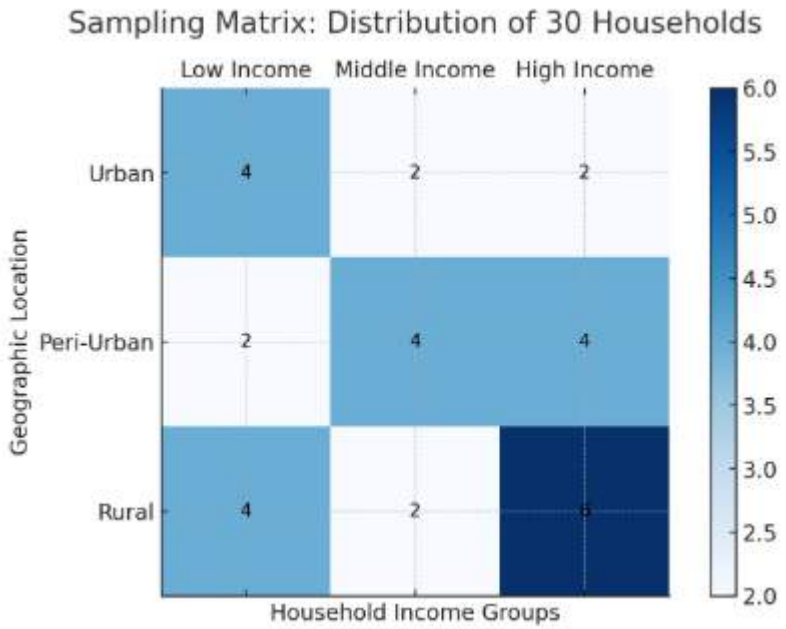

Figure. 1: Sampling Matrix (Geographic vs Income) (By Author)

Data Collection Methods

Data were collected through semi-structured interviews, household energy diaries, and direct observation over a six-week period. Semi-structured interviews (45–60 minutes each) were conducted with adult household members responsible for managing electricity usage. The interviews explored themes such as appliance use, energy-saving behaviour, seasonal variations, cost awareness, and experiences with load shedding. Energy diaries were kept by each household for a period of one week to log daily appliance use, time of use, and purpose. This method offers detailed insight into actual behaviour and temporal patterns (Hitchings, 2012). Observational visits were used to verify appliance ownership and usage practices. These visits helped triangulate self-reported data and revealed informal or unanticipated practices (e.g., use of extension cords, appliance sharing, or hidden appliances).

Data Analysis Approach

Data were analysed using thematic analysis, following [26]'s six-phase approach, i.e., Familiarization with the data, Generating initial codes, Searching for themes, Reviewing themes, Defining and naming themes, and Producing the report. Software was used to manage and code the data systematically. Emerging themes were cross-validated against existing literature on domestic electricity consumption, energy poverty, and appliance usage trends.

Key themes included, to capture the complexity of household behaviour, cultural nuances, and the significance of informal practices, are economic coping strategies (e.g., appliance rationing, switching fuels), gendered use of electricity (e.g., division of domestic tasks), influence of housing type and meter configuration, behavioural responses to load shedding and rising costs, and perceptions of energy efficiency technologies. These qualitative research tools offer a richer, more contextualised understanding of electricity use patterns [6], [26].

Ethical clearance was obtained from the relevant institutional ethics committee. All participants gave informed consent, and confidentiality was maintained through anonymization. Data were stored securely and used only for research purposes. While the study does not aim for statistical generalization, its strength lies in the depth and richness of contextual understanding, which is essential for policy and intervention design in heterogeneous settings like South Africa. A qualitative approach is particularly justified in this case because the goal is not just to measure consumption.

But the goal is to understand the meaning and reasoning behind consumption patterns, a task ill-suited to purely quantitative models [27]. Moreover, the choice of multiple methods of data collection (interviews, diaries, observation) improves data triangulation and credibility [28]. The study design builds directly on recommendations in the energy literature that call for integrating behavioural and social perspectives into energy research [29].

4 RESULTS

This section presents the key findings from the qualitative investigation into household electricity consumption trends in South Africa. Data collected from 30 case study households across urban, peri-urban, and rural settings were analyzed thematically. The findings are organized around four emergent themes: (1) Appliance Use and Consumption Patterns, (2) Socio-Economic and Contextual Drivers, (3) Adaptive Behaviour and Coping Mechanisms, and (4) Perceptions of Energy Efficiency and Sustainability. Each theme is discussed in light of the study's theoretical framing, particularly practice theory and current literature. The section also highlights capability gaps and emerging best practices.

Across all household types, electricity consumption was strongly linked to the type, number, and usage patterns of appliances, consistent with findings from [25] and [20]. Households in urban areas displayed higher appliance density, including high-energy-use devices such as electric stoves, geysers, microwaves, and entertainment systems. In contrast, rural

households exhibited lower appliance penetration but still demonstrated spikes in consumption related to seasonal appliance use (e.g., heaters in winter).

Urban households showed a daily peak demand between 6–9 PM, coinciding with cooking, heating water, and evening entertainment, highlighting a strong alignment with [22]'s concept of bundled practices occurring within fixed temporal rhythms. Peri-urban and rural households, many using pre-paid meters, exhibited erratic consumption patterns shaped by the availability of credit and load-shedding schedules. Appliances were often used intermittently to manage cost, revealing the flexibility and fragility of energy use practices in lower-income areas.

Household income levels, dwelling types, and the structure of energy tariffs in the particular city or municipality demarcation were key contextual factors influencing electricity usage. Many low-income households adopted non-electric alternatives, such as paraffin, coal, or wood for cooking and heating, due to rising electricity prices. This confirms earlier findings by [27], who noted that energy decisions are shaped by affordability and access more than preference.

The study also found that subsidies and tariffs, such as Free Basic Electricity (FBE), had only a limited effect on reducing household energy vulnerability. While FBE temporarily buffered the poorest households from disconnection, it was insufficient to support meaningful energy access, particularly in larger households or those with more appliances. This finding resonates with research by [29], who argued that FBE overlooks intra-household needs and usage diversity. Thus, subsidies were found to have little to insignificant impact on energy decisions.

Many participants described engaging in adaptive behaviors in response to financial constraints, unreliable supply, and seasonal variations in electricity demand. These adaptive behaviors included, amongst others, the staggered use of appliances to reduce peak loads, load-shedding preparedness, including the use of candles, gas stoves, and battery-powered lights. Appliance-sharing practices between households, particularly in peri-urban settings, and electricity budgeting, where household members closely monitored pre-paid meter usage and reduced non-essential appliance use.

These adaptive behaviors illustrate what [22] describe as the recruitment and defection from practices, where individuals dynamically modify their routines in response to socio-material constraints. The implication is that electricity consumption is not fixed, but fluid and responsive, conditioned by multiple overlapping influences. Across the sample, there was limited awareness of energy efficiency technologies, despite a strong interest in cost-saving measures. Only a few urban households had adopted energy-saving bulbs, solar water heaters, or time switches for geysers.

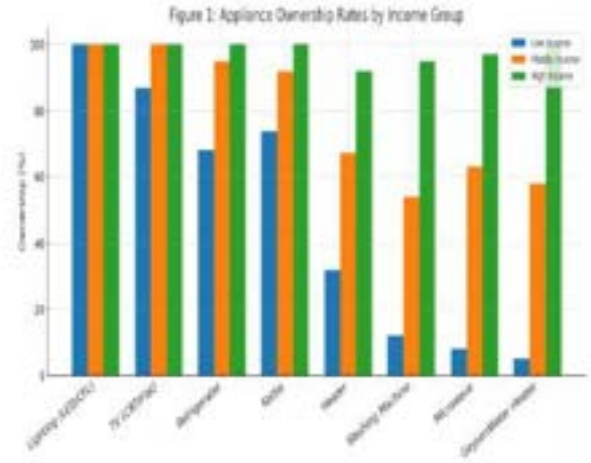
Knowledge gaps and high upfront costs were the most cited barriers, even among those expressing environmental concerns. However, an emerging best practice was noted in several urban and peri-urban households that adopted hybrid energy solutions, e.g., combining grid electricity with gas for cooking or solar for lighting. These households reported greater resilience during load-shedding and improved control over energy expenses. This aligns with best practice recommendations from [25] on the value of distributed generation and mixed-energy strategies in enhancing energy resilience.

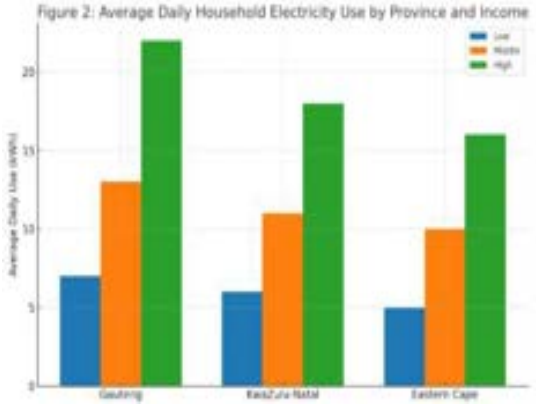
Capability gaps identified through this study include low technical literacy about appliance consumption and energy-saving behaviors. Inadequate feedback mechanisms on energy use, especially with pre-paid meters that lack historical data displays. Limited policy responsiveness to user realities, particularly in tailoring FBE allocations or incentivizing appliance efficiency. Conversely, emerging best practices include community-level knowledge exchange, where neighbors informally share strategies for reducing electricity bills.

Drawing from practice theory, the findings reinforce the view that energy consumption in South African households is socially organized, materially constrained, and shaped by daily routines, not merely by economic rationality or individual decision-making (Table. 1&2). The study challenges techno-economic models that isolate appliance use from context, advocating instead for integrated, human-centred interventions. Importantly, the data show that electricity consumption is not just a technical issue, but a social and infrastructural process that reflects broader inequalities in housing, access, and services.

Table. 1: Energy Usage per Appliance Ownership

Table. 2: Average Daily Household Energy usage per province





Recognizing this, energy policy in South Africa must shift from supply-side management to demand-side engagement that reflects everyday practices and user capabilities. Electricity consumption trends in South African households are shaped by a dynamic interplay of appliance availability, socio-economic conditions, behavioural adaptations, and infrastructural limitations. Practice theory offers a powerful lens to interpret this complexity, revealing that consumption patterns are embedded in everyday routines and shaped by both material and social contexts.

5 DISCUSSION

The findings of this study highlight the multifaceted and deeply contextual nature of household electricity consumption in South Africa. Building on the themes presented in the results section, this discussion integrates the findings with the practice theory framework, while drawing out broader implications for policy, energy planning, and household behaviour change. This section further elaborates on how the study advances understanding of domestic electricity trends in South Africa, identifies systemic challenges, and highlights scalable innovations.

The analysis challenges the conventional understanding of household electricity use as a predictable, economically driven function of appliance count and technical efficiency. Instead, as [22] argue, electricity consumption must be understood as a product of social practices, embedded within routines, meanings, and infrastructures. For example, the widespread evening peak in usage was not just about electricity demand but about bundled domestic activities (cooking, bathing, leisure) that occur in specific temporal patterns.

Despite improvements in grid connectivity, energy poverty persists, especially in rural and peri-urban areas. The Free Basic Electricity (FBE) policy, designed to ensure equitable access, was shown to be both insufficient and inconsistently applied, echoing earlier criticisms [27], [6]. Households with larger family sizes or many dependents often exhausted their FBE

allocation within a few days, forcing them to either revert to unsafe fuels or reduce essential electricity use.

This points to a key capability gap, that access to electricity does not guarantee the capability to use it meaningfully or safely. Here, [26]'s concept of capability deprivation becomes relevant, highlighting that the real value of electricity lies in what it enables households to do, not merely in access. Without addressing affordability, appliance accessibility, and infrastructure quality, true energy justice remains elusive. One of the most significant findings is the extent to which South African households, especially in low-income settings, are engaging in adaptive and resilient behaviours to navigate a volatile energy landscape.

The volatile settings are marked by load shedding, high tariffs, and limited technical literacy, and the adaptive behaviours include informal knowledge-sharing, time-shifting of energy use, energy rationing, and hybrid energy use. These practices demonstrate the agency and innovation of households in managing their energy needs, even when formal systems fall short. This has important policy implications: rather than solely focusing on top-down efficiency programs or grid reliability, there is value in supporting grassroots innovations and localized energy solutions (e.g., subsidizing low-cost solar lighting or facilitating community appliance-sharing programs).

The findings point to the need for more differentiated, responsive policy tools that reflect household diversity. A one-size-fits-all model, such as flat FBE allocations or general appliance rebate programs, fails to account for the wide variation in household composition, income, climate, and usage patterns. There is a case for contextualized energy policy, informed by ethnographic and qualitative insights, and supported by fine-grained data from mixed-methods research. For instance, tariff structures could be reformed to better reflect actual consumption needs and seasonal variations.

The lack of real-time feedback on electricity usage emerged as a key constraint. Households using pre-paid meters often lacked historical data or visibility into which appliances contributed most to usage spikes. This limits households' ability to make informed decisions about reducing consumption. This aligns with international findings [29] that show how feedback systems, like in-home displays, mobile apps, or smart meters, can significantly shift behaviour when combined with actionable insights.

This study contributes to the South African and global literature by demonstrating how qualitative, practice-oriented approaches offer richer, more nuanced understandings of electricity consumption. The integration of interviews, energy diaries, and observation offers methodological robustness and allows for triangulation of data. Moreover, situating the analysis within practice theory allows researchers and policymakers to move beyond techno-centric views and consider the social, material, and temporal dimensions of energy use.

6 CONCLUSION

The goal of this study was to determine patterns in South African household power consumption, paying special emphasis to the ways that demand is influenced by differences in appliance ownership, usage patterns, and household income among three provinces. The results demonstrate that the kind and intensity of appliance use, which in turn reflects socioeconomic situations, significantly influences household energy use in addition to built environment factors.

It is therefore apparent that household electricity consumption in South Africa is not simply a matter of access or technology, it is a dynamic interplay of socio-economic, cultural, behavioural, and infrastructural factors. Through the lens of practice theory, this study reveals the complexity and richness of domestic energy use, offering new insights into how and why households consume electricity the way they do. To address South Africa's domestic energy

challenges, policies must be nuanced, inclusive, and responsive to the realities on the ground. By acknowledging the centrality of everyday practices and by empowering users through knowledge, tools, and flexibility, the country can foster a more equitable, efficient, and resilient energy future. The study emphasizes the need for a sophisticated perspective that incorporates technical appliance profiles and socioeconomic diversity in order to comprehend energy demand at the household level. In order to create responsive energy policies, direct home efficiency initiatives, and aid South Africa's larger shift towards sustainable and equitable energy systems, it is imperative that the body of evidence at this level be strengthened.

As South Africa grapples with energy insecurity, climate commitments, and socio-economic inequality, this research underscores the need for an inclusive energy transition, one that considers not only infrastructure and supply but also everyday practices, user capabilities, and local innovation. By identifying capability gaps and highlighting scalable best practices, this study provides a roadmap for more human-centred and resilient energy systems. Supporting low-income households in adopting energy-efficient behaviours and technologies, while ensuring policy responsiveness to diverse needs, is not just an energy imperative, it is a social justice initiative.

ABSTRACT

This study highlights the optimization of a 4IR digital newspaper processing system, Technology-Assisted Intelligent Processor (TAiP), to tackle late publication due to high volumes. Failure to address such delays leads to dissatisfied stakeholders initiating litigation against the print company, thus leading to financial losses, resource strain, and damaging its reputation. TAiP is a Robotic Process Automation (RPA) tool designed to optimize processing times by mimicking human processing, utilizing pre-defined and rule-based algorithms. Its Assisted Intelligence (AI) is powered to accelerate production, while human oversight ensures accuracy and adaptability. The implemented solution enabled customer satisfaction and addressed issues of resource constraints by ensuring on-time publication. Efficiency gains include 0% improvement in document review, a 100% reduction in data entry time, and a 33.33% efficiency boost in quality assurance. This study emphasizes the potential of AI-driven automation in administrative processing, emphasizing its role in improving operational outcomes and service quality.

Keywords: Process optimization, Robotic Process Automation, Assisted Intelligence, Scalability, Quality Assurance

1 INTRODUCTION

In the era of the Fourth Industrial Revolution (4IR), the use of assisted artificial intelligence in operational processes has become a critical driver of efficiency, scalability, and process optimization. Assisted AI is defined as a technology that enhances productivity by supporting human innovators with tasks that catalyze creativity and by evaluating their problem-solving abilities [23]. It has demonstrated a potential for improving productivity within organizations [24]. Furthermore, it helps in detecting potential risks that might occur in production at an earlier stage [25].

Despite these advancements, many sectors still rely on manual processes, which often result in various challenges such as poor decision-making, inaccuracies, errors, and scalability issues. These issues lead to less efficient and more resource-intensive operations. One of the South African print industries faced challenges in publication delays due to an increase in the high volume of article submissions, resulting in financial losses, strained resources, and damage to reputation. Therefore, by implementing an assisted artificial intelligence system, the print company could improve the operation speed. This study examines the implementation of a Technology Assisted Intelligent Processor (TAiP) within a digital newspaper publishing system to streamline the editorial workflow. The goal of the study was to assess the effectiveness of TAiP as a 4IR process optimization tool. The secondary objectives include evaluating its impact on data entry efficiency, quality assurance turnaround time, and the overall publishing cycle. The author selected this topic due to a professional interest in digital transformation within the media industry, where innovation is critical to survival in a saturated information economy.

This research utilizes a qualitative case study approach, supported by a comparative analysis of operational metrics before and after the implementation of TAiP. Data was collected from internal system logs, process observations, and stakeholder interviews to assess changes in performance across the editorial workflow.

The remainder of this paper is organized as follows: Section 2 presents the literature review. Section 3 details the implementation of TAiP. Section 4 provides the findings and results. Section 5 presents the limitations of the study. Finally, Section 6 offers the conclusion, while Section 7 presents recommendations.

2 LITERATURE REVIEW

2.1 Intelligent Automation for Workflow Optimization

Automation technologies provide the foundation of innovations such as TAiP, with rule-based execution of tasks that imitate human control with efficiency at scale. [1] Suggest a CI/CD-style publishing framework that maximizes cooperation and reduces publication latency via ordered automata. [2] displays that intelligent publishing models are able to enhance conventional media loops to make them more responsive.

Additional advancements are reported by [3], with a suggestion to standardize editorial processes to simplify operations and eliminate errors. [4] and [5] provide us with scalable workflow architectures, such as XML-based pipelines, that are easily integrated with current IT infrastructure; an essential requirement for TAiP systems. Both studies affirm that automation increases throughput, minimizes turnaround time, and paves the way for intelligent process tools in publishing.

The 4IR has created revolutionary transformations by combining intelligent systems and automating technologies. One of the key drivers of optimizing high-volume workflows, especially within administrative contexts, is Robotic Process Automation (RPA). As [6] noted, RPA simulates human-to-machine and machine-to-machine interactions by applying algorithms

based on pre-set rules, providing operational effectiveness and minimizing errors. Figure 1 illustrates the typical workflow of RPA within digital systems.

Table 1: ***RPA Workflow in High-Volume Environments***
(Source: Van Dijck et al., 2020)

Stage	Description
Input Processing	Data and documents are captured.
Rule-Based Execution	Specific algorithms execute tasks.
Quality Assurance	Human oversight ensures accuracy.
Output Delivery	Optimized results are provided.

This process closely resembles the fundamental operations of TAiP, maintaining its position as a niche RPA solution designed specifically for operations in the publishing of newspapers.

2.2 Challenges in Automation

Although TAiP showcases immense promise, incorporating RPA systems within current workflows is not without limitations. [3] see change management and the integration process complexity as impediments to widespread adoption.

Equation 1: Characterizes the cost-effectiveness of the automations in comparison to initial cost.

Where:

$$Return\ on\ Investment\ (ROI)\ = \left[\frac{Total\ Savings\ from\ Automation}{Initial\ Cost\ of\ Implementation}\right] \quad \textbf{(1)}$$

Reduction in operational costs over time = (Return on Investment)(Total Savings from Automation)

2.3 AI and Machine Learning for Assisted Intelligence:

TAiP's underpinnings in Assisted Intelligence are consistent with wider applications of AI within content personalization and operations augmentation. [7] Demonstrate that AI increases responsiveness by automating news coverage and personalized dissemination. Aram and [8] identify that AI-based engagement tools enhance user satisfaction, just like TAiP expands back-end processing to fulfill stakeholder expectations.

[9] Explains AI's effectiveness in real-time content analysis and user profiling, reflecting TAiP's dynamic adaptability of rule-based processes. [10] Further explains AI's extent in day-to-day journalistic duties like transcription and data cleansing, reflecting upon how humans and machines consolidate to make processes faster in bulk settings. Such discoveries affirm AI's capability to hasten processes without compromising quality assurance, a signature element of TAiP.

2.4 Strategies of Digital Transformation and Service Responsiveness:

Integrating TAiP within back-end newspaper systems reflects more general patterns of digital change where timeliness and efficiency are key. Furthermore, examples are provided by [11] and by [12] explaining the way transformed operations and reskilling staff generate responsiveness within print-to-digital shifts. [13] Offers an enterprise example of Axel Springer embracing digital technologies to enhance market responsiveness, and [14] charts the effect of data-driven strategies at The New York Times.

[15] Call special attention to workforce commitment and digital skill, underpinning TAiP's framework that involves human supervision of quality assurance. Such viewpoints underscore that improved publishing performance in real time relies upon collaborative models that supplement software with human adaptability.

2.5 4IR Technologies and Scalable Integration:

TAiP is a prime example of intelligent and scalable integration over current infrastructures, an approach not seen in recent 4IR literature in publishing. Such integration is, however, advocated by a framework of big data governance and AI ethics of [16]. Core AI functions (e.g., NLP, optimization) that form the basis of TAiP's architecture and algorithms are categorized by [17]. The Fourth Industrial Revolution (4IR) has transformed publishing by integrating cyber-physical systems with intelligent automation [18]. Local governments in South Africa have embraced 4IR technologies to counter service delivery inefficiencies, reflecting the general use of automation in resource-poor settings. Digital publishers are also presented with issues related to time-consuming manual processing bottlenecks, leading to such publications not being made available in a timely manner, a situation that demands scalable measures like TAiP [20]. Examples like, Adresseavisen and Forbes show that the integration of modular AI systems within established IT infrastructures enhances workflow efficiency without compromising editorial standards [21]. In the absence of direct literature specifically addressing IoT or cloud applications in publishing newspapers, such research indicates a direction towards TAiP-type systems that integrate several 4IR technologies. This leaves an essential research direction to analyze intelligent processors within larger digital ecosystems.

2.6 Conceptual Framework

The research conceptualizes TAiP within a logical-functional model defined as:

$$RPA_{output} = f(I, R, T) \quad \textit{(2)}$$

Where:

I_I = Input data (documents).

R_R = Set of pre-defined rule-based conditions for document processing (Sorting except those with submission type of Failed Submission, Payment Allocation, Update Notice Submission, Cancel Notice Submission, SPAM Notice Submission).

T_T = Automated tasks (processing).

The rules are further represented as:

$$R = \{(c_1, a_1), (c_2 a_2), \dots (c_n, a_n)\} \quad \textit{(3)}$$

Where each condition c_i triggers an associated task a_i.

3 METHODOLOGY

This study uses the Design Science Research (DSR) approach outlined by [22] to create, construct, and evaluate the Technology-Assisted Intelligent Processor (TAiP), a rule-based Robotic Process Automation (RPA) tool. DSR was chosen to stress iterative design and rigorous evaluation of socio-technical artifacts that address real-world problems in organizational environments. The goal was to optimize operational workflows in a high-volume digital newspaper production system, focusing on challenges such as publication delay, resource restrictions, and service quality. The DSR method consisted of three main phases: (1) problem

identification and objective definition, (2) artifact design and development, and (3) demonstration and evaluation.

3.1 Artifact Design and Development:

TAiP was designed to mimic human processing behaviours using rule-based algorithms. It integrates with existing IT infrastructure and is equipped with an Assisted Intelligence (AI) capability to enable real-time adaptability.

The implementation followed a four-stage RPA process:

3.1.1 Stage 1: Input Processing:

Input processing was managed by a mail sorter using ETL (Extract, Transform, Load) techniques to extract information from incoming digital forms. It filtered and routed content into structured processing queues based on predefined document schemas. At this stage, data integrity checks and spam filters were also applied to ensure clean and reliable input.

3.1.2 Stage 2: Rule-Based Execution:

TAiP performed document processing utilizing deterministic logic based on operational rules. Figure 1; shows a pseudocode version of this logic. The rule engine processed structured content autonomously, eliminating the need for human judgment and maintaining 100% consistency for compliant inputs.

```
submission_types = []

for i in Articles:
    if submission_types[i] == "new submission":
        CloseTask()
    else:
        pass  # Remain in Sorting

def CloseTask():
    MoveToQueue()
    if numberOfSubmissions > 0:
        Priority = "TAip"
    else:
        raise Exception("FAILS")
```

Figure 1: A pseudocode logic driving TAiP automation outlining input rules used in the execution of TaiP.

3.1.3 Stage 3: Quality Assurance

While TAiP handled deterministic processing, human Quality Assurance (QA) was retained to evaluate ambiguous outputs, formatting issues, and content requiring contextual or creative intervention. This hybrid human-in-the-loop model ensured output validity while optimizing processing time.

3.1.4 Stage 4: Output Delivery

To assess TAiP's impact on operational performance, a structured comparative analysis framework was employed. This involved gathering both pre-implementation and post-implementation data across critical dimensions of output delivery, with a particular emphasis on process optimization. Key elements included:

- Time Efficiency Tracking: Measurement of average time per document for data entry, review, and quality assurance tasks.
- Cost Comparison: Analysis of overtime expenditure to quantify cost-saving outcomes driven by automation.
- Quality Monitoring: Evaluation of QA effort and error reduction to ensure that speed did not compromise accuracy.
- Risk Exposure Mapping: Identification of legal, financial, reputational, and operational vulnerabilities before and after TAiP deployment.

The data was sourced from operational logs, financial reports, legal records, and stakeholder feedback, allowing for a multidimensional view of TAiP's effects.

Process optimization was central to this analysis. Particular attention was given to:

- Workflow automation through TAiP's rule-based logic engine, which eliminated repetitive manual tasks like data entry.
- Real-time human oversight, ensuring quality assurance while maintaining throughput speed.
- Load distribution enhancements, which reduced bottlenecks and balanced task intensity without increasing labour inputs.

3.2 Evaluation Design

The artifact was evaluated over a six-month deployment in a live production environment at a national newspaper publisher. The evaluation criteria included:

- Document Review Time
- Data Entry Time
- Quality Assurance Time
- Monthly Overtime Costs
- Publication Deadlines Met
- Stakeholder Satisfaction (Qualitative Survey)

Baseline data (pre-TAiP) were compared with post-implementation performance using a comparative analysis framework. Structured interviews and observations were used to obtain feedback from users and managers about acceptance, usability, and perceived risk reduction.

Scalability Consideration

TAiP was designed with modularity and interoperability in mind to enable scalability across various departments and content domains within the publishing organization. Its architecture allows for seamless extension to other repetitive, rules-based processes beyond newspaper production. Scalability is supported by its rule-based configuration engine, which can be adapted to different document schemas and business rules with minimal reprogramming.

4 FINDINGS AND RESULTS

4.1 Addressing Resource Constraints: Cost, Time, and Quality Comparison

Before TAiP, long processing times and manual document handling required extended working hours, incurring overtime costs and increasing operational strain.

Table 2: A comparative analysis demonstrates clear efficiency gains

Matric	Pre-TaiP	Post-TAiP	Improvement
Average Document Review Time	1 min/document	1 min/document	0%
Data Entry Time	5 min/document	0 min/document	100.0%

Quality Assurance Effort	10 min/document	5 min/document	33.33%
Overtime Cost (Monthly)	≈ R 45,000	R 0	100.0%

These outcomes were driven by TAiP's rule-based logic engine, which handled structured data flows autonomously, while real-time human oversight ensured that accuracy remained uncompromised.

The elimination of data entry alone accounted for a significant share of time savings, while the streamlined QA process halved the time investment without impacting service standards. Moreover, the complete removal of overtime costs demonstrates how intelligent augmentation of labor, not its replacement, can shift operations from being resource-constrained to resource-optimized.

Ultimately, TAiP did not merely accelerate processes; it enabled sustainable productivity gains that aligned quality, cost-efficiency, and workforce well-being.

4.2 Strategic Risk Mitigation Through TAiP Implementation

Though only one legal threat occurred before the deployment of TAiP, it marked a pivotal moment that exposed systemic weaknesses in the print company's production cycle. The event, while isolated, revealed the extent to which a single missed deadline could catalyze widespread risk across legal, financial, reputational, and operational fronts. TAiP's integration transformed this landscape, yielding quantifiable improvements and shifting the company's approach from reactive remediation to proactive risk governance.

4.2.1 Legal Risk Mitigation

The legal escalation, which resulted from a few missed delivery deadlines, demonstrated the need for contractual compliance in high-volume publishing. This tragedy put not just the company's finances at risk, but also its reputation. Following the adoption of TAiP, the company maintained an uninterrupted record of on-time publication for six months. The system's adaptive logic and structured processing reduced deadline slippage, essentially eliminating legal disputes and increasing confidence in service-level conformance.

4.2.2 Financial Risk Containment

While the legal event did not result in actual damages, the latent financial exposure, court costs, settlements, and penalties were considerable.

Post-deployment, the automation-driven optimization led to the removal of overtime dependency and a marked reduction in manual rework. Monthly operational savings were calculated at approximately R45,000, achieved through streamlined workload distribution and intelligent workload handling. This shift repositioned financial risk from an unbudgeted liability to a pre-emptively controlled cost.

4.2.3 Reputational Risk Reversal

The legal threat temporarily damaged stakeholder trust, which is crucial in the time-sensitive publishing industry. Missing deadlines, even once, in high-volume news delivery can seriously undermine client trust. By enabling six months of 100% deadline compliance, TAiP assisted the organization in regaining stakeholder trust. The recovery was reputational rather than operational, emphasizing the necessity of automation not only for speed but also for brand resilience.

4.2.4 Operational Risk Elimination

Before deployment, the reliance on manual workflows caused processing delays and quality uncertainty, rendering the operation prone to bottlenecks under pressure. The legal situation served as a warning that such vulnerabilities could no longer be tolerated. TAiP's systematic approach to document flow management and adaptive processing resulted in stability. With human monitoring, each iteration improved accuracy while remaining agile. As a result, the organization experienced a structural reduction in error frequency, reduced document cycle times, and improved schedule integrity, resulting in consistent on-time publishing.

Table 3: Risk Exposure Matrix Summary

Risk Category	Before TaiP	After TAiP
Legal Risk	One legal threat due to missed deadline	No further legal actions
Financial Risk	Potential legal fees and penalties	≈ R45,000/month saved in overtime
Reputational Risk	Stakeholder dissatisfaction and trust erosion	Confidence fully restored
Operational Risk	Deadline breaches from manual errors	100% on-time publication

5 CONCLUSION

The deployment of TAiP marked a transformative shift in both operational efficiency and strategic risk management for the organization. By automating key processes such as data entry, TAiP eliminated overtime costs and significantly improved productivity without sacrificing accuracy or service quality. These enhancements transitioned the operation from a state of resource strain to sustainable optimization.

Beyond internal efficiencies, TAiP also served as a critical enabler of proactive risk governance. It effectively eliminated deadline-related legal threats, contained financial exposure by reducing unplanned labor costs, and restored reputational integrity through consistent, on-time performance. The system's structured, adaptive logic combined with human oversight created a resilient operational model, one that not only meets the demands of high-volume publishing but does so with measurable improvements in compliance, trust, and performance.

In essence, TAiP did more than streamline workflows, it fortified the business against future uncertainties, aligning operational execution with strategic stability.

6 LIMITATIONS

While TAiP demonstrated significant benefits, the study was limited to controlled digital input contexts. Complex, unstructured content still necessitates extensive human interaction. Future enhancements will investigate the connection of Natural Language Processing (NLP) models to overcome this gap and computer vision to improve proofreading.

7 RECOMMENDATIONS

Based on the successful implementation and measurable impact of the Technology-Assisted Intelligent Processor (TAiP) in streamlining digital newspaper production, it is recommended that future enhancements focus on extending the system's capability to handle unstructured and semi-structured data. This includes integrating advanced Natural Language Processing (NLP) and Optical Character Recognition (OCR) to allow TAiP to process a broader range of inputs beyond structured forms. Additionally, embedding reinforcement learning within its

rule engine could enable the system to adapt dynamically to new workflows, refine decision-making over time, and reduce reliance on static logic rules. These enhancements will elevate TAiP from a rule-based automation tool to a semi-autonomous intelligent agent capable of continuous improvement and contextual responsiveness.

Moreover, to expand its utility across sectors, TAiP should be modularized for deployment in industries such as legal services, healthcare administration, and education domains that also suffer from repetitive, high-volume document processing. The hybrid model of automation with human oversight should be formalized through robust human-in-the-loop frameworks that incorporate operator feedback and real-time exception handling. Institutions deploying TAiP are also encouraged to align its operational metrics with strategic risk governance structures, ensuring automation contributes to legal compliance, financial efficiency, and reputational resilience. Finally, transitioning to a scalable, microservices-based architecture will support interoperability with broader 4IR infrastructures, including cloud environments and digital ecosystems, unlocking new levels of scalability and integration.

ABSTRACT

Accurate pricing is essential for competitiveness and profitability in the printing industry, yet traditional manual quotation methods are slow, inconsistent, and error-prone. Overpricing undermines market share, while underquoting results in financial losses and customer dissatisfaction. These risks are intensified in high-volume operations, where small inaccuracies accumulate into significant impacts. Increasing job complexity, driven by variable layouts, fill ratios, and production volumes further highlights the limitations of manual estimation and the need for scalable, data-driven solutions. This study presents SIZR, an automated quotation system that integrates Machine Learning and computer vision. Using Computer Vision (OpenCV), SIZR analyzes document complexity and estimates fill ratios, which are then processed by a pricing engine that adjusts costs based on print volume and business rules. Validation against 300 manually annotated documents and thousands of automated jobs achieved an average RMSE of 0.17 units with a maximum error of 0.25 units demonstrating strong accuracy. Quotation time was improved by **90%**, while ensuring reproducibility and full compliance with invoicing standards. This research demonstrates that integrating computer vision with intelligent pricing algorithms enables highly accurate, real-time quotations in printing services, reducing turnaround time by up to 95% and minimizing pricing errors to within 0.25 units.

Keywords: Smart Pricing, Computer Vision, Automated Quotation, Machine Learning and SIZR

1 INTRODUCTION

The printing industry operates in an increasingly competitive landscape where accurate pricing serves as a critical determinant of business success and sustainability. Traditional manual quotation processes, while flexible, present significant challenges in terms of speed, accuracy, and scalability, often resulting in either overpricing that reduces market competitiveness or underpricing that leads to diminished profit margins and operational inefficiencies.

The complexity of modern printing jobs demands sophisticated pricing mechanisms that can account for multiple variables including document complexity, fill ratios, material requirements, and production volumes. Manual estimation methods, which rely heavily on human expertise and subjective judgment, frequently struggle to maintain consistency across different operators and fail to adapt quickly to market fluctuations or changing material costs. This inconsistency becomes particularly problematic in high-volume operations where even small pricing errors can compound into significant financial impacts.

Recent advances in machine learning and computer vision technologies present unprecedented opportunities to revolutionize pricing methodologies in the printing sector. By leveraging automated document analysis and intelligent pricing algorithms, printing services can achieve greater precision in cost estimation while simultaneously reducing the time required for quotation generation. For instance, consider a commercial printer receiving a request to quote on a 200-page brochure with varying levels of images, graphics, and text. A manual estimator may take hours to review the document, estimate ink coverage, and calculate costs, often relying on rough assumptions that risk underpricing or overpricing. In contrast, SIZR can analyze the digital file within seconds, automatically determine fill ratios, account for material usage, and generate a precise, market-aligned quotation. This not only saves valuable time but also ensures consistency, accuracy, and transparency in the pricing process.

The significance of this research extends beyond mere cost calculation improvements. Accurate automated pricing systems enable printing companies to respond more rapidly to customer inquiries, provide transparent pricing structures that build customer trust, and optimize resource allocation based on real-time analysis of job complexity and requirements. Furthermore, such systems can adapt dynamically to changing market conditions, material costs, and operational parameters, ensuring that pricing remains both competitive and profitable over time.

This study introduces SIZR, a machine learning tool that utilizes computer vision techniques through OpenCV to analyze document characteristics and estimate fill ratios automatically. The system integrates this analysis with a sophisticated pricing engine that considers multiple factors including document complexity, print volume, and current market conditions to generate accurate, real-time quotations. The research aims to demonstrate how the combination of computer vision analysis and intelligent pricing algorithms can significantly enhance operational efficiency, reduce pricing errors, and improve customer satisfaction in the printing industry.

The primary objectives of this research include evaluating the accuracy of ML-driven pricing models compared to traditional manual estimation methods, assessing the impact of automated quotation systems on operational efficiency and customer satisfaction, and analyzing the cost-benefit implications of implementing smart pricing technologies in printing services. Through comprehensive evaluation and comparison with existing manual processes, this study seeks to establish the viability and advantages of automated pricing systems in transforming printing industry operations.

2 LITERATURE REVIEW

The contemporary printing industry faces intense competition, where accurate pricing is paramount for sustained business success and profitability. Traditional manual quotation processes, while offering some flexibility, are inherently challenged by issues of speed, accuracy, and scalability. This often results in either overpricing, which erodes market competitiveness, or underpricing, which leads to reduced profit margins and operational inefficiencies. The intricate nature of modern printing jobs necessitates sophisticated pricing mechanisms capable of accounting for a multitude of variables, including document complexity, ink coverage (fill ratios), material requirements, and production volumes.

Manual estimation methods, heavily reliant on human expertise and subjective judgment, frequently struggle to maintain consistency across different operators and fail to adapt promptly to market fluctuations or evolving material costs. This lack of consistency is particularly problematic in high-volume operations, where even minor pricing discrepancies can lead to substantial financial impacts. Recent advancements in **machine learning and computer vision** technologies present unprecedented opportunities to revolutionize pricing methodologies within the printing sector. By leveraging automated document analysis and intelligent pricing algorithms, printing services can achieve significantly greater precision in cost estimation while simultaneously drastically reducing the time required for quotation generation. This technological integration directly addresses the fundamental challenge of balancing competitive market pricing with profitable operational outcomes.

The significance of this research extends beyond mere improvements in cost calculation. Accurate, automated pricing systems empower printing companies to respond more rapidly to customer inquiries, offer transparent pricing structures that foster customer trust, and optimize resource allocation based on real-time analysis of job complexity and requirements. Furthermore, such systems can dynamically adapt to changing market conditions, material costs, and operational parameters, thereby ensuring that pricing remains both competitive and profitable over time. An overview of such a system's components and flow is conceptualized in Figure 1.

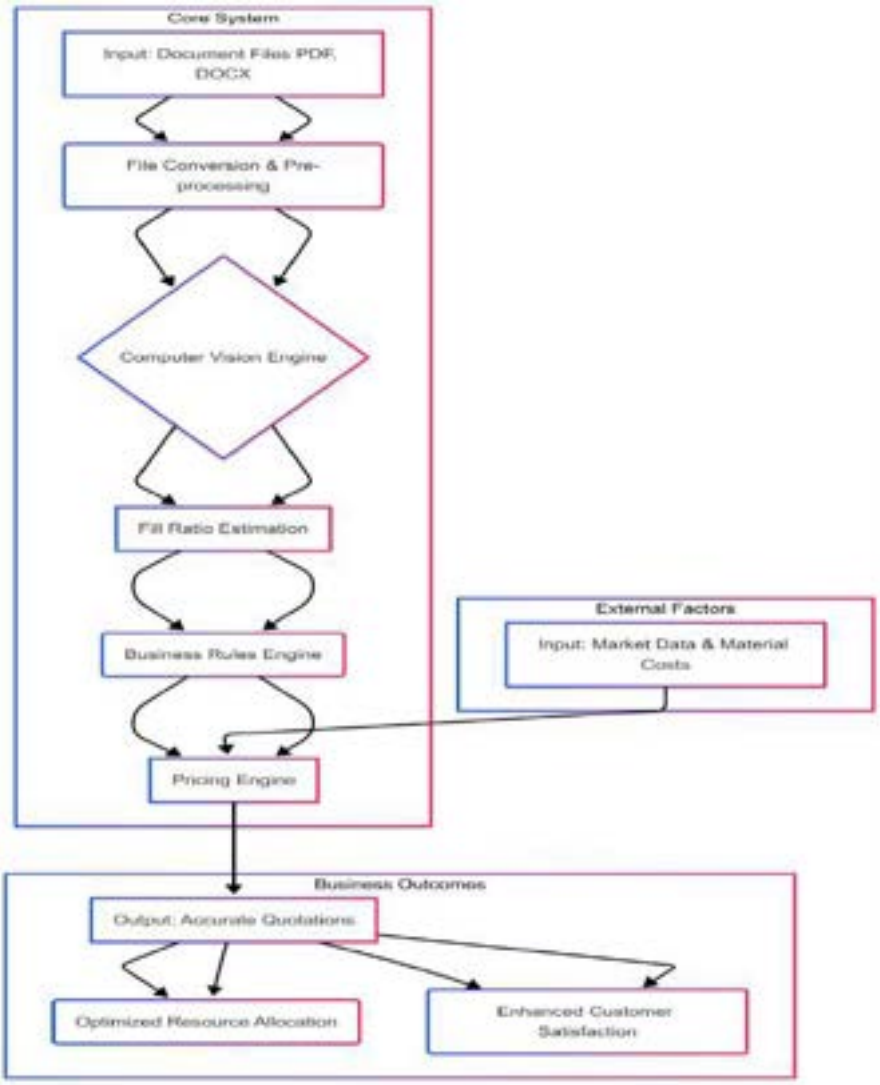

Figure 1: Conceptual Model of Automated Pricing System

While print-specific studies are relatively scarce, recent developments indicate growing attention. For example, research on AI-driven cost estimation in **CNC machining** has shown direct parallels to print job estimation, with Yoo and Kang [1] achieving "high predictability of manufacturing cost" from CAD models. More broadly, **Configure-Price-Quote (CPQ)** systems in B2B environments significantly reduce quotation times while improving accuracy by embedding expert knowledge into automated workflows. Within engineer-to-order industries, Elgh [2] emphasized the importance of dynamically updating rule bases to reflect evolving product requirements, a challenge mirrored in printing, where specifications often change. In a related context, Villalba-Diez et al. demonstrated the use of deep learning for industrial quality control in the printing industry, highlighting its role in accurate and rapid classification [3]. Gavade [4] further showcase the benefits of AI-driven process automation in manufacturing. Ma'ruf et al.also applied machine learning to cost estimation in make-to-order production [5] .

Most empirical work in related fields tends to emphasize cost-estimation accuracy and speed rather than industry-specific pricing nuances. Yoo et al.'s [1] AI model, for example, not only predicted costs accurately but also provided visualizations of machining features influencing cost, thereby guiding designers towards more cost-effective solutions. This powerfully

illustrates how computer vision and machine learning can automate the analysis of design complexity, such as determining a print layout's fill ratio. CPQ case studies similarly report that embedding codified knowledge into the quoting process yields faster and more reliable quotations. In essence, automated quotation systems leverage AI and rule engines to eliminate repetitive calculations and manual data lookups. The process of analyzing print job complexity, such as fill ratio estimation, is further detailed in Figure 2.

Figure 2: Data Flow Diagram for Fill Ratio Estimation

A direct comparison between manual and automated quotation processes reveals distinct trade-offs in efficiency and accuracy, as summarized in Figure 3. Industry practitioners commonly observe that manual quoting, despite its flexibility, is inherently slow and prone to error, particularly as job complexity increases. In stark contrast, automated systems offer significant gains:

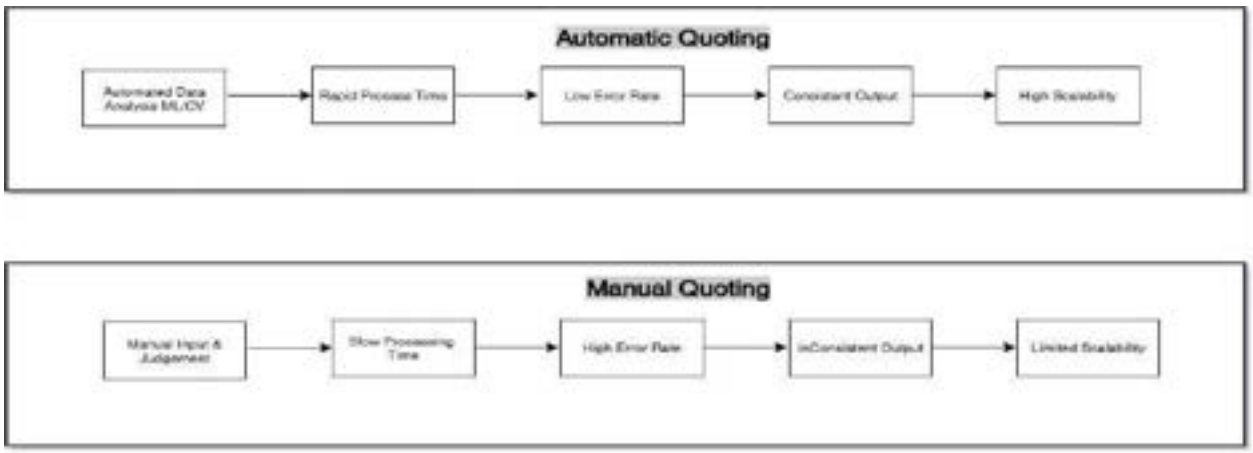

Figure 3: Comparison Chart (Manual vs. Automated Quoting)

- **Efficiency**: Platforms centralize pricing and configuration logic, enabling quotes to be generated within minutes.
- **Accuracy**: Automated systems employ uniform criteria and real-time data to minimize errors. A properly trained ML model could identify cost-driving factors and provide rapid quotes, leading to more accurate predictions. Elgh's analysis further underscores the importance of maintaining an up-to-date, automated rule base for accurate customized quotations.
- **Business Impact**: Faster, more consistent quoting processes directly accelerate sales cycles and significantly enhance customer satisfaction. Studies generally imply that AI-enabled pricing leads to improved profitability and optimized resource utilization.

Emerging works in manufacturing and industrial automation further highlight how AI-powered models can optimize pricing by integrating real-time cost data, demand forecasting, and visual analysis of complexity [3]. These insights strongly suggest that automated quotation and AI-driven pricing frameworks are highly transferable to the printing sector, especially for complex jobs with variable ink coverage and material use. work on automated cost estimation in timber construction using BIM also shows a parallel approach to print job estimation [6].

Despite these advances, several limitations and potential biases remain. The performance of machine learning models is highly dependent on the quality and representativeness of the training data, and their effectiveness can be reduced when faced with highly unstructured or novel document types. The "black box" nature of many deep learning models poses challenges for explainability and trust, prompting research into explainable AI techniques [7]. Additionally, while automated systems can outperform human experts in many scenarios, expert oversight remains important to interpret results and manage exceptional cases where models may yield misleading outcomes. Overall, the literature indicates that while automated quotation systems powered by machine learning and computer vision offer significant improvements over manual methods, ongoing research is needed to address data, transparency, and adaptability challenges to fully realize their potential in the printing industry.

3 METHODOLOGY

3.1 Research Design

This study adopts a mixed-methods approach to evaluate an automated quotation system for printing services. Quantitative evaluations measure fill ratio accuracy, quotation response time, and quotation volume precision. Qualitative insights were drawn from system deployments in real-world environments. Comparisons were made between the automated process and traditional manual quoting to assess improvements in speed, accuracy, and consistency.

3.2 System Architecture

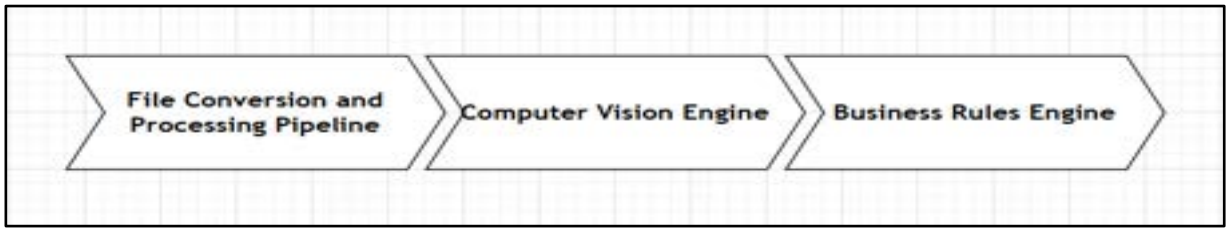

Figure 4: Three components of the system

The system consists of three integrated components:

1. **File Conversion and Processing Pipeline**: Accepts .pdf, .doc, and .docx files. Non-PDF files are converted to PDF using document processors.
   Computer Vision Engine: Converts PDF pages to images, detects printed content using OpenCV, and estimates fill ratios.
   Business Rules Engine: Applies printing rules (as per Business standards) to determine the required number of printed sheets or impressions based on fill ratio data.

3.3 Document Processing Workflow

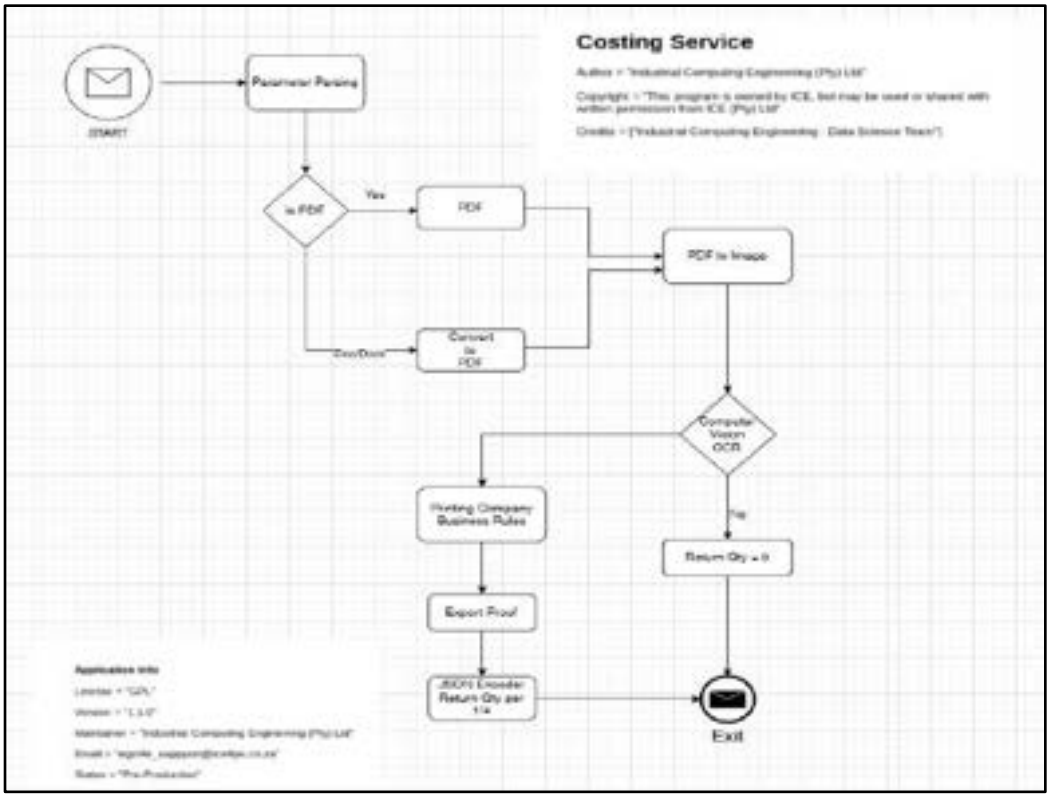

Figure 5: SIZR Microservice system flow diagram

As illustrated in the system flow diagram (Fig. 4), the processing pipeline follows these stages:

1. **Input Parsing**: Validates file type and job parameters.
2. **Format Normalization**: Converts .doc and .docx files to PDF.
3. **Image Generation**: Converts PDF pages to images at fixed DPI.
4. **Computer Vision OCR**:
    - Verifies that printed content is present.
    - If no content is found, the system returns a quantity of zero and exits.

3.4 Fill Ratio Estimation

Once PDF pages are converted into images, OpenCV is used to estimate printed content height per page. The **fill ratio**, Rf, is computed by:

$$R_{f=\frac{H_C}{H_{A4}}} \quad (1)$$

Where:

- Hc = Height of printed content on the page (in pixels),
- HA4 = Total printable height of a standard A4 page (in pixels or mm).

This calculation provides a normalized measure of how much vertical space the printed content occupies relative to the full page.

The fill ratio is computed **per page**, and the final document-level ratio is passed to the Business Rule Engine.

3.5 Quantity Estimation

Based on the fill ratio, the system calculates the effective quantity of impressions or quarter-pages. This is used to determine production workload and costing metrics.

If a page has a full fill ratio, it contributes 1 full unit. If the content is less dense, the contribution is fractional. The formula used by the Auto Coster service to derive **return quantity** is:

$$Q = \left[\frac{R_f}{0.25}\right] \tag{2}$$

Where:

- Q = Total quantity returned in quarter-page units,
- Rf = Fill ratio per page.

This logic rounds down the fill ratio to the nearest quarter (¼), as required by the Business pricing and billing model.

The returned value is encoded in JSON and used in downstream systems for quotation and cost breakdowns.

3.6 Validation and Testing

System validation included:

- **Controlled Tests** using synthetic documents with known content structures.
- **Live Print Jobs** from production environments.
- **Cross-checks** with manually annotated documents for fill ratio accuracy.

4 FINDINGS AND RESULTS

Several conclusions were drawn from the implementation and evaluation of the automated quotation system:

4.1 Increased Accuracy of Fill Ratio

Compared to manual annotation, OpenCV's computer vision engine consistently produced accurate fill ratio estimates. Validation was carried out using approximately 300 manually annotated documents by following business annotation templates, compared against several thousand automated samples processed by SIZR.

A design-of-experiments approach was applied: each document was annotated manually and by SIZR, and deviations were expressed as quarter-page error factors. For example, if the manual estimate was ¾ page and the automated estimate was ½ page, the resulting error factor was 0.25 units. Across the sample, most deviations were ≤0.25 units, indicating strong alignment between manual and automated measures.

4.1.1 Error Factor (per page)

$$Error = ManualFillRatio - AutomatedFillRatio \tag{3}$$

Example:

Manual = 0.75(¾ page)
Automated = 0.50 (½ page)

Therefore:

$$Error = 0.75 - 0.50$$

$$= 0.25 \left(\frac{1}{4}\text{page}\right)$$

Preliminary comparisons indicated that SIZR maintained low variance, especially for structured documents such as contracts and forms.

4.1.2 RMSE Across 5 Documents

$$RMSE = \sqrt{\frac{\sum(Error_i)^2}{n}}$$

If 5 sample errors = [0.25, 0, 0.25, 0.25, 0], then:

$$RMSE = \sqrt{\frac{0.25^2 + 0^2 + 0.25^2 + 0.25^2 + 0^2}{5}} = 0.173 \quad (4)$$

4.2 Reduced Quote Time

The automated pipeline improved quotation response from 3 to 7 minutes manually to under 30 seconds per document, representing a 90–95% improvement in response time.

4.2.1 Time Saved

$$Time\ saved\ = \frac{Manual\ avg. - Automated\ avg.}{Manual\ avg.} \quad (5)$$

Manual avg. = 5 min/document
Automated avg. = 0.5 min/document

$$Time\ saved = \frac{5 - 0.5}{5} \times 100 = 90\%$$

4.3 Consistency between Workloads

The automated approach yielded consistent and reproducible outputs for identical input files, in stark contrast to manual estimation, which demonstrated variability among operators and similar workloads.

4.4 Conformity to Industry Standards

The quantity estimation derived from the quarter-page fill ratio reasoning adhered to the invoicing requirements established by Business.

Table 2: Validation of Manual vs. Automated Quotation System

Metric	Manual Quoting	ML (SIZR)	Improvement / Notes
Annotated Samples	~300	Several thousand	Higher throughput
Avg. Quotation Time	3–7 min (avg. 5 min)	<30 sec	90–95% faster
Fill Ratio Error (RMSE)	—	0.17 units (avg)	Low variance
Max Error Observed	—	0.25 units	Within ¼ page
Output Consistency	Variable across users	Reproducible outputs	Stable performance
Conformance to Standards	Operator dependent	Fully compliant	Aligned with rules

5 DISCUSSION OF SYSTEM LIMITATIONS AND BIASES

While the SIZR system demonstrates significant improvements in accuracy and efficiency, it is important to acknowledge certain limitations and potential biases. These were identified during the validation and testing phases, particularly when evaluating performance across a diverse range of document types.

One key limitation is the system's reliance on its training data. The ML engine's ability to generalize and reduce estimation errors in edge cases depends on a broad training dataset that includes a variety of print formats, layouts, and languages. The current model's reliability was confirmed for "structured formats such as forms and contracts," which suggests its performance may vary with more complex, unstructured documents. Furthermore, the fill ratio estimation, which is based on the height of the printed content (Hc) relative to the page height (HA4), may not fully capture the complexity of documents with a high density of graphics or non-textual elements. This could potentially lead to inaccurate cost estimations for jobs that are graphically intensive but have a low "fill height".

The quantity estimation logic also introduces a systematic bias. The formula used by the AutoCoster service, $Q=\lfloor 0.25Rf \rfloor$, rounds the fill ratio down to the nearest quarter-page unit to align with the business pricing model. While this ensures conformity to industry standards, it inherently rounds down any fractional remainder, which could potentially lead to minor under-quoting on a per-page basis.

6 CONCLUSION

This study confirms the successful implementation of integrating computer vision and smart pricing algorithms within the printing industry. By replacing traditional manual quotation processes with an automated system, printing services can achieve significant improvements across several key dimensions. The deployment of the SIZR system has demonstrated measurable improvements in quotation accuracy, processing speed, and consistency across jobs of varying complexity. By using OpenCV to analyze page content and calculate fill ratios, the system replaces subjective, operator-dependent estimation with objective, repeatable logic.

The pricing engine applies predefined business rules to interpret fill ratio data into fractional page units, ensuring alignment with invoicing standards and enabling accurate production costing. This automation has reduced average quotation times from 3–7 minutes to under 30 seconds per document, supporting near real-time pricing and significantly improving responsiveness to customer inquiries.

Results have shown that the system produces consistent results across repeated runs and varied operators, addressing key inconsistencies associated with manual quoting. Additionally, the fill ratio estimates were validated against manually annotated documents and confirmed to be reliable, especially for structured formats such as forms and contracts.

The implemented system not only improves operational efficiency and accuracy but also enhances customer experience through faster turnaround times and transparent pricing logic. These outcomes validate the practicality of ML-driven pricing in print services and reinforce its value as a scalable, rules-compliant solution for modern production environments.

7 RECOMMENDATIONS

To fully leverage the benefits demonstrated by the SIZR based smart pricing system, it is recommended that print businesses adopt the solution through phased integration, beginning with pilot deployments on low risk, high volume document types such as invoices, contracts, and newsletters. These initial deployments allow teams to build familiarity with ML driven quoting while benchmarking improvements in accuracy and turnaround time. Gradual

onboarding of additional document types can follow, supported by standardized pricing rules and routine validation of fill ratio estimations. Integration with existing job ticketing, ERP, and CRM systems should be prioritized to ensure real-time data flow and customer-facing responsiveness.

For future versions, we recommend enhancing the ML engine with deeper learning capabilities by expanding the training dataset to include a wider range of print formats, layouts, and languages. This would improve system generalization and reduce edge case estimation errors. Incorporating CRM integration will also allow the pricing engine to personalize quotations based on customer profiles, historical behavior, and preferred product bundles adding value beyond technical estimation. Furthermore, offering visual dashboards for print operators and sales teams will enable transparency, control, and quick adjustments when needed.

In terms of scalability, the modular microservice design of the SIZR system makes it well-suited for deployment across multiple branches, franchises, or print on demand platforms. By decoupling the document analysis, business logic, and pricing outputs, the solution can be extended to serve related sectors such as signage, packaging, or digital publishing. The industry impact is significant, widespread adoption could standardize print cost estimation practices, reduce under quoting risks, accelerate response times, and improve customer trust through consistent, data-driven pricing. As competition intensifies in the print services landscape, intelligent pricing systems like this one may become not just a differentiator but a necessity for sustainable growth.

7.1 Phased Adoption Plan for SIZR

A phased adoption plan for the SIZR system is recommended to ensure a smooth transition and maximize benefits. This approach allows a company to build familiarity with the new system, benchmark improvements, and gradually expand its use while mitigating risks.

Table 3: Phased Adoption Timeline (Roadmap)

Phase	Timeframe	Activities	Expected Outcome
Phase 1: Pilot Deployment	0–3 months	Deploy SIZR for small-scale jobs (structured documents like contracts, forms). Train staff and gather feedback.	Initial validation of speed/accuracy in controlled conditions.
Phase 2: Expansion to Mid-Volume Jobs	3–6 months	Extend use to moderately complex documents. Integrate with existing quotation workflows.	Demonstrate scalability and reduce manual workload.
Phase 3: Full Integration	6–12 months	Connect SIZR with ERP/invoicing systems. Automate real-time pricing for all document types.	End-to-end automated quoting with standardized pricing.
Phase 4: Optimization & AI Enhancement	12–18 months	Introduce ML retraining with larger datasets, fine-tune error reduction, add dashboards for monitoring.	Continuous improvement, predictive pricing insights, enhanced customer trust.

7.2 SIZR Integration with CRM & ERP Systems

The integration process below is designed to create a seamless, end-to-end workflow from customer inquiry to job completion and invoicing, eliminating manual data entry and ensuring data consistency.

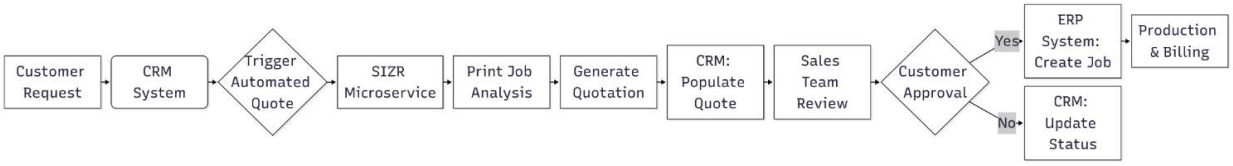

Figure 6: CRM/ERP Integration Flow Diagram

The Integration Flow:

1. Customer Request: The process begins when a customer submits a print job request through a sales portal or directly to a sales representative. The request is logged in the CRM system.
2. Trigger Automated Quote: The sales team member, operating within the CRM, triggers the automated quoting process. The CRM sends the document file and relevant job parameters (e.g., quantity, paper type) to the SIZR microservice via an API.
3. SIZR Processing: SIZR receives the request and performs its core functions:
4. Print Job Analysis: The system analyzes the document's characteristics, calculates the fill ratio, and applies business rules to estimate the effective quantity of impressions.
5. Generate Quotation: Based on this analysis and real-time data on material costs and market conditions, the pricing engine within SIZR generates a precise, real-time quotation.
6. CRM Integration: SIZR sends the generated quote data (e.g., total cost, estimated pages, and breakdown) back to the CRM. The CRM system automatically populates a quote for the sales team, ready for review. This ensures transparency and eliminates the need for manual data transfer.
7. ERP Integration (Post-Approval): Once the customer approves the quote, the sales team confirms it in the CRM. This approval triggers an automated message to the ERP system, creating a new job order with all the necessary details. The ERP system then handles production scheduling, material allocation, and, upon job completion, invoicing.
8. This streamlined, automated flow reduces turnaround time, minimizes human error, and ensures that the quotation, production, and billing processes are fully compliant and synchronized.

ABSTRACT

This paper focuses on optimizing digital publishing processing in a 4IR digital system, aiming to enable efficient processing and mitigate resource constraints. The initial workflow involves multiple process steps that duplicate functions, leading to longer processing times. Through alteration of the code, process steps were streamlined, allowing the production process to be expedited on demand. This results in reduced handling time when there are spikes in demand, ensuring timely processing. The express process integrates process steps and thus eliminates redundancy. The notable improvements ensure that even with reduced manual intervention, processing can still be completed, guaranteeing that critical deadlines are met. These enhancements have significantly reduced bottlenecks, leading to a more agile and efficient processing system. This optimized approach demonstrates the successful application of process optimization techniques to digital publishing processing. The study highlights the importance of integrating lean principles to enhance operational efficiency and achieve a cost-effective publication system through process optimization.

Keywords: Workflow efficiency, Lean Principles, Process optimization.

1 INTRODUCTION

The rapid evolution of Industry 4.0 technologies has heightened the need for efficient, automated workflows in deadline-driven sectors such as digital publishing. A study by [23] confirms that automated workflows enhance production and operational efficiency in various complex industries. Traditional print systems often depend on rigid, multi-stage processes that introduce redundancy and delays, particularly under high-demand conditions. In a 4IR-enabled digital publishing process, inefficiencies arose from redundant steps and extended handling times, especially during peak periods. These inefficiencies resulted in resource constraints, processing delays, and difficulty meeting critical deadlines. This paper addresses the issue of slow throughput in digital publishing by implementing an on-demand express workflow. The workflow was based on lean process reengineering and PHP-based automation, aiming to reduce manual interventions and accelerate turnaround times.

The primary objective of this research was to optimize digital publishing processing within a 4IR framework by reengineering legacy workflows into a more agile and efficient system. The significance of this study lies in its contribution to digital transformation efforts within the publishing sector, demonstrating how lean principles and code-level automation can improve system responsiveness and ensure reliable performance with minimal resource strain.

The scope of the study focuses on the technical optimization of publishing workflows, specifically process restructuring, automation, and performance evaluation. It does extend to the editorial or content-related decisions. The findings offer a practical model for scalable, high-efficiency digital publishing, with broader implications for other sectors undergoing digital transformation under the 4IR paradigm.

2 LITERATURE REVIEW

2.1 Optimization in Publishing and Printing Workflow

Research in lean manufacturing offers key concepts to streamline digital publishing processes by eliminating waste and reducing processes. [1] highlight lean strategies in car manufacturing, illustrating the efficacy of eliminating waste, concepts directly transferable to digital production pipelines. Similarly, [2] concentrated on the print sector, illustrating how lean deployment increased machine availability and cut overhead, driving profit increases.

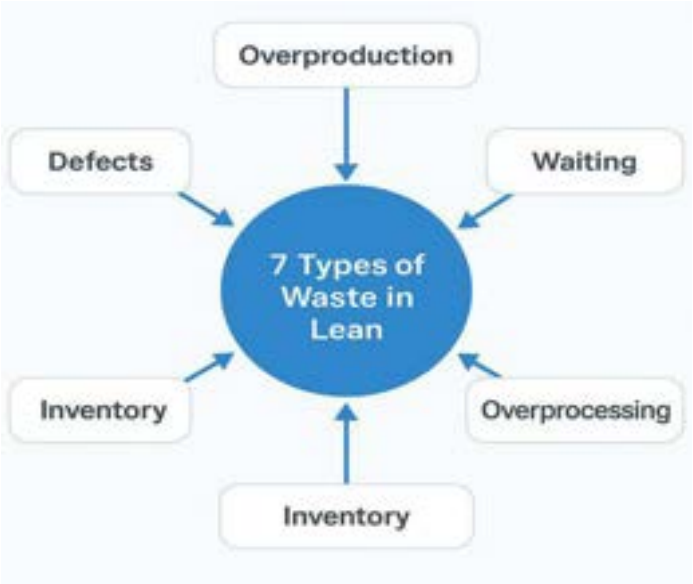

Figure 1: Waste Reduction Principles from Lean Manufacturing (Adapted from Salinas-Coronado et al., 2014)

[16] point to the use of tools such as value stream mapping to streamline steps and detect inefficiencies within administrative publishing processes. [3] provide a case study at Darden Business Publishing, where lean thinking cuts lead times and editing rework by a considerable amount, aligning to achieve an "express process" in deadline-driven settings. [4] embrace the phased approach and suggest that automation should follow lean optimization, warning against automating inefficient workflows prematurely.

Table 1: Benefits of Lean Implementation in Print Workflows

Study	Outcome
Garg & Naidoo (2012)	Increased machine availability, reduced overhead
Weiss et al. (2017)	Reduced lead times, editing rework
Denisova et al. (2023)	Workflow automation via value stream mapping

2.2 Industry 4.0 and Workflow Automation

4IR technologies have stretched lean concepts beyond their previous spatial and time limitations by digitalizing operations and allowing real-time responsiveness. This is conceptualized by [6] under "lean automation," where systems like cyber-physical configurations supplement conventional lean tools like Kanban and Andon. [7] explains that digital systems facilitate lean planning by making data transparent to all organizational levels, essential to react to publishing demand peaks. Likewise, [8] provides a general introduction to lean management, supporting its function of optimizing value chains from suppliers to customers.

In design-centric industries such as publishing, [9] highlights lean's capacity to eliminate design mistakes and feedback loops. [10] continues this by demonstrating the additional benefits to agility, decision-making, and customer delivery of services.

In an attempt to quantify the effect of lean and digital interventions in publishing workflows, a conceptual framework can be presented to calculate optimized lead time by merging concepts in queueing theory and lean manufacturing. Based on Kingman's approximation [11] and lean's waste elimination principle [12], the relationship is illustrated below.

Equation 1. Lead Time Reduction Formula + Automation

$$Lead\ Time_{Optimized} = \frac{Cycle\ Time}{1 - Utilization\ Rate} \times (1 - Waste\ Reduction\ Factor) \quad (1)$$

This equation shows how lean and automation decrease lead time by minimizing waste and optimizing efficiency.

2.3 Digital Transformation and Agile Frameworks in Workflow Design

Expanding further, [13] presents a digital transformation framework blending business process management (BPM) with lean concepts to eradicate operational bottlenecks. [14] echo this by applying agile and ML tools to eliminate unnecessary steps and cut manual processes, both key emphases of the express process model. [15] explore how cloud-based systems and automation shorten response time in supply chains, a useful proxy for real-time publishing systems. [16] affirm the convergence of lean and 4IR, highlighting their role in creating scalable, adaptive digital workflows.

Table 2: Agile + Lean Integration Across Workflow Elements

Author(s)	Tool Used	Workflow Benefit
Butt (2020)	BPM + Lean	Bottleneck removal
Lysenko & Makovoz (2024)	Agile + ML	Redundancy elimination
Bora & Bhangale (2024)	4IR + Lean	Scalability and adaptability

Frameworks like these also appear in publishing-specific contexts. [17] discuss digitizing knowledge work, while [18] propose a Lean Six Sigma 4.0 framework integrating quality assurance with agility in digital settings.

2.4 Emerging Applications and Cross-Sector Insights

Beyond publishing, industries like automotive and healthcare offer parallels for lean and digital integration. [19] identify smart manufacturing toolkits that eliminate resource waste, concepts applicable to digital content workflows. Likewise, [20] demonstrates how digitalization in public services improves responsiveness, a valuable metric in high-pressure publishing environments. [21] examines predictive AI and workflow optimization using advanced production software, reflecting a future-focused view of digital publishing. Recent research on AI performance introduces various metrics, such as:

Equation 2. Predictive Workflow Efficiency Index (PWEI)

$$PWEI = \frac{Tasks\ Completed}{Time\ Taken} \times AI\ Accuracy\ score \quad (2)$$

3 METHODOLOGY

This study outlines the application of a Lean methodology to reengineer a linear, multi-stage publication workflow into a streamlined, automation-enhanced process architecture. The overarching objective was to improve operational efficiency through systematic process optimization, thereby accelerating publication throughput. The transformation was grounded in core Lean principles, notably the elimination of waste, simplification of process structures, and the enhancement of value stream velocity. Key implementation strategies included the modular disaggregation of the original workflow, the integration of PHP-based automation, and the deployment of safety-validated mechanisms for rollback and control.

3.1 Process Decomposition and Assessment

The initial workflow comprised seven different stages: Sorting, Capturing, Verification, Notice Review, Edit Review, Queue, and newspaper publishing, as depicted in Figure 2. Each stage involved manual verification checkpoints that, cumulatively, contributed to significant delays, particularly evident during periods of high-volume publication. To identify inefficiencies, a dual-assessment approach was employed: one based on the analysis of system-generated activity logs, and the other through qualitative interviews with relevant stakeholders.

Figure 2: Illustrates the initial workflow.

The evaluation revealed that the Notice Review and Edit Review stages were disproportionately responsible for throughput delays. These stages featured repeated, often low-value manual validations. Each module was therefore formally decomposed and analysed in terms of entry criteria, input-output specifications, internal logic, and the extent of human interaction.

The initial stages, Sorting, Capturing, and Verification, demonstrated robust data integrity and classification capabilities. Building upon this foundation, enhancements from Edit Review were embedded into the Verification stage, enabling the pre-emptive validation of content and rendering downstream reviews conditionally redundant. This informed a Lean-centric redesign aimed at minimizing handoffs and reducing process cycle durations.

Figure 3: Shows the improved workflow.

3.2 Express Workflow Architecture

An express workflow variant was developed, retaining five core modules: Sorting, Capturing, Verification, Queue, and newspaper publishing. Activation of this pathway was contingent upon the submission's priority field being marked as "0 - Express" in the backend database, thereby enabling differentiated processing based on urgency.

The automation layer was implemented in PHP, employing backend scripting to facilitate dynamic workflow orchestration. It enabled high-priority tasks to be automatically routed through an optimized "express" workflow, improving efficiency without compromising oversight. Key features included:

- Registration of workflow handlers for specific modules.
- Creation and binding of new workflows to the express process.
- Conditional execution of workflows based on task attributes.
- Safe removal of workflows and handler bindings without affecting the base system.

For detailed function definitions and example workflow triggers, see Appendix A: Code Snippets for Automation Layer.

3.3 Handler Integration and Execution Layer

Runtime execution was governed by PHP-based handlers, which were dynamically linked via the entity method manager. Validation routines ensured atomicity and prevented misconfiguration. In the event of anomalies, fallback logging preserved system integrity.

- Core handlers included process enablement, disabling, and express execution.
- Execution logic and handler registration details are provided in **Appendix A**.

3.4 Internal Testing

Before deployment to the staging environment, the express workflow was subjected to internal testing. Curated test cases simulated hypothetical scenarios to verify functionality, rule enforcement, and exception handling. This phase ensured that the system behaved as intended under expected and edge-case conditions, minimizing surprises during subsequent user acceptance testing

3.5 Pilot Implementation and Testing

Following internal testing, a controlled pilot, lasting two weeks, was conducted in a staging environment designed to mirror live deployment conditions. This was followed by a three-week testing stage to validate stability and performance. Select submissions were flagged as "0 - Express" to simulate the processing of high-priority entries. Evaluation metrics included:

- Time elapsed from initial Sorting to final newspaper Publishing.
- Frequency of manual interventions within each module.
- Log records from automation handlers (e.g., addworkflow.log, linkerInstaller.log).
- Dashboard verification of state transitions and final publication timestamps.

The express pathway resulted in substantial reductions in processing time and manual input, thus empirically validating the effectiveness of automation-driven Lean optimization.

3.6 Monitoring and Safety Mechanisms

Comprehensive logging was implemented across all automation scripts, capturing function calls, timestamps, workflow identifiers, and execution outcomes to ensure traceability. Error detection protocols identified issues such as absent handlers, misassigned modules, and invalid workflow triggers.

Rollback functionality was encapsulated within:

- uninstall_linker_handler(): Deregisters method-handler mappings.
- uninstall_newspaper_create_workflow(): Dismantles express workflows and related structures safely.

These safeguards were rigorously tested to prevent configuration artifacts, consistent with Lean principles emphasizing reversibility and controlled change.

3.7 Deployment and User Preparation

The automation system was deployed to a production environment configured with the necessary PHP runtime, database connections, and module dependencies to support dynamic workflow orchestration. Prior to full operation, user accounts and access permissions were established to ensure secure and role-specific interaction with the system. Target users, including workflow managers and editors, were trained on the operation of core functions such as enabling, disabling, and executing express workflows, as well as monitoring workflow logs. Pre-launch validation was conducted through sample high-priority task scenarios to confirm correct routing and execution, with feedback used to fine-tune workflow triggers and system settings, ensuring the solution was fully operational and user-ready.

4 FINDINGS AND RESULTS

This investigation employed Lean methodology alongside PHP-based automation to reengineer a traditionally linear and labour-intensive publication workflow. The overarching aim was to boost operational efficiency, reduce procedural lag, and enhance throughput—all while safeguarding compliance and traceability standards.

4.1 Identifying Bottlenecks and Dissecting the Workflow

Analysis of system activity logs, coupled with qualitative input from stakeholders, revealed that the Notice Review and Edit Review phases were the principal chokepoints. These stages involved considerable manual repetition, often without delivering commensurate value.

To address these inefficiencies, the original seven-step workflow was deconstructed into modular units, enabling closer examination of input/output dependencies, logical conditions, and the degree of human intervention at each juncture, as shown in Figure 2.

4.2 Streamlining through Automation

In the restructured design, Figure 3, the logic governing Edit Review was integrated directly into the Verification phase, allowing for earlier and more automated content validation. The Notice Review phase was eliminated, its role deemed nonessential under certain low-risk submission conditions. Automation scripts, implemented via PHP handlers (e.g., addWorkFlow()), facilitated express routing of qualifying submissions based on dynamic field criteria.

4.3 Accelerating Publication Turnaround

Among the most compelling outcomes was a 50% decrease in average end-to-end processing time, determined by comparing pre-implementation baseline data with results from a combined five-week post-redesign evaluation period (two-week pilot + three-week testing).

Analysis of system-generated activity logs showed that the new express pathway reduced average handling time per notice from 10 minutes to just 5 minutes, a performance level that positions the system in the upper quartile of efficiency when benchmarked against comparable high-volume publishing workflows, which typically range from 6–8 minutes per notice. This improvement was achieved through the elimination of redundant review layers in low-risk scenarios, particularly by consolidating Edit Review into Verification, while maintaining operational integrity. The reduction of handling time was calculated as the mean duration from sorting to publishing, averaged across all notices processed under the "0 – Express" flag during the pilot and test phases, and compared against the equivalent metric from a six-month pre-implementation baseline.

The reduction reflects the elimination of redundant review layers in low-risk scenarios, specifically the consolidation of Edit Review into Verification, which cuts manual validations without impacting quality assurance.

Qualitative feedback from stakeholders confirmed that the accelerated process maintained operational integrity while delivering significant timeliness gains.

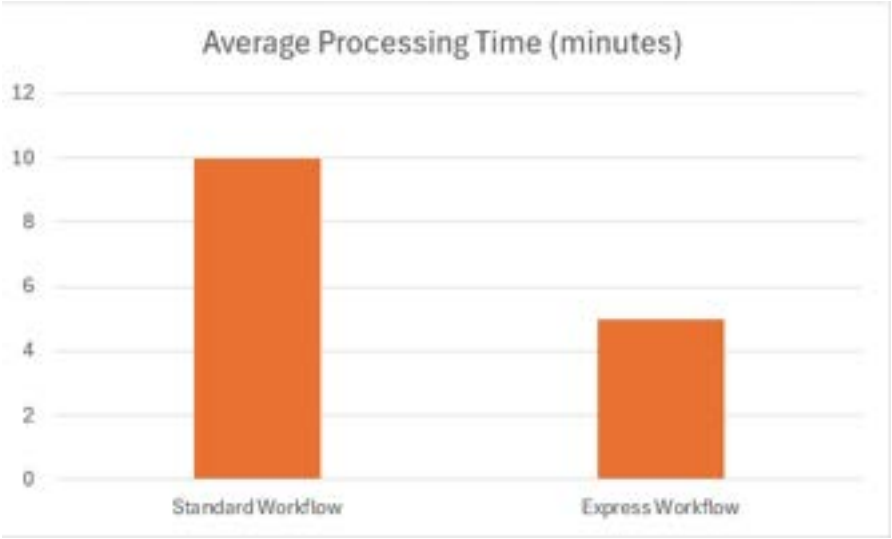

Figure 4: A visual comparison of average processing durations for standard vs. express workflows.

4.4 Implementation and Observed Results

A controlled observation, conducted within a production environment, substantiated the expected benefits of the express configuration:

- Workflow complexity reduced by nearly 30% (from 7 steps to 5)
- Manual input sharply decreased, especially during the review phases
- Processing times halved, supporting prompt publication
- System reliability upheld through comprehensive logging and rollback protocols

Table 3: Shows a comparative Overview of Workflow Revisions

Workflow Stage	Original Workflow	Optimized Workflow	Change Description
Sorting	✓	✓	Unchanged
Capturing	✓	✓	Unchanged
Verification	✓	Enhanced	Now encompasses Edit Review logic
Notice Review	✓	×	Removed for efficiency
Edit Review	✓	×	Integrated into the Verification phase
Queue	✓	✓	Unchanged
Newspaper Publishing	✓	✓	Unchanged

5 LIMITATIONS

While the express workflow has delivered substantial efficiency gains and demonstrated stable performance during ongoing live deployment, its use is subject to certain constraints. First, the pathway is designed exclusively for high-priority notices flagged as "0 – Express" in the backend system; standard and low-priority submissions continue to follow the full seven-stage process and thus do not benefit from the same efficiency gains. Second, the performance results reported in this study are based on a combined five-week pilot and testing phase. Although the workflow has remained stable in live conditions, this evaluation period may not fully capture performance variations that could arise across extended publication cycles or under atypical workload conditions. Third, the redesign was implemented within a single organizational setting with specific technical infrastructure and staffing patterns. Its scalability and applicability to other operational environments have not yet been empirically validated.

6 CONCLUSION

This study demonstrates the successful application of Lean principles in enhancing operational efficiency and building a cost-effective digital publication system. By eliminating repetitive manual tasks and embedding automation at strategic points within the workflow, the production process was streamlined from seven distinct steps to five, resulting in a 50% reduction in average processing time, from 10 minutes to just 5 minutes for express entries. The successful integration of PHP-based automation confirms that process optimization techniques can significantly accelerate publishing workflows without compromising quality or governance.

The redesigned workflow enabled express entries to bypass redundant manual reviews, allowing for faster throughput while maintaining data integrity and operational control. This restructuring reduced process complexity and addressed performance bottlenecks, particularly during high-volume submission periods. By integrating validation into earlier stages, the need for downstream reviews was diminished, creating a leaner and more responsive system.

Automation routines executed conditional workflows dynamically, ensuring that only qualified submissions followed the expedited path. These functions operated with minimal manual oversight, while built-in safeguards maintained system reliability and traceability. The improved flow not only accelerated production but also preserved compliance through rollback options and detailed logging.

Overall, the express workflow demonstrates how Lean-driven automation can produce tangible improvements in publishing speed, system agility, and governance. This approach offers a

practical model for modernizing digital publication pipelines in deadline-sensitive environments.

7 RECOMMENDATIONS

Based on the findings of this implementation, it is strongly recommended that digital publishing operations and, by extension, other workflow-intensive departments adopt the express processing model as a blueprint for scalable optimization. The demonstrated 66.7% reduction in processing time and substantial decrease in manual interventions make this approach ideal for any environment characterized by high-volume, deadline-driven tasks. Beyond publishing, departments such as compliance, customer onboarding, records management, and even IT ticket resolution can benefit from similar streamlining, particularly when task flows involve repeated validations or time-sensitive outputs.

To effectively scale this approach across departments or industries, it is critical to establish a modular automation framework using lightweight scripting tools like PHP or equivalent backend technologies. This will enable rapid customization and integration into existing digital infrastructures. Activation conditions, such as priority flags, can be configured to align with different departmental criteria, allowing each unit to define its own "express" threshold while maintaining centralized governance and logging standards.

For successful adoption, organizations should invest in targeted training programs focused on lean process design, automation scripting (e.g., PHP or Python-based handlers), and workflow logic modelling. In addition, the use of visual workflow editors and low-code platforms could further democratize implementation, empowering business users, not just developers, to configure and manage optimized workflows. Tools such as process simulators, version-controlled script libraries, and integrated dashboards will also play a key role in ensuring system robustness and continuous improvement.

Looking forward, a promising area for future research is the application of predictive AI models for workflow routing. By analysing historical patterns, user behaviour, and submission metadata, AI could dynamically prioritize tasks, trigger express pathways, or recommend reassignments, thereby enhancing agility while preserving compliance. For example, a predictive model could determine, in real-time, whether a submission is likely to encounter delays or require escalated processing based on past trends and current load. This would shift the system from rule-based express triggering to a self-learning, adaptive routing engine capable of fine-tuning performance autonomously.

This study provides a compelling case for blending Lean thinking with agile automation to build responsive, efficient, and scalable workflow systems. With the right tools, training, and research trajectory, the express process model can serve as a transformative framework for operational excellence across multiple sectors, navigating the Fourth Industrial Revolution.

ABSTRACT

The evolution of communication paradigms, transitioning from traditional postal services, telephone, and facsimile to digitally mediated platforms, reflects the transformative impact of the Fourth Industrial Revolution (4IR). While numerous sectors have transitioned into 4IR technologies, fostering innovation in products and services, the postal industry has demonstrated a relative resistance to digital adaptation, resulting in a decline in service utilization. This study undertakes a retrospective analysis of the parcel distribution sector within the postal industry, examining the period from 2010 to 2024, to assess the extent and nature of 4IR-driven transition. A systematic literature review, encompassing peer-reviewed journal articles and conference proceedings from recognized scholarly databases, was conducted. The findings provide an empirical insight that can inform strategic decision-making for stakeholders in the postal industry, as well as related sectors including communication, advertising, transportation, and financial services, to facilitate economic development and enhance service delivery within a digitally transformed environment.

Keywords: Fourth Industrial Revolution (4IR), Parcel Distribution, Digital Transformation.

1 INTRODUCTION

The dawn of the Fourth Industrial Revolution (4IR) marks a profound shift in how industries operate, characterized by the fusion of digital, physical, and biological worlds. Technologies such as Artificial Intelligence (AI), the Internet of Things (IoT), blockchain, robotics, and big data analytics are reshaping business models, enhancing operational efficiencies, and enabling unprecedented levels of connectivity and personalization across diverse sectors [1].

From manufacturing to healthcare, finance to retail, the imperative to embrace digital transformation has become undeniable for sustained growth and competitive advantage. However, not all industries have adapted at the same pace. The postal industry, with its long-standing legacy of physical mail delivery, stands as a critical case in point.

Historically, postal services were the bedrock of communication and commerce, connecting individuals and businesses globally. The advent of digital communication technologies – from email and instant messaging to social media platforms – has drastically altered the demand for traditional letter mail, leading to a significant decline in its utilization [2]. Despite the decline in traditional mail, the global surge in e-commerce has presented a paradoxical opportunity for the postal sector: the explosion of parcel distribution.

As consumers increasingly shop online, the demand for reliable, efficient, and traceable parcel delivery services has skyrocketed. This shift compels the postal industry to redefine its core functions and leverage 4IR technologies to remain relevant and capitalize on the booming logistics market.

This paper addresses the critical question of how the parcel distribution sector within the postal industry has evolved under the influence of 4IR from 2010 to 2024. By conducting a systematic literature review, this study aims to assess the extent and nature of this digital transition. The insights gained will not only inform strategic decision-making for postal operators but also provide valuable lessons for interconnected sectors such as communication, advertising, transportation, and financial services, all of which rely on robust delivery networks for economic development and enhanced service delivery in a digitally transformed era.

2 LITERATURE REVIEW AND BACKGROUND

2.1 The Fourth Industrial Revolution and Its Impact

The Fourth Industrial Revolution, a term coined by Klaus Schwab, transcends mere technological advancements, signifying a comprehensive transformation of entire systems of production, management, and governance [1] Its core tenets revolve around cyber-physical systems, IoT, cloud computing, AI, machine learning, big data, additive manufacturing, and autonomous robotics. These technologies enable unprecedented levels of automation, data-driven decision-making, hyper-connectivity, and personalization, fundamentally altering industries and economies worldwide [3]

Sectors like manufacturing have embraced "Industry 4.0" concepts, leading to smart factories where machines communicate autonomously, optimizing production lines and reducing waste. The retail sector has leveraged e-commerce platforms, AI-driven personalization, and sophisticated logistics to redefine customer experience. Financial services have seen the rise of FinTech, blockchain, and automated trading systems. This widespread adoption underscores 4IR's potential to unlock new value propositions and drive efficiency gains.

2.2 The Postal Industry: A Legacy Challenged

The postal industry, rooted in centuries of physical mail delivery, has faced unique challenges in the digital age. Its traditional business model, heavily reliant on physical infrastructure and manual processes, has been significantly disrupted by the rise of digital communication (e.g.,

email, instant messaging, online billing). This has led to a steep decline in letter mail volumes, which historically constituted a significant portion of postal revenues [2].

Despite this challenge, the burgeoning e-commerce market has opened a new frontier: parcel distribution. As online shopping continues its exponential growth, the demand for reliable, efficient, and traceable package delivery has surged, positioning postal operators as key players in the "last mile" delivery ecosystem [4] However, success in this new landscape requires a departure from traditional operational paradigms and a proactive embrace of 4IR technologies.

2.3 The Importance of Parcel Distribution in the Digital Economy

Parcel distribution is now arguably the most critical service offered by postal organizations and related logistics providers. It serves as the physical backbone of the digital economy, connecting online retailers with their customers. The efficiency, speed, cost, and reliability of parcel delivery directly impact customer satisfaction, online retailer competitiveness, and overall economic activity .

Factors such as same-day delivery expectations, detailed tracking, flexible delivery options (e.g., locker systems, alternative pick-up points), and reverse logistics capabilities have become standard demands. This intensifies pressure on postal and logistics companies to innovate their parcel networks, pushing them towards greater automation, data utilization, and integrated supply chain solutions – all areas where 4IR technologies offer significant potential.

3 METHODOLOGY

This study employed a systematic literature review (SLR) approach to examine the evolution of the parcel distribution sector within the postal industry concerning 4IR-driven transition between 2010 and 2024. An SLR is a rigorous, transparent, and replicable method for identifying, evaluating, and synthesizing all relevant studies on a particular topic [5].

The following steps were undertaken:

3.1. ***Defining Research Questions:*** The primary research question guiding this review was: "To what extent and in what nature has the parcel distribution sector within the postal industry transitioned under the influence of 4IR technologies between 2010 and 2024?"

3.2. ***Identifying Relevant Databases:*** Key scholarly databases were systematically searched, including Scopus, Web of Science, IEEE Xplore, ACM Digital Library, and Google Scholar.

3.3. ***Developing Search Strings:*** Comprehensive search strings combining keywords related to the postal industry, parcel distribution, 4IR technologies, and digital transformation were formulated (e.g., "postal industry" AND "4IR" OR "Fourth Industrial Revolution" AND "parcel logistics" OR "e-commerce delivery" AND "digital transformation" AND "automation" AND "AI" AND "IoT" AND "robotics"). Date filters were applied (2010-2024).

3.4. Inclusion and Exclusion Criteria:

- ***Inclusion:*** Peer-reviewed journal articles, conference proceedings, and reputable industry reports focusing on the postal sector or last-mile delivery, explicitly discussing 4IR technologies, digital transformation, and published between 2010-2024.
- ***Exclusion:*** Opinion pieces, non-peer-reviewed articles, studies not directly related to parcel distribution, or those outside the specified timeframe.

3.5. Screening and Selection: Initial screening was based on titles and abstracts. Full-text articles of potentially relevant studies were then retrieved and assessed against the inclusion criteria. A PRISMA-like flow diagram would typically illustrate the selection process [6]

3.6. Data Extraction and Synthesis: Key information from selected articles was extracted, including specific 4IR technologies discussed, their application in parcel distribution, perceived benefits, encountered challenges, case studies, and recommendations. Thematic analysis was then used to synthesize the findings and identify common trends and patterns of transition.

This systematic approach aimed to minimize bias and provide a comprehensive overview of the academic discourse surrounding the postal industry's digital evolution in parcel distribution.

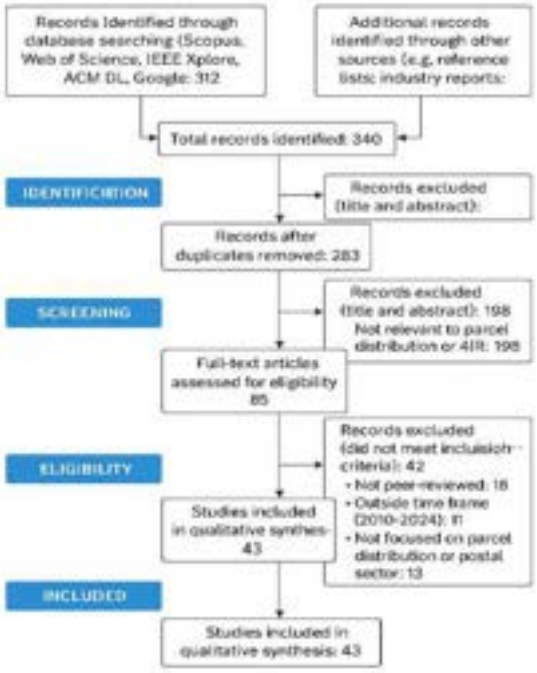

Figure 1: PRISMA flow diagram of the study

4 CONCEPTUAL FINDINGS AND DISCUSSION

Based on the premise of the abstract and general knowledge of the postal industry's trajectory from 2010-2024, the systematic literature review would likely reveal a significant picture of 4IR adoption in parcel distribution. While some resistance to digital change was observed in traditional postal services, while the parcel segment's adaptation has grown, it has frequently been a reactive rather than a proactive process.

4.1 Initial Resistance and Legacy Challenges (2010-2015)

In the earlier part of the review period (2010-2015), the postal industry, particularly legacy national operators, demonstrated a relative resistance to embracing radical digital transformation in their parcel operations. This resistance could be attributed to:

- **Legacy Infrastructure**: Significant investment in physical sorting centres, delivery vehicles, and a vast human workforce built around traditional mail, making radical shifts costly and complex.
- **Regulatory Hurdles**: Public service obligations and complex regulatory environments often slowed down innovation and commercial agility [7].

- **Cultural Inertia**: A deeply entrenched organizational culture focused on historical mail services, potentially leading to a lack of urgency, or understanding of the e-commerce paradigm shift.
- **Limited Initial Capital**: Declining traditional mail revenues meant less capital available for significant digital investments.

During this period, primary adaptations were often limited to basic online tracking systems and e-commerce integration, primarily driven by external competitive pressure from private courier companies.

4.2 Reactive Adaptation and Incremental Automation (2015-2020)

As e-commerce exploded globally, the postal industry could no longer ignore the immense opportunities and competitive threats in parcel delivery. The period from 2015 to 2020 would likely show a more reactive, yet increasingly determined, push towards 4IR adoption in parcel distribution.

- **Increased Automation in Sorting**: Investment in automated sorting machines, conveyor belts, and robotics within major parcel hubs to handle escalating volumes more efficiently. This aimed to reduce manual labour costs and speed up processing [8].
- **Enhanced Tracking and Visibility**: Development of more sophisticated online tracking systems, real-time updates via mobile apps, and estimated delivery windows, driven by customer demand for transparency.
- **Expansion of Delivery Networks**: Introduction of parcel lockers, pick-up points (PUDO), and flexible delivery options to cater to customer convenience and mitigate failed deliveries.
- **Early Trials of Advanced Technologies**: Pilot projects involving drones for remote delivery autonomous vehicles for last-mile delivery, and data analytics for route optimization.
- **Focus on Last-Mile Efficiency**: Recognizing the cost-intensive nature of the last mile, emphasis shifted towards optimizing delivery routes using GIS and basic AI algorithms and exploring crowd-sourced delivery models.

Despite the adjustments, these shifts were frequently small-scale and disconnected, making it hard for many postal organizations to truly integrate various technologies into a single, smart system.

4.3 Accelerating Digital Integration and Strategic Partnerships (2020-2024)

The latter part of the review period, especially accelerated by the COVID-19 pandemic which pushed more commerce online, would reveal a more proactive and strategic approach to 4IR integration.

4.3.1. AI and Machine Learning for Demand Forecasting and Route Optimization: Sophisticated AI algorithms are now being used not just for static route planning but for dynamic adjustments based on real-time traffic, weather, and fluctuating demand patterns. Machine learning is also improving parcel volume forecasting, optimizing resource allocation.

4.3.2. IoT for Asset Tracking and Predictive Maintenance: Sensors embedded in vehicles, containers, and even parcels provide real-time data on location, temperature, and handling conditions, enhancing security, traceability, and enabling predictive maintenance for fleet management.

4.3.3. Robotics in Warehousing and Sorting: Beyond basic automation, advanced robotics, including collaborative robots (cobots) and automated guided vehicles (AGVs), are increasingly common in large sorting centers and warehouses to improve throughput and reduce human intervention

4.3.4. Blockchain for Supply Chain Transparency: While still nascent, some postal services are exploring blockchain for enhanced transparency, security, and traceability of high-value parcels, especially in international shipments, streamlining customs and payment processes.

4.3.5. Data Analytics for Customer Insights: Leveraging big data to understand customer preferences, predict delivery failures, personalize services, and optimize marketing campaigns.

4.3.6. Strategic Partnerships: Recognition that no single entity can master all 4IR technologies, leading to increased collaborations between postal operators and technology firms, logistics startups, and e-commerce giants.

The findings suggest that while the postal industry initially lagged, the parcel distribution segment has begun to embrace 4IR technologies more aggressively, driven by competitive pressures and the immense growth of e-commerce. However, challenges remain in system integration, workforce reskilling, and the significant capital investment required.

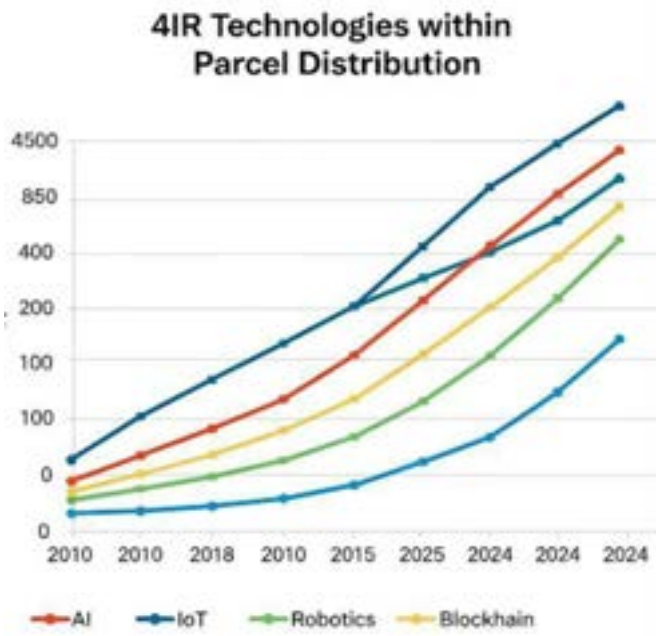

Figure 2: 4IR Technologies within parcel distribution.

Figure 2 is a graph which illustrates the increasing trend of 4IR technology adoption in parcel distribution from 2010 to 2024. The integration of technologies like AI, IoT, Robotics, and Blockchain has steadily grown over this period.

Authors [30] and [31] explore early innovations in last-mile deliveries, with [31] specifically discussing parcel lockers as a solution to support e-commerce logistics. More recent works, such as those by [22], [23], and [24] provide comprehensive reviews of innovative solutions, practices, and future directions for last-mile delivery. Authors [25] and [26] specifically link last-mile changes in courier and postal services to the growth of e-commerce.

[16] and [10] discuss early robotic and automation systems for parcel handling. This is expanded upon by [27], who explore AI-augmented self-driving robots for last-mile deliveries, and by [29], who analyze the impact of AI on last-mile delivery in the e-commerce sector. [13] specifically review the use of AI in postal and parcel sorting.

[20] and [12] focus on IoT's role in creating smart, automated postal and parcel systems. Authors [11] identify key success triggers for the digital transformation of postal services while [3] provide a foundational view of Industry 4.0, which underpins the technological shifts discussed by other authors. [1] offers a broader perspective on the Fourth Industrial Revolution, which serves as a conceptual framework for many of these technological changes.

A number of authors connect logistics and technology to sustainability, authors [32] compare the CO2 emissions of direct deliveries versus automated parcel locker systems. [35] and [38] discuss green postal services and the broader concept of green logistics for sustainability.

Authors [33] and [41] explore how technology is transforming transport and logistics into more sustainable systems.

5 IMPLICATIONS FOR STRATEGIC DECISION-MAKING

The retrospective analysis of 4IR transition in the postal parcel distribution sector offers several critical implications for strategic decision-making for various stakeholders:

5.1. For Postal Operators:

5.1.1. Prioritize Digital Investment: Continued and accelerated investment in AI, IoT, and robotics is not an option but a necessity to remain competitive and efficient.

5.1.2. Focus on Last-Mile Innovation: The last mile remains the most expensive and complex part of delivery. Strategies should focus on smart lockers, drone/robot delivery trials, and data-driven route optimization.

5.1.3. Talent Transformation: Reskilling the existing workforce and attracting new talent with digital and analytical skills is crucial to manage and leverage 4IR technologies.

5.1.4. Embrace Partnerships: Collaboration with technology providers, start-ups, and e-commerce platforms is vital for agile innovation and expanding service offerings beyond traditional mail.

5.1.5. Data Monetization: Leverage the vast data collected from parcel movements to create new value-added services (e.g., market insights for e-commerce clients).

5.2. For Related Sectors (Communication, Advertising, Transportation, Financial Services):

5.2.1. Enhanced Last-Mile Capabilities: For e-commerce businesses, the digital transformation of postal parcel services translates to improved last-mile capabilities, impacting customer satisfaction and delivery speed. This directly affects advertising effectiveness and communication with customers.

5.2.2. Integrated Logistics Solutions: Financial services can leverage enhanced traceability and real-time delivery information for secure payments and insurance products linked to goods in transit.

5.2.3. New Advertising Channels: Smart parcel lockers or delivery vehicles could become new touchpoints for targeted advertising.

5.2.4. Economic Development: Efficient parcel networks are a key enabler of e-commerce growth, especially in emerging markets, contributing significantly to national and regional economic development by facilitating trade and job creation.

5.2.5. Infrastructure Planning: Transportation and urban planners must consider the evolving needs of parcel delivery, including potential for drone hubs, electric vehicle charging infrastructure, and efficient micro-fulfilment centres in urban areas.

6 CONCLUSION

The postal industry, particularly its parcel distribution arm, stands at a pivotal juncture. While the abstract correctly identifies an initial resistance to digital adaptation stemming from its legacy operations, the period from 2010 to 2024 has witnessed a gradual yet accelerating embrace of Fourth Industrial Revolution technologies within the parcel segment Intense e-commerce growth and competition have pushed postal operators to evolve from basic tracking to advanced automation, AI optimization, and even blockchain exploration.This literature-based review conceptualises a trajectory that began with cautious incremental changes and evolved into more strategic and integrated digital initiatives, particularly in the latter half of the review period. The findings underscore that successful navigation of this landscape requires not just technological adoption, but a fundamental shift in business models, organizational culture, and strategic partnerships. For all stakeholders, from postal services themselves to the broader ecosystem of communication, advertising, transportation, and financial services, understanding this evolution is paramount to leveraging digital transformation for economic development and enhanced service delivery in the increasingly interconnected global economy.

Limitations and Future Research: This conceptual paper is based on a systematic literature review's typical finding. An actual empirical study would involve a detailed analysis of specific papers, quantifying trends, and potentially identifying specific case studies or geographical variations. Future research could conduct a meta-analysis of the impact of specific 4IR technologies on operational efficiency or customer satisfaction in postal parcel delivery or compare the digital transformation trajectories of national postal operators versus private courier companies.

ABSTRACT

Digital transformation is regarded as an important aspect central to the mining sector's development. Resultantly, mining companies are investing in digital technologies to improve productivity, safety and sustainability. However, progress is slow, particularly in developing regions like South Africa, due to insufficient infrastructure, finances and skilled labour. A key barrier is a growing digital skills gap that negatively impacts workforce readiness and adaptability. This paper explores the South African and global mining sectors' digital transformation environments, its drivers and obstacles with a focus on workforce implications. Through a scoping literature review employing a Boolean search strategy across multiple academic databases and industry findings, the study highlights the underrepresentation of human factors and digital skills in the digital transformation literature. The findings emphasise the need for a structured digital skills framework tailored to the sector's needs. By focusing on digital skills, this paper contributes to the broader debate of workforce modernisation.

Keywords: Digital transformation, mining sector, digital skills, South Africa

1 INTRODUCTION

The importance of digital transformation in the modern economy is widely recognised [1]. Kraus *et al*. [2] argue that it has shifted from being perceived as a technological prospect to being recognised as an imperative, essential for maintaining competitiveness and sustainability over the long run. While many definitions of digital transformation exist, this paper defines it as "the use of digital technologies to create new or modify existing business processes, culture and customer experiences in order to meet changing business and market needs" [3]. Its influence across various industries has been vastly reported with linkages to operational efficiencies, productivity enhancements, cost reduction, value creation, innovation and long-term sustainability [4], [5]. For the local mining industry, the emergence of digital transformation is both timely and necessary. It is currently regarded as a key driver of industry development and is expected to help address critical challenges, including high operating costs, low productivity and efficiency, depletion of high-grade reserves and hazardous working conditions [6].

Despite its potential, however, the industry is reported to be lagging behind other comparable industries in terms of implementing digital transformation, particularly in developing regions, including South Africa [6], [7]. Furthermore, companies which have implemented digital transformation initiatives often report limited success in achieving their intended outcomes [8]. While issues such as a lack of a digital strategy, infrastructure limitations, organisational structures and processes, culture and technology integration challenges have been noted as contributing factors, human capital is increasingly being recognised as a key enabler in the context of digital transformation [4], [6], [9], [10], [11].

Notably, academic literature on digital transformation in the mining sector remains limited [12], particularly in relation to human and workforce dimensions which underpin successful transformation. Much of the existing literature focuses on technology, processes and strategy [13] giving insufficient attention to the people who must implement and operate these systems. Despite a growing concern among mining stakeholders regarding the widening digital skills gap, which poses a significant barrier to workforce adaptability and readiness [14], [15], [16], [17], [18], human factors and digital skills development remain underrepresented in both academic and industry discourse. Furthermore, the existing literature on digital skills tends to be largely concentrated in the global north, leaving a dearth of studies pertaining to Sub-Saharan Africa, notably South Africa [19].

In response to these gaps, this paper offers three contributions. Firstly, it examines the digital transformation landscape in mining both globally and within South Africa. Secondly, it adds to the limited body of knowledge on digital skills by addressing a dual underrepresentation. Geographically, it focuses on South Africa and contextually it examines digital skills within an industrial workplace setting, namely the mining sector. Thirdly, it integrates digital skills and digital readiness, domains often treated in isolation, thereby contributing to a more holistic understanding of workforce capability in digitally evolving work environments.

Through a structured literature review and industry insights, the paper explores key challenges, trends and opportunities associated with digital transformation. It argues for the urgent need for a structured context-specific digital skills framework tailored to the mining sector. The focus on digital skills contributes to the broader discourse on digital transformation and workforce modernisation.

2 METHODOLOGY

Given the broad and under-researched nature of digital transformation workforce dimensions and digital skills in the mining sector, the study upon which this paper reports, employs a scoping review methodology. This approach is appropriate for mapping key concepts,

identifying gaps in the literature and informing future direction of research [20]. The objective was to consolidate existing knowledge, identify recurring themes and uncover gaps in both global and local (South African) discourses related to mining digital transformation and human capital development. The review serves as a foundational step toward developing a context-specific digital skills framework that reflect the realities of workforce transformation in the mining sector, particularly in emerging economies.

2.1 Research questions

Four central research questions guided the review:

1. What are the main drivers and barriers to digital transformation in the mining sector?
2. To what extent are human factors and digital skills addressed in digital transformation literature?
3. What human factors affect the digital readiness of the workforce?
4. How are digital skills defined, categorised, or conceptualised in the context of the mining sector?

2.2 Research design

Due to the multidisciplinary nature of the study, three separate searches were conducted to ensure adequate coverage of the topic, each using carefully constructed Boolean search strings. This approach has been widely adopted in academic scoping and systematic reviews due to its ability to balance breadth and precision (e.g., [21], [22], [23],). The searches were conducted across ScienceDirect and Google Scholar (for supplementary and grey literature due to the emerging nature of the topic).

The first search used the search string “Digital transformation” AND “digital skills” AND “mining sector” OR “mining industry. The second search used the key “human factors” AND “digital transformation” whilst the last search used the key "digital transformation" AND "digital readiness" OR "workforce readiness" OR "employee readiness ".

2.3 Eligibility Criteria

To ensure relevance and focus, the following inclusion and exclusion criteria were applied:

Inclusion criteria:

1. Peer-reviewed journal articles, reports, thesis conference proceedings and industry publications
2. Published between 2015 and 2024 (to capture recent and relevant developments)
3. Studies that mention or explore digital skills, digital competencies or technological competencies in the mining sector.
4. Studies that discuss workforce readiness or human factors were not limited to the mining sector due to the limited availability of literature relating to the mining context.
5. Had relevance to the study objectives.
6. Publications in English

Exclusion criteria:

1. Articles mentioning or exploring digital skills not related to the mining industry.
2. Studies focusing on general skills not related to digital transformation.
3. Published before 2015
4. Had no relevance to the study objectives.
5. Non-English publications

2.4 Data Analysis

Thematic analysis was applied to the selected literature to identify and categorise key concepts under three broad themes:

1. Digital transformation in the mining sector
2. Human factors and digital readiness
3. Digital skills requirements in the mining sector.

This analysis provided the foundation for the critical evaluation presented in subsequent sections and informed the recommendation for a tailored digital skills framework for the mining sector.

3 DIGITAL SKILLS AND TRANSFORMATION IN MINING: A REVIEW

The reviewed literature reveals a notable underrepresentation of the human dimension on digital transformation within the mining sector. This is particularly the case as far as workforce skills and behavioural readiness are concerned. However, studies from other sectors do demonstrate that human factors are closely linked to digital readiness. These factors often determine the failure or success of digital transformation initiatives. These findings suggest that strengthening workforce capabilities, attitudes and adaptability of the mining workforce could accelerate digital transformation in the South African mining sector. The following review examines these themes in detail. It begins with an overview of digital transformation in the mining sector, followed by evidence from other industries on the role of human factors and digital readiness. It concludes with a review of digital skills requirements specific to the mining sector for effective adoption.

3.1 Digital transformation in the mining sector.

Defined as the integration of digital technologies and data analytics to achieve mining organisations' objectives, digital transformation is widely recognised as a key driver for the sector's future competitiveness and sustainability [24]. Despite this recognition, the sector's trajectory toward digital adoption has been inconsistent and, in many cases, slower than anticipated. This has led to the growing interest in understanding the underlying causes behind the lag. Gao *et al*. [7] suggest that the low adoption rate of digital technologies in mining may be attributed either to intentional resistance or pervasive challenges.

The existing literature tends to support the latter explanation, with several studies highlighting not only the urgent need for digital transformation but also the sector's stated commitment to it. Notably, a survey of mining executives from over 151 mining organisations globally revealed that 90% of them are actively incorporating digital transformation into their strategies and decision-making processes [25]. In South Africa, a survey by PricewaterCoopers and Minerals Council South Africa [26] revealed that mining executives across the sector unanimously reported a shift toward digital operations. This growing momentum reflects the sector's recognition of the need to adapt to a rapidly changing operational landscape.

3.1.1 The need for digital transformation

At the heart of this transformation are several broad driving forces, which can be categorised into physical [25], [27], [28], market [29], and policy-related factors [30], [31]. The physical challenges of accessing more complex and remote ore bodies, market volatility and evolving consumer demands necessitate a shift in operational practices. Policy changes, particularly those related to environmental regulations and social responsibility, also play a key role [27]. It is important to note that these factors drive many aspects of change in mining, with digital transformation providing a significant though not standalone, response that complements other strategic, operational and policy measures. Figure 1 below summarises these factors in the global mining sector.

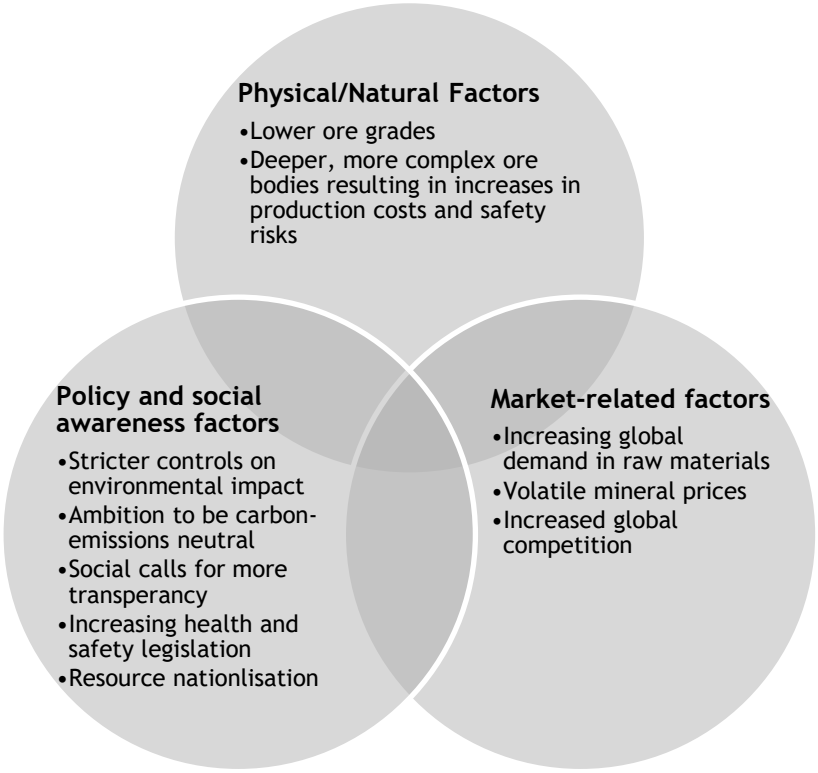

Figure 1: Factors driving digital transformation in the mining sector, Adapted from [27]

In addition to the global challenges, South African mining organisations have to contend with other unique challenges. These include labour availability and utilisation, an uncertain regulatory environment, escalating government demands and energy reliability issues due to its national energy provider [32], [33]. As traditional mining methods and practices become increasingly unsustainable, the case for transformation cannot be clearer. The overwhelming consensus is that the mining sector must accelerate its digital transformation [34], [35]. The risks of falling behind developed economies are too great as demonstrated by the global decline in mining productivity over the past decade [36]. Moreover, Sánchez and Hartlieb [25] identified digital effectiveness as a top industry risk for mining, underscoring the urgency of embracing new technologies.

3.1.2 The impact of digital transformation.

The impact of digital transformation in mining reveals two sides of the story. While anticipated benefits such as increased productivity, enhanced maintenance, improved safety, reduced operational costs and minimised environmental harm [37] are well documented in the literature, the reality on the ground tells a more nuanced story. There are notable examples of effective digital integration such as Rio Tinto's Pilbara mine, which has achieved significant improvements in safety and productivity through automation, BHP's autonomous drills which have reduced cost by 40% and increased productivity by 25% [38], Codelco' s autonomous trucks have led to reduced collision risk and enhanced productivity [25]. However, the broader sector picture remains more nuanced, as many organisations continue to face challenges in translating digital aspirations to tangible value [29], [39]. This brings the discussion back to the presence of systemic challenges hindering widespread digital adoption in mining.

3.1.3 Challenges or barriers to implementing digital transformation in the sector.

Challenges to implementing digital transformation are not unique to the mining sector. In fact, prior research estimates that as much as 70% of all digital transformation initiatives do not reach their stated goals [40]. However, there are several characteristics distinguishing its context from other industries. Buck *et al*. [37] highlight the sector's substantial asset base and its operational distance from consumer interaction as defining factors. The challenges are grouped into clusters and discussed in Table 1 below.

Table 1: Barriers and challenges associated with digital transformation in the mining sector.

Barrier cluster	Specific barrier	Source
Infrastructure limitations	Connectivity challenges, particularly in remote or deep mining areas	[33]
	Limitations with existing Information Technology (IT) infrastructure	[5]
	Lack of Internet of Things (IoT) standards	[12]
	Lack of access to standardised data	[37]
Technology related challenges	Inability of technology providers to offer customised solutions	[24]
	Lack of proven technology	[34]
	Lack of maturity in technologies	[12]
	Lack of compatibility of new technology with existing processes and systems	[35], [37], [34]
Digital strategy	Lack of genuine ownership of the digital strategy	[36]
	Strategic misalignment between organisational goals and anticipated benefits of technology	[34]
	Lack of digital reorganisation – digital technology not integrated into every function of the organisation	[36]
Organisational culture and resistance	Short-term focus on Return-on-Investment. Fixation with immediate results.	[35], [36]
	Lack of emphasis on creativity. Performance recognition systems overly focused on efficiency and short-term gains	[35]
	Lack of employee involvement in decision-making	[35]
	Lack of change management	[6]
	Employee-management relationship	[12]
	Negative attitude towards technology particularly in older workers.	[7], [6]
Financial challenges	Low capital reserves	[34]
	Capital-intensive nature of the sector	[35]
	Market volatility	[38]
Workforce skills gaps	Skills and knowledge deficits	[34], [37]
	Lack of investment in employee training	[36]

Source: Author compilation

The table reveals a heavy emphasis on technical and infrastructural barriers. There is a notable underrepresentation of the human dimension, particularly in relation to workforce skills and behavioural readiness. While organisational culture and resistance appear as a barrier cluster, the depth of analysis on employee attitudes, specific skills deficits and training investment is limited. Most studies only mention skills gaps in general terms, without offering specific

insights into how the demand for digital skills in the sector unfolds. Although the scarcity of discussion in the literature could suggest it is perceived to have less impact than technical or infrastructural barriers, research from other sectors indicates that workforce skills and behavioural readiness are critical to the success of digital transformation initiatives [61], [67], [77]. It is therefore necessary to further explore this within the context of the mining sector to determine the reasons. This lack of granularity is particularly problematic in underrepresented regions such as Sub-Saharan Africa, where systemic education and digital literacy challenges [42] intersect with mining's labour-intensive operations [43] .

3.1.4 The importance of the human dimension for the sector.

The lack of representation on the human dimension reflects a broader trend in the digital transformation research despite the growing recognition of the criticality of the human role towards successful digital transformation [44]. Moreover, there are a few distinct characteristics of the South African mining sector that makes this discussion not only pertinent but timely.

Table 2: Dynamics characterising the context of the South African mining sector.

Characteristic	Relevance (Why is it important?)
Various reports on human capital indicators have indicated a significant gap pertaining to South Africa's ability to leverage its human capital in implementing digital transformation. South Africa scored poorly on "*Readiness for the Future of Production*" and "*Automation Readiness Index*", [45], [46]	This suggests that the sector is already at a disadvantage by virtue of its location in a context characterised by broader developmental constraints, rendering it ill-prepared for digital transformation. The continued neglect of digital skills development may not only hinder technological progress but also exacerbate already high unemployment rates and contribute to the widening of the digital divide. [42], [47]
The South African mining sector features a notable presence of semi-skilled and low-skilled labor [48]	These groups are vulnerable to job displacement without the intervention of upskilling and reskilling [49]
Trade unions within the highly unionised mining workforce has expressed concern about job losses associated with modernisation [50]	Attitudes towards technologies could be influencing workforce digital adoption. Greunen *et al*. [51] argues for the inclusion of individuals' motivation in digital transformation discourse. They contend that unless individuals are motivated to engage in technology usage to achieve their objectives, concrete benefits will remain limited.
Like its host nation which is among the globe's most unequal societies [47] , the sector workforce demographic reveal that only 12% of mining employees hold a qualification [52]	Bergson-Shilcock *et al*. [53] indicate that lower levels of education are highly correlated with limited digital skills. Furthermore, the World bank [54] notes that highly inequal societies are at an elevated risk for high levels of digital exclusion.
The mining sector struggles with competing for talent [6]	This emphasises the importance of developing the skills of the current internal workforce

Source: Author compilation

Owing to the paucity of the human dimension in the mining digital transformation literature, a wider net was cast to explore the literature beyond the mining sector to gain insight into the human factors influencing adoption and integration of digital technologies as part of the global digital transformation. The next section thus examines evidence from other sectors linking human factors and digital readiness as critical to achieving sustainable digital transformation.

3.2 Human factors and digital readiness: Evidence from other sectors.

According to Winter *et al*. [51], the recognition of human factors as a scientific discipline date back to the era of World War II in response to the rapid introduction of technologies during that time. The original intent around the concept was to ensure that the designs of systems incorporated the capacities and limitations of their intended users. Neumann et al. [56] categorise human factors into three main domains: mental, physical and psychosocial. The mental domain encompasses the development and application of capabilities, skills, experience, education and behavioural attributes. In contrast, the physical domain focuses on the bodily and ergonomic dimensions of work, emphasising worker safety, manual operations and overall physical well-being. Finally, the psychosocial domain focuses on social and psychological dynamics that influence workplace behaviour and organisational culture, including employee involvement, motivation, job satisfaction and feedback.

Reinforcing the importance of the employee role, Cetindamar Kozanoglu and Abedin [53] argue that digital transformation depends not only on technological integration, but also on employees' ability and willingness to engage with the digital technologies. This necessitates a structured approach to digital skills development. They note the neglect of the employee role and experience in digital transformation literature and call for the reimagination of both. Their perspective on skills, framed through the affordance theory suggest that opportunities for behaviour do not automatically result in actualisation. A critical implication of their argument is that digital skills development must go beyond knowing how to use digital technologies. It must also include the awareness of when and why to engage with them. This notion suggests that knowledge, perceptions and attitudes of employees towards technologies are just as important as their ability to use them. Such insights are of particular interest to the mining sector given its reported low rate of digital technology adoption [8].

In the same line of thought, Roberts *et al*. [54] argue that digital innovations are only successful if they are adopted, used and integrated into work practices. There is therefore a need to understand the factors shaping adoption behaviours [40]. To explore these factors, the paper draws insights from the technology adoption literature. This body of work consistently demonstrates that adoption is not solely a technical process but a complex interplay of human behaviour, cognitive factors and external influences. While a comprehensive analysis of technology adoption models is beyond the purview of this paper, their examination reveals two key themes central to the current discourse. Firstly, individuals' attitude towards the technology, whether positive or negative is crucial in determining adoption. Secondly, the perceived effort required to use technology influences users' confidence in their ability to navigate it. This paper argues that this confidence is inherently linked to a user's digital skills[59].

Nadeem *et al*. [56] consider employees to be the primary stakeholders in digital transformation. They argue that organisations must manage workforce challenges beyond upskilling and reskilling. These challenges include employee motivation, resistance to change and a fear of losing jobs, all of which can significantly influence the success of digital transformation initiatives. Similarly, Rocha *et al*. [57] advocate for the development of a digital mindset which goes beyond digital literacy and technical skills. Such a mindset includes an understanding and appreciation of the value of digital transformation, as well as the knowledge of how a data-driven business operates.

Some studies stress the need to create opportunities for active participation and involvement in digital transformation efforts. It is noted that involving employees in decision-making, enhances not only their openness to transformation, but also their willingness to learn [44], [62]. In their literature review on the prevalence of human elements in digital transformation, Kaszás et al. [59] found the need for change in attitudes amongst employees, the importance

of skills and continuous learning, and lastly collaboration and communication as key elements to consider.

The literature on human factors in digital transformation points to increasing expectations from the future workforce, raising a pertinent question: Are employees ready for this transformation? Cetindamar Kozanoglu and Abedin [57] caution that employees who are not prepared for digital transformation will have feelings of information overload and anxiety, which can have disastrous outcomes for the digital transformation process. While much of this literature originates outside the mining sector, the insights are particularly relevant given mining's unique challenges. Low levels of digital adoption in the sector have been linked to workforce capacity challenges and transformation efforts often confront entrenched organisational cultures and skills gaps [7], [34], [35].Mahmoodi *et al*. [64]'s finding that employees' digital readiness can increase technology adoption rates by as much as five times further highlights its criticality towards digital transformation.

3.2.1 Digital readiness and workforce implications

The paper defines digital readiness as the ability and confidence to effectively use digital technology while maintaining a positive outlook towards their use [59], [61], [65], [66]. Workforce readiness is a critical factor in the success of digital transformation, yet much of the existing literature has focused on organisational readiness rather than employee readiness. While various studies examine workforce readiness in manufacturing [67], education [66], [68] and healthcare [44], research on workforce readiness within the mining sector remains scarce. This gap reinforces the urgent need for industry-specific studies, particularly because mining presents unique technological and operational challenges.

Bahyan et al. [65] advocate for raising awareness among employees to prepare them for the inevitable changes brought by digital transformation. Althubaiti et al. [66] suggest that this awareness can be accomplished through structured technology sessions. Similarly, Paryanto et al. [70] highlight openness to change coupled with strong digital capabilities as fundamental aspects of workforce preparedness.

Recent research emphasises the importance of robust change management practices. Some studies argue that the inevitable change associated with digital transformation is almost impossible without the assistance of change management specialists [61], [71], [72], [73]. Mutambik *et al*. [74] note that resistance to change not only slows down digital transformation but can exacerbate existing problems in the workplace, particularly when employees perceive change as disruptive or threatening. Narbariya *et al*. [68] contend that readiness is shaped by the employees' belief about their own and the organisation's capacity to change, as well as the perceived benefits of doing so. Mutambik *et al*. [74]'s empirical study supports this view, finding that direct benefits to employees – (*those directly affecting the employee*) have a stronger influence on acceptance than indirect organisational benefits. These findings align with Paryanto et al. [70], who found that employees are generally more receptive to change if it perceived to improve their daily tasks.

Yet, a critical challenge remains in understanding whether digital transformation initiatives truly benefit individual employees. While the broader organisational gains are well-documented [75] , the question of whether employees perceive such changes as advantageous to their roles and well-being is frequently overlooked [44], [74]. A case study conducted by Bulgheroni et al. [44] at a hospital in Italy highlights this disconnect. The study found that resistance to digital technologies initially stemmed from management's failure to clearly demonstrate how digital tools would directly benefit staff. Once employees began to perceive tangible improvements in their day-to-day work, adoption increased significantly. The authors concluded that the alignment of digital tools with existing workflows and employee needs was a critical factor in successful adoption.

Resistance to digital transformation is frequently driven by employees' own perceived lack of digital skills or technological competence. Employees who feel unprepared or incapable of using new technologies are more likely to experience stress, anxiety and fear of job displacement. Beyond the acquisition of digital skills, the literature increasingly points to the importance of continuous learning and adaptability as crucial components of digital readiness. Rocha *et al*. [61] point to a lack of motivation and initiative to learn new things as key issues for readiness. They stress the need for employees to develop their ability to learn on a continuous basis. Similarly, Pham *et al*. [43] state that to achieve digital readiness, it is not sufficient to just develop the digital skills but also foster individual learning. Anatan [67] and Zabelina et al. [76] found that unskilled employees are less likely to embrace training opportunities, particularly when these come at a personal cost. This is very relevant for mining considering their notable presence in the sector.

The current paper could identify only a limited amount of research pertaining workforce digital readiness. A broader review of organisational digital readiness models was therefore conducted to identify which themes were covered related to the human or workforce aspect. Only the dimensions dealing with human aspects were considered. The findings are presented in Table 3 below.

Table 3: Human factors representation in organisational digital readiness models

Source	Industry	Factors considered
[77]	Manufacturing	ICT employee skills; qualifications; knowledge in digital transformation areas; continuous training
[78]	SMEs, in the Food industry	Experience of leaders; education levels; entrepreneurial experience; views of social capital
[79]	Manufacturing SMEs	Employee skills; skills acquisition; knowledge sharing and collaboration; innovation management; integrity of leaders
[80]	Supply chain ecosystem	Education; training and development; digital skills and knowledge of digital transformation; access and usage of internet
[71]	Not specified	Motivation for change; digital competencies
[67]	SMEs, industry not specified	Knowledge about digital technologies; management support; motivation to work with digital technologies, competencies to work with digital technologies
[81]	Health	Knowledge, skills, experience; digital leaders; training
[82]	Education	Individual attitude; technology literacy; organisational culture; leadership qualities
[59]	Education	Information seeking behaviour; information sharing behaviour; Digital media awareness
[61]	Manufacturing (large firms)	Digital leadership & sponsors; people engagement; socio-technical capabilities development; digital mindset; breaking resistance

Source: Author compilation

A noticeable trend in industry representation is the concentration of research on manufacturing, education and SMEs while studies on the mining sector remain limited. Even with the variations in the conceptualisation of readiness, common themes emerge. Most models emphasise education, training, digital literacy, digital awareness and leadership as key dimensions of digital readiness. It is therefore reasonable to assume that similar factors would influence digital readiness in the mining workforce. Given the fragmented nature of digital transformation in mining, a pattern similar to that reported by Zabelina *et al*. [76], employee perceptions and attitudes toward technology adoption, training opportunities and job security are likely to play a significant role.

Skills consistently emerge in the literature on human factors and digital readiness, yet they present only one part of the equation. This suggests that workforce capability for digital

transformation should be understood as more than a function of skillsets alone. Consequently, a digital transformation skills framework for the mining sector should include not only technical skills but also digital awareness and adaptability. The next section examines the specific digital skills identified in existing industry discourse and literature within the context of the sector's transformation.

3.3 Digital skills requirements in the mining sector

Digital skills may be broadly defined as attitudes, behaviours capabilities, character traits, competencies and knowledge linked to the use of digital technologies and applications [83]. Their increasing prominence is evidenced by the prevalence of frameworks aimed at understanding and defining these skills. However, much of these frameworks have been generic and developed from a societal perspective [10], [84] with the workplace context mostly neglected.

While there is consensus that the adoption of digital technologies is transforming the nature of work in the mining sector, the sector has been accused of not doing enough to equip its workers for this transformation [17]. Mahmoodi *et al*. [64] highlight the stress increase experienced by employees due to the introduction of technology, particularly when employees lack the necessary skills. Additionally, Ramdoo *et al*. [49] indicate that the policies concerning employment in the sector need to clearly articulate how they will address the concerning mismatch between existing skills and those needed in the mine of the future.

It is reported that while all occupations will be affected, it will not be to the same extent [85]. The Minerals Council Chile [14] estimates that workers from the extraction, processing and maintenance parts of the value chain are the ones most impacted by digital technologies. Due to the paucity of research regarding the conceptualisation of digital skills in the South African mining sector, a broader approach was taken to include the global view. To identify the digital skills requirements globally, skills lists from three mining jurisdictions as presented by their respective Mineral Councils were clustered thematically. Table 4 below presents the results:

Table 4: Digital skills requirements in the mining sector across various regions

Thematic cluster	**Canadian Mining Workforce** [15]	**Australian Mining Workforce** [86], [87]	**Chilean Mining Workforce** [14]	**Prevalence***
Data, analytics and decision support	"Data mining", "data analytics", "statistics", "data interpretation", "mathematics", "statistical analysis", "data-based decision-making"	"Data analytics", "data and digital literacy", "data management", "data modelling", "trend analysis and forecasting", "judgement and decision-support skills"	"data analysis", "judgement and data driven decision-making", "logical-mathematical reasoning"	25%
Engineering/Technical systems	"STEM basic skills", "systems development", "mechanics and advanced engineering", "systems integration", "mine modelling", "programming and coding"	"Operational and planning skills", "troubleshooting", "technical diagnostic", "systems thinking", "scenario planning, predictive modelling and options analysis", "market forecasting", "advanced system development"		20%
Digital operations and Equipment Interaction	"Virtual reality", "artificial reality", "hand eye coordination and quick reaction time"	"Multitasking and real time-monitoring", "simulation proficiency", "spatial awareness", "situational awareness", "digital interface proficiency", " manage autonomous systems"	"Managing integrated operations", "digital management",	17%
Problem-solving and innovation	"Problem solving", "Ability to "think outside the box"", "creativity", "research and product development"	"Advanced problem solving", "design skills"	"Creativity and innovation", "critical thinking"	13%
Collaboration and communication	"Ability to work in diverse groups", "communication", "teamwork"	"Communication and collaboration skills", "interpersonal skills"		8%
ICT and software proficiency	"Computer and software skills", "electronics and maintenance", "IT operations"	"Business information systems operations"		6%
Leadership and change management	"Leadership skills"	"Change management skills"," complex stakeholder engagement",		5%
Adaptability and learning mindset	"Ability to learn and adapt to new knowledge", "lifelong learning"			3%
Sustainability			"Circular economy", "climate change"	3%

Source: Author compilation

From the table above, it is evident that the future mine worker will be expected to be highly data oriented. As such, the ability to interpret and analyse data is considered a core competency. This aligns with Ramdoo *et al*. [49], who identify data as the central force behind disruptive technologies. In addition, workers must be technology savvy. They must possess the technical ability to operate digital tools as well as the ability to interpret digital output. There is also a pronounced emphasis on engineering and technical skillsets. Workers are expected to have a blend of foundational STEM knowledge along with the ability to design, operate and optimise complex mining systems. Cognitive skills such as complex decision-making, creativity and critical thinking are somewhat less emphasised. However, it is argued that the demand of these skills will grow as digital technologies become more integrated, given their resistance to automation [16]. Notably, consistent with the broader digital transformation literature, there is less of an emphasis on softer interpersonal skills, particularly change management and the capacity for continuous learning.

The study upon which this paper reports could not identify any academic literature specifically addressing digital skills needs in the South African mining industry. As a result, the Sector Skills Plan (SSP) - a document compiled annually by the Mining Qualifications Authority in compliance with national legislation was explored as an alternative. The SSP serves as a key mechanism for capturing mining organisations' skills needs and outlining planned interventions to address identified gaps [88] . Notably, digital transformation was identified as a key driver of changing skills requirements in both the 2022-2023 and the 2024-2025 editions. In the earlier edition, digital literacy and computer literacy were highlighted as the most common skill gaps across all occupational levels. However, the latter edition mentions only computer literacy. This raises uncertainty as to whether progress has been made in addressing digital literacy or whether the issue has fallen off the sector's radar. Additionally, digital literacy was merely conceptualised as being digitally informed, familiar with new technologies and possessing the ability to operate said technologies. The absence of a formal framework outlining digital skills requirements in the South African mining sector despite sectoral recognition of digital transformation as a key driver of change highlights a critical disconnect between policy awareness and structured capability development.

4 TOWARDS A DIGITAL SKILLS FRAMEWORK FOR THE SOUTH AFRICAN MINING SECTOR

The preceding sections have highlighted a clear and growing need for digital skills for the mining sector driven by the increasing adoption of digital technologies. Furthermore, a report by the World Economic Forum [15] revealed that 73,3% of mining companies identified a lack of skills as key deterrent from adopting new technologies. Even so, Rotatori *et al*. [89] note a shortage of research informing upskilling decisions and strategies as well policies to support employees in digitally transforming work environments. While international digital skills frameworks and skills lists might frame our understanding of digital skills, Kruss and. Wildschut [90]warn against simply adopting contextually inappropriate frameworks for skills development from advanced economies who have different development trajectories.

Within the South African mining context, this paper positions workforce capability as a function of readiness, skills and adaptability and argues for a digital skills framework that is sensitive to not only skills but also attitudinal elements. Informed by both global literature and regionally relevant insights the proposed framework must strike a balance between technical, technological, cognitive and data related skills while also incorporating the soft interpersonal skills linked to the adaptability of individuals. Furthermore, it should integrate elements of readiness such as perception and attitudes towards digital technologies, access to and uptake of training, employee inclusion and involvement, awareness and understanding of digital tools, confidence in their use and change enablement. As the literature highlights, the motivation and willingness to engage in continuous learning are indispensable in an evolving work environment and should be explicitly addressed in digital transformation efforts.

This paper accepts Pham *et al*. [91]'s characterisation of the reciprocal nature of the relationship between digital skills and digital readiness. They note that the development of digital skills is both a precursor to and an indicator of an employee's readiness to engage with digital technologies. As skills develop through experience, training and confidence, they enhance readiness, which in turn supports further skill acquisition. This interplay forms a foundational premise for the framework proposed in this paper. The paper proposes that a digital skills framework that manages this interplay will be crucial in advancing digital adoption.

5 CONCLUSION AND RECOMMENDATIONS

This article examined the digital transformation landscape of the mining sector both globally and locally, with a particular focus on workforce implications. Digital technologies are anticipated to play a decisive role in addressing critical challenges of high operating costs, depletion of high-grade reserves and hazardous conditions, while enhancing operational efficiency, safety and sustainability. Nonetheless, the rate of digital adoption has been uneven across geographies with infrastructure, regulatory and work-force related challenges often cited in developing regions. The literature however remains heavily weighted towards technical and infrastructural barriers, with comparatively limited focus on the human dimension.

Evidence from other sectors emphasise that human factors, such as digital confidence, adaptability and attitudes toward technology are critical to achieving digital readiness and ultimately successful transformation. Yet, these dimensions remain underrepresented in mining-specific research, especially within developing regions like South Africa. This suggests that targeted interventions to strengthen workforce capabilities, attitudes and adaptability could accelerate digital readiness in the South African mining sector and enhance the effectiveness of technological investments.

A critical gap was also identified between the digital demands of modern mining operations and the existing skills profile of the workforce from a global perspective. Compounding this for the South African mining sector is the fact that the country already has challenges with regards to its human capital as evidenced by various human capital indicators. The lack of a context-specific framework in South Africa highlights the need for a more grounded understanding of digital skills and workforce dynamics within the local mining sector. The paper calls for digital transformation skills framework that integrates human factors, digital readiness and skill categories. Furthermore, it argues for the involvement and engagement of the mining stakeholders in the development of this framework. While literature is a good starting point to provide foundation, Ramdoo *et al*. [49] points out that it is mining companies themselves that are the most appropriate and informed stakeholders for identifying the future skills required in the sector.

Future research could focus on the systematic development and empirical validation of the proposed framework across various mining contexts. Additionally, comparative studies could explore the applicability and adaptation of similar frameworks in other industrial sectors, enabling cross-sectoral learning and refinement.

ABSTRACT

The beef supply chain is important to South Africa's economy, food security, and rural development, with cattle handling facilities playing a critical role in animal welfare, operational efficiency, and meat quality. However, many facilities evolve through trial-and-error designs that neglect cattle behavioural needs, creating stress hotspots and inefficiencies. This study addresses the gap between ethological research and engineering practice by developing behavioural state diagrams that model cattle movement and stress responses across five universal handling phases: movement to sorting pens, passing gates, pen transfers, chute entry, and crush exit. Using an iterative narrative review and UML modelling, observed behaviours and environmental triggers were formalised into discrete states and transitions. The resulting framework links specific design features to behavioural outcomes, enabling more humane, efficient, and evidence-based facility layouts. This approach lays the groundwork for decision-support tools that integrate behavioural science into cost-effective, welfare-driven livestock facility design.

Keywords: Cattle handling facilities, Animal welfare, Facility design, Ethology, Unified Modelling Language

1 INTRODUCTION

The beef supply chain is critical to South Africa's economy, food security, and rural development, with its growth offering significant opportunities for inclusive progress, provided that persistent challenges such as disease management are addressed [1-3]. Within the beef supply chain, cattle handling facilities serve as critical infrastructure from cow-calf operations to abattoirs, delivering both economic and animal welfare benefits [4].

The beef supply chain is a complex process that involves multiple stages, from raising cattle to delivering beef products to consumers. It all starts at cattle production on a farm of any scale with the cow-calf operation, breeding cows to produce calves. Calves are separated from their mothers at the appropriate time to feed on a diet of grass, hay, or specific feed. Farmers sell their fattened-up cattle through an auction or directly to a feedlot for a finishing phase. Here, cattle are brought to an optimal weight for slaughter through a high-energy diet. Abattoirs process the cattle into primal cuts and package them to distribute to wholesalers for further packaging to meet consumer demand.

Each stage is vital to deliver the correct amount of beef product across South Africa. During the stages, cattle are handled through a facility. Cattle handling facilities are crucial at every stage of the beef supply chain because they ensure animal welfare, operational efficiency, and meat quality. On farms, well-designed "kraals", pens, and chutes allow for safe vaccinations, tagging, and sorting, reducing animal and worker stress [5-8]. Reducing stress in feedlots, weighing scales, feed bunks, and hospital pens helps improve cattle health and growth, ensuring optimal weight gain before slaughter. At abattoirs, lairage pens and humane restraint systems comply with food safety and animal welfare regulations, preventing contamination and ensuring ethical treatment. Even in auctions and transport, proper handling facilities minimise injuries and stress, which can affect meat tenderness and safety [9]. Without these systems, the entire supply chain—from farm to fork—would face higher risks of disease, inefficiency, and poor-quality beef, impacting farmers, processors, and consumers alike.

Despite their importance, many cattle handling facilities have evolved through generational trial and error rather than scientific design. Such legacy layouts often prioritise human convenience at the expense of animal welfare, neglecting key behavioural factors like flight zones and herd dynamics [10-13]. Common design flaws, including narrow chutes, dead ends, and inconsistent lighting, create predictable stress hotspots that trigger adverse responses[4]. Although stress behaviours in livestock are well documented, practical tools to translate these insights into engineering design parameters remain limited [7, 13].

A critical gap exists between ethological research, the scientific study of animal behaviour, and engineering practice. Ethology records behavioural thresholds but rarely expresses them in ways compatible with simulation tools [14, 15]. Meanwhile, engineering models tend to treat cattle as passive units rather than responsive, conscious beings [16, 17].

To address this gap, there is a need for an evidence-based approach that integrates behavioural science with engineering design principles. While the value of behaviourally informed facility design is acknowledged, its implementation depends on two pillars: empirical behavioural modelling and systematic engineering validation.

Currently, no software exists that enables farmers or designers to benchmark their facilities against behaviourally enhanced alternatives quantitatively. This hinders the ability to identify stress-inducing bottlenecks or justify improvements through cost-benefit analysis.

Therefore, this study aims to develop a behavioural state diagram to model cattle movement and stress responses within handling facility designs by translating animal behaviour into actionable, expert-informed design insights.

2 LITERATURE REVIEW

2.1 Cattle movement and behaviour in confinement

Cattle behaviour in handling facilities is shaped by the conflict between their evolutionary instincts and the constraints of artificial environments. In open fields, cattle exhibit fluid, self-directed movement primarily motivated by grazing and social interaction [18]. However, when confined, they encounter stressors such as restricted space, human proximity, and sensory overload. These conditions trigger observable stress behaviours, including baulking, vocalisation, and heavy breathing.

The likelihood of transitioning between behavioural states depends heavily on facility design parameters [13]. For example, cattle maintain defined flight zones, personal space buffers typically ranging from 1.5 to 5 meters, which, when breached, can induce panic responses [10, 12, 19]. Their panoramic vision (approximately 330°) and sensitivity to motion make them highly reactive to visual and auditory stimuli [13]. Cattle often misinterpret shadows or changes in floor texture as obstacles, due in part to limited depth perception caused by minimal binocular overlap [20, 21]. These biological traits create predictable stress hotspots in poorly designed facilities, particularly in areas with narrow chutes, abrupt lighting transitions, or sharp-angled turns.

Understanding these behavioural triggers is essential for developing handling environments that support smooth cattle movement and reduce fear-based reactions.

2.2 Behaviour variability and herd dynamics

Cattle behaviour is not uniform across individuals or contexts, and this variability presents further design challenges. Herd dynamics typically show that 70–80% of cattle will follow a leader, but breed-specific differences are well documented. For instance, Bos indicus cattle generally exhibit greater reactivity and sensitivity to handling compared to Bos taurus breeds [11, 21, 22]. Reproductive state also influences behaviour. Cows in heat tend to increase locomotion, while maternal aggression in dams with calves requires handlers to adapt their approach [23-25].

GPS tracking studies have shown that, under low-stress conditions, cattle navigate pastures using looping paths over 10–100-meter ranges. These movement patterns are efficient for resource exploitation and typically follow a stop-and-move rhythm [9, 26]. However, when under stress, this behaviour shifts to bunching and rapid flight movements, a pattern exploited by low-stress handling techniques that mimic predator-avoidance responses using 45°–60° approach angles [7, 9].

These behavioural dynamics underscore the need for adaptable facility designs that account for individual differences and herd-based flow tendencies.

2.3 Facility design

Effective cattle handling facilities must integrate three interdependent systems: spatial layout, environmental conditions, and human–animal interaction protocols [4]. Research shows that radial corral layouts reduce stress by minimising the need for 180° turns. Similarly, curved chutes with radii of 12–15 meters outperform angular designs by obscuring the exit and encouraging forward movement [4, 27, 28].

Structural components such as backing gates and solid-sided alleys also contribute to smoother flow [4]. For adult cattle, chute widths of 0.7–0.9 meters prevent reversal behaviours, while solid walls reduce peripheral distractions that may cause hesitation. The sensory environment plays a crucial role as well. Uniform, diffuse lighting eliminates shadow-induced hesitation, and non-slip flooring with a slope of less than 3% supports confident footing.

Human factors are equally significant. Quiet handling has been shown to reduce cortisol levels by up to 20%, while effective positioning of handlers, particularly maintaining the animal's point of balance, can promote voluntary forward movement [9].

Together, these design elements form a behavioural management system in which facility geometry actively influences animal responses, rather than simply containing them.

3 METHODOLOGY

Academic iterative narrative reviews require continuous refinement of search criteria, integration of diverse analytical methods, and robust quality control measures. Iterative narrative reviews in academic research require a cycle of three core components: integrative search and selection, methodological integration, and quality assurance.

This study was initiated by developing behavioural state diagrams based primarily on findings from existing literature. The aim was to formalise cattle behavioural patterns observed in handling facilities into discrete states and transitions that could be used for simulation and design analysis. Key sources included academic publications in ethology, animal handling, and facility design, with particular attention to studies reporting observable stress behaviours, movement tendencies, and environmental triggers. These behavioural insights were extracted, categorised, and mapped into structured state diagrams representing cattle responses across five key facility phases.

Preliminary state diagrams were constructed using Unified Modelling Language (UML)tools (specifically Draw.io) to model behavioural transitions observed during cattle handling. These diagrams were informed by a structured literature review and supported by informal field observations. Key behavioural states such as grazing, calm movement, and resisting were encoded alongside specific environmental triggers, including handler presence, gate movement, and physical confinement. New behavioural states such as hesitation and baulking were added, and transition conditions were refined for improved realism and clarity.

All cattle handling facilities, whether simple "kraals" or advanced modern systems, consist of the same basic phases. The five key phases—moving from the field to a sorting pen, passing through gates, transferring to smaller pens, entering the working area (chute and crush), and finally standing in and exiting the crush—are universal. Even if a facility is high-tech, with automated gates, or a basic setup with wooden fences, these core stages remain consistent. The differences lie in scale, materials, and automation, but the fundamental process ensures that cattle are handled with minimal stress, whether on a small farm, a large feedlot, or an abattoir. This structured approach allows for smooth transitions between different points in the supply chain while maintaining animal welfare and operational efficiency.

The handling process was divided into five functional phases, each corresponding to a distinct physical segment of the facility:

1. Movement from the field to the sorting pen.
2. Passing through a gate.
3. Transfer from a larger pen to a smaller pen.
4. Entry into the working area (chute pen to chute, then crush).
5. Standing in and exiting the crush.

For each phase, a corresponding state diagram was drafted to capture common cattle responses under varying environmental and operational conditions.

3.1 Phase 1: Movement from the field to the sorting pen

The process begins by moving cattle from an open field or pasture into a designated sorting pen. This area is usually larger and allows the animals to gather before being directed further. Workers may use gentle herding techniques, such as walking behind the cattle or using trained dogs, to guide them without causing stress. The sorting pen helps group the animals based on specific needs, such as size, age, or health status, before they proceed to the next stage.

3.2 Phase 2: Passing through a gate

Once sorted, the cattle are guided through a gate that leads them into a more controlled pathway. This gate acts as a funnel, narrowing the space to encourage the animals to move in a single file or small groups. Proper gate design ensures smooth movement while preventing overcrowding or jamming. Workers may stand nearby to assist if an animal hesitates or needs gentle encouragement to move forward. This phase repeats throughout the entire facility each time cattle are moved through a gate.

3.3 Phase 3: Transfers from a larger to a smaller pen

After passing through the gate, the cattle enter a smaller pen, which further restricts their movement. This step helps manage their flow and prepares them for closer handling. The reduced space makes it easier to guide them toward the next stage without causing confusion or stress. Smaller pens are often designed with solid sides to prevent distractions and keep the animals focused on moving forward.

3.4 Phase 4: Entry into the working area

The cattle are then directed into a chute pen, which leads to a narrow chute, a tight walkway that funnels them toward the crush (also called a squeeze chute). The chute restricts sideways movement, ensuring the animal moves straight ahead. Once inside the crush, the animal is gently restrained for procedures like vaccinations, tagging, or health inspections. The crush has adjustable sides to hold the animal securely without causing harm, allowing workers to perform tasks safely and efficiently.

3.5 Phase 5: Standing in and exiting the crush

While in the crush, the animal remains still for the necessary procedures. Workers ensure the process is quick and calm to minimise stress. Once completed, the crush is opened, and the animal exits into a release pen or returns to the pasture. Proper handling during this phase ensures the cattle remain calm and unharmed, making future handling easier.

4 FINDINGS

This section presents the behavioural state diagrams developed to model cattle movement across the five main phases of a handling facility. First, an overview will be given, followed by a detailed description of the phases. Each diagram visualises behavioural transitions in response to environmental stimuli, representing states as rectangles, transitions as arrows, and decision points as diamonds. These state diagrams enable probabilistic simulation of animal movement, where changes in facility design directly influence transition likelihoods and behavioural outcomes.

4.1 Overview

Figure 1 shows the top view of the cattle handling facility used to model movement phases. The layout includes an open field, sorting pen, pens of varying sizes, chute systems, and the crush area. Each zone reflects a typical real-world setup, serving as the spatial foundation for the behavioural diagrams.

The process starts on the left-hand side in the open field. Cattle are gathered in the open field, a large fenced pasture where cattle roam freely and graze on grass. The flow of cattle through the facility is from left to right. A sorting pen is a smaller enclosed area where cattle are gathered and can be separated into groups based on size, age, or purpose (such as medical treatment or sale). The separated groups are moved to a holding pen, a temporary space where cattle wait before being moved further through the facility, ensuring a controlled flow. The crush pen is a confined area that leads animals toward the chute, which is a narrow walkway that guides them single-file into the squeeze crush—a secure stall that gently restrains the animal so workers can safely perform tasks like vaccinations or health checks. Each part of the facility helps move cattle calmly and efficiently while keeping both animals and handlers safe.

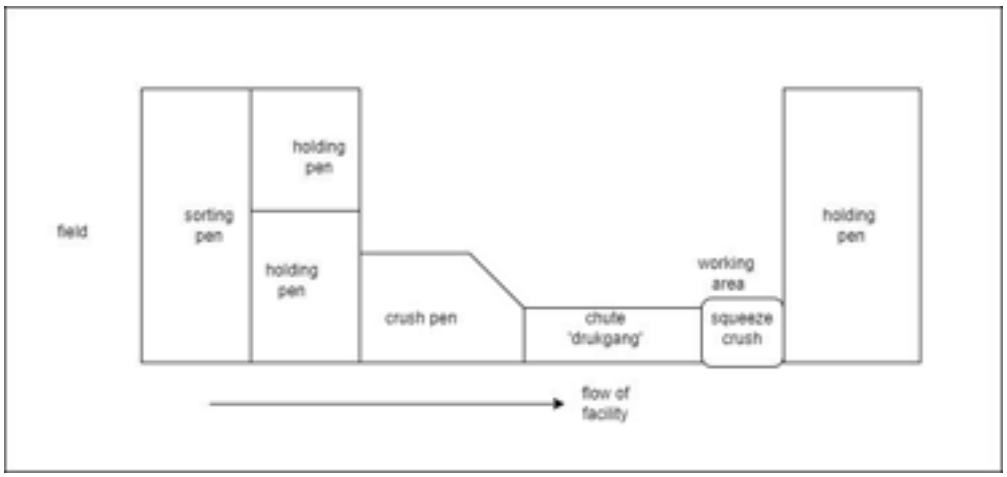

Figure 1: General handling facility top view

Figure 2 presents the high-level behavioural flow diagram, mapping the whole sequence of cattle movement through the facility. The diagram outlines mandatory location-based states and their transitions, providing a macro-level view of the process. The micro-levels will be explained in the sections to follow.

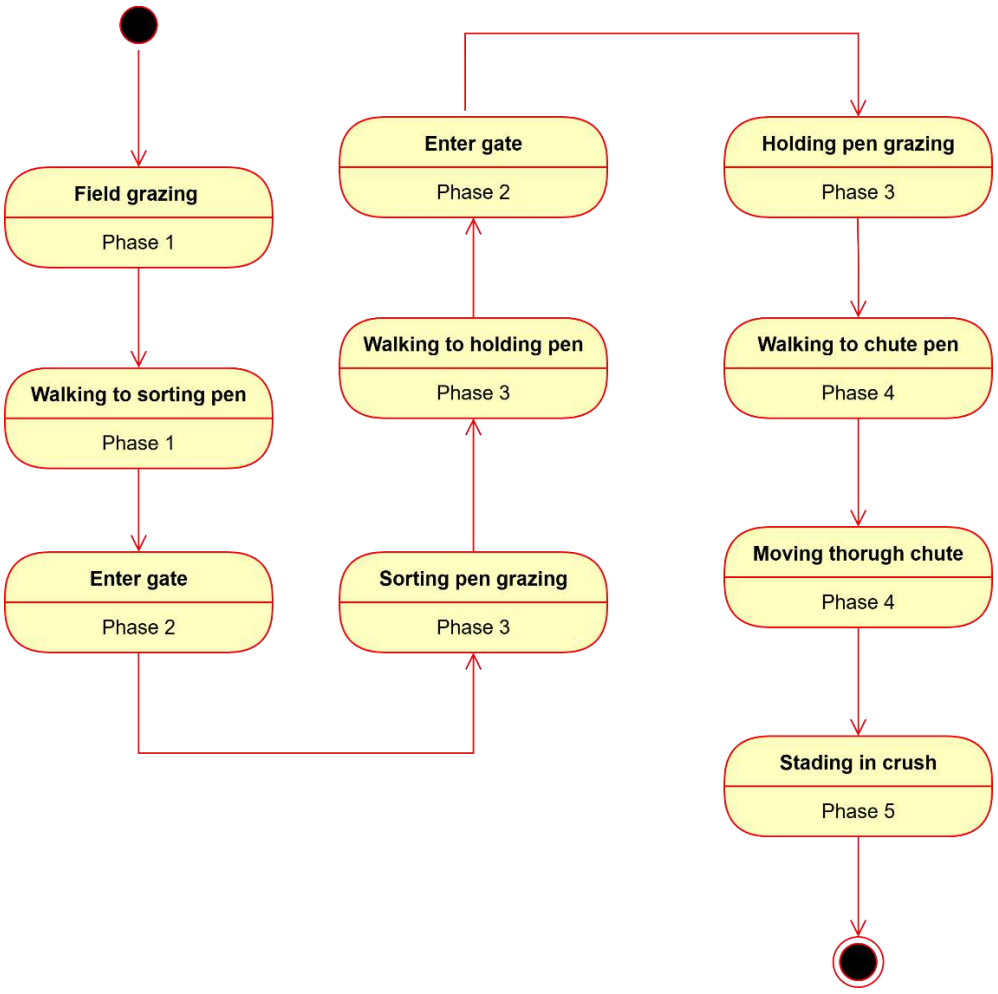

Figure 2: High-level behaviour flow

Two key behavioural bottlenecks are observed: (1) at the sorting pen, where cattle are divided into smaller groups, and (2) at the chute entry, where individual hesitation, baulking, or reversing behaviours often emerge. These points mark significant shifts in group dynamics and are critical for facility design interventions.

4.2 Phase 1 - from the field to the sorting pen

Figure 3 illustrates Phase 1, which captures cattle behaviour as they are moved from open grazing areas into the sorting pen. This phase involves a shift from low-stress states, such as grazing or standing still, to more reactive behaviours triggered by the handler's approach. Movement is often initiated by visual or auditory cues from handlers on foot, horseback, or in vehicles [29].

Common behavioural transitions include:

- From grazing to alert when the handler enters the flight zone.
- Alert to walk away or run, depending on the speed and direction of the handlers' approach.
- Pause or stand still before reaching the pen entrance.

Decision points are most frequent near gates or changes in terrain. Smooth transitions to calm movement are associated with low-pressure handling and clear visibility of the pen entrance [7, 28, 30]

Cattle graze freely in a pasture before they are brought or guided to a handling facility. As handlers approach the herd, cattle move and face a decision point depending on the stress factors. Each cow can face the decision point, or the herd breaks in smaller groups and turns to the handler if they approach too fast, or start running, or stand still if a handler is too close. From each decision point, the probability of more decision points is a possibility; however, in this case, we focus on the overall main probability of cattle returning to a calm movement towards the facility. Handlers will use different techniques and tools to guide cattle towards the final state, such as slowing down their speed, using flags or arm movements, and entering and exiting the cattle's flight zone.

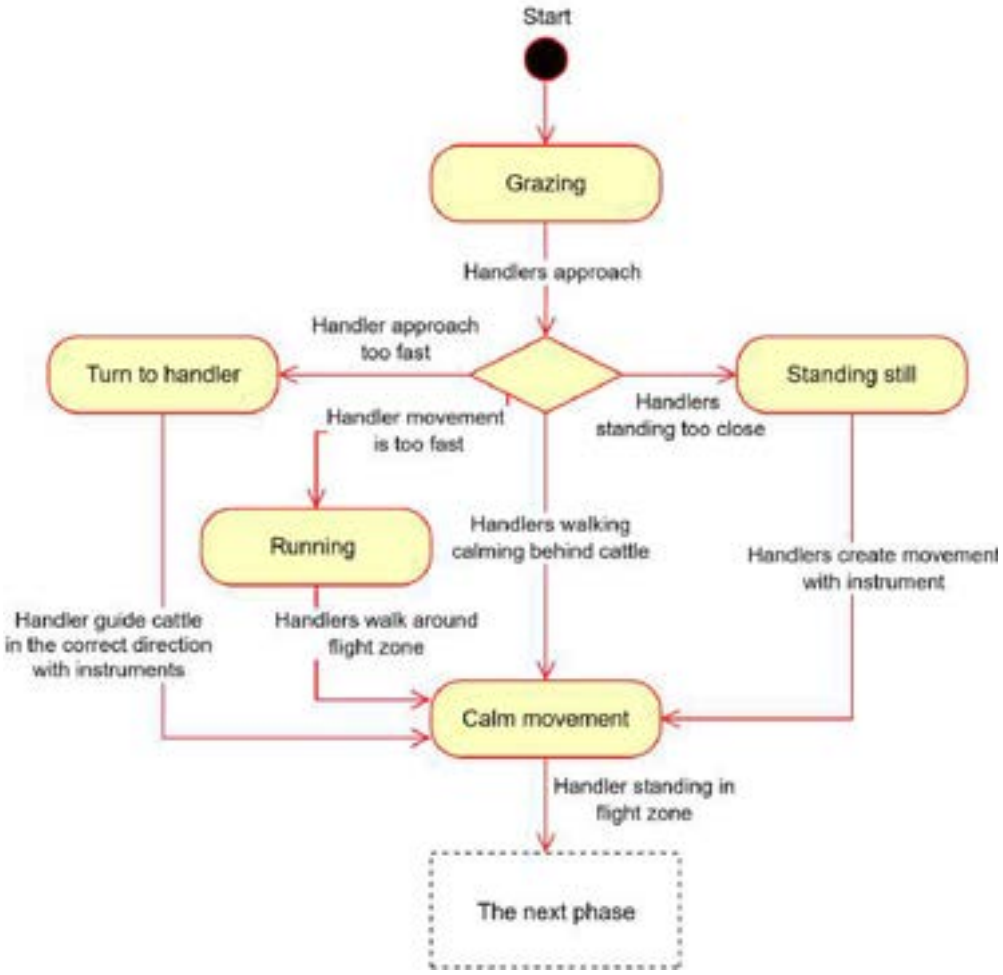

Figure 3: Phase 1 from field to sorting pen

4.3 Phase 2 - cattle passing through a gate

Figure 4 represents Phase 2, which focuses on cattle movement through gates, a frequent but critical transition point in handling systems. The diagram identifies hesitation, redirection, and stress behaviours such as turning back and vocalisation.

Video analysis for literature revealed that most of the observed flow disruptions occurred when gates were misaligned by more than 30° from the cattle's natural trajectory [4,31]. Transitions from walking calmly to hesitation or turning around were especially common at poorly positioned or unfamiliar gates.

Cattle will usually be calm before entering the gate as the gate is opened by a handler. A decision point is created, as there is a change in the close environment of the cattle. With an

open gate, cattle may walk hesitantly forward and through the gate as a handler is behind them and closing in. They may remain in a calm state and walk calmly, or turn around, as cattle are prone to return in the direction they came from. If they are startled, they will be at a dead stop until a handler puts close pressure in their flight zone. This results in different states. To conclude this phase, the goal is to get cattle from point A to point B, aiming to keep them calm as they enter, which improves over time as cattle get used to entering a handling facility.

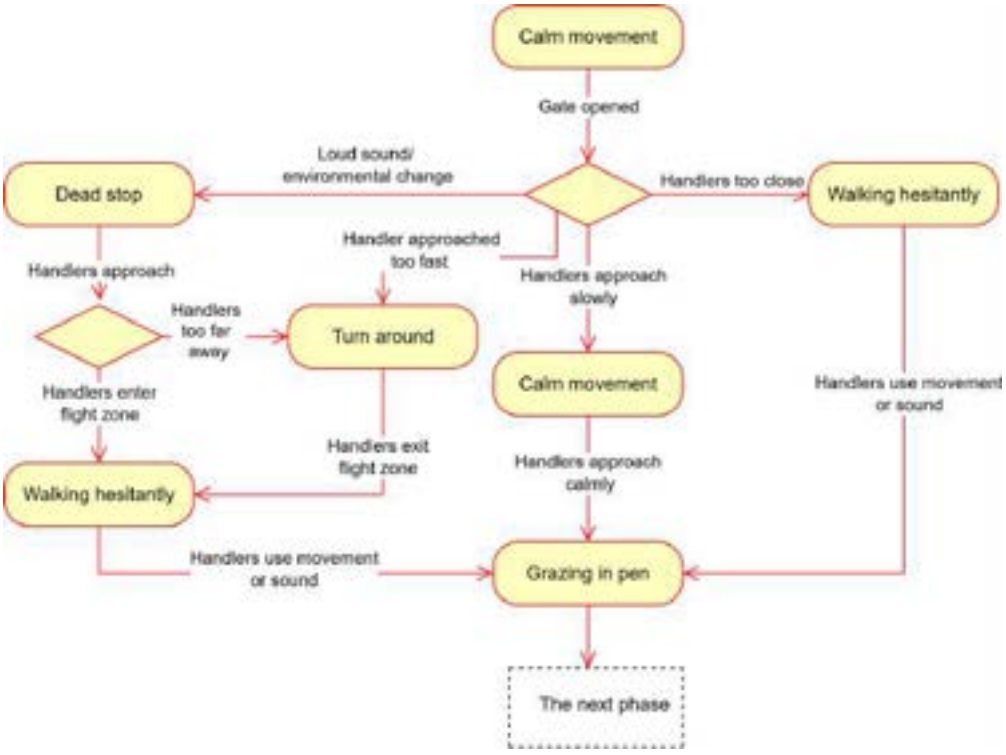

Figure 4: Phase 2 passing through a gate

Figure 4 highlights that gate orientation, visibility, and handler position significantly influence behavioural flow [4]. Well-designed radial gates with curved pathways help reduce indecision and prevent backflow [9].

4.4 Phase 3 – Moving from a larger to a smaller pen

Figure 5 models the transition from larger holding pens into smaller pens, often used to divide herds into manageable subgroups. This phase typically triggers heightened stress due to isolation, increased density, and limited movement options [13, 32].

Behavioural states such as vocalising, bunching, and running to corners were more widespread as group size decreased. Notably:

- Groups with fewer than five animals showed less aimless movement, indicating improved manageability in smaller, cohesive groups [31].
- Decision points increased near entry gates and corners, where cattle assessed crowding and visibility of conspecifics [31].

In Phase 3, cattle are generally observed grazing or standing calmly within the pen prior to any handler interaction. As handlers move closer, a decision point is introduced due to the change in proximity and the associated pressure exerted within the animals' flight zones. At this juncture, cattle may either turn around or move rapidly towards a corner, with the chosen response largely dependent on their perception of the handlers' approach and level of threat.

When turning around, cattle may proceed towards the entrance, walking hesitantly under the influence of the handler's presence, or execute a 180-degree turn if startled, which can also result in hesitant forward movement. Alternatively, when opting to run to a corner, further decision points emerge. Animals may remain stationary (freezing), attempt to jump the fence, or relocate to another corner if the handlers' approach is perceived as excessively fast. From this secondary corner position, movement towards the gate may occur, particularly if handlers continue to apply pressure within the flight zone.

Figure 5: Phase 3, from a large pen to a smaller pen

Throughout these behavioural pathways, the speed, movement, and auditory cues provided by handlers serve as critical stimuli influencing whether cattle transition to calm, directed movement or escalate into avoidance behaviours. The overarching objective in this phase is to facilitate the movement of cattle from their initial position in the pen towards the gate in a controlled and low-stress manner. With repeated exposure to the facility and handling processes, cattle are expected to exhibit reduced reactivity and improved flow, thereby enhancing handling efficiency and animal welfare outcomes.

The diagram suggests that modular pen designs, allowing for rapid herd division and visual continuity, may reduce stress-related behaviours during this phase [13, 26, 32, 33].

4.5 Phase 4 – The working area

Figure 6 represents Phase 4, detailing cattle behaviour as they are guided from a pen into the chute pen, then through the chute and into the crush. This stage involves significant spatial restriction, often resulting in increased behavioural compression [13].

Key findings from observational data include:

- Freezing behaviour was more likely in chutes narrower than 0.8 meters [7, 23].

- More than half of a herd transitioned from hesitant walking to calm movement within seconds when adequate lighting was provided [31].

In Phase 4, cattle typically enter the pen through the gate in a calm and orderly manner. Upon entry, a decision point occurs when environmental or social stimuli—such as vocalisations from other cattle or the division of the herd—affect their behaviour. In some cases, herd division may lead to freezing, followed by hesitant walking as the gate approaches, ultimately resulting in movement towards the chute. Alternatively, cattle may turn around in response to vocal cues or handler movement, moving back towards the gate.

When progressing towards the chute, the closing of the gate behind the animals may help maintain calm movement; however, changes in lighting or the sudden appearance of an opening may cause some to rush forward. Vocalisations from other cattle can induce freezing, after which animals may resume movement hesitantly under the influence of handler movement or sound.

Within this phase, another critical decision point arises when animals are startled or stressed. This may lead to reversing out of position, which can escalate into freezing if handlers apply close pressure. Conversely, cattle in a calm state may continue forward movement, while hesitant walking may occur if the handler's presence is perceived as uncertain or inconsistent.

Throughout this phase, handler actions—particularly movement patterns, speed, and auditory cues—are decisive in influencing behavioural transitions. The goal is to maintain cattle in a calm, forward-moving state towards the chute while minimising stress-induced behaviours such as freezing, rushing, or reversing. With repeated exposure and consistent handling practices, cattle are expected to navigate this stage with improved flow, thereby reducing handling difficulty and enhancing overall animal welfare.

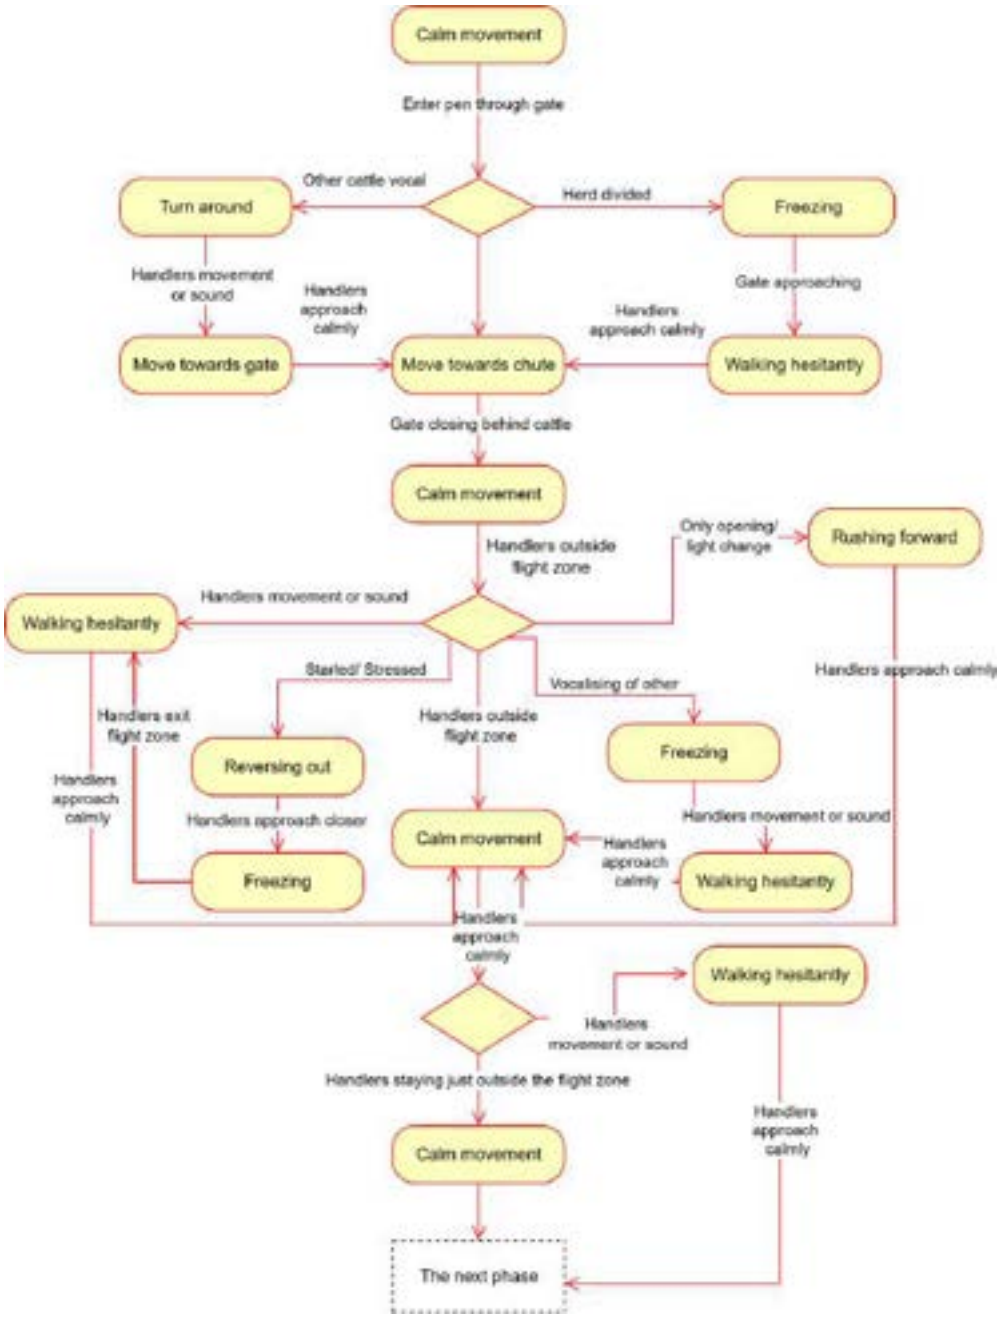

Figure 6: Phase 4, the working area

The state diagram demonstrates how proper chute geometry, lighting, and handler positioning can reduce flow resistance and encourage voluntary movement. Decision nodes in this phase were common at the chute entrance and within the crush approach corridor.

4.6 Phase 5 – Exiting the working area

Figure 7 models the final stage, where cattle stand still in the crush for handling procedures and are then released. This phase is critical, as it concentrates stress, and recovery is heavily influenced by the exit pathway design [4].

Behavioural transitions observed include:

- From standing still to trotting upon release, especially if the standing duration exceeded 30 seconds.

- Most cattle exhibited signs of stress (e.g., rapid movement, vocalisation) after prolonged restraint, especially if they were young and if it was the first time in the handling facility [31].
- Cattle exiting to open pastures resumed grazing a lot faster than those placed in unfamiliar or confined post-procedure pens [23, 31].

In Phase 5, cattle generally begin in a state of calm movement as they approach the crush, with handlers positioned within their flight zone to maintain forward progression. At this point, the opening of the crush introduces a decision point, where environmental factors such as loud sounds or sudden visual changes may cause reversing behaviour. This reversal can be managed through appropriate hands-on handling techniques, returning the animal to forward movement.

If the crush is opened without startling stimuli, cattle may stand still momentarily before resuming calm movement in response to the handler's presence, movement, or sound. Once positioned inside the crush, the gate is closed, and animals remain stationary while required handling or inspection procedures occur.

Upon completion, the crush is opened again, initiating another decision point. The presence of a loud noise at this stage may induce a startle response, resulting in a rapid walking or trotting exit. In the absence of startling stimuli, animals typically exit in a controlled manner, maintaining calm movement as they leave the facility.

The phase concludes with cattle entering the field, ideally in a relaxed state. Throughout this stage, the primary objective is to facilitate smooth and low-stress movement through and out of the crush, minimising hesitation, reversing, or startle responses. Effective handler positioning, quiet movement, and consistent pressure are critical in achieving efficient flow while safeguarding animal welfare.

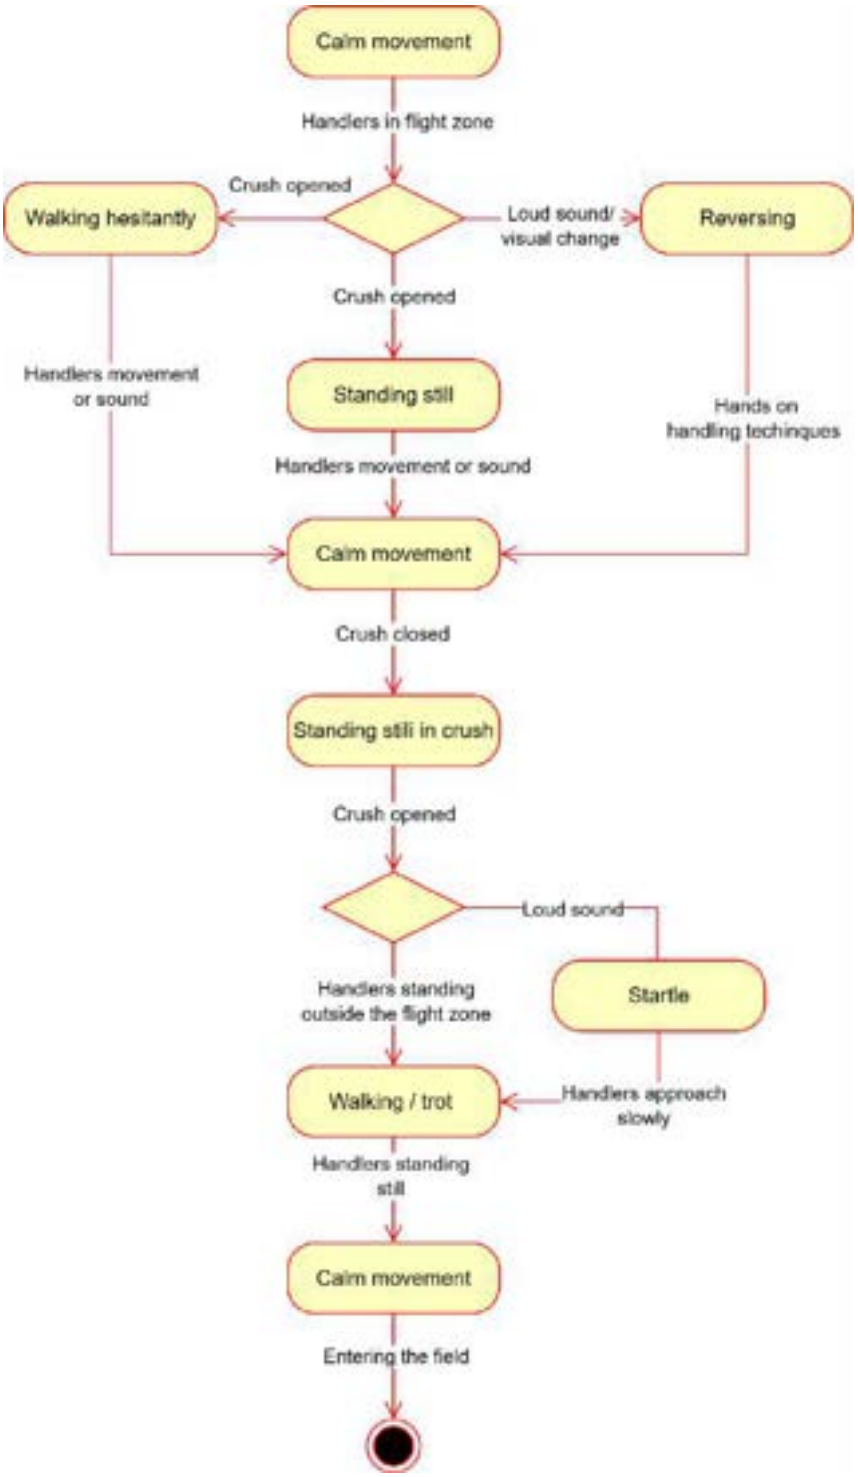

Figure 7: Phase 5 exiting the working area

The diagram highlights the importance of designing clear, calming exits from the crush to support behavioural recovery and maintain welfare.

5 DISCUSSION

The behavioural state diagrams developed in this study provide a structured framework for understanding how cattle respond to specific handling conditions within facility environments.

Rather than simply documenting movement, the diagrams formalise cattle decision-making processes in terms of spatial constraints and external stimuli.

The state diagrams presented in Figures 2 to 7 systematically guesstimate cattle behaviour across all facility phases. They establish clear links between design features (such as chute width, gate angle, and lighting) and behavioural responses (such as freezing, vocalisation, and baulking).

The observed transitions across all five facility phases demonstrate that cattle behaviour is not random but highly contingent on design features, such as gate alignment, pen dimensions, and lighting conditions. Stress hotspots consistently appeared at herd division points (Phase 3) and chute entries (Phase 4), underscoring the need for careful planning in these areas. This reinforces the need to design systems that anticipate and accommodate behavioural variability.

Importantly, the state-based models capture the distinction between voluntary flow behaviours and stress-induced reactions, offering a more nuanced perspective than traditional layout analyses. By translating qualitative behavioural insights into discrete, modelled states, the diagrams bridge an important gap between ethological observation and engineering application.

The inclusion of behavioural responses during the exit phase is particularly noteworthy. This is an area often overlooked in facility modelling, yet the findings suggest that how animals exit confinement has a measurable effect on their recovery. By encoding these post-release behaviours into the state model, the study extends the application of behaviour-based design beyond containment and restraint.

Overall, the diagrams bridge an important gap between ethological observation and engineering application by translating qualitative behavioural insights into discrete, modelled states.

6 CONCLUSION

This study has presented a behavioural modelling framework for cattle handling systems, using phase-specific state diagrams to formalise how cattle respond to environmental and human-induced stimuli across different facility zones. By integrating behavioural science with engineering principles, the research has identified key stress points, such as gate transitions, herd separations, and chute entries, that consistently influence animal welfare and flow efficiency. Through these continued efforts, the research aims to contribute to the development of humane, data-driven, and cost-effective cattle handling systems that align with long-term goals for animal welfare and sustainable agricultural practices.

6.1 Future research

While the current framework provides a foundational step toward a practical decision-support tool for livestock facility design, further validation through expert consultation and real-world testing remains essential to refine its predictive accuracy and operational reliability. Future work should prioritise expanding the behavioural state database to encompass a broader range of facility conditions, integrating economic modelling to assess cost-benefit trade-offs, and validating the framework through simulation tools in operational settings. A Delphi-style expert review process could further enhance the model's precision by systematically incorporating stakeholder feedback. Once refined, this tool will enable data-driven facility improvements by explicitly linking behavioural outcomes to measurable design parameters, ultimately serving as the behavioural foundation for scientifically grounded, yet practically applicable, predictive design tools.

ABSTRACT

The product space (PS) and economic complexity frameworks have made a significant contribution to the study of economic development. The extended input-output product space (IO-PS) has extended the economic complexity framework to the study of value chains. There are an increasing number of coding packages that support economic complexity analyses. To date, two packages have been released that support IO-PS analysis. One for MATLAB and the other for Python. This paper introduces IOPS, the first R package enabling value-chain based product space analyses. Addressing prior gaps, *iopspackage* introduce toggles to resolve metric calculation discrepancies and extends PS metrics to incorporate value chains, offering nuanced insights into specific industries. Key metrics include Revealed Comparative Advantage, Proximity, Relatedness Density, Economic Complexity Index, and Opportunity Value. The *iopspackage* essentially introduces input-output product space (IO-PS) analyses, combining PS metrics with global value chain analysis for the R environment.

Keywords: Input-Output Product Space, Economic Complexity, Global Value Chains, Trade Data Analytics, R

1 INTRODUCTION

The development of the *product space* (PS) [13] and the subsequent development of the economic complexity literature, based on the seminal work of Hidalgo and Hausmann [12], have led to new insights into how nations develop. These methods are increasingly used by researchers and practitioners to trace countries' development paths and to inform policymaking [8,11]. Open-source packages support the calculation of key PS metrics, yet discrepancies in implementation persist across packages [7]. Recent extensions, such as the value chain application of the PS described by Bam and De Bruyne [3], are not yet incorporated in existing R packages. These shortcomings have hampered the widespread uptake of PS-based analysis by relevant stakeholders. Open, reproducible tools are therefore required to underpin credible PS analysis and its extension to value chain perspectives. Policy and industry users increasingly rely on diagnostics such as complexity, density, distance, and opportunity value to guide diversification strategies, but functionality in R, where a substantial share of empirical work is conducted, remains fragmented, which reduces comparability through inconsistent metric definitions, and the absence of an integrated R workflow raises barriers to teaching, extension, and policy translation.

1.1 Research Problem

Despite growing interest in the PS and economic complexity frameworks, the absence of an open, reproducible, and R-native implementation for *Input–Output Product Space* (IO-PS) analysis limits adoption in research and policy settings. Existing toolchains either reside outside R or implement overlapping metrics with discrepant assumptions, which constrains comparability, reproducibility, and pedagogy in R-based workflows.

1.2 Research objectives

The paper aims to: (i) provide an R package that integrates PS metrics with a value-chain perspective; (ii) implement configurable toggles that make assumptions explicit and reproducible; (iii) enable direct ingestion of CEPII BACI data; and (iv) generate analyst-ready outputs at tier, product category, and product levels.

1.3 Research contribution

In this paper, we introduce a novel iopspackage. The package is the first R package to enable value chain-based product space analyses. It couples product space metrics with input–output value chain mapping, accepts CEPII BACI data directly, and exposes assumption choices through explicit toggles to resolve discrepancies identified by Du Plessis and Bam [7]. The integrated workflow delivers transparent and reproducible computation of widely used indicators and produces analyst-ready outputs at tier, product category, and product levels, thereby improving comparability across alternative assumptions and supporting policy analysis where credible screening of diversification opportunities is required.

2 INPUT-OUTPUT PRODUCT SPACE

This section describes the calculation of the various metrics included in the *iopspackage*. Section 2.1 focus on the generic product space metrics and then turns to value chain metric calculation in Section 2.2.

2.1 Product Space Metrics

Sections 2.1.1 - 2.1.5 presents the PS metrics germane to the IO-PS, explains them briefly and gives the corresponding equations. The notation style follows Bam *et al.* [5] and is clarified where necessary.

2.1.1 Revealed Comparative Advantage

The concept of *Revealed Comparative Advantage* (RCA) was first proposed by Balassa [1] to measure how much a country specialises in exporting a certain good, relative to the world average. RCA is computed as:

$$RCA_{c_i} = \frac{\frac{Exp(c,i)}{\sum_i Exp(c,i)}}{\frac{\sum_c Exp(c,i)}{\sum_{c,i} Exp(c,i)}} \quad \textbf{(1)}$$

Where $Exp(c,i)$ denotes the value of exports of product i by country c. $\sum$ of i, c or c,i denotes sum of all exports per product, country, or product from country, respectively. These four terms are used consistently in the subsequent formulas. RCA_{c_i} thus measures share of country c's exports that product i represents relative to the share of exports that products i represents in world trade.

RCA compares a product's share in a country's exports with its share in world exports. It is therefore an export-share indicator and does not account for import intensity, trade balance, or domestic absorption. A country can exhibit $RCA > 1$ in a product while being a net importer of that product if overall imports are large relative to exports. Analysts commonly complement RCA with additional diagnostics (for example, net-export ratios or symmetric RCA) when trade-balance context is material to the question at hand.

2.1.2 Proximity

Hidalgo et al. [13] define proximity as the likelihood that two products are co-exported by a country with a revealed comparative advantage ($RCA > 1$), under the assumption that similar products rely on overlapping capabilities and resources, including institutions, infrastructure, physical inputs, technology, or a combination thereof. Proximity reflects the idea that a country's productive potential depends on its existing basket of products and the relatedness among them. When constructing the product space, proximity is used as a metric of distance between two products [10]. Proximity is formally calculated as the minimum of the conditional probabilities of exporting one product given that another product is exported [13]. The mathematical expression for the proximity between products i and j is:

$$\theta_{ci} = min\left[P\left(M_{ci}|M_{cj}\right), P\left(M_{cj}|M_{ci}\right)\right] \quad \textbf{(2)}$$

Where the RCA formula is used to construct the so-called M matrix which is a binary matrix indicating all products that countries export with a revelated comparative advantage. A value of 1 is assigned to the country-product entry in the matrix if the RCA of country c for product p is larger than 1, and equal to zero otherwise.

2.1.3 Relatedness density and distance

Relatedness density is a concept that captures how related a country's production structure is to the capabilities required for producing a particular good. The more similar a new good is to the goods that a country already produces, the higher the relatedness density [13]. Relatedness density is calculated as the sum of all the proximities between a new good and the goods that a country already exports, normalised by the total number of proximities of products to the focal product. $Density$ is mathematically expressed as:

$$Density = \omega_j^c = \frac{\sum_i M_{cj}\theta_{ij}}{\sum_i \theta_{ij}} \quad \textbf{(3)}$$

Where θ_{ij} refers to the proximity between products i and j. M_{ci} is a binary value equal to 1 when a country has an RCA > 1 for product i, and 0, if country c has an RCA < 1 for product i.

Density values closer to 1 indicate high relatedness, while density value closer to 0 indicate lower relatedness.

The complement of density, $distance$, is also used to indicate the unrelatedness of a product to a country's production structure. Distance is calculated as the sum of all the proximities between a new good and the goods that a country does not export yet, normalised by the total number of proximities of products to the focal products [10]. Hence:

$$Distance = \delta_j^c = \frac{\sum_i (1 - M_{ci})\theta_{ij}}{\sum_i \theta_{ij}} \quad \textbf{(4)}$$

$Distance$ is a value between 0 and 1, where values close to 0 indicate that country c exports most of the products that are connected to product i, and values close to 1 indicate that country c exports very few of them (given RCA > 1).

2.1.4 Complexity

Hidalgo and Hausmann [12] proposed a complexity metric that utilises trade data as a bipartite network to assess a nation's economic complexity. This metric has a positive correlation with a country's income level, and any deviations from this correlation can indicate future growth prospects. The *Economic Complexity Index* (ECI) assesses a country's complexity based on the complexity of products the country produces, while the *Product Complexity Index* (PCI) measures the complexity of the products based on the complexity of the countries producing them. These two metrics are thus interdependent and was initially calculated using the *method of reflections* (M.o.R.) [12]. The M.o.R. first estimates the complexity of a country based on the diversity of products it exports, and the complexity of products based on the number of countries that export a product. Another iteration of country complexity is then calculated based on the initial product complexities calculated. Similarly, the second iteration of product complexity is a function of the countries that export a product with an RCA > 1. These operations can be repeated until the complexity rankings of products and countries stabilise (generally after no more than 18 iterations). A more commonly used alternative to the M.o.R., known as the vector method, derives from substituting the expressions for PCI and ECI into one another. The vector method then calculates the eigenvector corresponding to the second largest eigenvalue that satisfies the equation, as this eigenvector captures the most variance in the system and thus serves as the indicator of economic complexity. Regardless of whether the M.o.R. or vector methods are used to calculate PCI and ECI, the values are normalised by considering the mean and standard deviation of the raw values. Hence, ECI is mathematically defined as:

$$ECI = \frac{\vec{K} - <\vec{K}>}{stdev(\vec{K})} \quad \textbf{(5)}$$

Where $\vec{K}$ is the eigenvector of $M_{cc`}$, associated with the second largest eigenvalue. $M_{cc`}$ is calculated as:

$$\widetilde{M_{cc`}} = \sum_p \frac{M_{cp} M_{c`p}}{M_c M_p} \quad \textbf{(6)}$$

Similarly, PCI can be calculated as:

$$PCI = \frac{\vec{Q} - <\vec{Q}>}{stdev(\vec{Q})} \quad \textbf{(7)}$$

Where $\vec{Q}$ is the eigenvector of $M_{pp`}$, associated with the second largest eigenvalue. $M_{pp`}$ is calculated as:

$$\widetilde{M_{pp`}} = \sum_c \frac{M_{cp} M_{cp`}}{M_c M_p} \quad \textbf{(8)}$$

For both ECI and PCI, < > denotes the average of the vector values and $stdev()$ is the standard deviation of the vector values.

2.1.5 Opportunity Value and Opportunity Gain

The concepts of *Opportunity Gain* and *Opportunity Value* are integral to understanding a country's economic growth potential. While both terms are related, they differ in their approach to measuring a country's export potential.

The concept of Opportunity Value is used to estimate the potential for future economic growth in a country. It takes into account the complexity of products that a country can potentially export, based on its current capabilities and productive structures [10]. This value reflects a country's preferred placement in the product space, combining complexity and density. Moreover, Opportunity Value predicts future increases in ECI and economic growth [10]. The mathematical formula for $Opportunity\ Value$ is as follows:

$$Opportunity\ Value_c = \sum_j \omega_j^c PCI_j \quad \textbf{(9)}$$

In this case, j, represents all products for which a country does not have an RCA > 1. Opportunity Value is a measure of a country's potential to generate economic growth by considering the alignment with existing capabilities and complexity of the products it could potentially export in the future. Opportunity Gain, on the other hand, measures the change in a country's Opportunity Value over time. In essence, Opportunity Gain measures the increase or decrease in a country's ability to export a diverse range of complex products. Therefore, both measures are crucial for policymakers and investors in assessing a country's economic growth potential and identifying opportunities for investment and growth.

2.2 Value Chain Analysis

The usefulness of product space metrics can be further extended when refocused on particular industries. This is clearly illustrated in the value chain-based IO-PS analyses applied to the titanium [6], steel [4], aerospace [16], forest [18] and automotive industries [5]. The IO-PS framework combines product space analysis with input-output analysis. IO-PS analysis requires the mapping of a specific value chain into tiers, categories and products [5]. Each tier and category, has associated metrics, calculated from the average of all the product level metrics in that tier or category. An increasing number of open-source value chain mappings have become available, and IO-PS analyses hold clear utility for guiding policymaking. However, the open-source tools to support the greater uptake of the IO-PS approach have been lacking — something the *iopspackage* introduced in this paper seeks to address.

3 EXISTING PACKAGES AND NEW IOPSPACKAGE

Several packages implementing product space metrics and *global value chain* (GVC) mappings for different applications already exist. Section 3 provides an overview of these packages and compares their functionality.

3.1 EconGeo

The *EconGeo* R package is a tool created by Balland [2] at Utrecht University to perform analysis on the spatial distribution and geographical patterns of economic activities.

EconGeo calculates various indices that are widely used in fields such as economic geography, economic complexity, and evolutionary economics. These indices describe the location, distribution, spatial organisation, structure, and complexity of economic activities. The functions range from simple spatial indicators such as location quotient, Krugman specialisation index, Herfindahl or Shannon entropy indices, to more advanced functions that compute different forms of normalised relatedness between economic activities or network-

based measures of economic complexity [2]. *EconGeo* provides over fifty different functions that mostly requires a matrix as an input.

3.2 economiccomplexity

The *economiccomplexity* package [17, 19] is an R package a tool used for economic complexity-related analyses. It works with preprocessed trade data and calculates product space metrics using a specific function that the user invokes. The input data must have columns for countries, products, and export values to compute the RCA. The functions take these outputs as inputs and estimate the complexity indices, proximities, and opportunity gain.

3.3 decompr and gvc

decompr performs three different methods to break down the value-added content of exports by country and sector. The first method follows Hummels *et al.* [14] and calculates the value added origin of exports for each country and sector. The second method follows Koopman *et al.* [15]. and divides the value added of exports for each country into 9 categories, such as domestic value added and absorbed abroad, and foreign value added in exports. The third method follows Wang *et al.* [20] and further distinguishes the value added of bilateral exports into 16 categories, such as domestic value added consumed by direct importer, and domestic value added and returned home.

The *gvc* package accompanies the *decompr* package. Several GVC indicators can be computed using *gvc* based on the *decompr* methods calculated, such as backward and forward participation, and length of production chains.

4 IOPSPACKAGE

The novel *iopspackage* is introduced in this section. Section 4.1 provides an in-depth explanation of the *iopspackage* operations and functionality. The CEPII BACI trade data and processing thereof is described in Section 4.2, while Section 4.3 compares the existing and new packages.

4.1 Overview and Usage

The user follows three steps when using the *iopspackage*: Installation, input requirements, and output results (Section 4.1.1- 4.1.3 respectively).

4.1.1 Installation

The *iopspackage* can be accessed using the RStudio IDE and installing the package through either the GitHub or CRAN platform. The process for installation via the Industrial Policy Research Group's GitHub repository is demonstrated in
devtools::install_github("WoutersResearchGroup/R-IO-PS")
library(iopspackage)
Code block **1: *iopspackage* installation via GitHub**, which involves using the *devtools* function. Similarly, the package could be installed via the CRAN network using RStudio's built-in package installer.

```
devtools::install_github("WoutersResearchGroup/R-IO-PS")
library(iopspackage)
```

Code block 1: *iopspackage* installation via GitHub

4.1.2 Input requirements

The IOPS function follows the RStudio IDE function-calling convention. It requires six input variables, with two being mandatory and four being optional. Code block 2 provides an example of the input requirements for the IOPS function. The six input variables are:

1. *CountryCode*: Mandatory input that accepts any ISO country code. For instance, "United Kingdom," "GBR," "GB," or "828" would all be accepted if the desired country is the United Kingdom.
2. *tradeData*: Mandatory input that accepts any raw trade data following the CEPII BACI data convention.
3. *GVCMapping*: Optional input that allows the user to specify the desired value chain to be analysed*. The value chain must contain columns "Tiers," "Activity," and "HSCode" in any order.
4. *ComplexMethod*: Optional input that allows the user to specify the chosen method to calculate the complexity measures. The user can choose one of the following: "fitness," "reflections," or "eigenvalues." The default is "eigenvalues."
5. *interCompl*: Optional input that allows the user to specify the number of iterations that the chosen complexity measure must use. This option only applies to the "fitness" and "reflections" methods. The default is iterCompl = 20.
6. *tradedigit*: Optional input that accepts an integer of 6 or 4 to indicate the raw trade digit summation level. The default is 6.

```
### Run IOPS with Input Trade Data and Value Chain Mapping ###
IOPS (
        CountryCode = 710, # Required
        tradeData = TradeDataused, # Required
        ComplexMethod = "eigenvalues", # Optional
        iterCompl = 20, # Optional
        GVCMapping = VCDataUsed, # Optional
        tradedigit = 6 # Optional
)
```

Code block 2: *iopspackage* example usage

4.1.3 Output results

The *iopspackage* produces a primary and a secondary output. The primary output comprises of two files, one in *.csv* and the other in *.xlsx* format, with identical content. These files are saved in the current working directory and contain three tabs that display the results of Product Category, Product, and Tier. On the other hand, the secondary output is a data frame list which is restricted to the RStudio environment. The list comprises of various metrics, including ECI, PCI, Opportunity Gain, Distance, and Density, for every country in the selected BACI trade data. It also contains the binary and absolute M-matrices used to calculate the metrics. Furthermore, the list includes *Product Complexity Results* (PCR), *Product Results* (PR), and *Tier Results* (TR), which are used to write the primary output.

* In the default case, where no value chain input is specified, the default computations for IO-PS metrics are executed at the highest accessible trade digit level. An additional conditional evaluation is undertaken to ascertain whether the computations were conducted at the 6-digit or 4-digit level of trade classification.

4.2 Data Preprocessing: CEPII BACI

The trade used for economic complexity analyses is most commonly based on the self-reported *harmonised system* (HS) based figures from the UN Statistical Division (Comtrade) database. The data captures exporter and importer declarations of bilateral trades flows. Different practices in trade code usage between importing and exporting countries (among other issues) often result in discrepancies between the bilateral trade flows that countries declare.

To address this issue, the *Centre d'Etudes Prospectives et d'Informations Internationales* (CEPII) (a renowned research centre in France that specialises in global economic expertise [21]), has developed a harmonisation procedure that effectively "cleans" the bilateral Comtrade data. The resulting BACI data set offers data on the bilateral trade flows of 200 countries [9]. The CEPII BACI data set has become a widely recognised source of reliable bilateral trade data. Hence, the *iopspackage* is specifically designed to be able to use this data directly. As the *iopspackage* utilises the *economiccomplexity* package to calculate the PS metrics, which is not directly compatible with the BACI data format. The *iopspackage* preprocesses the raw CEPII BACI data to the required three column data frame required for the *economiccomplexity* package.

4.3 Comparison of packages

Table 1 depicts how the existing packages differ in their functionalities. Apart from the *iopspackage*, there are two kinds of packages that can be used for the IOPS analysis process. One kind focuses on the Product Space and the various ways of measuring the relevant metrics. The *EconGeo* and *economiccomplexity* packages belong to this kind. The other kind concentrates on building, using, and examining a GVC for a specific sector or industry. The *decompr* and *gvc* packages are examples of this kind. The *iopspackage* integrates the two kinds of packages and use the PS along with the GVC to conduct IO-PS analysis.

The features and benefits of the developed *iopspackage* are indicated in Table 1. The *iopspackage* accepts BACI data (the only product space package to do so) and adds the ability to perform IO-PS analysis, which combines PS metrics and a GVC lens. The *iopspackage* relies on the *economiccomplexity* package for computing the PS metrics, but it does not need any other external packages for adding the value chain lens, though it does require the value chain used as input.

Table 1: Comparison of existing R packages' functionality

Package	Accepts BACI data	Product Space	Global Chain	Value	IO-PS
EconGeo		✓			
economiccomplexity		✓			
decompr				✓	
gvc	✓			✓	
iopspackage	✓	✓		✓	✓

The IO-PS package offers two primary and two secondary additional features that can be accessed through the optional input toggles of the function. One primary toggle feature is the *tradedigit* input, which enables the user to perform a summation of unaggregated bilateral trade data. The summation can be done on either a 6-digit level, which is the default and matches the CEPII BACI trade data input, or a 4-digit level, which requires processing the trade data to remove the last two digits from the 6-digit level.

The optional *GVCMapping* input variable allows the second primary toggle feature, which is useful when the user does not provide a value chain input. This functionality computes the outputs from the given trade digit level and includes all the relevant lower-level digits for

some product trade codes. For example, if the raw trade data is at the 6-digit level, it also includes the 4- and 2-digit levels in the calculations, but if the raw trade data is at the 4-digit level, it only adds the 2-digit level to the computations.

The secondary *ComplexMethod* toggle allows the user to specify the chosen method to calculate the complexity measures (using the *economiccomplexity* package). The secondary *interCompl* toggle allows the user to specify the number of iterations that the chosen complexity measure must use.

4.4 Worked example

Consider South Africa ($CountryCode = "ZAF"$) with CEPII BACI data at the 6-digit level. Running the package with $tradedigit = 6$, $ComplexMethod = "eigenvalues"$, and an automotive value-chain mapping produces (i) a country-level panel of *ECI*/*PCI*, *density*, *distance*, and *opportunity value*; and (ii) tier/category/product tables with the same metrics. Analysts can compare the opportunity set under alternative assumptions by toggling the complexity method or summation level. For policy, two decision-oriented screens are typical: (1) high opportunity value and low distance to prioritise products that are both complex and aligned with extant capabilities; and (b) tier-level bottlenecks, where low density flags capability gaps in specific segments of the value chain. The outputs therefore support supplier-development programmes, import-replacement priorities, and sequencing of industrial interventions.

5 CONCLUSION

This paper has presented the *iopspackage*, a novel contribution to Input–Output Product Space analysis within the R environment. The development of this package accompanies a detailed examination of economic complexity metrics, as well as the integration of global value chains into the product space framework. By introducing flexible toggles to address discrepancies and extending existing metrics to incorporate value chain dynamics, the iopspackage enables a more nuanced interpretation of industrial pathways and economic development patterns.

The iopspackage is distinguished by its adherence to principles of efficient software design and its emphasis on usability. Far more than a technical utility, the package represents a meaningful step towards advancing empirical tools in economic complexity research. Its versatility ensures broad relevance across academic, policy, and applied settings. As it becomes available via the CRAN repository, the iopspackage reflects the continuing innovation and collaborative spirit of the R community.

LEAN 5.0: NAVIGATING THE WAVES OF CHANGE IN SOUTH AFRICA

M. Mangaroo-Pillay[1*]

[1]Department of Industrial Engineering
Stellenbosch University, South Africa
miamangaroopillay@sun.ac.za

ABSTRACT

Lean philosophy has made waves over the past decades due to its robust business improvement tools and concepts, which are widely applied across various industries. While previous research has examined the intersection of Lean and Industry 4.0, the emergence of Industry 5.0 necessitates a deeper exploration of their alignment. This study conducts a systematic literature review (SLR) to analyse and extract key tools, concepts, and technologies associated with Lean and Industry 5.0. Findings reveal a strong conceptual overlap, particularly in the synergy between Lean's efficiency-driven approach and the human-centric focus of Industry 5.0. The integration of these philosophies offers numerous benefits, including enhanced adaptability and sustainability. Based on these insights, this research proposes a Lean 5.0 framework tailored for South Africa, providing a strategic foundation for future implementation. The framework aims to guide organizations in leveraging Lean principles within the evolving landscape of Industry 5.0.

Keywords: Lean Philosophy, Lean 5.0, SLR, South Africa, Lean framework

1 INTRODUCTION

The journey of industrial evolution has continually reshaped human civilisation, progressing through distinct phases marked by transformative technologies and societal shifts. This is even more evident when we consider how it has reshaped the face of our manufacturing industry. Figure 1 depicts the phases of industrialization over the years.

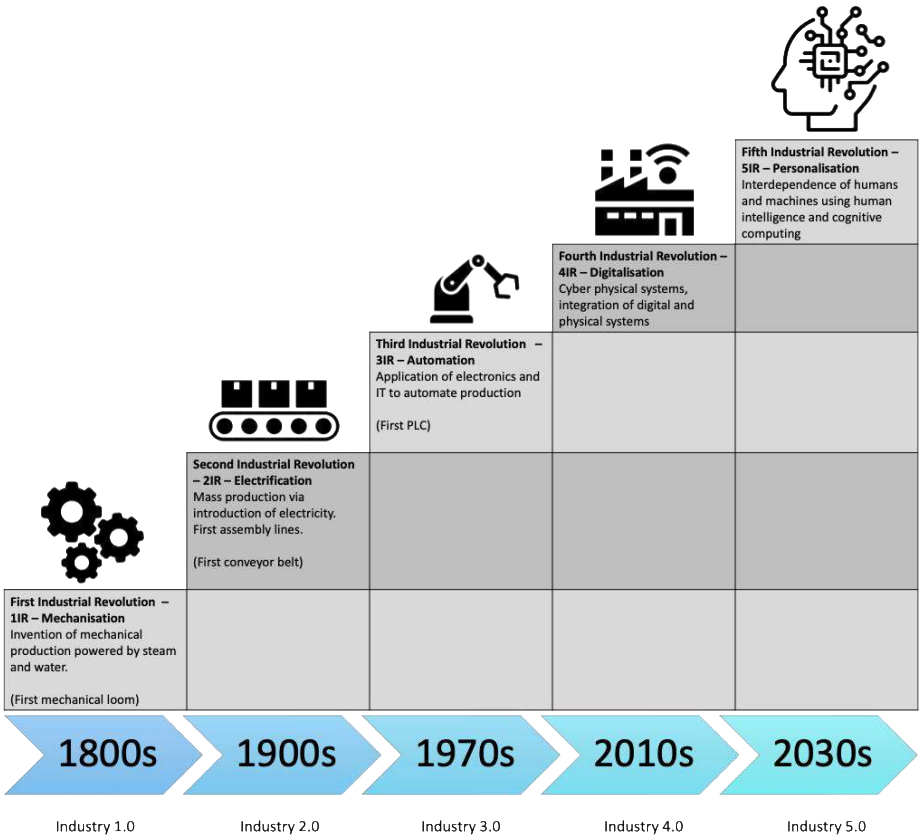

Figure 1: Phases of Industrialisation (Adapted from Mangaroo-Pillay [1])

Beginning with Industry 1.0 in the late 18th century, characterised by mechanisation, water, and steam power [2], industries transitioned from manual production to machine-driven processes. The 19th century ushered in Industry 2.0, powered by electricity and leading to mass production and assembly lines [2], [3]. The latter half of the 20th century saw the rise of Industry 3.0, driven by electronics, information technology, and automation, enabling mass customisation through programmable logic controllers and communication technologies [2], [3]. Currently, we are immersed in Industry 4.0, which originated in Germany in 2011. This phase is defined by the intelligent networking of machines and processes through Cyber-Physical Systems (CPS), fostering real-time communication, data-driven decision-making, and the flexible production of high-quality personalised products with mass efficiency [2], [4]. Industry 4.0's technological portfolio is extensive, encompassing Big Data and analytics, autonomous robots, simulation, Industrial Internet of Things (IIoT), cybersecurity, cloud computing, additive manufacturing, and augmented reality, all aimed at enhancing efficiency and productivity [2], [5].

Despite the advancements brought by Industry 4.0, a new paradigm, Industry 5.0, has emerged, primarily championed by the European Commission in 2021 [6], [7]. While Industry 4.0 is largely technology-driven, focusing on digitalisation and AI to increase efficiency and flexibility; Industry 5.0 introduces a fundamental shift towards a value-driven approach [2], [3]. Industry 5.0 is not merely a chronological continuation but a complementary evolution,

addressing the perceived limitations of Industry 4.0 regarding social fairness and sustainability [2], [8].

At its core, Industry 5.0 is defined by three key concepts: human-centricity, sustainability, and resilience [6], [9]:

- Human-centricity places the well-being of the industry worker at the centre of the production process, emphasising human-machine collaboration (cobots) where human creativity and intelligence are combined with machine efficiency and precision [3], [10]. This involves upskilling workers for cognitive labour, empowering them to make decisions, and creating a symbiotic relationship with autonomous systems [9]. Technologies like Human Interaction and Recognition Technologies (HIRT) and Industrial Smart Wearables (ISW) play a crucial role in enabling safer and more pleasant human-machine interaction [7].
- Sustainability recognises the power of industry to achieve societal goals beyond just jobs and economic growth, by ensuring that production respects planetary boundaries and contributes to environmental and social responsibility [2], [9]. This includes resource and energy efficiency, waste prevention, and the integration of renewable energy sources [2], [7].
- Resilience refers to the ability of industrial systems to maintain or quickly recover stability during and after disruptions, such as geopolitical shifts or natural emergencies, ensuring robust provision of prosperity [2], [9].

Beyond these core characteristics, the essence of Industry 5.0 is further articulated through concepts such as collaborative intelligence, which signifies the mutual-cognitive coordination between human and artificial intelligence to co-innovate and co-create [11]. It also involves multi-objective interweaving, integrating diverse goals like human efficiency, productivity, and customer individualised requirements with social and ecological considerations [11]. Furthermore, Industry 5.0 calls for multi-technology restructuring, moving from a simple stacking of technologies to a timely empowerment of value-driven demands, and multi-discipline integration, adopting interdisciplinary approaches across engineering, technology, life sciences, environmental, and social sciences [11]. Finally, multi-sector symbiosis fosters a harmonious relationship between technology, society, and ecology across various national sectors to achieve shared goals [11]. These ideas collectively underpin Industry 5.0's vision of a future industrial system that is intelligent, adaptable, and profoundly aligned with human and planetary well-being.

Manufacturing environments have significantly benefited from the widespread adoption of Industry 4.0 principles and digital transformation, leading to enhanced efficiency, productivity, and flexibility through the intelligent networking of machines and processes [2], [4]. The integration of cyber-physical systems, IoT, Big Data analytics, and automation has enabled smart factories to achieve real-time communication, data-driven decision-making, and the customisation of products with mass efficiency [2], [5]. However, as the focus of industrial evolution shifts beyond mere technological advancement, current research is increasingly pushing for the broader implementation of Industry 5.0. This new paradigm seeks to complement Industry 4.0 by prioritising human-centricity, sustainability, and resilience, addressing the social and environmental implications of advanced manufacturing [2], [6], [9]. In a parallel development within operational excellence, previous research has indicated the utility of "Lean 4.0," which integrates Lean principles with Industry 4.0 technologies to further improve manufacturing challenges and enhance processes [10]. Building on this trajectory, "Lean 5.0" is similarly emerging, aiming to align Lean methodology with the human-centric, sustainable, and resilient tenets of Industry 5.0, thereby promising a more holistic and ethical approach to manufacturing improvement [10].

Lean philosophy is an all-encompassing management approach associated with business improvement and the elimination of waste, whilst simultaneously focusing on people's development and the fostering of a problem-solving culture [12]. Although Lean originated within the manufacturing industry, it has been widely adopted and researched across various other sectors, including healthcare and environmental sustainability, amongst others. This attests to the well-established nature of the research field surrounding Lean, in contrast to the emerging and evolving body of research concerning Industry 5.0.

Drawing upon the aforementioned literature and to contribute to the ongoing discourse surrounding Lean 5.0, this research study aims to explore the breadth of the existing Lean 5.0 literature. Ergo, the primary objective of this study is to gather and synthesise the available academic work pertaining to the scope, benefits, barriers, and enablers of Lean 5.0, with the ultimate goal of developing a conceptual framework for its implementation within the South African context.

2 RESEARCH METHODOLOGY

A systematic literature review (SLR) was utilised as the research methodology to collect the available literature. This took the form of a scoping SLR, which allowed for the investigation of the definitions, benefits, barriers and enables of Lean 5.0. Figure 2 illustrates the SLR methodology proposed by Albliwi et al. [13] that guided this research process. The following subsections detail each step of the process.

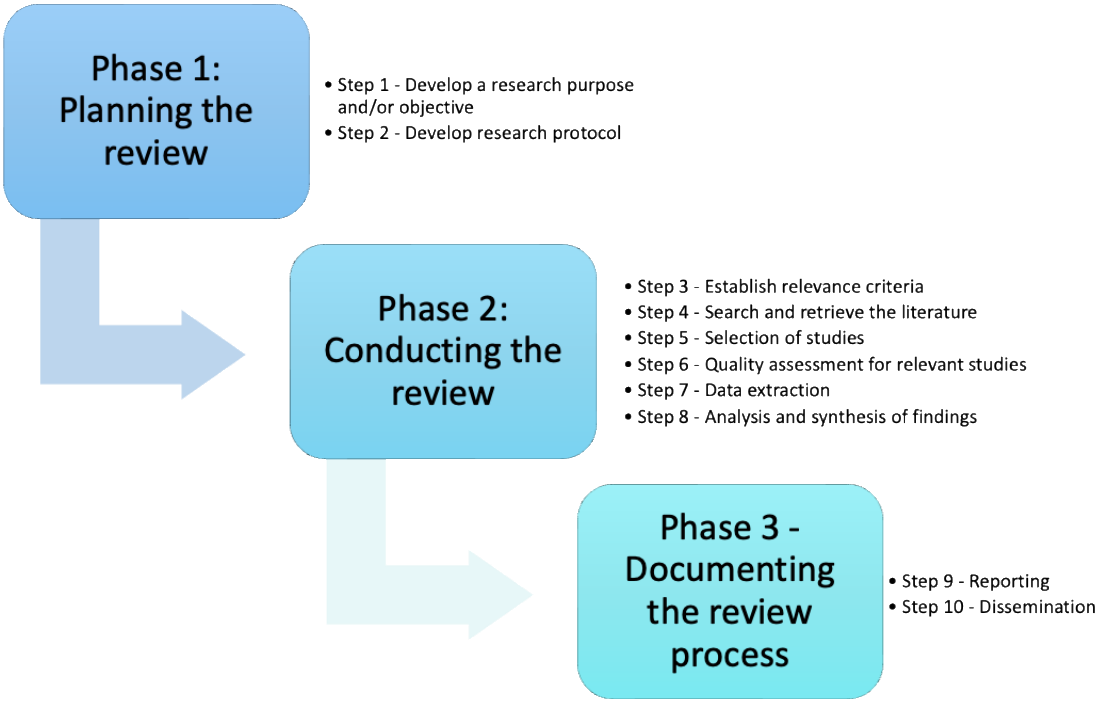

Figure 2: SLR methodology (Adapted from Albliwi et al[13])

2.1 Step 1 - Develop a research purpose

The purpose of this study was to gather and synthesise the available academic work pertaining to the scope, benefits, barriers, and enablers of Lean 5.0, with the ultimate goal of developing a conceptual framework for its implementation within the South African context.

2.2 Step 2 - Develop a research protocol

A research protocol was developed (as captured in table 1).

Table 1: Research review protocol (Structure adapted from Xiao et al. [14])

Purpose of the study	• To gather and synthesise the available academic work pertaining to the scope, benefits, barriers, and enablers of Lean 5.0.
Inclusion criteria	• Literature that contains "Lean 5.0" in the title, abstract or keywords • Literature that discusses the definition, barrier, enablers and benefits of Lean 5.0
Exclusion criteria	• Non-English studies • Lean-X focused studies (e.g. Lean Six Sigma, Lean Supply chain)
Search databases	• Science direct • Scopus • Web of Science • Emerald Insight
Keywords	• "Lean" AND "Industry 5.0"
Quality assessment criteria	• All duplicate literature must be removed • Literature must be checked for relevance • Literature must be checked for correct understanding and interpretation of Lean • Studies must be scientific • Studies must have transparent data collection

2.3 Step 3 - Establish relevance criteria

At the time of writing and publication of this study, the body of research on Lean 5.0 is limited with the earliest publications in the early 2020s. Ergo, in order to widen the search criteria, the following relevance criteria was developed:

- Only literature containing the term "Lean 5.0" in its title, abstract, or keywords will be considered for inclusion.
- The scope of selected literature will be restricted to studies that comprehensively address the definition, identified barriers, key enablers, and anticipated benefits associated with Lean 5.0.
- To ensure consistency, non-English language studies will be omitted from the review.
- Research concentrating on specific Lean sub-disciplines, such as Lean Six Sigma or Lean Supply Chain, will be excluded. This decision is based on the distinct nature of their applications and the emergence of their own Industry 5.0-aligned subgroups (e.g., Lean Supply Chain 5.0), which fall outside the immediate focus of this study.

2.4 Step 4 - Search and retrieve the literature

During Step 4, the search and retrieval of relevant literature was executed utilising the databases specified in Table 1, yielding a total of 138 papers. The 'Identification' section of Figure 3 illustrates the detailed breakdown of papers acquired during this phase.

2.5 Step 5 - Selection of studies

For Step 5, the removal of duplicate entries was performed, leaving a refined set of 103 papers. This selection process, including the reasons for exclusion, is comprehensively captured in Figure 3. Papers were omitted for various reasons, including instances where they did not adequately discuss the definitions, benefits, or issues pertinent to Lean 5.0, or explored the historical aspects of Lean without specific details on Lean 5.0. Furthermore, non-English studies (specifically German versions without English counterparts) were excluded. Other grounds for removal included a focus on Lean-X concepts, a conflation of Industry 4.0 and Industry 5.0 concepts, or an exclusive focus on Lean applications and calculations.

2.6 Step 6 - Quality assessment for relevant studies:

The 17 studies selected for inclusion in the systematic literature review (SLR) underwent a rigorous quality assessment, as detailed in Table 1 and summarised in Figure 3. This process was designed to ensure that only the most robust and relevant contributions were incorporated into the review. To this end, duplicate records were systematically removed to avoid redundancy, and each source was evaluated for its relevance to the research objectives. Particular attention was paid to verifying the accurate understanding and interpretation of Lean principles, as misinterpretations could undermine the validity of the findings. Furthermore, only studies underpinned by a scientific approach were considered, ensuring methodological soundness. Finally, transparency in data collection was a critical criterion, as it provides the basis for replicability and strengthens the credibility of the evidence base. Together, these measures ensured that the SLR was informed by high-quality, trustworthy, and contextually relevant literature.

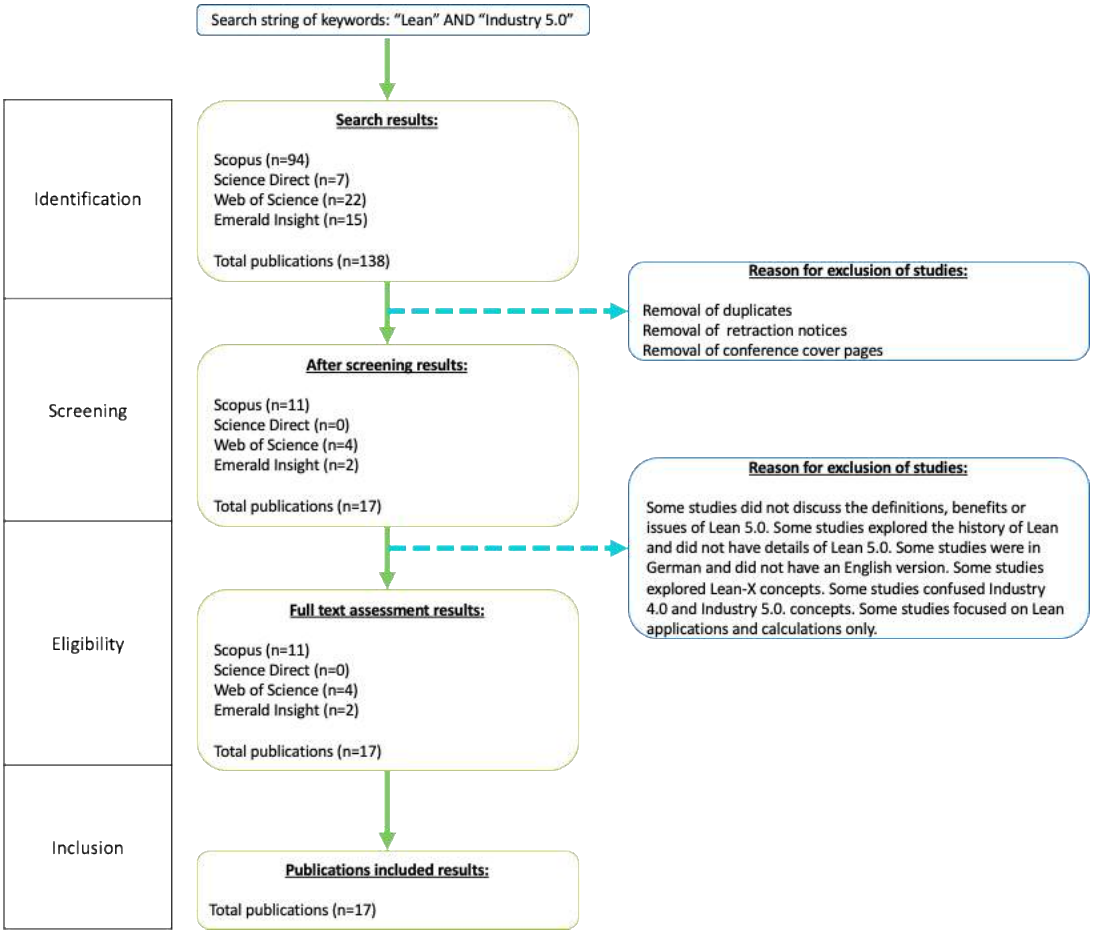

Figure 3: Selection process chart (As per PRISMA guidelines)

3 FINDINGS

The findings from the 17 papers are analysed and synthesised in section 3.1 and 3.2, respectively.

3.1 Step 7: Data extraction

Once the final list of studies for inclusion was confirmed, the full texts were reviewed and relevant data extracted. Table 2 presents the included studies along with the specific data

obtained from each. Although the systematic literature review (SLR) did not restrict studies by publication year, it is noteworthy that all identified publications were from recent years.

Table 2: Table of SLR result

3.2 Step 8: Analysis and synthesis of findings

3.2.1 Annual distribution of studies

Although the research protocol did not specify a fixed timeframe for data collection, the selected studies indicate that references to Lean 5.0 began emerging as early as 2021. The majority of publications, however, were from 2024. This surge in publications is likely due to the systematic literature review being conducted in June 2025. Figure 4 showcases the number of publications per year.

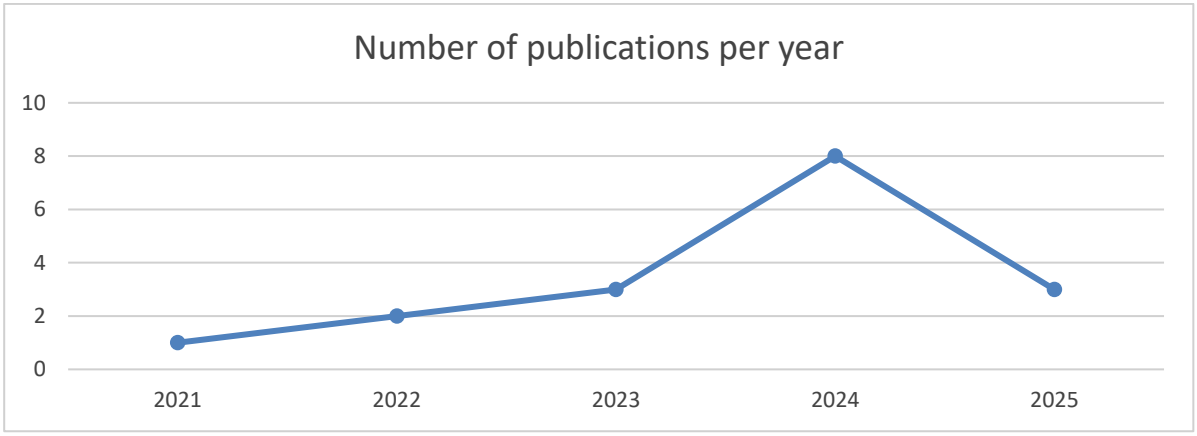

Figure 4: Number of publications per year

3.2.2 Keywords

The word cloud generated in figure 5 from the keywords of the 17 selected papers provides a visual representation of the most frequently occurring themes in the current Lean 5.0 literature. Prominent keywords such as “Lean,” “Industry 5.0,” “digital transformation,” “human-centric,” and “sustainability” suggest that the integration of advanced technologies with human values is a central focus in recent research. The visibility of terms like “cyber-physical systems,” “resilience,” and “artificial intelligence” highlights the growing emphasis on the role of digital tools and intelligent systems in supporting Lean practices. Additionally, the appearance of “smart manufacturing” and “collaboration” points to the importance of interconnected systems and teamwork in evolving production environments.

Figure 5: Word cloud of keywords

3.2.3 Overlap in Lean and Industry 5.0 concepts

From the results of the SLR, the overlap between Lean and Industry 5.0 was highlighted. Table 3 depicts the overlap.

Table 3: Overlap between Lean and Industry 5.0 concepts

Lean Tool/Concept	Industry 5.0 Concept(s)	Supporting Details/Mechanism
Lean Philosophy/Thinking	Human-centricity, Sustainability, Resilience	Lean, with its emphasis on respect for people and placing workers/people at the center, is naturally aligned with Industry 5.0's human-centric approach. Its focus on waste elimination and continuous improvement drives sustainable production. Lean approaches like system thinking and lead time reduction contribute to resilience. Lean is considered an essential mindset for Industry 5.0 transformation. LS5.0 integrates I5.0 principles with lean services.
Lean HC (Human Factory Engineering)	Human-centricity	Combines Lean with an emphasis on the respect, well-being, and needs of employees. Aims to boost operational performance by improving empowerment and engagement. The human-centric approach fosters greater adherence and acceptance of improvement initiatives by actively engaging employees.
Kaizen (Continuous Improvement)	Human-centricity, Sustainability, Resilience	Aims for the pursuit of perfection by continuously searching for waste. Utilizes new technologies to foster continuous improvement methods. Supports scientific learning and data-oriented decision-making when integrated with technology. Involves teamwork and problem-solving culture. Linked to Innovation in the multi-domain matrix. Contributes to resilient value chains.
VSM (Value Stream Mapping)	Sustainability, Human-centricity (indirect)	Used to identify inefficiency and eliminate waste in the value chain. Can be supported by technologies like augmented reality. A tool for continuous improvement. Can involve teambuilding.
5S	Human-centricity, Sustainability, Resilience	A tool for organizing the workplace to reduce waste and disorder. Contributes to a safe and sustainable work environment. Linked to Human-centricity, Resilience, Sustainability in the multi-domain matrix. Also linked to Security.
SMED (Single Minute Exchange of Die)	Human-centricity, Sustainability, Process Efficiency	Method for reducing setup times. Human-Centric SMED (H-SMED) integrates I4.0, Lean, and Ergonomics to focus on worker's requirements, tasks, and well-being, supporting the social dimension of sustainability. Linked to Human-centricity in the multi-domain matrix.
Jidoka (Stop in time / Autonomation)	Human-centricity, Sustainability, Resilience	Pillar of TPS focused on building quality into the process. Enables stopping production when problems occur to prevent defects/waste [500 - Fig 10g]. Supports building quality with ownership among workers, linking to human-centricity. Linked to Human-centricity, Resilience, Sustainability in the multi-domain matrix.
Kanban (Pull System)	Human-centricity, Sustainability, Resilience	A tool for managing production flow based on customer demand (pull). Linked to Human-centricity, Resilience, Sustainability in the multi-domain matrix.
Toyota Kata	Human-centricity, Technology (Enabler for I5.0)	A structured routine for continuous improvement and learning. Supports a human-centric approach. Technologies support scientific learning within the Kata routine. People and technology learn together about processes and value.
Poka-Yoke (Error Prevention)	Human-centricity, Sustainability, Resilience	A method ensuring error prevention. Aims at prohibiting working mistakes. Reduces defects, contributing to sustainability goals. Linked to Human-

		centricity, Resilience, Sustainability in the multi-domain matrix.
Human-Machine Collaboration/Co-working	Human-centricity	A core focus of Industry 5.0. Lean thinking supports the integration of humans and machines for value delivery. Aims to achieve the best combination of human and robot competencies.
Reciprocal Learning (RL)	Human-centricity, Technology (Enabler for I5.0)	Human-machine symbiosis based on symmetrical knowledge exchange. LS5.0 aims to create this learning environment. Enabled by I5.0 technology providing data.
Training & Skill Development	Human-centricity, Technology (Enabler for I5.0)	Essential for developing the workforce. Supports workers in using new technologies. Part of the Hitozukuri (making people) concept. Enables human adaptation to technology demands.
Job Enrichment/Job Rotation	Human-centricity	Practices that enhance worker satisfaction, versatility, and mitigate monotony of repetitive tasks. Part of Lean HC practices. A human-centric approach aims to increase worker satisfaction.
Empowerment & Engagement	Human-centricity	Lean HC domains. Lean HC aims to boost operational performance by improving empowerment and engagement. Human-centric approach actively involves employees. Industry 5.0 emphasizes talents, diversity, and empowerment. Companies closer to Lean 5.0 ideals support a more engaged and empowered workforce.
Problem Solving Culture	Human-centricity, Resilience	An essential human capability. Developed through methods like Toyota Kata. Crucial for managing changes and disruptions.
Data-oriented decisions/Scientific thinking	Technology (Enabler for I5.0), Human-centricity, Sustainability, Resilience	Enabled by I4.0/I5.0 technologies providing data. Supports scientific learning within Lean (e.g., Toyota Kata). Better decision-making implicitly supports efficiency, waste reduction, and adaptability, contributing to all three I5.0 pillars.
Customer First / Value Identification	Human-centricity, Sustainability	Lean principle focused on identifying or creating value from the customer's perspective. In Industry 5.0, this extends to focusing on the well-being of the operator and societal goals beyond just growth. LS5.0 aims to create, enhance, and deliver customer value. Society 5.0 aims for a human-centered society that provides value at the right moment.

3.2.4 Benefits of Lean 5.0

The literature presents Lean 5.0 as an emerging paradigm that builds on the foundational principles of Lean by integrating advanced digital technologies and human-centric values. This paradigm retains Lean's emphasis on efficiency and waste elimination, while incorporating the technological advancements associated with Industry 4.0 and the socio-technical orientation of Industry 5.0. Within this framework, Lean Services 5.0 (LS5.0) extends the application of Lean 5.0 specifically to service organizations, where it is defined as the integration and symbiosis of Industry 5.0 technologies and principles with Lean service practices. Several key benefits of Lean 5.0 and LS5.0 are identified in the reviewed literature:

- Waste-Free Operational Excellence: Lean 5.0 aims to eliminate waste by integrating human-centricity with digital technologies for continuous value creation.
- Operational Efficiency: It enhances efficiency through optimized collaboration between human insight and automation.

- Worker Satisfaction and Empowerment: Lean 5.0 fosters higher employee engagement and well-being by embedding empowerment in improvement practices.
- Competitiveness and Sustainable Growth: It boosts competitiveness and long-term sustainability by aligning innovation with human and customer value.
- Human-Technology Integration: Lean 5.0 enables seamless human-machine collaboration for value co-creation and innovation.
- Continuous Improvement and Adaptation: It supports adaptive learning and data-driven refinement through real-time feedback and technological enablers.

3.2.5 Barriers to Lean 5.0

Despite the potential benefits associated with Lean 5.0, several barriers complicate its implementation. These challenges span conceptual, technological, organizational, and contextual domains and must be critically addressed to support the successful adoption of this emerging paradigm, such include:

- Conceptual and Knowledge Gaps: There is a lack of integrated theoretical models and empirical research bridging Lean, Industry 4.0, and Industry 5.0, particularly for SMEs.
- Integration Challenges Between Paradigms: Misalignment between Lean's human-centric philosophy and Industry 4.0's tech-driven approach complicates their integration and practical application.
- Human and Organizational Resistance: Resistance to cultural change, fear of automation, and skills gaps hinder effective adoption of Lean 5.0.
- Technological and Resource Constraints: Limited infrastructure, financial barriers, and ethical challenges restrict sustained digital transformation.
- Challenges Specific to SMEs: SMEs face resource, capability, and structural limitations that inhibit Lean 5.0 adoption and global value chain participation.

These barriers underscore the need for a holistic and context-sensitive approach to Lean 5.0 implementation. This includes not only the integration of advanced technologies but also deliberate investment in organizational culture, leadership development, workforce upskilling, and strategic alignment. Advancing the Lean 5.0 agenda requires more than technical upgrades; it necessitates systemic change rooted in the interdependence of people, processes, and technology.

3.2.6 Drivers for Lean 5.0

The adoption of Lean 5.0 and Lean Services 5.0 is motivated by the ambition to establish an advanced industrial ecosystem that balances operational efficiency, technological advancement, and human well-being. These drivers arise from the integration of Lean's foundational principles with the technological capabilities of Industry 4.0 and the human-centric, sustainable, and resilient aspirations of Industry 5.0. Key drivers identified in the literature include:

- Waste-Free Operational Excellence: Lean 5.0 aims to achieve operational excellence by eliminating waste through continuous improvement and digital integration.
- Operational Efficiency: It enhances efficiency by combining human insight with intelligent automation and data-driven decision-making.
- Human Well-being and Contribution: Lean 5.0 places people at the center, valuing human dignity, creativity, and intuition alongside technological progress.

- Worker Engagement and Empowerment: Engaged and empowered employees are seen as key drivers of sustained performance and innovation.
- Sustainability and Responsibility: Lean 5.0 embeds environmental and social sustainability into operational practices through waste reduction and circularity.
- Resilient Systems: It builds resilience by using Lean principles to strengthen supply chains against disruptions.
- Human-Technology Synergy: Lean 5.0 promotes collaborative human-machine systems that empower workers and enable shared learning.
- Business Competitiveness: Lean 5.0 boosts agility and competitiveness, supporting sustainable growth in dynamic markets.
- Beyond Industry 4.0 Limitations: It addresses Industry 4.0's shortcomings by balancing technological advancement with human and ethical considerations.
- Continuous Improvement and Innovation: Lean 5.0 sustains a culture of Kaizen, using digital tools to accelerate learning and innovation.

4 FRAMEWORK

Building upon the nuanced insights garnered from Section 3, a comprehensive conceptual roadmap for the strategic implementation of Lean 5.0 within the South African industrial landscape has been meticulously formulated, as visually represented in Figure 5. This roadmap is meticulously delineated into three interconnected and progressive phases, each designed to address distinct yet complementary facets of the Lean 5.0 paradigm.

Phase 1 initiates with a critical interactional shift, marking a deliberate transition from the prevailing mastery of Industry 4.0's technology-focused advancements towards the inherently human-centric orientation of Industry 5.0. Industry 4.0, characterised by its emphasis on automation, data exchange, and smart technologies such as the Internet of Things (IoT), Cyber-Physical Systems (CPS), and Artificial Intelligence (AI), has undeniably propelled manufacturing efficiencies. However, its primary focus often remains on technological optimisation, sometimes at the expense of human well-being and societal values. Conversely, Industry 5.0 extends this technological foundation by prioritising human-centricity, sustainability, and resilience. This phase underscores the necessity of a philosophical reorientation, moving beyond mere technological adoption to a symbiotic integration where technology serves humanity, augmenting human capabilities rather than displacing them. It involves cultivating an environment where humans and intelligent machines collaborate seamlessly, fostering enhanced creativity, problem-solving, and adaptability within industrial processes. This initial shift is pivotal for laying the groundwork for a truly integrated and value-driven approach to industrial transformation.

Phase 2 delves into the core tenets of Lean management philosophy by focusing on its Four Ps (4Ps), which are traditionally understood as Purpose, Process, People, and Problem-solving. This phase mandates a rigorous application of these principles, ensuring that organisational objectives are clearly defined (Purpose), operational workflows are optimised for value creation and waste elimination (Process), the workforce is empowered, developed, and engaged (People), and a culture of continuous improvement through systematic root-cause analysis is embedded (Problem-solving). Crucially, this phase is grounded in a firm foundation of digital ubuntu. Digital ubuntu, a novel concept particularly relevant to the South African context, signifies the integration of digital technologies with the profound philosophical principle of ubuntu—emphasising interconnectedness, collective well-being, human dignity, and communal harmony. In a practical sense, this involves leveraging digital tools and platforms not merely for efficiency, but to foster enhanced collaboration, knowledge sharing,

and empathy among employees, supply chain partners, and even customers. It implies a conscious effort to ensure that technological advancements reinforce social cohesion and ethical considerations, creating a supportive and inclusive digital work environment. This unique contextualisation ensures that Lean implementation is not a rigid, imported methodology but a culturally attuned framework that resonates with the local societal values.

Finally, Phase 3 places significant emphasis on mastering the Lean tools to tangibly enhance the diverse dimensions of Industry 5.0. This phase moves from conceptual understanding and foundational principles to practical application, enabling organisations to operationalise the human-centric, sustainable, and resilient goals of Industry 5.0. Key Lean tools, such as Value Stream Mapping (VSM) for identifying and eliminating waste, 5S for workplace organisation and efficiency, Kaizen for continuous incremental improvement, and Kanban for just-in-time production and flow management, become instrumental. Their mastery allows for a systematic approach to optimising processes, reducing environmental impact (e.g., through waste reduction in VSM), building organisational resilience (e.g., via flexible systems enabled by Kanban), and empowering human workers by involving them in problem-solving and improvement initiatives (e.g., through Kaizen events). By strategically applying these tools, organisations can achieve tangible benefits, such as improved operational efficiency, reduced resource consumption, enhanced responsiveness to market fluctuations, and a more engaged and empowered workforce. This synergistic approach ensures that the human and sustainable values of Industry 5.0 are not merely aspirational but are deeply embedded and systematically pursued through established Lean methodologies.

In essence, this conceptual roadmap proposes a holistic and iterative journey for South African organisations, commencing with a fundamental shift in mindset, progressing through the culturally sensitive application of Lean principles, and culminating in the strategic deployment of Lean tools to realise the comprehensive objectives of Industry 5.0. It offers a structured

pathway for navigating the complexities of modern industrial transformation, ensuring that technological progress is harmonised with human flourishing and environmental stewardship.

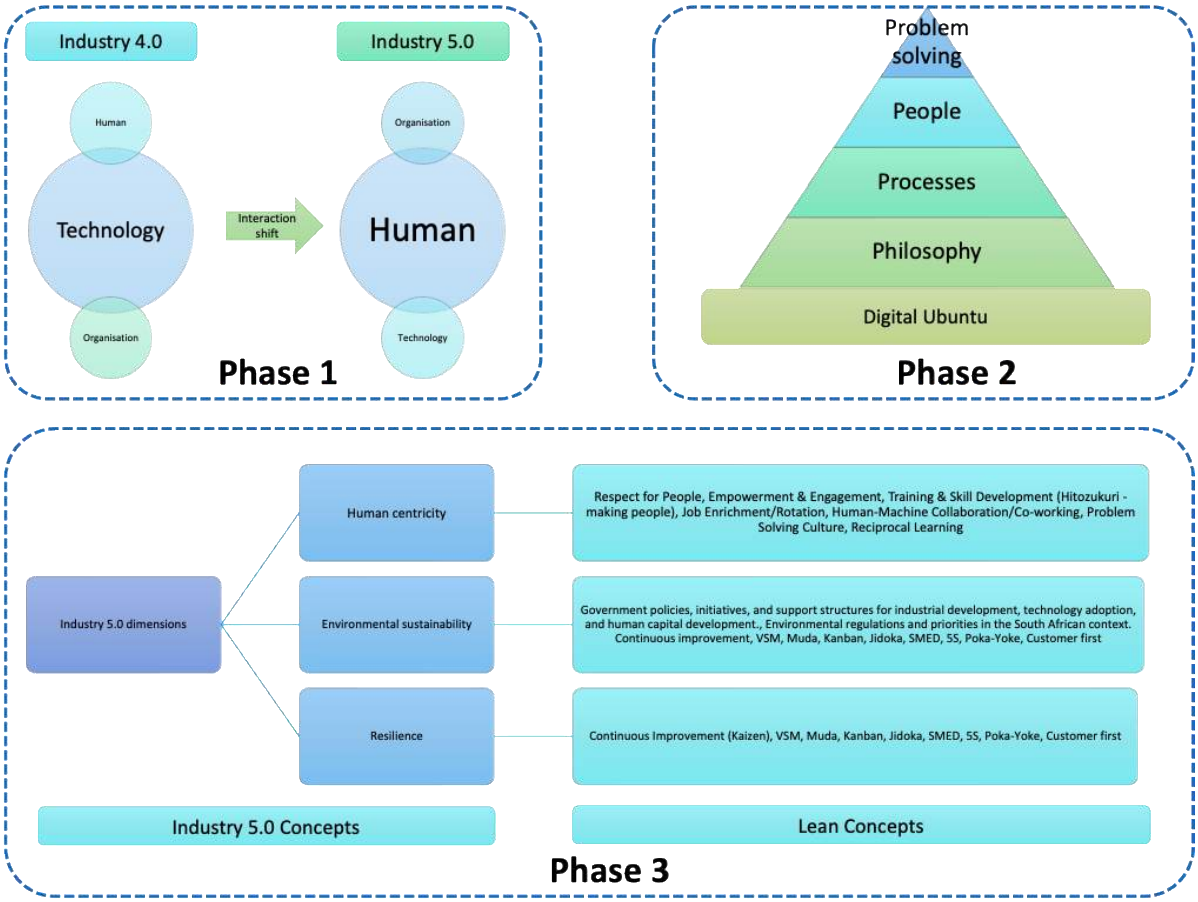

Figure 6: Lean 5.0 Implementation roadmap for SA

5 CONCLUSION

This study conducts a rigorous systematic literature review to examine the emerging paradigm of Lean 5.0, revealing substantial conceptual convergence between Lean philosophy and the human-centric, sustainable, and resilient principles underpinning Industry 5.0. It is noted that industry 5.0 is an emerging field of research, with limited available literature on the topic; ergo, this SLR resulted in only 17 studies and it is recommend that future studies expand on this. The findings highlight that Lean 5.0 is not a linear evolution from Industry 4.0, but rather a synergistic integration that addresses the limitations of technology-centric automation by reasserting the importance of human well-being, ethical values, and environmental responsibility. This shift marks a transition from a narrow focus on efficiency to a more holistic and purposeful vision of industrial development. Traditional Lean tools—long associated with waste elimination and continuous improvement—are shown to gain renewed relevance within the Industry 5.0 framework, particularly through the integration of human-machine collaboration and reciprocal learning.

A context-specific Lean 5.0 framework is proposed to guide South African industries through this transformation. This framework adopts a phased approach. Phase one facilitates a paradigm shift from the technological dominance of Industry 4.0 towards the human-centric ethos of Industry 5.0, emphasizing the workforce's evolving role in symbiosis with advanced technologies. Phase two builds on this by aligning Lean's 4Ps—People, Process, Product, and

Place—with the concept of digital ubuntu, thereby embedding local values of community and human connection into digital transformation efforts. In phase three, the framework focuses on the strategic application of Lean tools to operationalize Industry 5.0 principles and enable measurable outcomes. It is important to note that this study only focuses on the conceptual design of the framework, future research should explore real-world implementation and testing.

The implications for South African industry are substantial. The proposed framework offers a practical roadmap to enhance adaptability, sustainability, and global competitiveness. It addresses key barriers—including conceptual ambiguity, resistance to cultural change, and skill shortages—while promoting enablers such as human-technology integration, continuous improvement, and data-informed decision-making. As such, the framework not only supports operational excellence and waste reduction but also fosters a resilient, inclusive, and environmentally conscious industrial ecosystem. Ultimately, Lean 5.0 provides a strategic foundation for sustainable growth and social equity in an increasingly dynamic global economy.

ABSTRACT

An effective preventive maintenance strategy assists organizations to minimise failures by mitigating potential issues before they occur. This paper presents the development of a survival-based preventive maintenance (PM) scheduling model tailored to optimise equipment management by exploring inefficiencies in audio-visual maintenance practices at a tertiary institution. The current time standards for equipment maintenance were not being met at the institution due to poor resource allocation and inefficient workflows. Multiple modelling approaches were analysed to help reduce downtime. From this, the survival modelling approach was selected for its adaptability, efficiency and predictive accuracy. The chosen maintenance model leveraged mathematical formulation methodologies by integrating Weibull distribution for predictive failure analysis and Cox proportional hazard modelling to incorporate significant covariates. The optimised model achieved significant improvements, increasing preventive maintenance coverage and raising uptime from 87% to 92.58%, resulting in optimised workflows and cost reduction.

Keywords: Preventive maintenance scheduling model, Failure analysis, Weibull distribution, Cox proportional hazard modelling

1 INTRODUCTION

In tertiary institutions, audio-visual equipment is vital for supporting educational services, including lectures, presentations, and events. However, maintenance practices often face challenges, such as budget constraints, high utilisation driven by poor scheduling, and environmental factors like dust and power surges. These limitations frequently result in reactive maintenance, increasing downtime and reducing reliability. At the tertiary institution where the study was conducted, the observed uptime was 87%, falling short of the institution's target of 90%. This highlighted that the current approach was inefficient, reinforcing the need for an optimised PM strategy that prioritises prevention over reaction.

The maintenance of critical systems, including audio-visual (AV) equipment, is essential for operational efficiency and uninterrupted service delivery within organisations, such as high-stakes events like graduation ceremonies, lectures and conferences where equipment failure can cause significant disruption. Equipment degradation leads to potential failures and causes disruptions that impact productivity and service quality. As a mitigative effort to these disruptions, preventive maintenance (PM) has emerged as a cornerstone strategy, as highlighted in various research studies. By conducting regular, pre-emptive interventions, PM extends equipment lifespan, reduces downtime, and enhances overall reliability [1]. Unlike reactive maintenance, which is performed after a failure occurs [2], PM focuses on anticipating issues before they arise, thereby minimising operational risks as well as the associated costs [3].

PM is important in organisational contexts, where equipment reliability directly impacts service delivery quality, for example, ensuring functionality of AV systems in corporate boardrooms for client presentations, or maintaining conferencing equipment in government facilities to support decisions in real-time during emergency response operations. It involves the anticipation and prevention of potential failures, which minimises interruptions and optimises resource allocation. One of its most significant benefits is downtime minimisation [4], which ensures that operations continue while also alleviating the workload on maintenance personnel, enabling them to focus on improving systems rather than constantly addressing emergencies. Additionally, the root-cause focused approach of PM results in long-term cost savings and operational stability [3], making it indispensable for sustainable, broader management of systems.

PM strategies can be broadly categorised into schedule-based and condition-based approaches. Schedule-based PM adheres to predetermined intervals, regardless of the equipment's current state [5]. This is undoubtedly straightforward to implement, but it can lead to inefficiencies, such as unnecessary interventions or over-servicing, which consumes resources without necessarily adding value. In contrast, condition-based PM leverages real-time data to assess the state of equipment and perform maintenance only when specific conditions indicate potential failure [5]. This aids in minimising the waste of overprocessing within an organisation, thereby reducing the burden placed upon available resources, which aligns with lean management principles of reducing "muda" (waste) and "muri" (overburden) [6], [7].

The paper introduces a survival-based preventive scheduling model, where "survival-based" refers to the application of statistical analysis techniques to predict the time until equipment failure. This approach integrates predictive analytics and utilises Weibull distribution and Cox proportional hazard modelling. The model was utilised to estimate equipment failure rates and prioritise maintenance tasks based on the likeliness of failure. This framework identified high-risk components and schedules maintenance accordingly by clustering AV equipment based on degradation covariates.

This paper bridges gaps in current maintenance practices by proposing a scalable and adaptable PM framework. While demonstrated within tertiary environments, the model is applicable across various organisations reliant on critical systems.

The structure of this paper is as follows: the literature review section discusses previous work on scheduling models for preventive maintenance with a focus on the Cox proportional hazard models and Weibull distribution modelling. The method section introduces the general framework for preventive maintenance and details the design of the proposed model. The performance results of the scheduling model, as well as the outcomes from the scheduling model, are presented in the results section. In the Model Efficiency and Downtime Optimisation section, the enhancements in resource utilisation and system performance due to the optimised maintenance strategies in simulated conditions, are discussed. The Microeconomic Preventive Resource Implications section analyses the impact of implementing the proposed scheduling model on cost-effectiveness and resource allocation. The last section concludes the study.

2 LITERATURE SURVEY

PM scheduling problems have generally been approached through various modelling techniques, including Artificial Intelligence (AI), multicriteria decision-making methods, simulation models, and mathematical formulations. AI-driven approaches, such as genetic algorithms (GA) and neural networks, are particularly effective for handling complex decision-making and uncertainty in scheduling problems [8]. Similarly, multicriteria decision-making methods like the Analytical Hierarchy Process (AHP) prioritise maintenance tasks by evaluating multiple conflicting criteria [9]. However, while these methods are valuable, the trade-offs in complexity, resource needs, and practical applicability must be carefully considered when selecting an approach for preventive maintenance scheduling [10], particularly in industry contexts.

Despite the advantages of AI and multicriteria methods, mathematical formulations have received significant attention for addressing preventive maintenance problems, according to Basri [10]. Mathematical modelling approaches are preferred because of their analytical precision and exactness in the theoretical sense for producing actionable results, but their practicality is questioned for the same reason [11]. These methods include probability-based formulations, such as the Cox Proportional Hazard model and Weibull distribution, which provide tools for modelling equipment reliability, optimising maintenance intervals, and minimising downtime. Given their suitability for PM applications, this study focuses on the application of these two mathematical approaches in combination with simulation modelling.

The Cox Proportional Hazard model, referred to as the Cox model in this paper, is one of the most widely used tools in survival analysis, a branch of statistics focused on modelling the time until a specified event occurs, such as equipment failure. The model evaluates the hazard rate, which represents the likelihood of equipment failure over time, based on covariates or factors influencing the outcome [12].

A major advantage of the Cox model is its semi-parametric nature, which does not require assumptions about the baseline hazard function [12]. This flexibility makes it well-suited for systems where multiple factors influence failure rates over time, such as in universities. In the work presented by Austin, the author describes techniques for simulating survival times under a Cox model, which can incorporate time-invariant or time-varying covariates [13]. The research presented closed-form expressions for generating survival times when a time-varying covariate influences the hazard function. These simulations allow researchers to evaluate the performance of Cox models in different settings and provide a means of testing statistical power [13]. While the Cox model excels at analysing the impact of covariates on failure rates, it does not provide insights into the time-to-failure distribution. This limitation is addressed

by pairing the Cox model with parametric methods, such as the Weibull distribution, which explicitly model the shape and scale of failure times.

The Weibull distribution is a cornerstone of reliability engineering and preventive maintenance scheduling due to its ability to model diverse failure rates. The distribution's shape parameter, k, distinguishes different failure patterns. If k < 1, it indicates decreasing failure rates (infant mortality). If k = 1, it indicates a constant failure rate (random failures), and if k > 1, it indicates increasing failure rates [14]. The scale parameter, b, defines the characteristic life, representing the time at which 63.2% of components are expected to fail [15]. When the Weibull distribution was applied, researchers assessed failure time accurately, comparing Weibull results with those from other distributions, such as exponential, normal, log-normal, and gamma, to identify the impact of distribution choice on preventive maintenance intervals [16]. Additional research by Bartholomew-Biggs et al. employed Weibull distribution models with hazard rates to estimate system failure frequency, optimising maintenance scheduling by focusing on cost efficiency [17]. When calculating the mean preventive maintenance cost through Weibull-based analysis, an optimal interval was determined to balance preventive maintenance costs with equipment reliability and availability. The utility of the Weibull distribution lays the foundation for effectively solving the inherent complexities of maintenance scheduling.

Maintenance scheduling problems are typically classified as NP-hard, a term from computational complexity theory used to describe problems for which no known algorithm can solve all instances efficiently in polynomial time [18]. These problems are computationally intensive due to their complexity and the large number of variables and constraints that are involved. In NP-hard problems, the time required to find an optimal solution increases exponentially as the problem size grows [11]. By using simulation, it is possible to experiment with different scheduling strategies and evaluate their effectiveness in improving these metrics. Since maintenance scheduling is an NP-hard problem, simulation is a powerful tool that allows for the exploration of various scenarios under complex constraints without the need for a mathematically exact solution in terms of how it is programmed. Monte Carlo Simulation [19], Discrete Event Simulation (DES) [20], and Simulation Analysis (SIMAN) [21] are some of the methods used in simulation analysis.

Simulation modelling complements the mathematical formulation approaches by validating their performance under dynamic, real-world conditions. Together, these methods form a foundational framework for PM scheduling and offer a scalable solution for minimising downtime, improving reliability, and optimising resource allocation.

3 METHOD

This section introduces the general PM scheduling approach and outlines the methodology employed to tackle inefficiencies in maintenance strategies. The approach provides a flexible methodology that can adapt to diverse operational contexts relevant to each practitioner's own unique case, while the model used in this case applies specific statistical techniques to solve identified challenges at a tertiary institution. The proposed PM scheduling approach operates in a cyclical process designed to continuously integrate new data and refine maintenance schedules. The phases and steps in this approach are detailed in Figure 1.

The rest of this section then continues to outline the methodology for designing the survival-based PM scheduling model at a tertiary institution, which was used as a case study. This model aimed to improve inefficiencies in maintenance strategies, particularly downtime, resource allocation, and scheduling limitations. Utilising survival analysis methods, the model leverages mathematical formulation techniques with Weibull distribution and Cox model to meet specific requirements and constraints. The model was designed to fulfil these requirements:

- **Uptime** – Increase equipment uptime to a minimum of 90% to ensure minimal disruptions.
- **Worker utilisation** - Balance workloads by improving junior technician utilisation while alleviating the overburdening of senior technicians.
- **Adaptability** - Integrate with existing systems and allow for flexibility as equipment usage patterns evolve.
- **Confidence interval** – Ensure the model predictions and evaluations include 95% confidence intervals (CI) to provide reliable and statistically significant results.

Figure 1: PM scheduling model approach

The development process is constrained by maintenance timeslots that are dictated by the organisational schedules. These constraints shaped the model's functional requirements and implementation strategy.

Data collection was carried out through direct observation of maintenance operations, supplemented by semi-structured interviews with technicians to capture insights and validate recorded insights. Triangulation was used to reduce bias and ensure completeness. Recorded variables included equipment type, failure type, failure incidents, usage intensity, and environmental conditions. Purposive sampling was employed for the intentional selection of participants with expertise. A systematic probability sampling was an optimal data collection method for observational data as it allowed for a structured and consistent observation process across different locations and times. Data integrity measures included cross-checking

observational findings against technician interviews. However, one limitation was that the original raw data was securely destroyed after the research phase to comply with institutional confidentiality and ethical protocols, which restricts the possibility of reanalysis.

The development process, illustrated in Figure 2, began with data collection and preprocessing. Initial data included equipment use, failure incidents, and environmental factors, such as dust levels and power surges. The raw data underwent cleaning to remove inconsistencies and prepare it for survival analysis. The model employs two core survival analysis techniques:

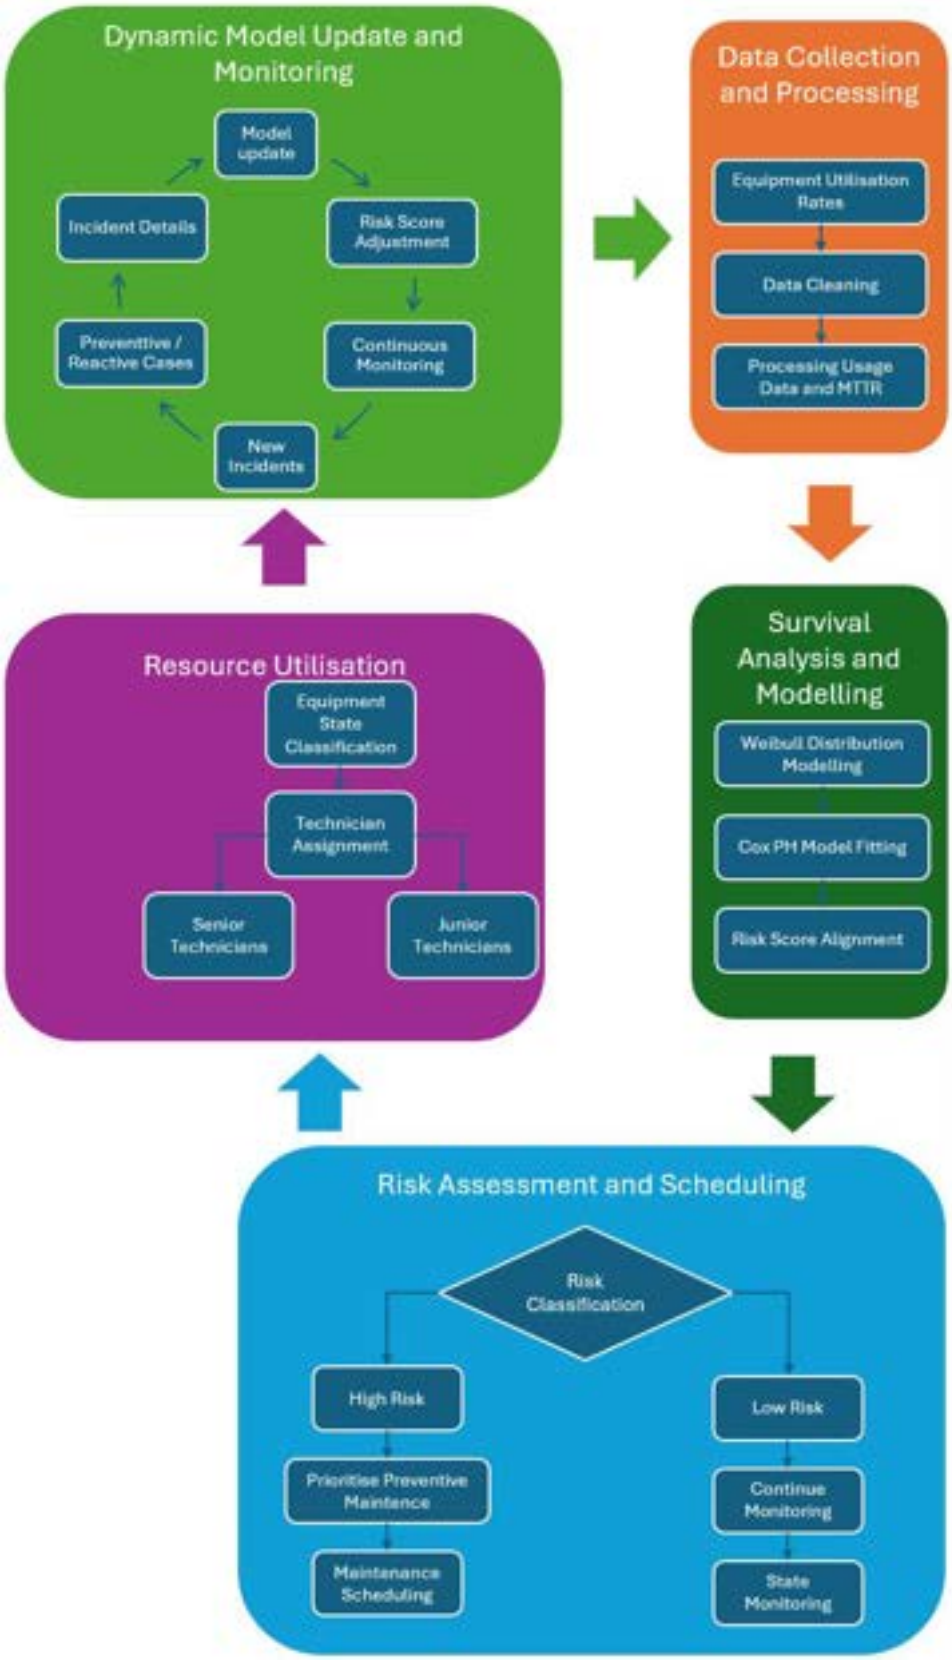

Figure 2: Development of Survival Model

1. Weibull distribution - Used to model equipment degradation and predict failure probabilities. Weibull parameters, which are shape (k) and scale (b), were estimated based on initial data to determine the likelihood of failure over time. Equipment failure rates followed a discrete pattern; the discrete hazard rate and CDF used in modelling are shown below [21]:

$$h(t;k,b) = \frac{F(t+1;k,b) - F(t:k,b)}{1 - F(t;k,b)} \qquad (1)$$

$$F(t;k,b) = 1 - e^{-bt^k} \qquad (2)$$

2. Cox model - Applied to incorporate covariates such as equipment type and venue size, which were identified to impact preventive scheduling. The model generates hazard ratios for each covariate, identifying high-risk equipment for prioritisation. The hazard function, $h(t|X)$, is defined as [22]:

$$h(t|X) = h_0(t)e^{B_1X_1+B_2X_2+\cdots+B_pX_p} \qquad (3)$$

where h_0 is the baseline hazard function, B represents the coefficients for the covariates X, and t denotes time.

The functional steps required to achieve the model's objectives are detailed in Figure 3. The steps can be described as follows:

1. **Load Initial data:** Import research data on class sizes. Data suggests that equipment in larger classes degrades faster.
2. **Create database:** Create a database with equipment details as repository for storing information.
3. **Initial Weibull model prediction:** Use Weibull modelling to predict failure probability based on initial collected data for equipment hazard rates.
4. **Accumulate more data:** Accumulate and simulate more data over time to demonstrate model functionality.
5. **Create Cox Proportional Hazard Model:** Use Cox-fitted model to view model functionality under different covariates.
6. **Prioritise features:** Create priority scores by identifying key features indicating failure using the Cox PH model covariates.
7. **Allocate technicians:** Implement technician logic with Markov chain modelling.
8. **Schedule preventative maintenance tasks:** Schedule tasks based on failure probabilities from Weibull.
9. **Assign technicians:** Assign technicians to reactive and critical tasks after equipment failure.
10. **Create dashboard:** Creation of dashboard to provide users with a visual interface to track performance metrics.
11. **Enable user interaction with dashboard:** Allow users to adjust various inputs and observe how they influence the model.
12. **Continuous model improvement:** User-collected data to improve accuracy and predictions over time.

Technician allocation was optimised to solve the inefficiencies in resource utilisation. The initial workforce configuration, with 8 junior and 2 senior technicians, was rebalanced to include 5 junior and 4 senior technicians. This adjustment was achieved by upskilling two junior technicians, enhancing their expertise to handle complex tasks. Additionally, tools such as ladders were strategically placed across 19 buildings to minimise motion waste and improve task efficiency.

Markov chain modelling was employed to simulate equipment state transitions and ensure balanced task distribution for technicians. Preventive maintenance tasks were prioritised during available time slots, with a fixed intervention time of 45 minutes for routine tasks and an additional 30 minutes for critical interventions. Critical cases typically require senior technicians.

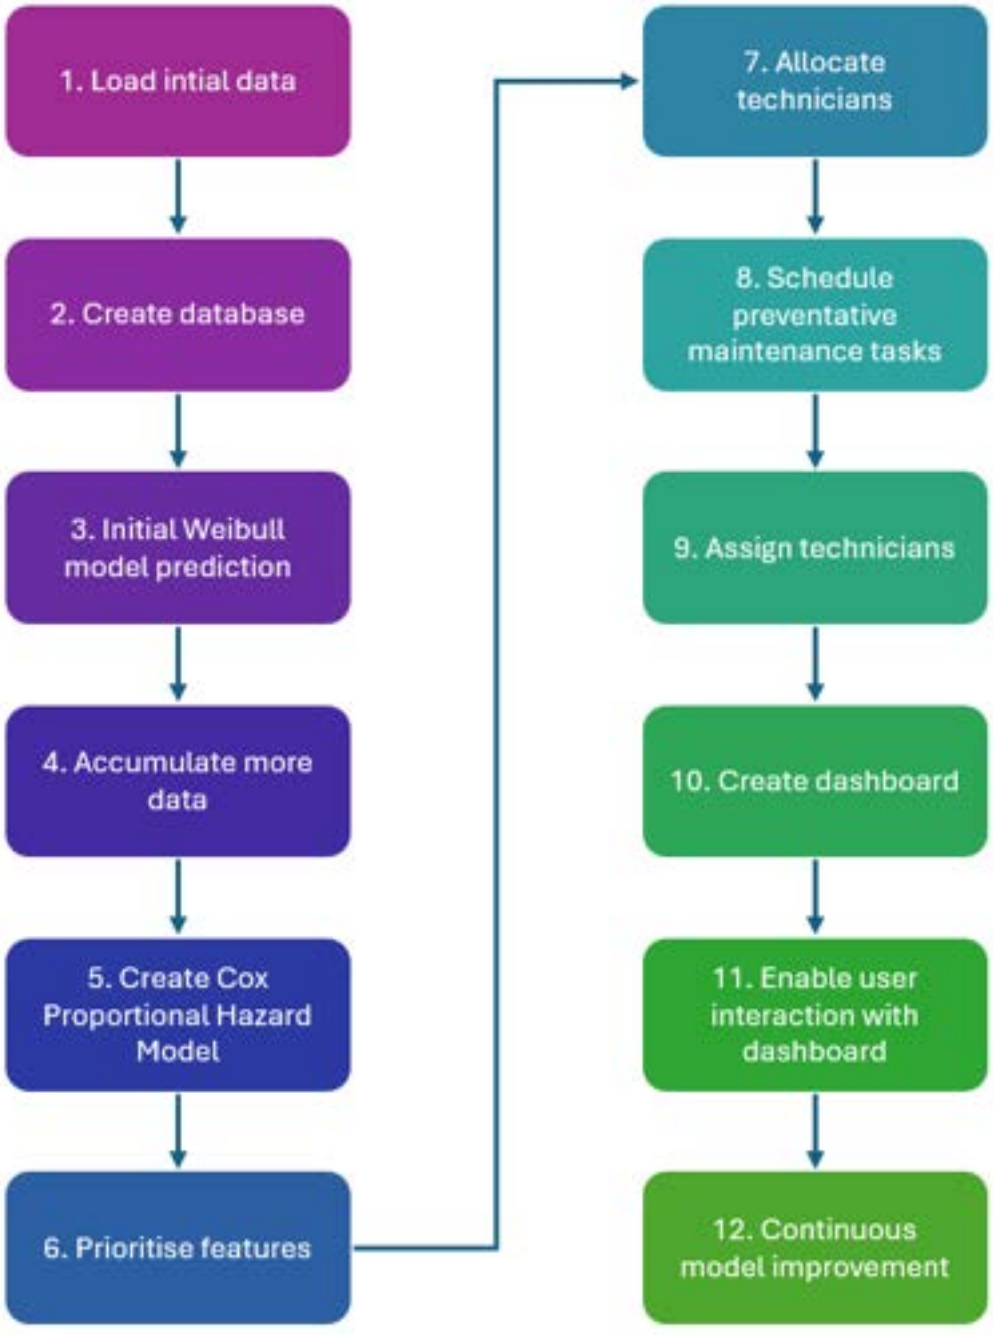

Figure 3: Steps to Achieve Functional Requirements

4 RESULTS

The PM scheduling model aimed to address inefficiencies in AV equipment maintenance, including low uptime and suboptimal resource allocation. The initial dataset captured AV equipment failures across lecture rooms. The Pareto analysis, in Figure 4, revealed that

transmitters, projectors and public address (PA) systems contributed to over 80% of observed failures. Since transmitters are a subcomponent of projectors, their contributions are combined under the projectors category, resulting in the projectors and PA systems being identified as the dominant sources of failures. This effectively justified their prioritisation in the model's initial implementation.

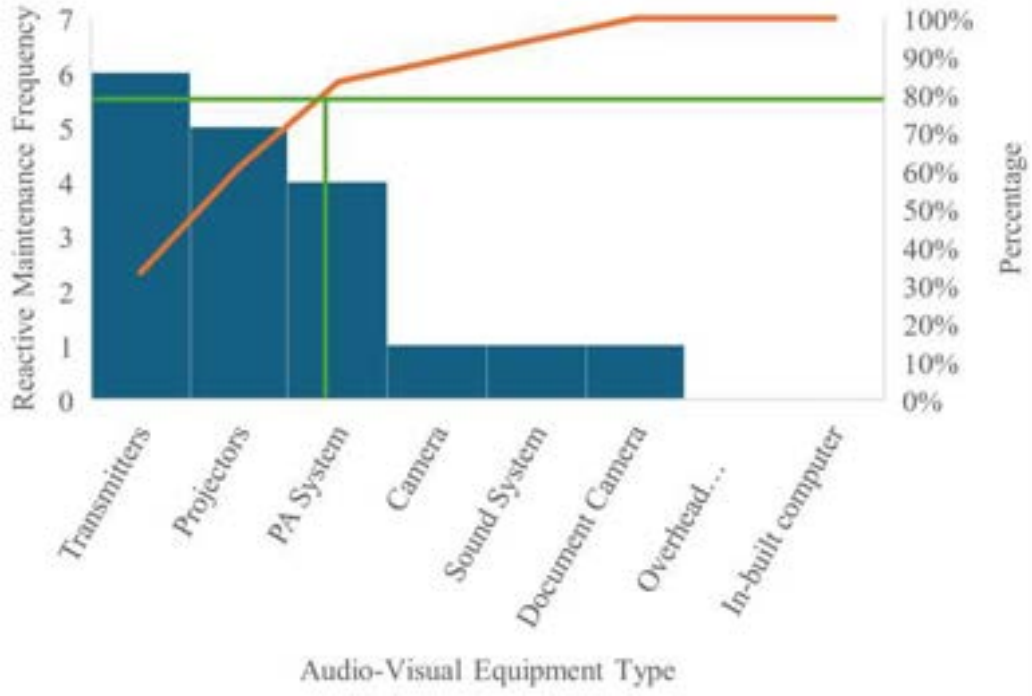

Figure 4: Failure Frequencies with Pareto Analysis

The failure rate was estimated at 1.24%, reflecting significant room for improvement. Using Weibull analysis, the shape (k) parameter was determined to be greater than 1, highlighting the increasing likelihood of failure over time. An assumption was made that the shape parameter is constant, but the scale parameter (b) will differ over time. This means the general pattern of failure was assumed to be the same, but the time scale over which equipment failure occurs was different. Discrete hazard rates, shown in Figure 5, revealed that data projectors in large rooms had the highest risk of failure, and these were used as the base parameter in modelling. Hazard rates of equipment in each type of room are then shown.

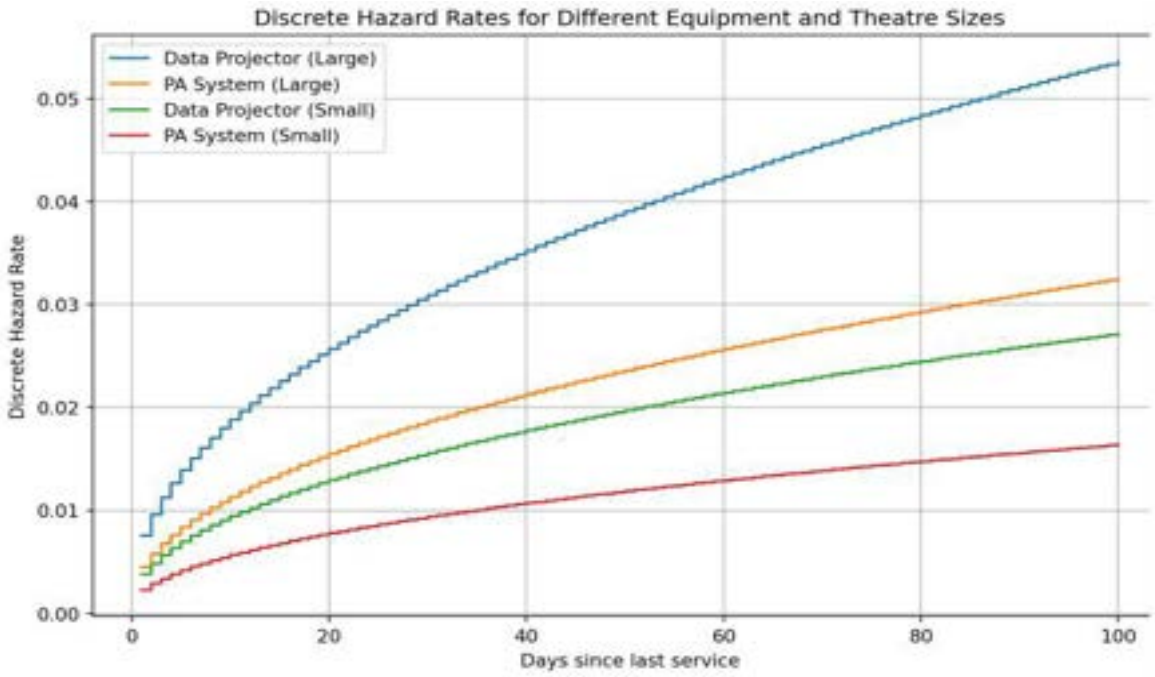

Figure 5: Discrete Hazard Rate for Equipment at Different Class Sizes

While observational data suggested that equipment type and venue size influenced failure rates, additional data was integrated into the model to enhance its predictive capability over time. The developed Cox model demonstrates the functionality of the preventive scheduling framework. The data provided insights into failure probabilities under varying covariates, such as class size and equipment type.

The analysis clustered venues into four categories based on class size, shown in Table 1:

Table 1: Clustering Class Sizes for Cox Model

Clustering	Capacity
Small	Class sizes of fewer than 100 people
Medium	Class sizes between 100-200 people
Large	Class sizes between 200-300 people
Extra-Large	Class sizes greater than 300 people

The Cox model identified significant hazard ratios, while others were found to be insignificant. This is summarised in Table 2.

Table 2: Hazard Ratios from the Cox model

Covariates	Hazard Ratio	Description	Lower Interval (95% CI)	Upper Interval (95% CI)
Medium Venues	HR = 1.207	20.7% higher failure risk.	0.8362	1.7427
Large Venues	HR = 1.927	92.7% higher failure risk.	1.3521	2.7471
Extra-Large Venues	HR = 1.950	95.0% higher failure risk.	1.3247	2.8707
PA Systems	HR = 0.586	41.4% reduction in the hazard.	0.4685	0.7332

One covariate per category was the baseline against which other covariates were tested against. In this case, the small venue category was used as a baseline against the other covariates in that cluster. The Cox model results revealed that the hazard rate increased with an increase in the class size capacity, as shown in Figure 5. Equipment in larger classes is at a higher risk of failing. There is also a representation of the 95% confidence intervals (CI) for

the log hazard ratios from equation (3). More covariates can be added to the model as more data becomes available, and the model accounts for this.

These covariates guide the prioritisation of equipment with a higher risk of failure for preventive maintenance. In Figure 6, 4 different equipment were randomly selected to show the probability of equipment survival over a 30-day period. Equipment with the highest probability of failure, meaning the lowest survival probability, is prioritised for preventive maintenance.

To test the model's applicability, the allocation of senior and junior was modelled. The allocation of these technicians is driven by "states" of equipment modelling, which shows the transitions each piece of equipment may undergo during its lifecycle, shown in Figure 7.

Technician roles were assigned based on task complexity and expertise. Junior technicians were responsible for handling both preventive maintenance and reactive tasks as they occurred. However, when junior technicians were unable to resolve critical or complex reactive tasks, these were escalated to senior technicians, who possess advanced expertise. These tasks were broken down between 8 junior technicians and 2 senior technicians.

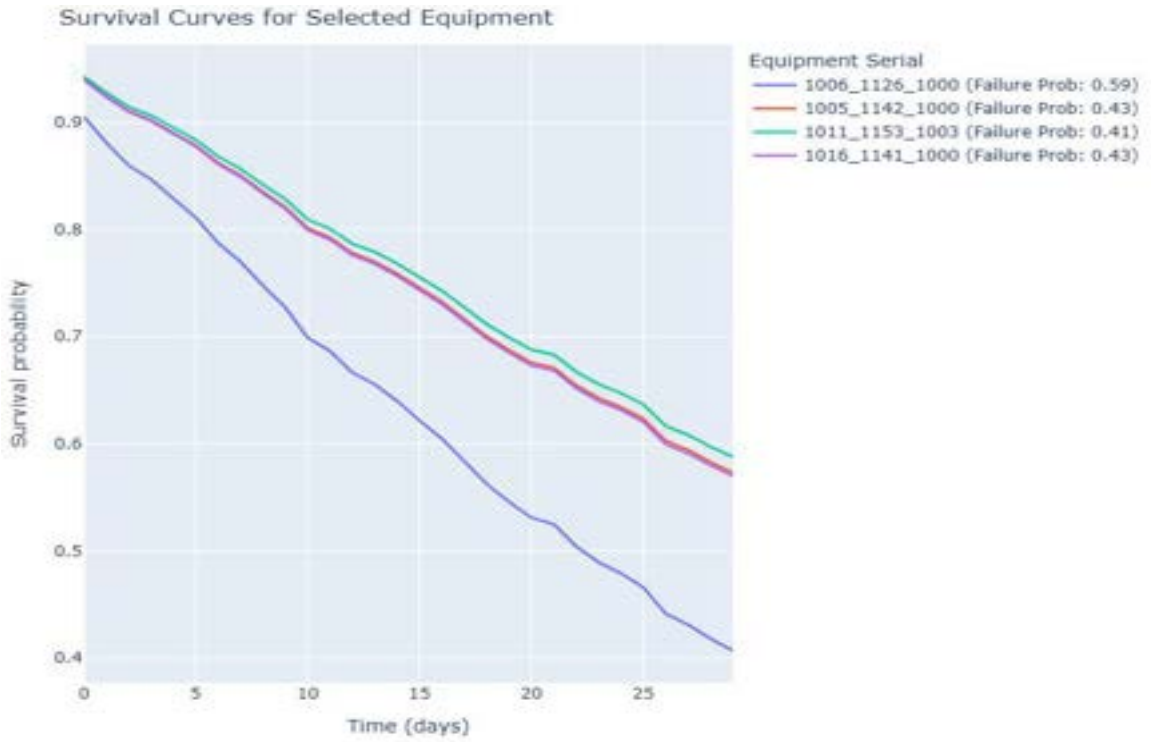

Figure 6: Survival Curves of Equipment

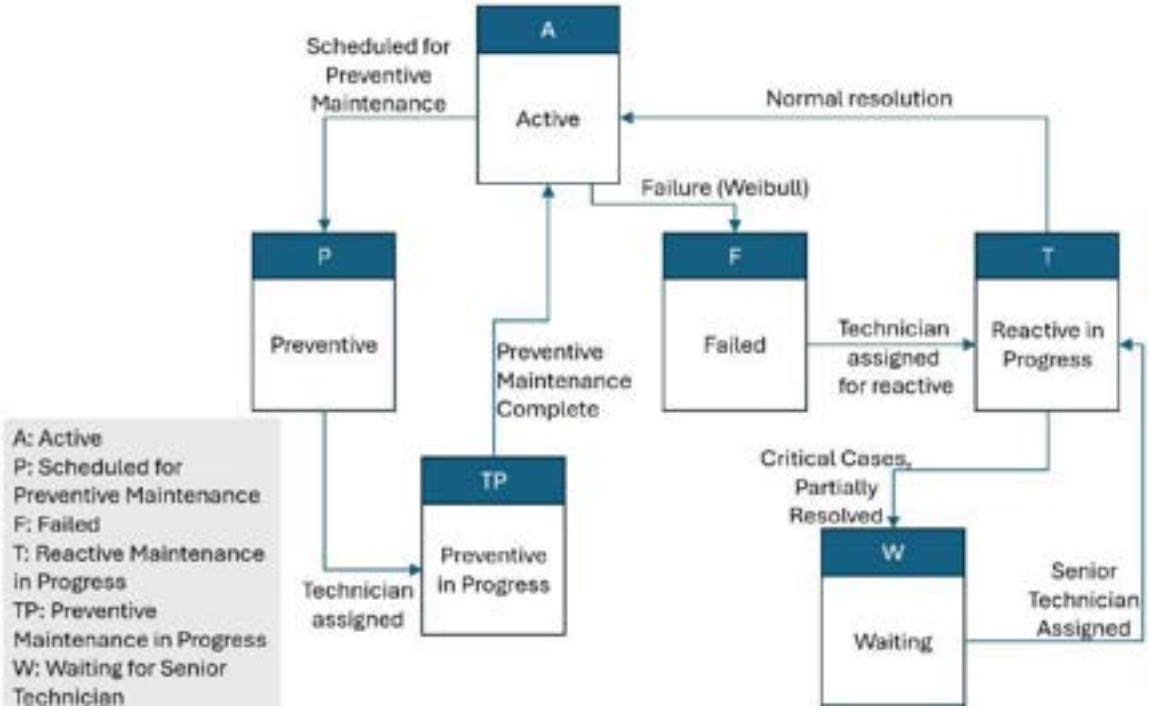

Figure 7: State Definitions of Audio-Visual Equipment

5 MODEL EFFICIENCY AND DOWNTIME OPTIMISATION

The preventive maintenance scheduling model's efficiency was evaluated by optimising technician allocation and reducing downtime. The optimisation focused on tackling the inefficiencies in technician expertise distribution and consequently, improving maintenance task workflows, increasing uptime and resource utilisation.

The original technician allocation comprised 8 junior and 2 senior technicians, leading to inefficiencies for tasks requiring senior-level expertise. A significant number of maintenance tasks were critical and could only be resolved by senior technicians, resulting in delays, prolonged downtime, and reduced preventive maintenance coverage. Figure 8 highlights this imbalance, which resulted in prolonged downtime and reduced the effectiveness of preventive maintenance. The uptime was 89.9% at 6 daily preventive tasks, and technician utilisation was 52.14%.

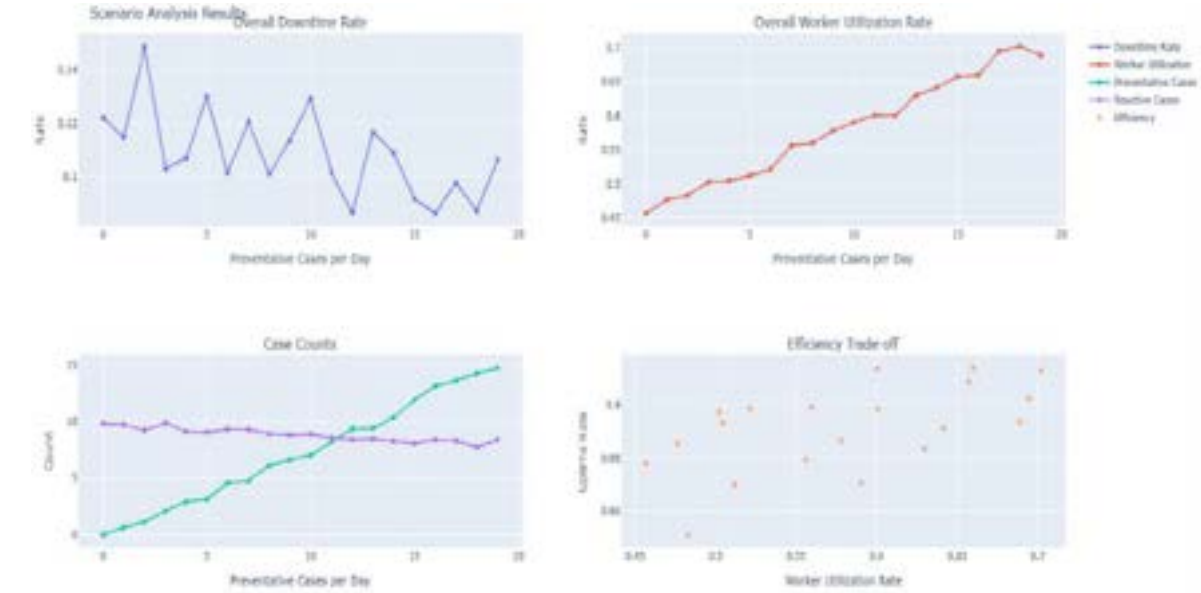

Figure 8: Model-predicted current state

To solve these issues, the technician workforce was reconfigured. Two junior technicians were upskilled to senior-level expertise, achieving a new distribution of 5 junior and 4 senior technicians. Adjustments were made to balance the labour cost structure without increasing overall expenses by removing one junior technician to offset the additional compensation required for the upskilled workforce. The optimisation assumed a constant schedule of six daily preventive tasks, aligned with organisational maintenance windows, to effectively maintain cost neutrality while improving workload distribution.

The optimised allocation resulted in a significant increase in uptime, from 87% (observed state) to 92.58%, surpassing the target of 90%. This improvement reflects the model's ability to streamline workflows and prioritise preventive tasks effectively. Figure 9 compares the model-predicted uptime of the current workforce configuration (89.9%) with real-world observations, validating the model's accuracy. It also shows the optimised state.

Worker utilisation improved substantially under the optimised configuration. In the model-predicted current state, technician workloads were unevenly distributed, leading to idle time for junior technicians and bottlenecks for senior-level tasks. The optimised model increased worker utilisation from 52.14% to 61.02%, reflecting more balanced workloads and reduced idle time.

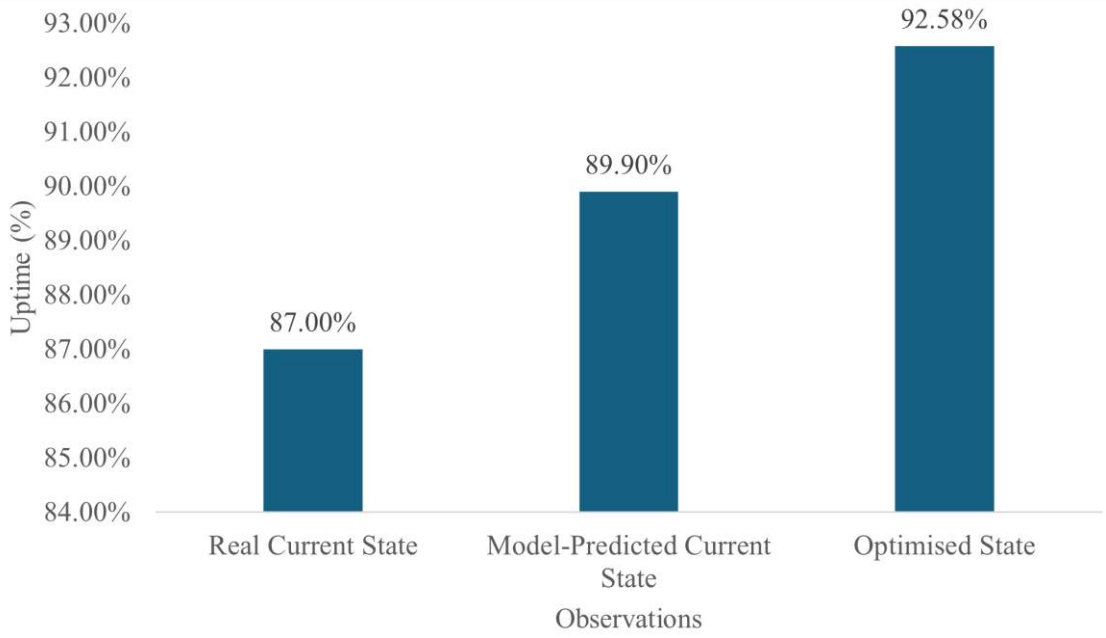

Figure 9: Model Accuracy and Optimised Uptime

Figure 10 illustrates the difference in worker utilisation across both configurations, implying reduced idle time and more balanced workloads. This improvement ensures that technicians are effectively engaged, maximising productivity without overburdening the workforce. The utilisation rate may appear moderate, but it reflects the reality that technicians have additional responsibilities beyond AV maintenance. The optimised model accounts for these complexities while still delivering significant improvements in maintenance task efficiency.

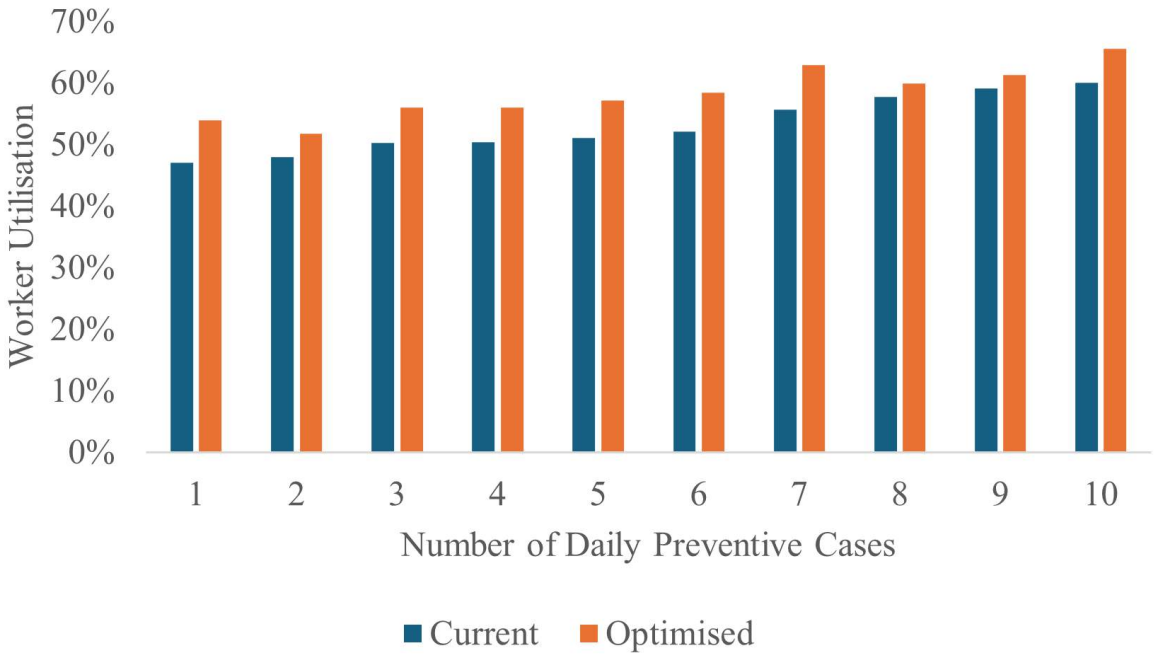

Figure 10: Optimised Worker Utilisations

The optimised technician allocation also increased the cumulative number of preventive tasks completed over a 100-day period. Figure 11 shows that the optimised state enabled the completion of 52 additional preventive tasks compared to the current state. This increase in preventive task coverage reduces the frequency of reactive maintenance incidents, ultimately enhancing equipment reliability and lifespan.

Both the current and optimised models assume that 6 preventive tasks are targeted per day. However, the model accounts for instances when a maintenance task cannot be completed within its designated time slot. In such cases, the task carries over to the next available slot. This continuity ensures that all planned preventive maintenance tasks are ultimately completed, and it minimises any backlogs and enhances equipment reliability. The optimised state's increased task completion rate demonstrates the model's potential to extend equipment lifespan through enhanced preventive scheduling.

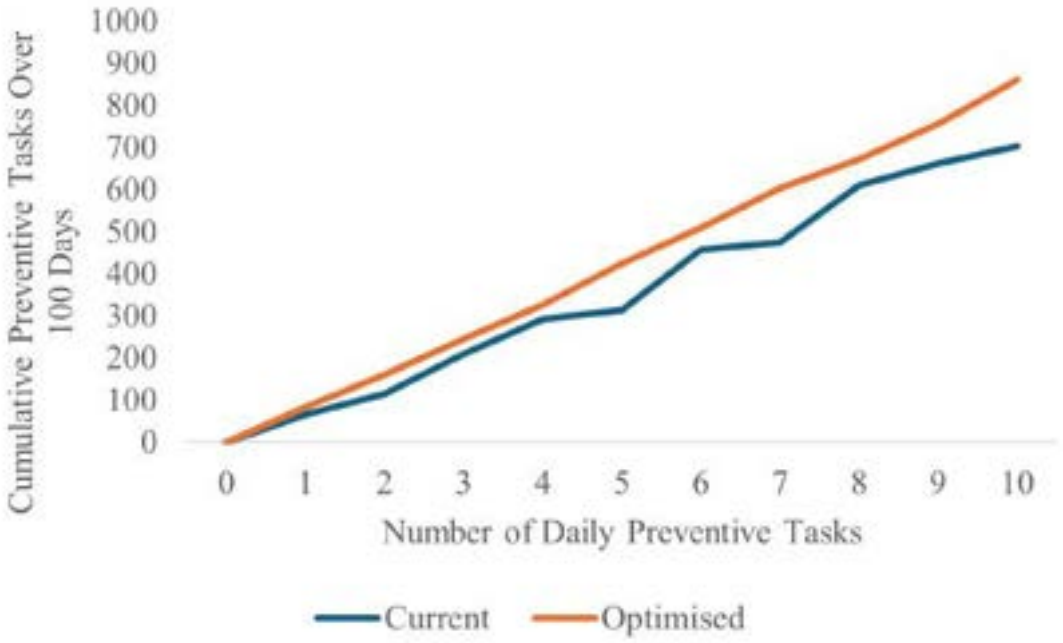

Figure 11: Preventive Maintenance Tasks Over 100 Days

One of the preventive scheduling model's strengths is its adaptability to evolving conditions. The model is designed to improve accuracy over time by incorporating more data as it is logged into the system, such as equipment maintenance incidents and the addition of equipment. As such, the Weibull parameters are recalibrated, and the system refines its failure predictions, enhancing the reliability of maintenance schedules.

Additionally, the model also supports the transition to standardised equipment and incorporates new assets into the preventive maintenance schedule in a seamless fashion. This adaptability ensures that the framework remains relevant in dynamic operational environments, providing a sustainable solution for maintenance efficiency in the long term.

6 MICROECONOMIC PREVENTIVE RESOURCE IMPLICATIONS

The implementation of the PM scheduling model has significant microeconomic implications when considering the optimisation of limited organisational resources. The model reduces idle labour time while simultaneously addressing overburdened senior technicians by reallocating technician roles and improving task efficiency. This workload redistribution increases worker productivity while simultaneously maximising the value extracted from the existing workforce, ensuring that resources are utilised cost-effectively. Removing one junior technician without

compromising task completion rates further exemplifies the model's ability to streamline operational costs while maintaining or improving output. These adjustments result in a more sustainable workforce configuration and align resource allocation with the organisation's operational needs and budgetary constraints.

In addition, the investment in upskilling two junior technicians to senior-level expertise exemplifies a strategic consideration of resource development that enhances the organisation's long-term economic stability. The associated costs of certification programs are offset by the reduced dependency on external hires or temporary contractors for senior-level tasks, providing a sustainable solution to addressing skills gaps. Furthermore, the strategic placement of ladders across buildings to minimise motion waste enhances efficiency and reduces indirect labour costs, such as time spent on non-value-adding activities. These measures collectively demonstrate the model's capacity to deliver significant cost savings while ensuring that critical resources are deployed where they are most impactful, thereby fostering an efficient maintenance system.

7 CONCLUSION

This study introduced a preventive maintenance scheduling framework designed to enhance equipment reliability and optimise resource utilisation in operational environments reliant on critical systems. By integrating survival analysis methods, that is, the Weibull distribution for failure prediction and the Cox model for analysing covariates, the model demonstrated its capability to improve maintenance scheduling and adapt to evolving operational needs. Simulated implementation significantly improved system uptime and achieved a predicted 92.58%, alongside enhanced technician utilisation.

The framework's adaptability is a major strength, allowing for continuous refinement as additional data becomes available. While this study employed Weibull distribution and Cox modelling techniques, the framework is flexible enough to incorporate alternative methodologies suited to other operational contexts. This model lays the foundation for improved preventive maintenance practices by providing a scalable and sustainable approach and ultimately offers practitioners a tool for minimising downtime, optimising resource allocation, and ensuring operational continuity across various organisational settings.

ABSTRACT

The transition from internal combustion engines (ICE) to electric vehicles (EV) demands a parallel evolution in the skillsets of technicians involved in maintenance and manufacturing. Virtual Reality (VR) presents a promising opportunity to develop immersive training platforms for upskilling workers in EV technologies. This study conducts a systematic literature review (SLR) to explore the current applications of VR in the EV sector. The findings identify key applications, drivers and barriers. The largest application areas of VR in EV are safety simulation training and virtual showrooms. Enabling technologies such as Unity 3D and HTC Vive, as well as major industry drivers including the demand for skilled labour and compliance with safety regulations support the sustainable expansion of the EV sector. By synthesizing existing research, this study identifies critical gaps and provides guidance for future investigations in this domain. The insights gained contribute to the development of more effective VR-based training solutions, ensuring a workforce that is well-equipped to navigate the technological shift toward electric mobility.

Keywords: Electric Vehicles, Virtual reality, EV, VR, SLR, South Africa

1 INTRODUCTION

The transport industry stimulates global economic activity [1]. As concerns regarding the industry's environmental impact increase, so too does the need to develop novel and sustainable solutions that drive economic growth [2]. The rapid development of the automobile sector has presented an opportunity for electric vehicles (EV) to mitigate environmental pressures [3]. Although currently in its infancy, the EV industry has the capacity to reduce dependency on non-renewable resources [4]. According to recent studies, South Africa's EV industry anticipates a 19% reduction in greenhouse gas (GHG) emissions by 2050 [1].

Research studies indicate that operational excellence is vital to achieving environmental goals and facilitating expansion across the transportation sector. Maintenance practices are a critical component for the sector's efficiency and sustainability [8]. The International Standard Industrial Classification (ISIC) system standardizes and categorizes operations by allocating specific codes to various economic activities. For example, ISIC code 4530 represents automobile maintenance and repair. The classification system serves as a global standard for organizing economic activity and facilitating statistical analyses [5].

The incorporation of Virtual Reality (VR) training tools in the EV sector signifies the progression of equipping the EV workforce with effective training opportunities [6]. In response to this demand, automotive groups are actively working to provide VR-based training solutions that improve standard operating procedures (SOP) training. The technologies offer an immersive and dynamic setting, allowing service technicians with effective training tools to enhance their skills in immersive, simulated environments [7]. This study aims to investigate this by exploring current applications of VR in the EV sector, key application areas, drivers and barriers can be identified. More effective VR-based training solutions can therefore be developed, empowering the EV workforce in the skills transition from internal combustion engines to electric vehicles.

2 RESEARCH METHODOLOGY

In order to review existing literature on the top, a systematic literature review (SLR) was conducted. An SLR identifies, evaluates, interprets relevant research with the objective of answering a specific question [9]. The methodology followed is described in the following steps:

- **Step 1 - Develop a research purpose:** Clearly define the objective of the SLR
- **Step 2 - Develop a research protocol:** Prepare a research protocol including inclusion and exclusion criteria, search databases, keywords, and quality assessment criteria
- **Step 3 - Establish relevance criteria:** Clarify reasoning for whether literature is relevant to this study
- **Step 4 - Search and retrieve the literature:** Explore scientific databases for relevant literature
- **Step 5 - Selection of studies:** Select studies based on inclusion and exclusion criteria
- **Step 6 - Quality assessment for relevant studies:** Consider the quality of each selected study
- **Step 7 - Data extraction:** Extract relevant data from literature
- **Step 8 - Analysis and synthesis of findings:** Analyze and synthesize information from selected studies to identify trends and patterns
- **Step 9 – Report:** Present detailed report findings

- **Step 10 – Dissemination:** Publish the report

Steps 1 to 8 are included in this review, however Step 9 and 10 will be conducted upon publication.

2.1 Step 1 - Develop a research purpose

The purpose of this research was to investigate key application areas, drivers, barriers and software used in VR solutions for EV training and manufacturing.

2.2 Step 2 - Develop a research protocol

A research protocol was developed and is captured in table 1.

Table 1: Research Protocol

Purpose of the study	The purpose of this research was to investigate key application areas, drivers, barriers and software used in VR solutions for EV training and manufacturing.
Inclusion criteria	• Studies containing the "Electric Vehicle", "EV", "Virtual Reality", "VR", "training", and "South Africa" in the title, keywords, abstract or introduction • Literature that discusses key application areas, drivers, barriers and software used in VR tools in the EV sector
Exclusion criteria	• Outdated studies (older than 10 years, prior to 2015) • Non-English studies
Search databases	• Scopus • Science direct • Web of science
Keywords	"virtual reality technologies" AND "electric vehicle"
Quality assessment criteria	• All duplicate studies must be removed • Relevance of literature must be checked • Ensure that the interpretations of literature are aligned with the purpose of this study • Literature studies must have transparent data collection • Literature must be scientific

2.3 Step 3 - Establish relevance criteria

The studies are considered relevant if they contain at least one of the following criteria:

- Keywords are present in the abstract, introduction or conclusion
- Purpose of this study must be directly addressed
- Study must be focused on the EV industry
- Key application areas of VR solutions must be addressed
- Target group of the study is South Africa
- The key drivers of VR solutions must be addressed
- The barriers VR solutions must be addressed
- Software used in VR solutions must be addressed
- Lessons learned in VR solution in the EV sector must be addressed
- VR solutions in EV training and maintenance must be addressed
- VR maintenance in EV training and maintenance must be addressed

2.4 Step 4 - Search and retrieve the literature

A systematic search was conducted using the advanced features of Web of Science, Scopus and Science Direct as primary data sources. The search strategy involved searching the keywords on the aforementioned databases. To refine the search, only review articles, research articles and conference papers in English that were published between 1 January 2015 and 18 April 2025 were considered. The initial search had a yield of 260 articles as shown in Figure 1, (Scopus = 15, Science Direct = 117, Web of Science = 134).

2.5 Step 5 - Selection of studies

The inclusion and exclusion criteria was applied in the selection process. Studies containing the keywords in the title, abstract and introduction were selected. Additionally, key applications, drivers, barriers and software used for VR in the EV sector were considered. Duplicate and retracted studies were identified and removed from the search results. Furthermore, only non-English and recent studies published within the last 10 years were considered for the purpose of relevance. Following a careful review, 16 literature studies were identified and included in this study. The full selection process followed in Figure 1.

2.6 Step 6 - Quality assessment for relevant studies:

To ensure that the quality assessment is conducted efficiently, duplicate studies are removed to eliminate redundancy. The screening of the abstract and introduction of each study was conducted, and literature that did not meet the relevance criteria detailed in Table 1 was excluded. Additionally, the interpretations that did not align with the purpose of this study were excluded. Thereafter, a full text assessment was conducted to evaluate the transparency of data collection and that the methodology is scientific. Studies that adhere to all quality assessment were selected for data extraction. Moreover, this resulted in the inclusion of 15 studies as depicted in Figure 1.

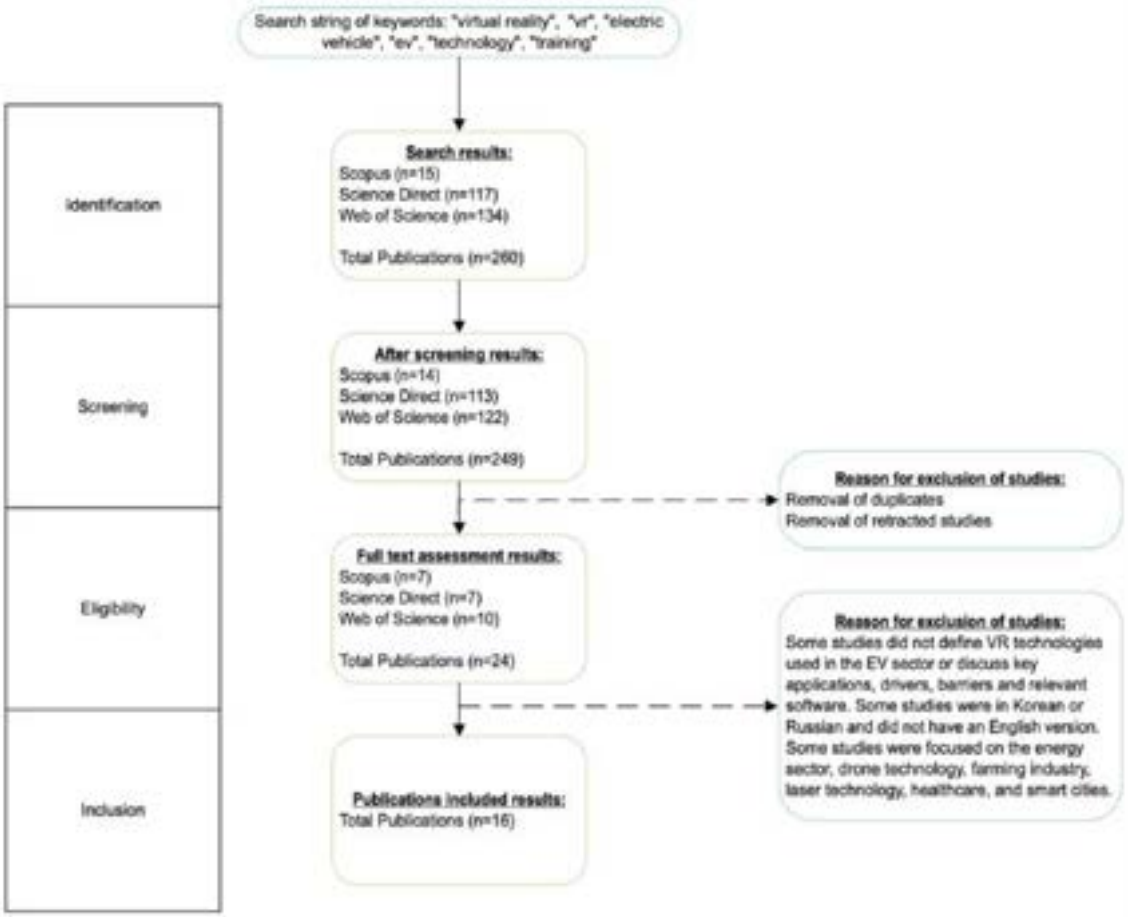

Figure 1: Prisma Selection Process

3 FINDINGS

Common themes and patterns in relevant literature were extracted and synthesized in this section to achieve the objective of this study.

3.1 Step 7: Data extraction

After the finalisation of the studies during the SLR, data was extracted and captured in table 2.

Table 2: Data extracted from applicable literature

#	Title	Authors and year	Application of VR	Barriers	Drivers	VR technology	Software	Future research	Ref

3.2 Step 8: Analysis and synthesis of findings

3.2.1 Keywords intersectionality

The intersectional nature of the various application areas is effectively illustrated in the keyword co-occurrence diagram in Figure 2. The size of each keyword represents the frequency of keywords in selected studies. Thus, the largest words, “Electric vehicles”, “Virtual reality”, “digital twin” are the most frequently occurring in publications. Other keywords such as “workforce development”, “education”, “disassembly” and “remanufacturing” are present. In this context, it is evident that there is a relationship between the forementioned keywords and major application areas extracted from literature namely technician training, assembly and maintenance.

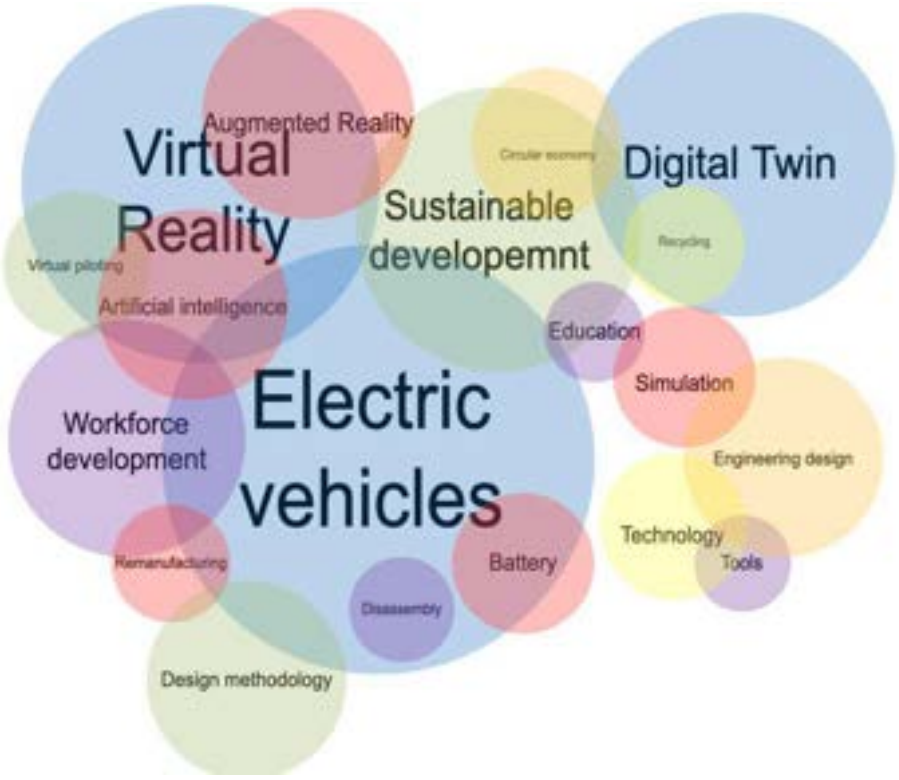

Figure 2: Keyword co-occurrence network

3.2.2 Annual distribution of studies

Figure 3 depicts the number of annually published articles on various VR applications in the EV sector. The highest number of published articles was 5 articles in 2024, comprising of 33% of the total number of relevant studies published in the 2015-2025 range. It is noteworthy that the number of articles published from 2020 until 2025 has increased substantially and accounts for 87% of the total published articles. Thus, indicating an increase in interest in research within the scope of this review. This trend may be a result of the rapid growth of the EV industry, introducing a need for supporting research of key applications for training, assembly and maintenance of EV components [3,4, 6, 7].

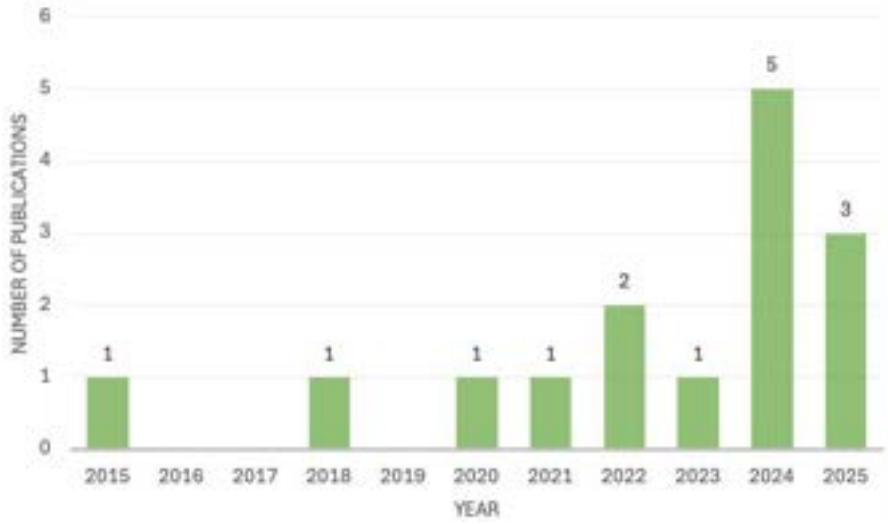

Figure 3: The distribution of publications per year

3.2.3 Key applications of VR in the EV sector

Virtual reality technologies provide innovative solutions for various stages of the value chain, rapidly revolutionising the EV industry. A key application area of VR is in safety simulation and training, which promotes safe and immersive environments to educate engineers and technicians on emergency protocols and handling high-voltage battery components [13,14,17,21]. VR environments are significant in visualising physical designs in early product design, allowing interactions with full-scale 3D models, virtual piloting as well as reducing overall costs and accelerating the product design development cycle [10,11]. Applications of VR are observed in the manufacturing and assembly line planning by facilitating virtual walkthroughs, the identification of inefficiencies, the optimization of facility layouts and employee training without disrupting production line operations [19,23]. Maintenance, aftersales and research and development operations greatly benefit from VR technologies [16]. Furthermore, virtual showroom experiences, test drives and product education are used to enhance customer experience and influence purchasing decisions [19,21,24].

3.2.4 Drivers of VR technology Applications in the EV sector

Several factors are working to accelerate VR adoption in the EV sector. In recent years, rapid technological development has increased the commercialization and accessibility of powerful VR systems [10,12,16]. The demand of skilled labor in the EV industry has encouraged companies to adopt VR-based training for rapid and effective upskilling [13,14,21]. Broader digital transformation initiatives foster a conducive environment for VR integration and alignment with Industry 4.0 [12]. Regulatory demands with a focus on worker safety and

environmental compliance supports the need for VR solutions that enhance training and reduce operational hazards [13, 17, 21].

3.2.5 Barriers of VR technology use in the EV industry

Despite its potential, widespread adoption of VR in the EV industry is impeded by multiple obstacles. The high initial investment costs of VR hardware, software development and content creation act as a significant obstacle [19, 24]. When combined with uncertainty of the return on investment, a commitment of substantial resources will not be made by most organisations. Connecting of VR tools with existing enterprise systems introduces integration challenges [19,23]. Moreover, a shortage of domain experts and content developers restrict the scalability and customization of VR technologies [13, 14, 17]. Organisational factors such as behavioural inertia as well as lack of trust and digital readiness act as an obstacle in the incorporation of VR into established workflows [22].

3.2.6 VR Software and Technologies enabling Applications in EV industry

The EV sector uses a range of specialized tools and VR development platforms with the objective of enhancing VR application. VR software provides the most flexible, powerful and versatile development environment for the facilitation of training modules and product design visualizations. Software technology used for educational purposes in literature were Unity 3D, Revia Technology, Vidinoti, TASCAR, while testing scenarios used PreScan, Simulink and Thrustmaster T300RS [2, 4, 9, 11]. Hardware tools such as HTC Vive Pro Head-mounted display, VR goggles, and Oculus Rift play a vital role by facilitating an immersive interface for visualization and user interaction [2, 4, 11]. Together, these technologies enable the scaling and customization VR solutions to satisfy various operating requirements in the EV sector. The table below illustrates the advantages and disadvantages of these VR technologies.

Table 3: VR technologies advantages and disadvantages

Technology	Advantages	Disadvantages
Unity 3D	• Is a flexible and powerful development engine • Supportive of multiple platforms [2]	• Steep learning curve for beginner software developers [2]
Revia Technology	• Easy to integrate with Unity 3D • Enhances realism [2]	• Limited customizability [2]
Vidinoti	• User-friendly • Compatible with mobile devices [4]	• Limited interactivity [4]
TASCAR	• Useful for auditory research [11]	• Requires an development expert in acoustic modeling [11]
PreScan	• High fidelity simulation [9]	• High-cost • Complex user interface [9]
Simulink	• Easy integration with MATLAB software • User-friendly [9]	• Requires technical knowledge and expertise [9]
Thrustmaster T300RS	• Realistic feedback for driving simulations [9]	• Requires extensive setup • Limited to driving context only [9]
HTC Vive Pro Head-mounted display	• Hiqh quality resolution [2,11]	• Expensive • Requires extensive setup [2,11]
VR goggles	• Lightweight • Immersive [2,4]	• May cause nausea, [2,4]
Oculus Rift	• Motion tracking • Economical [2]	• Requires external sensors [2]

3.2.7 Future Research

Although current applications of VR technologies in the EV industry are promising, that are significant gaps that future studies should address. An underexplored area is the EV supply chain upstream activities where training and optimizations may improve sustainability improvements [16, 19, 23]. Furthermore, the long-term effectiveness and return on investment of VR technologies in safety, training and manufacturing must be studied [13, 14, 17, 19, 21, 24]. Research on increasing the compatibility of artificial intelligence, Internet of Things and digital twins with VR systems should be conducted [16, 10, 11]. It is critical to address these research gaps in order to fully unlock the potential of VR technologies usage in the EV industry.

4 FRAMEWORK

The figures below illustrate the key applications areas, as well as the barriers and drivers of VR technologies in the EV industry.

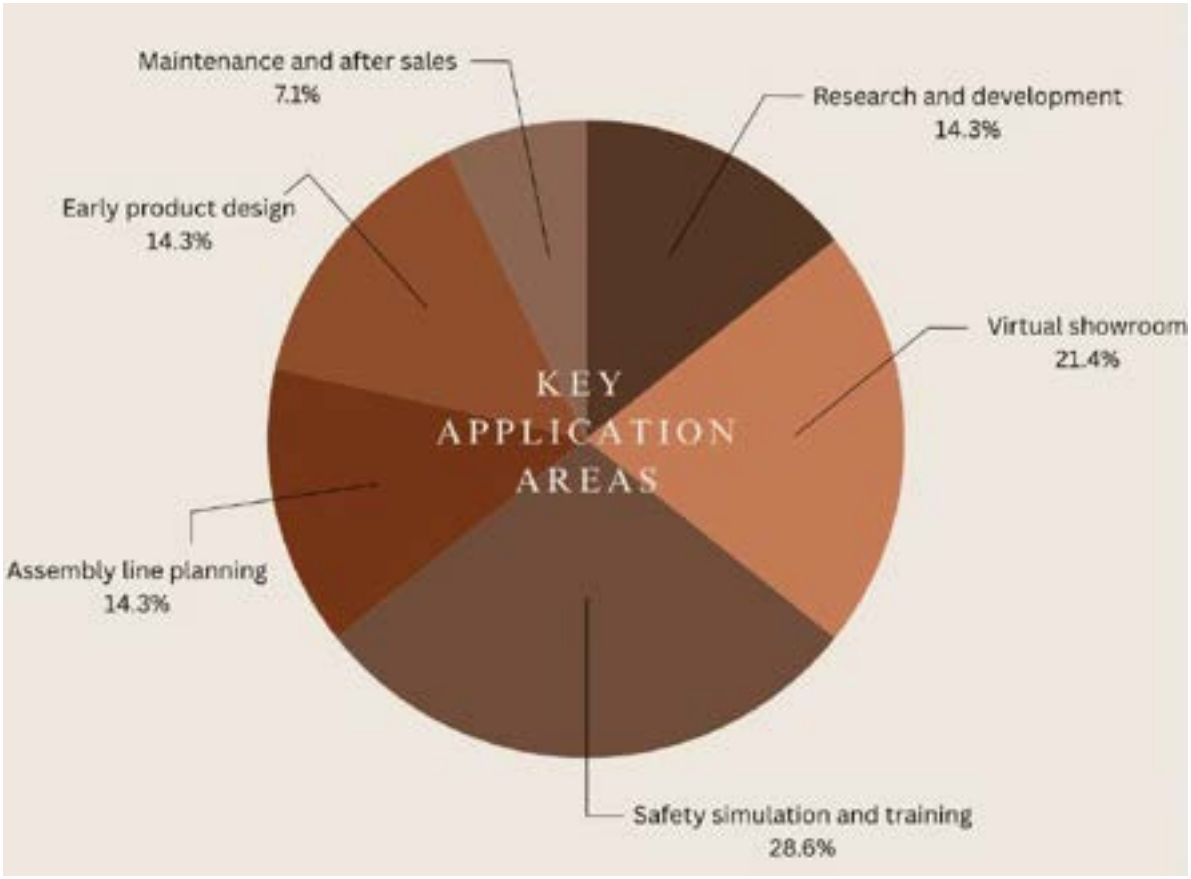

Figure 4: Key Application Areas of VR Technology as Percentages

VR technology is transforming the EV industry across various stages of the production cycle. Figure 4 illustrates the key application areas of VR technologies in the EV industry based on the amount of studies available. It is evident that the largest key application area is safety simulation and training, closely followed by virtual showrooms. Whereas, maintenance and aftersales is the least explored area, highlighting a notable gap in existing literature. Early product design, assembly line planning, and research and development have the same proportion of application that is more explored than maintenance and but less than virtual showrooms. These key application areas expose potential areas for future research.

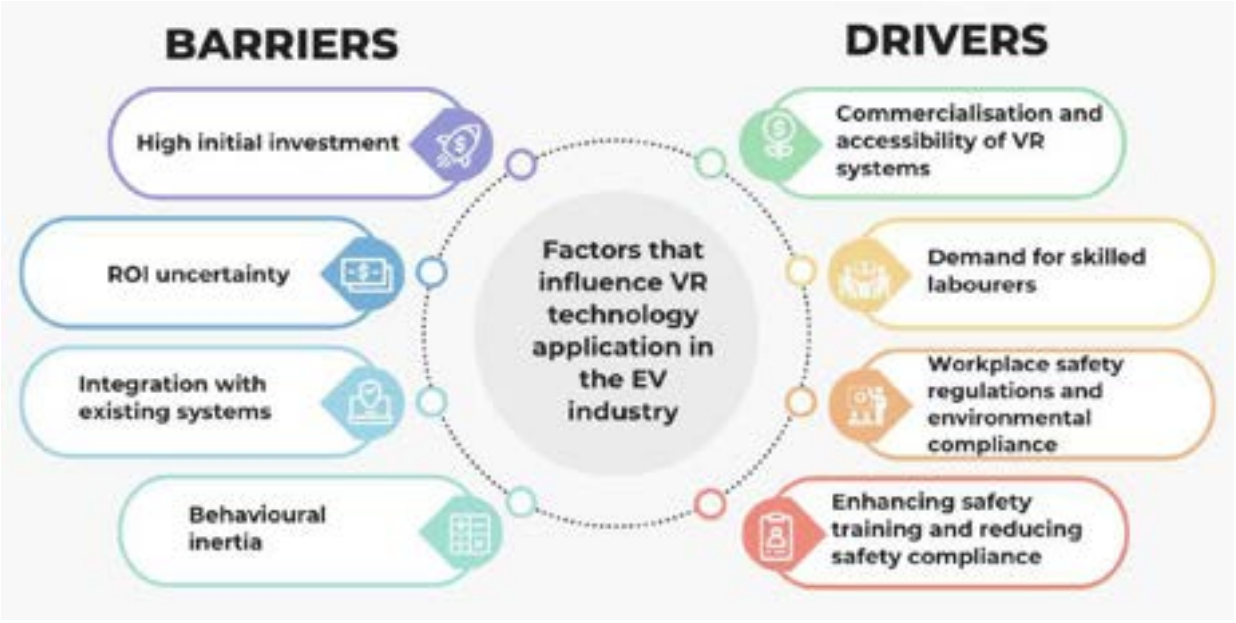

Figure 5: The barriers vs the drivers of VR technology application in the EV industry

Drivers and barriers influence the adoption of VR technology applications .Figure 5 visualises the barriers and drivers identified in Section 3 of this review. Developing a holistic understanding of these factors can improve the commercialisation and accessibility of VR technology. In this way, strategic planning and risk mitigation functions are supported and the full potential of VR can be harnessed [13,17,21]. Ultimately, empowering the EV workforce in its various functions in the product life cycle of EVs and promoting the sustainable growth of the EV industry [7].

5 CONCLUSION

South Africa's EV industry expects 19% reduction in greenhouse gas (GHG) emissions by 2050. The incorporation of Virtual Reality (VR) training tools in the EV sector signifies the progression of equipping the EV workforce with effective training opportunities [6]. In response to this demand, automotive groups are actively working to provide VR-based training solutions with technologies that offer an immersive and dynamic setting. Thus, equipping service technicians with innovative training tools to enhance their skills in immersive, simulated environments [7].

This systematic literature review provided a detailed analysis of the application areas of VR technology in the EV sector. The key application areas of VR usage, as well as drivers, barriers, and VR software were identified. This review's objective was to support the development of effective VR-based training solutions and empower the EV workforce. For this purpose, relevant literature was systematically selected, filtered and analyzed.

Research findings indicated a recent increase in publications from 2020 to 2025. Therefore, reflecting a rising interest in VR technology application in the EV industry. This trend further highlights the exponential growth that VR technology and the EV industry have seen in recent years. Industrial drivers such as the commercialization and accessibility of VR systems, the demand for skilled technicians, restrictive workplace safety regulations, environmental compliance standards and the need for effective safety training programs were identified. Despite these enablers, challenges remain and hinder the adoption of VR technologies in industries. These obstacles are high initial investment costs, ROI uncertainty, integration of VR systems with existing enterprise systems and employee behavioural inertia. Technologies such as HTC Vive Pro, Unity 3D and Oculus Rift, among others, facilitate the application of VR

usage in EVs. Although VR technology use in the EV sector has increased, it still has room for expansion and high growth potential.

Future research has the potential to further develop VR applications in EV to reach its full potential. There is currently a limited amount of research on VR technology applications in the EV industry, skills transition attitudes, adoption behaviors and industry growth of this novel technology is dependent on reliable research. Therefore, more industry research should be conducted to encourage further application of VR technologies. VR has the potential to alter the ways in which EVs are designed, manufactured, marketed and maintained as the industry develops.

ADOPTION OF BLOCKCHAIN TECHNOLOGY IN THE AGRICULTURE SUPPLY CHAIN OF SOUTH AFRICA

D. Botha[1*] and E. Van der Lingen[2]

[1,2]Department of Engineering and Technology Management
University of Pretoria, South Africa
[1]u23948419@tuks.co.za, [2]elma.vanderlingen@up.ac.za

ABSTRACT

In the agricultural sector, data collection is often expensive. Blockchain technology offers a reliable and immutable data source for tracking crops, inventories, and contracts. By enhancing traceability, blockchain fosters transparency in food supply chains and strengthens trust between producers and consumers. The adoption of blockchain technology in agriculture has reached a stage of maturity, often referred to as the Plateau of Productivity.

This systematic literature review comprehensively analyses scholarly articles and research papers on blockchain implementation in the agricultural supply chain. It examines the benefits and challenges associated with its adoption while evaluating the factors influencing its feasibility.

Keywords: Agriculture, Blockchain, Supply Chain, Sustainable Agriculture, Adoption.

* Corresponding Author

1 INTRODUCTION

Agriculture is a significant part of the economy of any country; it is the backbone that feeds a country's entire population. It serves as a vital link to all related industries. A strong agricultural base measures economic strength and is a key social and political stability indicator. As the global economic landscape rapidly changes, so do various sectors, including agriculture. Global farming enterprises, for instance, are increasingly using IoT devices to enhance soil preparation, planting, and harvesting and to manage soil moisture content, fertilisation, and pest control.

Blockchain is a digital ledger that records transactions or sensitive data across a vast network of participants. It is called a 'blockchain' because each transaction is recorded in a 'block', and these blocks are linked together in a chain. Using blockchain to capture and store information makes sharing and managing data more accessible than traditional data storage methods. The blocks are verified and added to the chain by selected participants using a consensus protocol [1].

Blockchain technology allows all parties to monitor the data flow through a designated process. The process involves the continuous verification of new data and the prevention of any unauthorised changes. The increasing attention from the academic world and the corporate sector towards blockchain technology is a testament to its potential. Its use of data and information in the agricultural industry has significantly increased its value, which is critical to developing productivity and sustainability. This inspiring potential of blockchain technology is paving the way for a brighter future for the industry [2].

Despite the political challenges and economic instability in South Africa, the agricultural industry is growing. South Africa is a net exporter of agricultural products and one of Africa's most prominent food producers; its products are mainly exported to Europe, Asia, and the Americas. Consumers are concerned with the sustainability and traceability of food products.

There has been a growing demand for supply chain traceability within the agri-food industry in South Africa. Numerous concerns exist regarding the advantages and feasibility of implementing blockchain technology within this sector.

This systematic literature review will explore the following research questions:

Main research question (RQ): How can blockchain technology foster innovation in supply chain management practices within the South African agricultural sector?

Sub research questions:

RQ1: What are the benefits and barriers of blockchain in the global supply chain?
RQ2: What is the feasibility of implementing blockchain within the supply chain of agricultural products?

2 REVIEW METHOD

This section outlines the systematic literature review (SLR) methodology for gathering, analysing, and synthesising data from relevant academic journals. It describes the systematic approach applied to ensure a comprehensive and unbiased selection of literature, aligning with the research objectives. It explains how specific databases and sources were searched, applying the criteria for including or excluding studies, and the tools used to manage and organise the data. Additionally, it outlines the techniques for analysing the findings, ensuring a rigorous synthesis that addresses the research questions. Clearly defining each process step ensures transparency and replicability, laying the groundwork for the subsequent analysis of blockchain technology applications in the agricultural supply chain.

The following keywords were used to conduct a comprehensive title, abstract, and author search in the academic databases:

1. "Blockchain" AND "Agriculture" AND "Supply Chain".
2. "Blockchain" AND "Agriculture" AND "Supply Chain" OR "Traceability" OR "Blockchain".
3. "Agriculture" AND "Blockchain Technology" AND "Supply Chain" OR "Traceability" OR "Adoption".
4. "Blockchain Technology" AND Blockchain" AND "Sustainable Technology" AND "Supply Chain".

Figure 1 depicts the literature screening, exclusion and inclusion method to select relevant journals for the systematic literature review. This was achieved by following the PRISMA 2020 guidelines.

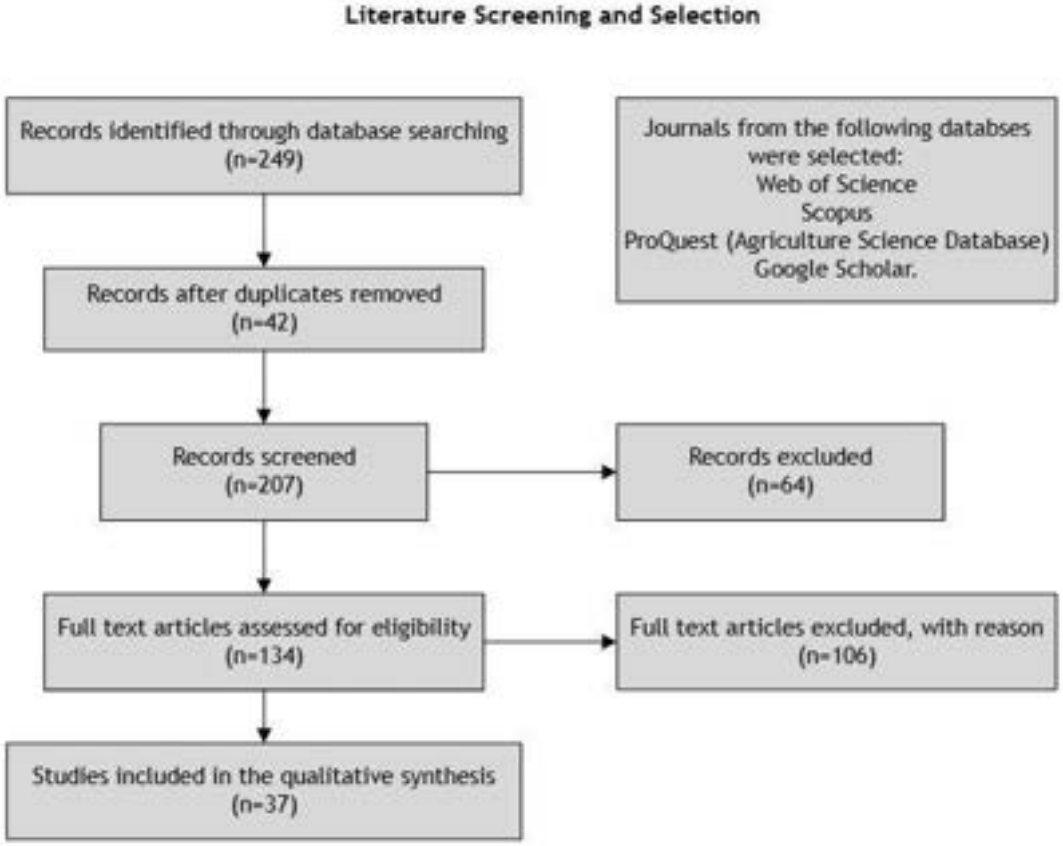

Figure 1: Literature screening and selection process (own compilation)

Inclusion or exclusion criteria were applied, initial search items, keywords, and search criteria were provided, and these assisted in reducing the literature population to a manageable and focused set.

Exclusion Criteria:

1. Journals published before 2020.
2. Journals unrelated to the research questions and keywords framework.

3. Non-English journals.
4. Non-peer-reviewed journals.
5. Grey literature and duplicated studies were omitted.

Inclusion Criteria:

1. Journals published between 2020 and 2024 focusing on recent developments.
2. Journals that concentrate on digital technologies and digital procurement.
3. Journals that address the impact of BC technology in the agricultural supply chain.
4. Journals that focus on developing blockchain technology within the agriculture sector and primary, secondary, and tertiary industries.
5. Articles that directly contribute to answering the research question.
6. Inclusion was limited to peer-reviewed journal articles, conference papers, and review papers relevant to the study.
7. Journals related to industry case studies and the development of blockchain technology in the agricultural supply chain.
8. Journals published about the agriculture supply chain.
9. Journals from the following databases were selected: Web of Science, Scopus, ProQuest (Agriculture Science Database), and Google Scholar.

Lastly, data extraction was conducted to extract the key concepts with ATLAS.ti. ATLAS.ti is a qualitative analysis software used to analyse information in an orderly manner. The literature was initially imported for evaluation. Relevant sections from within the literature were highlighted. Codes were then created, and similar sections were grouped. After that, group codes were analysed, and similarities within the group codes were evaluated and highlighted. Similar reports across various sections were created and prepared for presentation.

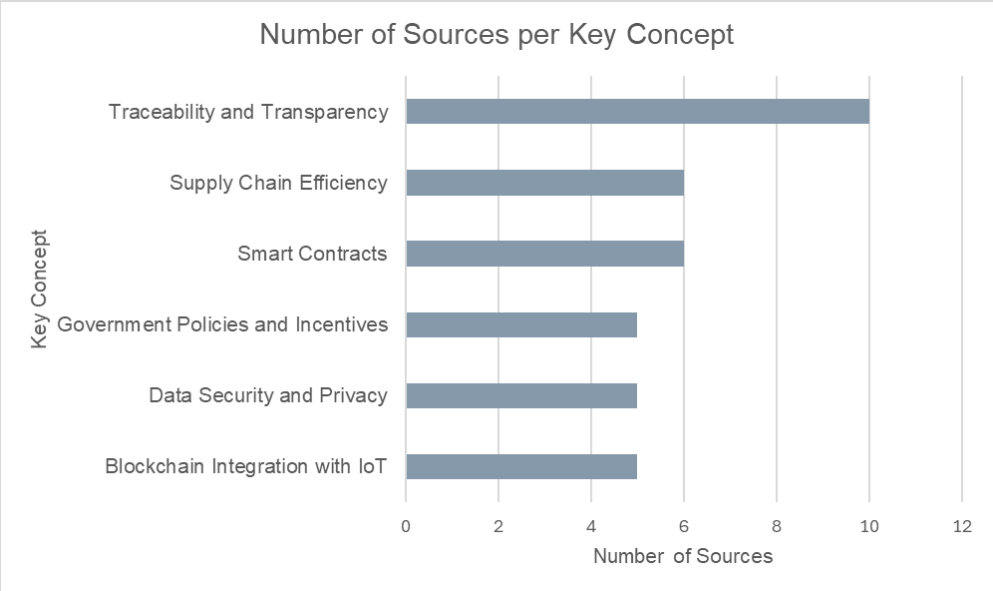

Figure 2: Key Concept Graph

3 FINDINGS AND DISCUSSIONS

This section presents the findings from the systematic literature review, offering a critical and comprehensive elaboration of the data gathered from the selected research articles. The review focuses on key themes, variations, and gaps identified in the literature.

3.1 Benefits of Blockchain in the Agriculture Supply Chain

The literature consistently highlights several key benefits of implementing blockchain in agricultural supply chains. Coding analysis conducted through ATLAS.ti represents these benefits and relationships between are depicted in Figures 3 and 4. Foremost among these are traceability and transparency. Blockchain's distributed, immutable ledger enables end-to-end product tracking, creating an auditable record that links each stakeholder's activities in a secure chain. As products move from farm to retail, sequential data entries ensure that each step can be independently verified. This level of traceability substantially improves the ability to track food items back to their origin, thereby enhancing accountability and consumer trust [3].

The decentralised architecture further ensures that no single actor exclusively controls the data; instead, all authorised stakeholders share custodianship. This promotes equitable access to information while safeguarding data integrity, since unilateral alterations are technically infeasible without consensus. As a result, blockchain mitigates the risk of data tampering or fraud, strengthening both system reliability and supply chain governance [3].

A second major benefit is improved efficiency in transactions and supply chain operations. The adoption of blockchain-based smart contracts, self-executing protocols that trigger actions once predefined conditions are met, automates processes traditionally reliant on intermediaries. Within agriculture, this functionality can expedite payments to farmers upon verified delivery or enforce quality standards before goods progress through the chain [4].

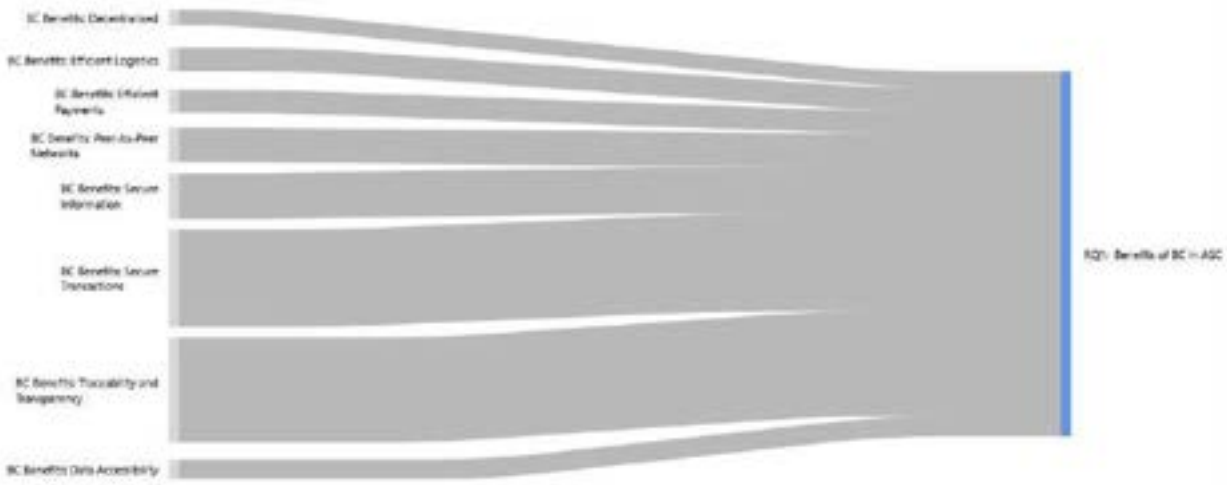

Figure 3: Sankey Illustration: Benefits of Blockchain in Agriculture Supply Chain

	RQ1: Benefits of BC in ASC 37 212	Totals
BC Benefits: Data Accessibility 5	5	5
BC Benefits: Decentralised 4	4	4
BC Benefits: Efficient Logistics 6	6	6
BC Benefits: Efficient Payments 6	6	6
BC Benefits: Peer-to-Peer Networks 9	9	9
BC Benefits: Secure Information 12	12	12
BC Benefits: Secure Transactions 25	25	25
BC Benefits: Traceability and Transparency 27	27	27
Totals	94	94

Figure 4: Table Illustration: Benefits of Blockchain in Agriculture Supply Chain

Empirical evidence suggests that such automation reduces delays in payment and distribution, lowers transaction costs, and minimises exposure to human error or corruption. For example, lenders in cooperatives can release funds promptly after contractual obligations are met, thereby enhancing liquidity and reducing financing risks. Moreover, by reducing reliance on brokers and other intermediaries, blockchain facilitates disintermediation, allowing farmers and buyers to transact directly [5]. This not only lowers commission costs but also enables earlier contract formalisation, resulting in improved cash flow for producers and processors [8].

The literature underscores blockchain's role in strengthening trust among supply chain participants. Its tamper-proof, transparent records provide all authorised farmers, processors, distributors, retailers, and consumers with confidence in the authenticity of shared data [6]. This feature is particularly valuable in ensuring food safety and quality assurance. In the event of contamination, blockchain systems enable rapid traceback to the source, allowing for targeted recalls and faster corrective action [4].

Consumers benefit from greater confidence in claims such as organic certification or pesticide-free production, as these can be verified through immutable records. In export markets, where compliance with ethical and sustainability standards is increasingly demanded, blockchain offers a reliable mechanism for demonstrating adherence and enhancing the reputation of exporting nations [4].

Finally, the integration of blockchain with complementary technologies amplifies its impact. Within the context of smart agriculture, the coupling of blockchain with Internet of Things (IoT) devices and big data analytics enables real-time recording of environmental and operational conditions such as soil quality, weather data, and storage temperatures, directly into the ledger. For example, IoT-enabled cold storage sensors can automatically verify compliance with temperature requirements for perishable goods, ensuring product integrity throughout transport [9]. This integration not only enhances transparency but also strengthens supply chain planning, forecasting, and sustainability monitoring, including carbon footprint

assessments. Collectively, these synergies position blockchain as a catalyst for leaner, more transparent, and resilient agricultural supply chains [5].

3.2 Barriers to Blockchain in the Agriculture Supply Chain

Despite its transformative potential, blockchain adoption in agriculture is hindered by significant barriers (Figures 5 and 6). A recurrent theme in the literature is legal and regulatory uncertainty. The absence of clear standards and governance frameworks creates ambiguity regarding data ownership, privacy, and liability in shared ledgers [2], [9]. For instance, if multiple actors contribute to a blockchain, questions arise over who owns the data and who is accountable for errors. Without established regulations, many firms adopt a cautious approach, delaying investment until legal clarity is achieved. Conversely, excessive regulation may constrain innovation. The challenge, therefore, lies in finding a balanced policy framework that provides certainty while fostering innovation, potentially through regulatory sandboxes or sector-specific guidelines [2], [10].

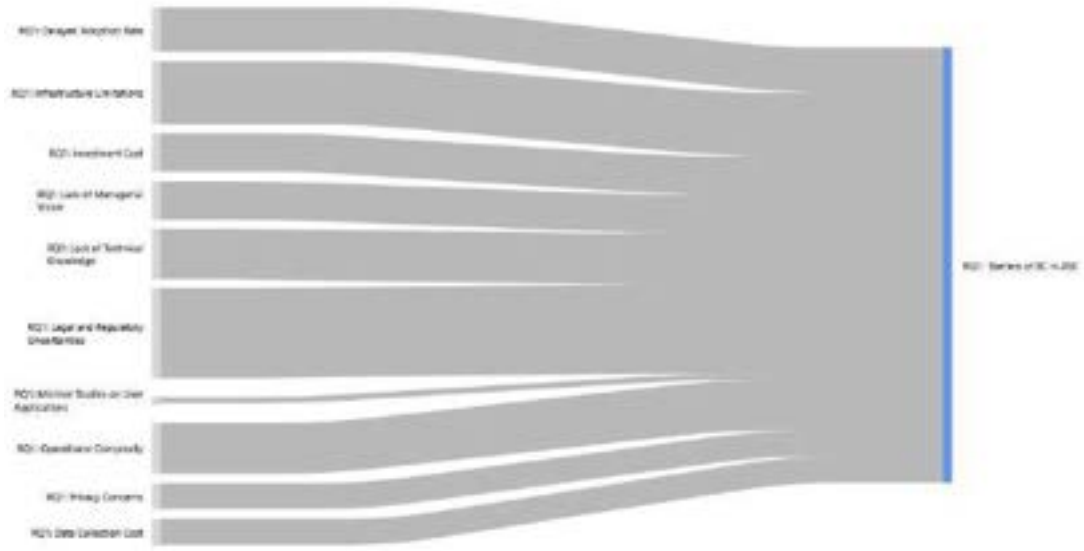

Figure 5: Sankey Illustration: Barriers of Blockchain in Agriculture Supply Chain

		RQ1: Barriers of BC in ASC 37 212	Totals
BC Barriers: Data Collection Cost	4	4	4
BC Barriers: Delayed Adoption Rate	7	7	7
BC Barriers: Infrastructure Limitations	10	10	10
BC Barriers: Investment Cost	6	6	6
BC Barriers: Lack of Managerial Vision	6	6	6
BC Barriers: Lack of Technical Knowledge	8	8	8
BC Barriers: Legal and Regulatory Uncertainties	14	14	14
BC Barriers: Minimal Studies on User Applications	1	1	1
BC Barriers: Operational Complexity	8	8	8
BC Barriers: Privacy Concerns	4	4	4
Totals		68	68

Figure 6: Table Illustration: Barriers of Blockchain in Agriculture Supply Chain

Infrastructural and resource constraints represent another critical barrier, particularly in developing and rural contexts. Effective blockchain systems require reliable connectivity and sufficient computational infrastructure resources, often scarce in rural South Africa [11]. Limited broadband access, high data costs, and a lack of blockchain-compatible hardware constrain participation, especially among smallholder farmers. In addition, the financial burden of adoption is significant: investments in IT systems, sensors, and tagging technologies (e.g., RFID or QR codes) may be prohibitive for producers with limited margins. These constraints risk exacerbating the digital divide, where large commercial farms can afford adoption and benefit from efficiency gains, while small-scale farmers are left behind [2].

Organisational and human factors can further complicate adoption [10]. Resistance to change among managers and decision-makers, often due to limited familiarity with blockchain or uncertainty about return on investment, slows uptake [14]. Adoption typically requires collaboration across multiple stakeholders, yet mistrust and failures often prevent the establishment of shared governance models. Moreover, low levels of digital literacy among farmer communities present operational risks, as user error and lack of training can undermine implementation [12], [13]. These socio-technical challenges suggest that adoption must be accompanied by capacity-building and change management initiatives [10].

Finally, technical limitations such as interoperability and scalability must be addressed. The coexistence of multiple blockchain platforms (e.g., Ethereum, Hyperledger) raises compatibility challenges with legacy systems, risking data silos and inefficiencies [11]. Concerns regarding scalability whether blockchain networks can manage the high volume of agricultural transactions without prohibitive costs or delays remain unresolved. Public blockchains are especially vulnerable to high transaction fees and energy demands, while permissioned blockchains, though more efficient, may compromise decentralisation [2].

A further barrier is the lack of empirical evidence in the South African agricultural context. While international studies highlight potential benefits and challenges, local case studies and pilot projects remain scarce. This gap hampers efforts to build stakeholder confidence and generate actionable insights for implementation. Pilot projects tailored to South Africa's

major agricultural exports, such as citrus and livestock, would provide valuable data to bridge this gap [14].

In summary, blockchain adoption in agriculture is constrained by regulatory ambiguity, infrastructural deficits, financial and human capacity limitations, and unresolved technical issues. Overcoming these barriers will require coordinated action across policymakers, industry leaders, and technology providers. Strategic interventions such as regulatory frameworks, investment in rural connectivity, training programs, and pilot implementations will be critical to realising blockchain's potential benefits at scale.

3.3 Feasibility of Blockchain in the Agriculture Supply Chain

Blockchain's capabilities must be leveraged to reduce costs and assist farmers in becoming more profitable. This section will discuss the factors contributing to BC's feasibility. Figure 7 indicates the areas where BC can be most beneficial and elevate the feasibility in the ASC.

Blockchain is highly beneficial in supporting farmers facing high trade transaction costs and unexpected losses due to market changes. Traditionally, banks conducted minimal business with agricultural businesses. There is an overall reluctance to understand the agricultural business model. Farmers can connect with buyers and traders on pre-determined conditions through smart contracts [15]. The predetermined conditions on the e-contract enable automated payments to improve transaction turnover times. Intermediaries are eliminated, and transaction costs are reduced. Reduction in transaction costs improves cash flows and the risk of payments defaulting [16].

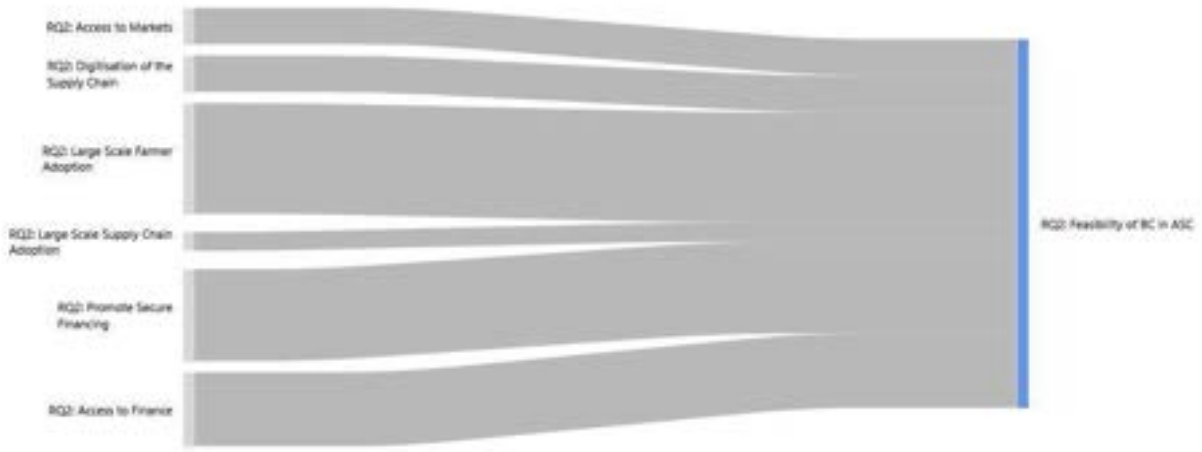

Figure 7: Table Illustration: Feasibility of Blockchain in Agriculture Supply Chain

Farmers are price takers; the price is determined by how much the producer is willing to sell it for. As a result, small farmers who supply the local market often sell their products for a loss or marginal profit. Blockchain allows intermediaries to be cancelled out; peer-to-peer networks can be strengthened [14].

Blockchain is being explored for various financial applications, including cross-border payments, trade finance, and asset management, due to its ability to streamline processes and reduce costs. Primary research on farmers who successfully adopted blockchain reveals a lower transaction cost. Farm size demonstrates a positive relationship, indicating economies of scale and that larger farms are likely to adopt blockchain [9].

Smart agriculture refers to the application of modern technologies such as the Internet of Things (IoT) and big data. Coupling modern agriculture technologies with blockchain enables the supply chain to be further decomposed into environmental data. IoT device data can be captured within the blockchain of the ASC; this allows information from third-party devices such as soil moisture, temperature, weather data, spray and fertiliser programs to be imported into the ledger. The connection of BC and IoT device data ensures that consumer food integrity and safety expectations are met [8].

4 DISCUSSION

This review examined the current and potential applications of blockchain technology in the agricultural supply chain of South Africa. The literature clearly demonstrates that blockchain offers significant potential, particularly in enhancing traceability, data transparency, and trust among parties in the supply chain. These features are especially relevant for a country like South Africa, where agricultural exports play a significant role and food traceability is becoming more important to international and local consumers.

The most frequently cited benefit of blockchain is its decentralised and immutable ledger, which facilitates secure and transparent data sharing among stakeholders across the supply chain. By recording transactions in a tamper-proof manner, blockchain enables each stakeholder, farmers, processors, distributors, retailers, and consumers to access real-time, verifiable data. This traceability is particularly relevant in addressing consumer concerns about food safety, origin, and sustainability, mainly for export markets that demand proof of ethical sourcing and compliance with quality standards.

Adopting smart contracts self-executing agreements coded within the blockchain further reduces transaction costs and eliminates intermediaries. The review also highlights several barriers that impede widespread adoption. Legal and Financial ambiguity emerged as a dominant concern; the lack of clear standards and frameworks compromises the adoption of blockchain technology. Furthermore, infrastructural limitations, such as limited access to high-speed internet and blockchain-compatible systems in rural areas, pose substantial challenges, particularly for small-scale farmers. The high cost of implementation, coupled with limited digital literacy and technological readiness, exacerbates the digital divide between large-scale commercial producers and smaller agricultural enterprises.

Organisational inertia and resistance from various decision-makers also contribute to the slow adoption of blockchain solutions. The literature suggests that while many managers recognise the disruptive potential of blockchain, uncertainty around its return on investment and integration with existing systems discourages commitment. The lack of empirical case studies in the South African agricultural context limits practical insights into implementation strategies and outcomes.

Additionally, the potential of blockchain integration with complementary technologies such as the Internet of Things (IoT) and big data analytics is significant. IoT-enabled devices can feed environmental and operational data, such as soil moisture, weather conditions, and fertilisation patterns, into the blockchain ledger. This convergence of technologies can potentially enhance data granularity and improve forecasting, supply chain planning, and regulatory compliance.

5 CONCLUSIONS

This review contributes to the growing knowledge surrounding blockchain implementation in agricultural supply chains by consolidating recent insights specific to the South African context. It evaluated the available research on adopting blockchain technology in the South

African agriculture industry. The PRISMA 2020 guideline was used to assess and determine the relevance of the question and topic.

Qualitative findings indicate that blockchain technology presents a viable and transformative solution for enhancing traceability, data transparency, and operational efficiency in the agriculture sector.

The review indicates that blockchain can potentially address critical inefficiencies in traditional agricultural systems. Benefits such as secure transactions, decentralised data management, and improved stakeholder trust make blockchain a compelling innovation for supply chain optimisation. Furthermore, its integration with digital agriculture tools, including IoT and smart farming platforms, solidifies blockchain's position as a strategic enabler of sustainable agricultural practices.

However, realising this potential requires overcoming significant barriers. Key impediments include infrastructural limitations, regulatory uncertainty, lack of interoperability, and digital exclusion of smallholder farmers. As such, strategic and policy-driven interventions are essential. These should focus on regulatory standardisation, investment in digital infrastructure, technical capacity building, and targeted support for under-resourced stakeholders.

Future research should prioritise empirical studies and industry-driven pilot projects that evaluate blockchain implementation in real agriculture and supply chain environments. Such research would offer valuable evidence to guide effective deployment and to inform policy and practice.

6 LIMITATIONS AND FUTURE RESEARCH

Despite offering valuable insights, this study is not without limitations. First, the existing body of literature on blockchain adoption in South Africa's agricultural sector remains sparse. Consequently, much of the synthesis relied on international case studies, which may not fully capture the socio-technical, infrastructural, and institutional specificities of the South African context. This reliance on extrapolated findings introduces potential bias and restricts the transferability of results. Second, the scope of the review was confined to peer-reviewed publications between 2020 and 2024.

While this ensured academic rigour, it excluded grey literature, industry reports, and unpublished pilot evaluations, which may contain practical insights of high relevance to local stakeholders. Third, the study adopted a qualitative thematic analysis via ATLAS.ti. While this approach enabled the systematic identification of recurrent themes, it does not provide quantitative validation of relationships or causal effects. Finally, the rapid pace of technological innovation in blockchain and related digital platforms implies that the evidence base is evolving; some conclusions may therefore be subject to temporal limitations as new applications emerge.

To advance knowledge in this domain and address the above constraints, several avenues for future research are recommended.

- Context-Specific Case Studies: Empirical investigations of blockchain adoption in South African agricultural supply chains are required. Pilot projects in critical sub-sectors such as citrus exports, rooibos production, and livestock traceability would generate contextually grounded evidence on feasibility, benefits, and barriers.
- Socio-Economic Impact Assessments: Future research could examine the distributive consequences of blockchain adoption. Questions such as whether blockchain enhances

smallholder farmers' bargaining power, improves rural incomes, or exacerbates digital divides remain underexplored.

- Technological Convergence Studies: Investigations into the integration of blockchain with IoT sensors, big data analytics, mobile financial services, and agri-fintech platforms could provide insights into building holistic digital ecosystems that reinforce supply chain resilience.
- Governance and Policy Research: Rigorous analysis of regulatory frameworks, data ownership models, and governance mechanisms is necessary to design policies that balance innovation with inclusiveness, trust, and data security. Comparative policy studies across emerging economies could also highlight transferable lessons.
- Longitudinal and Mixed-Methods Designs: Long-term studies that combine qualitative and quantitative approaches would provide stronger evidence of blockchain's sustained impact on efficiency, transparency, and competitiveness, while also capturing evolving stakeholder perceptions over time.

[3]maarten.coetzee@wits.ac.za

ABSTRACT

Audio-visual tools such as projectors, microphones and speakers must be maintained effectively as they are essential for effective communication and enhance the learning experience. This paper explores the critical role of training guides to address the maintenance challenges of audiovisual equipment at a tertiary institution. Data was collected through a mixed-methods approach, via interviews with maintenance personnel and in-situ observations. The key challenge identified included inconsistent maintenance practices resulting from a lack of structured training resources, leading to equipment malfunctions, reduced lifespans, and increased operational costs. Detailed, step-by-step procedures for tasks were developed for maintenance processes such as replacing projector lamps, microphones, and speakers. The training guides helped to foster workforce development as well as improve safety, efficiency, and consistency resulting in improved technical proficiency. Implementing structured training resources can enhance the reliability and longevity of audiovisual systems, contributing to seamless operations and supporting educational goals.

Keywords: Training guides, Audio-visual maintenance process, workforce development

1 INTRODUCTION

Audio-visual equipment has become a vital component in modern educational and professional environments. These tools, which include projectors, microphones, and sound systems, play an essential role in facilitating effective communication and enhancing the delivery of complex information [1]. audio-visual systems enable diverse learning methods, support engagement, and cater to various preferences, ultimately enriching the overall experience for users [2]. The functionality and reliability of audio-visual equipment are critical to ensuring seamless operations in settings such as classrooms, and conference halls. Regular maintenance, timely repairs, and adherence to structured protocols are essential to prevent technical failures that can disrupt activities and lead to productivity losses [3]. Inconsistent maintenance practices often result in reduced equipment lifespan, frequent malfunctions, and increased operational costs. As technological advancements continue to shape audio-visual systems, the demand for efficient maintenance solutions grows. Structured training and comprehensive guidelines are increasingly recognized as key strategies for maintaining these systems. Such practices ensure not only the consistent performance of audio-visual equipment but also their longevity, contributing to a sustainable and productive environment.

Given these challenges, training guides emerge as a practical and effective solution for promoting the consistent maintenance and optimal performance of audio-visual equipment. Offering clear and structured instructions, training guides provide technicians with a reliable framework to execute their tasks efficiently and adhere to established standards. This systematic approach to training enhances technical proficiency, improves employee motivation, and fosters operational consistency which is essential for achieving high-quality outcomes and reducing errors [4].

Furthermore, training guides contribute significantly to workforce development by fostering a culture of continuous learning and operational excellence. They provide technicians with the necessary knowledge to address challenges effectively, reducing errors and ensuring uniformity in maintenance practices. Aligning skill requirements with organizational goals enhances operational consistency, extends the lifespan of audio-visual equipment, and minimises disruptions caused by technical failures. Additionally, training guides play a pivotal role in building future leaders within organizations, as they provide structured pathways for career growth and skill enhancement [5].

Figure 1**Error! Reference source not found.** provides a comprehensive analysis of the challenges resulting from an ineffective maintenance process. These challenges result from several interrelated factors, including management priorities, environmental constraints, resource limitations, and workforce dynamics. For instance, limited awareness about the benefits of structured training, resistance to change, and budget constraints all contribute to the absence of comprehensive training guides. Additionally, environmental factors, such as overbooked venues and the improper handling of equipment, further complicate the implementation of consistent maintenance practices. The Fishbone diagram provides a detailed visualization of these root causes, emphasizing the importance of addressing these barriers to establish effective training programs. By understanding these underlying factors, organizations can take targeted actions to overcome these challenges, thereby enhancing the reliability and performance of audio-visual systems.

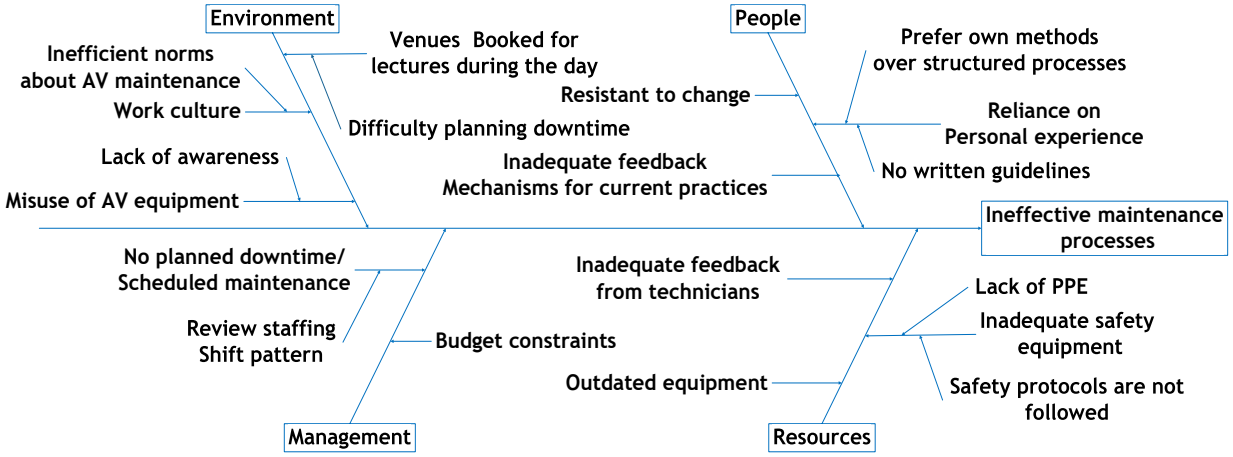

Figure 1: Fishbone diagram for ineffective maintenance processes

The paper highlights the critical role of training guides in ensuring the effective maintenance and optimal performance of audio-visual equipment within tertiary education. By addressing the challenges outlined in the Fishbone diagram, institutions can develop targeted strategies to overcome barriers such as limited awareness, budget constraints, and resistance to change. Implementing structured training guides not only enhances the technical proficiency and efficiency of maintenance personnel but also fosters a culture of operational consistency and continuous improvement. Ultimately, these efforts contribute to the longevity and reliability of audio-visual systems, ensuring seamless operations and supporting the broader goals of educational excellence and productivity.

The structure of this paper is as follows: Section "Introduction" outlines the significance of audio-visual equipment in educational settings and the challenges associated with their maintenance. Section "Literature Review" discusses previous research on training guides and the challenges of implementing them. Section "Methodology" details the mixed-methods research approach used to evaluate current maintenance practices and develop training guides. Section "Training Guides for audio-visual Maintenance" presents the developed visual step-by-step guides, including specific procedures for tasks such as blowing projectors, and replacing lamp lights, projectors, microphones, and speakers. Finally, the "Conclusion" summarizes the study's findings, highlighting the importance of training guides in ensuring effective audio-visual equipment maintenance, fostering workforce development, and supporting operational consistency in tertiary education

2 LITERATURE REVIEW

2.1 Training guides

Training guides are crucial tools designed to help employees improve their skills and gain proficiency in specific tasks. These resources provide detailed, step-by-step instructions for completing various responsibilities, complemented by recommendations for best practices and actionable tips for success [6]. Training guides are versatile, serving both new employees during onboarding by introducing them to their roles and experienced staff by helping them refine their skills and enhance productivity [6].

An effective training guide serves as an important resource for organizations, ensuring that employees are properly trained and equipped to carry out their duties effectively. These guides function as comprehensive manuals that provide essential guidance, clear instructions, and practical advice. When well-designed, they promote a uniform approach to training, enabling employees to quickly grasp an organization's processes and procedures [7]. Furthermore, centralized and organized training materials can reduce training costs by

eliminating the need for separate training sessions, making these guides a cost-effective solution [7].Training guides benefit both employers and employees alike. For employers, they ensure that staff fully understand their roles, responsibilities, and relevant organizational policies and procedures [7]. For employees, these guides act as a quick and reliable way to familiarize themselves with their job functions and workplace expectations [7]. Additionally, they serve as ongoing reference materials that employees can consult throughout their careers. By integrating training guides into their operations, organizations can build a well-trained and competent workforce, prepared to meet the demands of their roles efficiently and confidently [7].

Training guides are particularly essential in addressing the challenges posed by a lack of consistency in maintenance processes. Inconsistent procedures can lead to varying outcomes, inefficiencies, and increased equipment downtime, which ultimately hinder organizational performance. By providing clear, step-by-step instructions, training guides help standardize maintenance tasks, ensuring that all employees follow the same protocols regardless of their experience or skill levels. This standardization reduces errors, improves task execution, and promotes uniformity across teams. Additionally, training guides act as reliable reference materials, enabling employees to perform their duties confidently and consistently even in dynamic or unpredictable work environments.

2.2 Challenges of implementing training guides

2.2.1 Resistance from Employees

Employee resistance is a frequent challenge when implementing training and development programs. This reluctance often results from the belief that the training is either irrelevant or ineffective [8]. It is especially noticeable among experienced employees who feel they already have the required skills and expertise [8]. Factors that contribute to this resistance include training content that does not align with job responsibilities, lengthy sessions that interfere with work schedules, and a lack of practical, real-world applications [9]. When training is overly theoretical and lacks practical elements, employees may view it as unproductive, which further increases their reluctance [9]. Additionally, organizations that prioritize performance metrics over employee engagement may encounter heightened resistance, as training is perceived as distracting from productivity rather than adding value.

To address resistance, organizations must develop training programs that are both relevant and practical. Performing comprehensive needs assessments helps ensure that the training content targets specific skill gaps and aligns with organizational objectives [8]. Tailored materials that reflect actual tasks and competencies can increase motivation and engagement. Furthermore, incorporating interactive and hands-on learning techniques enhances knowledge retention and fosters active participation [8]. Linking training objectives to measurable workplace outcomes also helps employees understand its value, encouraging alignment with broader organizational objectives [8].

2.2.2 Budget Constraints

Insufficient financial resources often hinder the implementation of effective training initiatives. Many organizations struggle to provide diverse training tools, advanced technologies, and skilled instructors due to budgetary limitations [8]. High costs associated with corporate trainers, materials, facility rentals, and logistics further strain budgets, making it challenging to implement comprehensive training programs [8]. Organizations may implement cost-cutting strategies that can affect the quality of training. This may involve reducing the duration of training sessions, restricting access for some employees or limiting programs to certain teams [8]. This minimalist approach often overlooks the importance of adequately equipping employees to meet job requirements [10]. Innovative tools, such as simulation technologies, online platforms, and virtual reality applications, have shown

promise in enhancing learning engagement [11]. However, budget limitations frequently delay their adoption, along with learning management systems that can integrate materials and track training effectiveness [11].

Despite these limitations, investing in training yields significant benefits, such as increased productivity, reduced employee turnover, lower rework rates, and improved compliance [8]. Organizations can optimize their training initiatives by accurately identifying needs, aligning programs with job objectives, and moving beyond a "bare minimum" mindset [8]. Strategic allocation of financial resources ensures a more robust return on investment and long-term organizational benefits.

2.2.3 Inability to track and measure training effectiveness

Many organizations face difficulties in effectively assessing the return on investment (ROI) and overall impact of their training initiatives. This is particularly challenging when it comes to measuring indicators for soft skills training, which adds complexity to the evaluation process [8]. As a result, organizations often struggle to determine whether training directly contributes to achieving performance goals. Without clear evidence of success, training programs may be undervalued, leading to missed opportunities for growth and development [12]. In the absence of comprehensive assessments, organizations may hesitate to allocate additional resources to training programs, often redirecting budgets toward salary increases instead [12].

A variety of metrics can help determine whether training initiatives achieve their intended outcomes. For instance, productivity improvements can be measured by evaluating increases in output per employee hour, along with decreases in error rates and enhanced operational efficiency [8]. Cost savings are another key metric, which can be tracked through reductions in material waste, rework, and penalties related to non-compliance all contributing to higher quality and lower defect rates [8].A decrease in employee attrition can signal that training has successfully addressed staff needs for knowledge, skills, and engagement, thereby reducing turnover rates [13]. Customer satisfaction scores provide a concrete measure of training effectiveness, reflecting improvements in employee performance and service quality [8]. To justify increased investments in training, organizations must implement robust evaluation processes that demonstrate their effectiveness as a tool for improving performance and achieving organizational goals.

3 METHODOLOGY

The methodology for this research used multiple approaches and data types (qualitative and quantitative), to better understand the challenges of audio-visual equipment maintenance at the specific institution. Data was collected through informal interviews with maintenance technicians, managers, and other key stakeholders to gain insights into the current processes and challenges faced in maintaining audio-visual systems. Structured observations were performed with the use of a checklist to evaluate the maintenance activities in the different venues, capturing critical details on task execution, equipment handling, and maintenance outcomes. This dual approach ensured a well-rounded perspective, allowing for the identification of practical challenges and the validation of findings through observed evidence. The instruments used for data collection were interviews and observations, which are listed in Appendices A and B, respectively.

The first stage of the research focused on understanding the current maintenance processes and identifying key challenges. Interviews with technicians and managers explored their experiences, common obstacles, and recurring technical issues. These discussions provided valuable information about inefficiencies in the current practices and the factors contributing to equipment failures or downtime. Additionally, observations helped pinpoint specific issues, such as delays in repairs, inconsistencies in procedures, or improper handling of audio-visual

equipment. The second stage involved identifying gaps in the training and knowledge of maintenance personnel. The analysis of interview responses and observed practices highlighted a lack of standardized procedures, insufficient training resources, and varying skill levels among technicians, all of which contributed to operational inconsistencies.

The subsequent phase incorporated feedback and suggestions from technicians to ensure that the proposed training guides were practical and relevant to their daily tasks. This collaborative approach ensured that the training materials would address real-world challenges and align with organizational goals. Finally, the research involved the development of a structured implementation plan for the training guides. This plan outlines specific steps and timelines necessary for the effective deployment of the training guides, ensuring a smooth transition to standardized maintenance practices.

4 MAINTENANCE SCHEDULING

The current maintenance processes for audio-visual equipment at tertiary institutions typically involve both unplanned and planned activities. Planned maintenance involves regular inspections and preventive actions to ensure equipment remains functional and reliable. However, inconsistencies in execution often arise due to the absence of structured guidelines and scheduling limitations. Unplanned maintenance, which addresses sudden breakdowns, is frequently required.

The maintenance process for audio-visual equipment, involves inspecting input devices (e.g., microphones and HDMI connections), signal distribution systems, and output devices (e.g., speakers and projectors). Routine and reactive maintenance follow similar steps, beginning with an inspection to identify issues. If junior technicians are unable to resolve a problem, senior technicians are called for assistance, but response times can be delayed if they are handling other tasks. Additionally, venues with older equipment or those frequently used for extracurricular activities are often prioritised, leaving less-visited venues prone to overlooked issues that may escalate over time.

Scheduling constraints, such as overbooked venues, limit the time available for essential tasks like cleaning projectors or replacing parts, forcing technicians to mostly perform maintenance during short breaks. Without formalised procedures, maintenance tasks often vary based on individual experience, with newer technicians adopting inefficient methods due to the lack of guidance. Additionally, technicians often work without adequate safety equipment or clear protocols, increasing the risk of accidents. These challenges highlight the importance of standardised training guides to streamline maintenance processes, improve safety, and ensure consistent practices. The training guides were designed to address these gaps, offering clear and structured procedures to enhance the efficiency and effectiveness of maintenance activities at tertiary institutions.

5 TRAINING GUIDES FOR AUDIO-VISUAL MAINTENANCE

5.1 Blowing a projector

The first training guide is shown in Table 1 below and provides a detailed and structured process for maintaining projectors used in lecture venues, focusing on planned maintenance to ensure optimal performance and longevity. The guide specifically addresses the cleaning of projector filters and vents using a blower, a task essential for preventing dust build-up, which can cause overheating, poor image quality, and eventual equipment failure. Technicians can ensure that projectors remain reliable and functional, reducing downtime and minimizing disruptions in lecture venues by following this guide. This guide serves as a consistent standard for maintenance practices to ensure uniform quality.

Technicians are required to wear personal protective equipment, including safety goggles to protect their eyes from dust particles and gloves to handle the filters. Hazard inspections must

also be conducted to eliminate risks, with technicians ensuring the projector is turned off and unplugged before beginning any cleaning to avoid electrical hazards. Maintenance responsibilities are distributed among the team members to promote efficiency and collaboration. Junior technicians are tasked with performing the cleaning process by strictly following the training guide. Interns provide support to junior technicians, assisting with cleaning tasks, removing filters, and resetting timers as needed. Senior technicians oversee the entire process, ensuring all steps are completed correctly, and step in to address any issues or troubleshooting that may arise.

The step-by-step procedure for blowing out a projector is carefully designed to be both practical and easy to follow. Through the use of the training guide, technicians can ensure the projectors operate at peak performance, extending their lifespan and preventing disruptions during lectures.

Table 1:Blowing a projector

<table>
<tr><th colspan="3">Training guide title: Visual step-by-step for blowing a projector</th></tr>
<tr><td colspan="2">1. Scope: This training guide applies to all projectors used in lecture venues. It outlines the process for planned maintenance involving the cleaning of filters and vents using blowers.</td><td>2. Tools and equipment: Blower used to clean dust from the projector's filter and vents. Cloth for wiping external surfaces. Replacement filters if the existing filter is damaged or clogged beyond repair.</td></tr>
<tr><td colspan="2">3. Safety:

Personal Protective Equipment (PPE): Wear safety goggles to protect against dust and use gloves to handle the filter.

Hazard Inspection: Ensure the projector is off and unplugged before maintenance.</td><td>4. Roles and responsibilities:

Junior Technicians perform the cleaning of projectors by following training guides and assist senior technicians.

Interns support junior technicians during the maintenance process. Participate in the cleaning and resetting of filter.

Senior Technicians provide oversight for the process and step in for troubleshooting if issues arise.</td></tr>
<tr><th colspan="3">5. Procedure: Blowing out a projector</th></tr>
<tr><th>Task</th><th>Description</th><th>Image</th></tr>
<tr><td>Step 1: Turn Off the Projector.</td><td>Ensure the projector is powered off and unplugged from the power source to prevent electrical hazards during maintenance.</td><td>[14] </td></tr>
<tr><td>Step 2: Remove the filter of the projector.</td><td>Gently detach the air filter from the projector. The filter is usually located on the side or back and can be accessed by sliding a panel.</td><td>[15] </td></tr>
<tr><td>Step 3: Clean Filters</td><td>Turn on the blower and use it to remove dust and debris from the filter. Make sure the filter is thoroughly cleaned to maintain.</td><td>[16] </td></tr>
<tr><td>Step 4: Place back the filter and turn on the projector</td><td>Carefully reinsert the filter, ensuring it fits securely and power on the projector.</td><td>[16] </td></tr>
<tr><td>Step 5: Reset the filter timer</td><td>Access the projector's Settings Menu and reset the filter timer to zero to track the next maintenance interval accurately.</td><td>[17] </td></tr>
</table>

5.2 Replacing a lamp light

The training guide for replacing a lamp light is shown in Table 2 below and provides a clear and systematic approach to ensure the task is performed safely and efficiently in lecture venues. The process is critical to maintaining the functionality of projectors, as lamp lights degrade over time, leading to dim or inconsistent image quality. Following this guide aids the technicians with the requirements and steps to replace faulty lamps effectively, ensuring

minimal disruption to teaching activities and extending the lifespan of audio-visual equipment. This guide applies to all projectors installed in lecture venues and serves as a reliable standard for performing lamp replacements.

Safety remains a top priority during this procedure. Technicians are required to wear personal protective equipment, including gloves to handle the lamp safely and prevent contamination, and safety goggles to protect against potential glass shards. The projector must be turned off, unplugged, and allowed to cool before starting the replacement process to eliminate electrical hazards. The step-by-step procedure for replacing a lamp light first involves turning off the projector and unplugging it, allowing sufficient time for it to cool to prevent burns or other hazards. Once cooled, the technician uses a screwdriver to remove the panel covering the lamp compartment, ensuring access to the faulty lamp. The old lamp is carefully detached by loosening its securing screws and pulling it out slowly while wearing gloves to avoid contamination or damage.

The new lamp is then inserted into the compartment and secured by tightening the screws, ensuring a proper fit. After installation, the lamp timer is reset via the projector's settings menu to track the next replacement interval accurately. Finally, the projector is powered on, and its brightness and image quality are tested to confirm that the new lamp functions correctly. Any adjustments or troubleshooting can be performed under the supervision of senior technicians. This training guide emphasizes a systematic approach to projector lamp replacement, ensuring safety, accuracy, and consistency. Technicians can effectively maintain projector performance, minimize downtime, and enhance the quality of audio-visual presentations, by adhering to these steps. A well-maintained projector provides clear and reliable visuals, contributing to an optimal teaching and learning environment in lecture venues.

Table 2: Replacing a lamp light

<table>
<tr><th colspan="3">Training guide title: Visual step-by-step for replacing a lamp light</th></tr>
<tr><td colspan="2">1. Scope: This training guide applies to all projectors installed in lecture venues. It ensures that the replacement of lamp lights is performed efficiently and safely.</td><td>2. Tools and equipment: Replacement lamp. Screwdrivers for removing panels. Cloth for cleaning the projector lens and surfaces.</td></tr>
<tr><td colspan="2">3. Safety:
Personal Protective Equipment (PPE): Wear gloves to handle the lamp to prevent contamination and safety goggles to protect eyes from glass pieces.
Worksite Safety: Turn off and unplug the projector before replacement.</td><td>4. Roles and responsibilities:
Junior Technicians: perform the replacement following the training guides. Test the projector after installation.
Interns: Assist in the lamp replacement and testing process. Help with cleaning filters and resetting
Senior Technicians: Supervise complex replacements or troubleshooting.</td></tr>

<tr><th>Task</th><th>Description</th><th>Image</th></tr>
<tr><td>Step 1: Turn Off and Unplug the Projector</td><td>Ensure the projector is turned off and unplugged to prevent electrical hazards. Allow the projector to cool down.</td><td>[14] </td></tr>
<tr><td>Step 2: Open the Lamp Compartment</td><td>Use a screwdriver to remove the access panel covering the lamp compartment.</td><td>[18] </td></tr>
<tr><td>Step 3: Remove the Faulty Lamp</td><td>Carefully detach the old lamp by loosening the screws and securing it in place. Pull the lamp out slowly, using gloves.</td><td>[18] </td></tr>
<tr><td>Step 4: Install the New Lamp</td><td>Insert the new lamp into the compartment and secure it by tightening the screws. Ensure the lamp fits correctly.</td><td>[18] </td></tr>
<tr><td>Step 5: Reset the Lamp Timer</td><td>Access the projector’s Settings Menu and reset the lamp timer to ensure the next maintenance interval is accurately tracked.</td><td>[18] </td></tr>
<tr><td>Step 6: Test the Projector</td><td>Power on the projector and verify that the new lamp functions correctly by checking brightness and image quality.</td><td>[18] </td></tr>
</table>

5.3 Replacing microphones

This training guide in Table 4 below provides a structured process for replacing faulty microphones in lecture venues, ensuring smooth and reliable audio performance. This training guides focuses specifically on the replacement of XLR microphone cables, which are the most frequently damaged components. Before starting the replacement process, safety is prioritized by ensuring the power to the audio system is turned off to prevent electrical hazards. Gloves are worn to protect the equipment from contamination or accidental damage during handling. The procedure begins by identifying the faulty microphone or XLR cable through a systematic test with the audio system to locate the source of the problem. Once the fault is confirmed, the audio system is turned off, and the damaged microphone or XLR cable is carefully disconnected from the input port or mixer. If a wireless microphone is involved, the transmitter or receiver is removed. The XLR cable is then inspected for visible damage, such as fried wires, loose connections, or worn connectors. After repairing or replacing the cable, the technician reassembles the XLR connector, ensuring a tight and secure fit. The microphone or cable is then reconnected to the audio input or mixer. Finally, the audio system is powered on, and the microphone is tested by speaking into it to confirm clear audio output. This final step verifies that the replacement was successful and that the system is functioning as expected.

Table 3: Replacing microphones

Training guide title: Visual step-by-step for replacing a Microphone		
1. Scope: This training guide applies to all microphones used in lecture venues including wired, and wireless microphones. It is designed to guide technicians through the replacement process, ensuring that microphones are installed correctly.	**2. Tools and equipment:** Replacement microphones (wired or wireless). Cables. Cloth for cleaning connectors.	
3. Safety: Personal Protective Equipment (PPE): Wear gloves to protect equipment. Hazard Inspection: Make sure that power to the audio system is turned off when connecting and disconnecting the microphone.	**4. Roles and responsibilities:** Junior Technicians: Perform the microphone replacement following the training guide. Interns: Support the junior technician during the replacement process. Senior Technicians: Provide oversight for the task, especially during complex replacements.	
5. Procedure: Replacing a microphone		
Task	**Description**	**Image**
Step 1: Identify the Faulty Microphone or XLR Cable	Confirm that the microphone or XLR cable is not functioning by testing it with the audio system. Determine if the issue lies in the microphone, the XLR cable, or the audio input.	[23]
Step 2: Disconnect the Faulty Microphone or Cable	Turn off the audio system. Unplug the XLR cable from the input port or mixer. If it is a wireless microphone, remove the transmitter or receiver.	[24]
Step 3: Inspect the XLR Cable and Connections	Examine the XLR cable for fried wires, loose connections, or visible damage to the connectors. If damage is identified, attempt to repair it by soldering. If the cable cannot be soldered then, replace it with a new one.	[24]
Step 4: Solder the XLR Cable	Strip the damaged ends of the cable, reconnect the wires to the appropriate pins inside the XLR connector, and solder them securely to restore the connection.	[24]
Step 5: Reassemble, Reconnect, and Test the Microphone	Reassemble the XLR connector and ensure it fits tightly. Plug the repaired or replaced cable back into the input port or mixer. Power on the audio system and test the microphone by speaking into it.	[24]

5.4 Replacing a speaker

This training guide for replacing speakers in lecture venues is shown in Table 5 below and provides a step-by-step process for both wall-mounted and ceiling-mounted units. Replacing faulty speakers is essential to maintaining clear and consistent audio delivery, a critical component of effective teaching and presentations. This guide ensures the replacement process is performed efficiently, with proper testing to verify the new speaker's functionality and integration with the audio system. By following the outlined steps, technicians can address

speaker issues systematically, minimizing disruptions and ensuring high-quality sound in lecture venues.

Safety is a priority throughout the replacement process. Technicians must wear gloves to protect their hands while handling speakers and cables, and hearing protection is required when testing audio to avoid damage from high volume levels. To prevent electrical hazards, the audio system must be turned off before disconnecting cables or replacing components. For mounted speakers, technicians should ensure that ladders are stable and positioned securely to avoid accidents.

The replacement process begins with identifying the faulty speaker. Technicians confirm the speaker's failure by testing it with the audio system to rule out issues with cables or connections. Once confirmed, the audio system is powered down, and the faulty speaker is carefully disconnected from its cables and mounting bracket. The technician then inspects the cables for damage or loose connections, replacing them if necessary to ensure seamless operation with the new speaker. The replacement speaker is securely mounted onto the bracket or surface and connected to the appropriate audio cables, ensuring a stable installation.

After installation, the audio system is powered on, and the new speaker is tested. Technicians play audio to verify the sound quality, volume, and balance with other speakers in the room, ensuring proper integration into the existing audio setup. Any necessary adjustments, such as balancing the audio levels, are made to optimize performance. This training guide ensures speaker replacements are performed safely and efficiently, maintaining the integrity of the audio system and the quality of sound in lecture venues. By adhering to these steps, technicians can resolve speaker issues effectively, ensuring uninterrupted audio delivery and enhancing the overall learning and presentation environment

Table 4: Replacing a speaker

<table>
<tr><td colspan="3">Training guide title: Visual step-by-step for replacing a speaker.</td></tr>
<tr><td colspan="2">1. Scope: This training guide applies to all speakers installed in lecture venues including wall-mounted, and ceiling-mounted. It ensures that speaker replacements are performed efficiently and tested thoroughly.</td><td>2. Tools and equipment: Replacement speaker, Screwdrivers or mounting tools. Ladder (for wall or ceiling-mounted speakers). Audio cables.</td></tr>
<tr><td colspan="2">3. Safety:
Personal Protective Equipment (PPE): Use gloves to protect hands while handling speakers and cables. Wear hearing protection when testing audio.
Worksite Safety: Turn off the audio system before disconnecting cables to avoid electrical hazards. Ensure the ladder to access mounted speakers is stable.</td><td>4. Roles and responsibilities:
Junior Technicians: Perform the speaker replacement following the training guide. Test the new speaker and adjust settings if needed.
Interns: Assist junior technicians during the replacement process. Help with cable management and testing.
Senior Technicians: Supervise replacements or troubleshooting if issues arise.</td></tr>
<tr><td colspan="3">7. Procedure: Replacing a speaker</td></tr>
<tr><td>Task</td><td>Description</td><td>Image</td></tr>
<tr><td>Step 1: Identify the Faulty Speaker</td><td>Confirm the speaker is not functioning correctly by testing it with the audio system. Ensure the issue is with the speaker and not with cables or connections.</td><td>[25] </td></tr>
<tr><td>Step 2: Disconnect the Faulty Speaker</td><td>Turn off the audio system and carefully disconnect the faulty speaker from its cables and mounting bracket.</td><td>[25] </td></tr>
<tr><td>Step 3: Inspect Cables and Connections</td><td>Check audio cables for damage or loose connections. If necessary, replace the cables along with the speaker to ensure seamless operation.</td><td>[26] </td></tr>
<tr><td>Step 4: Install the New Speaker</td><td>Secure the new speaker onto the mounting bracket or surface. Connect the appropriate audio cables and ensure the speaker is firmly installed.</td><td>[27] </td></tr>
<tr><td>Step 5: Test the Speaker</td><td>Turn on the audio system and play audio through the new speaker. Verify the sound quality, volume, and balance with other speakers in the room.</td><td>[25] </td></tr>
</table>

6 DISCUSSION

The developed training guides are designed to address several key issues identified in the current maintenance processes for audio-visual equipment at tertiary institutions. For example, interviews revealed that new technicians are trained through shadowing and on-the-job learning, which have proven effective in building confidence and technical skills. However, without formal Standard Operating Procedures (SOPs), maintenance tasks often rely on individual technician experience, leading to inconsistencies in task execution. The training guides aim to standardize these processes by providing detailed, step-by-step instructions for tasks such as projector cleaning, lamp replacements, and speaker replacement [6]. This ensures that technicians, regardless of their experience level, follow a consistent approach, thereby improving task quality and efficiency.

It was also found that vendor-based training plays an important role in keeping technicians informed about the latest technologies and best practices. These sessions, offered through instructional videos, and training provided by original equipment manufacturers, provide technicians with valuable theoretical and practical knowledge. However, the constant demand for support in lecture venues often limits the time available for these training opportunities. The developed training guides help bridge this gap by serving as on-the-job reference materials that technicians can consult whenever needed. This ensures that they have access to up-to-date knowledge and procedures, even if they are unable to attend formal training sessions regularly. Furthermore, centralized and organized training materials can reduce training costs by eliminating the need for separate training sessions [7].

Observations further highlighted the challenges posed by tight schedules and overbooked venues, which often force technicians to rush through maintenance tasks. To mitigate this, shift distribution and workload balancing can enable planned downtime during periods of low demand. Currently, maintenance is performed during a single daytime shift, coinciding with peak lecture hours, leaving little time for thorough servicing. Introducing scheduled maintenance during off-peak hours, such as evenings, or weekends, would allow technicians to conduct preventative tasks without disrupting lectures. This approach would reduce rushed maintenance, minimize unplanned breakdowns, and improve overall equipment reliability. Additionally, structured training materials are essential to ensuring that maintenance procedures are followed consistently and effectively to further enhance efficiency. The training guides address this issue by streamlining maintenance processes and offering concise, clear instructions that help technicians perform tasks efficiently within limited timeframes. This will yield significant benefits, such as increased productivity, reduced employee turnover, lower rework rates, and improved compliance [8]

The developed training guides also address the safety concerns identified during maintenance activities. Observations revealed that technicians often work without proper protective equipment, such as safety boots, increasing the risk of injury during potentially hazardous tasks. Additionally, improper handling of audio-visual equipment, which contains delicate components, can lead to further damage and compromise the longevity of the systems. The training guides include safety protocols to mitigate these risks, such as guidelines for using personal protective equipment (PPE), safe handling techniques, and instructions for working in high-risk environments like ceiling-mounted installations. Adding safety measures to the maintenance procedures, to the guides not only protect technicians but also contributes to maintaining the equipment in optimal condition, reducing costly repairs and replacements. Additionally, linking training objectives to measurable workplace outcomes could also help employees to understand its value, encouraging alignment with broader organizational objectives [8].

In summary, the developed training guides serve as a vital solution to address the inefficiencies and inconsistencies identified in the maintenance and training processes for audio-visual equipment. By providing clear, standardized procedures, these guides ensure that technicians are well-prepared to handle both routine and complex tasks effectively. They also streamline maintenance activities, enabling technicians to work efficiently despite scheduling constraints or resource limitations. Ultimately, these training guides contribute to building a more competent and confident maintenance team, ensuring the reliable operation of audio-visual systems and supporting the seamless delivery of lectures and presentations in tertiary institutions.

7 CONCLUSION

This study underscores the importance of training guides in overcoming the challenges associated with audio-visuals equipment maintenance in tertiary institutions. The research highlights how structured procedures not only ensure the safe and efficient completion of tasks but also align maintenance practices with institutional goals. By addressing critical gaps such as inconsistent procedures, inadequate resources, and varying skill levels among technicians, training guides provide a practical solution for fostering operational consistency and reducing equipment downtime.

Moreover, these guides contribute to workforce development by enhancing technical proficiency, fostering collaboration, and building future leaders within maintenance teams. The implementation of training guides for tasks such as projector cleaning, lamp replacement, and microphone repairs has the potential to improve overall system reliability and extend equipment lifespan. Ultimately, this approach supports the uninterrupted delivery of audio-visual content, enabling institutions to meet their educational and professional objectives effectively. As institutions continue to evolve, adopting standardized training practices will remain pivotal in ensuring sustainable and high-quality audio-visual maintenance processes

9 APPENDIX

9.1 Appendix A: Interview Questions

Theory questions (TQ)	Interview Questions
Background	**1.** what is your role in maintaining audio-visual equipment?
	2. What are your primary responsibilities in your current role?
To evaluate the training of maintenance personnel on the policies and procedures.	**3.** Can you describe the training process for maintenance personnel? Probe: How long does the initial training period last? Probe: What specifically is the training method?
	4. What methods are used to assess the understanding and competency of maintenance personnel regarding the policies and procedures? Probe: Are there any written tests or practical assessments involved? Probe: What actions are taken if maintenance personnel do not meet the required competency level?
	5. How do you ensure that training materials and documentation are up-to-date and accessible to all maintenance personnel? Probe: What is the process for reviewing and updating training materials?
	6. How is feedback from maintenance personnel about the training programs collected and incorporated into future training? Probe: Are there any formal mechanisms for providing feedback (e.g., surveys, feedback forms)? Probe: How is the feedback reviewed and who is responsible for making improvements based on it?
	7. Are there standardized training materials or guidelines for teaching maintenance personnel how to perform tasks on audio-visual equipment? Probe: Can you provide examples of the training materials or guidelines used during the training process?
	8. What role does mentorship or peer learning play in the training of maintenance personnel? Probe: Are junior personnel paired with experienced technicians during their initial training?
	9. What support is available for continuous learning and skill development beyond the initial training? Probe: Are there workshops, online courses, or certifications available for maintenance personnel?
	10. What challenges or obstacles do maintenance personnel face in training for audio-visual equipment maintenance? Probe: Are there specific technical topics that are difficult to teach or learn? Probe: Are there logistical or resource-related challenges in providing comprehensive training?
	11. In what ways do you think the current training programs on policies and procedures can be improved to better support maintenance personnel? Probe: Are there any specific areas where you feel the training lacks? Probe: What additional resources or support would be beneficial for maintenance personnel?

9.2 Appendix B: Observation checklist

	Criteria (Ratings)				
Questions	**1 (Very Poor)**	**2 (Poor)**	**3 (Average)**	**4 (Good)**	**5 (Excellent)**
Training process for maintenance personnel	No clear training process, and unprepared personnel	Inadequate training, often unprepared personnel	Somewhat clear training process, sometimes prepared personnel	The clear training process usually prepares personnel	Very clear and thorough training process, always prepared personnel
Methods to assess understanding and competency of maintenance personnel	No assessment methods, competency often unknown	Minimal assessment methods, occasionally know the competency	Some assessment methods, sometimes know the competency	Clear assessment methods, usually know the competency	Comprehensive assessment methods, always know the competency
Ensuring training materials and documentation are up-to-date and accessible.	No process for updating materials, inaccessible	Rarely updated materials, occasionally accessible	Occasionally update materials, sometimes accessible	Regularly update materials, usually accessible	Always update materials timely, very accessible
Feedback collection and incorporation into training programs	No formal feedback mechanisms, feedback not incorporated	Rare feedback mechanisms are occasionally incorporated	Some feedback mechanisms, sometimes incorporated	Clear feedback mechanisms, usually incorporated	Comprehensive feedback mechanisms, always incorporated
Standardised procedures or guidelines for training maintenance personnel	No standardised procedures,	Minimal procedures, often not followed	Some standardised procedures occasionally followed	Clear standardized procedures, usually followed	Comprehensive, well-documented procedures, always followed
Challenges or obstacles encountered during maintenance tasks	Severe challenges, frequently impede maintenance	Significant challenges, occasionally	Moderate challenges, sometimes	Minor challenges, rarely impede maintenance	No significant challenges, do not impede maintenance
Role of mentorship or peer learning in training	No mentorship or peer learning opportunities	Rare mentorship, minimal peer learning	Occasional mentorship and peer learning are somewhat effective	Regular mentorship programs and peer learning are effective	Comprehensive mentorship and peer learning are highly impactful
Support for continuous learning and skill development	No support for continuous learning and development	Rare support, limited access to learning resources	Some support is available, and moderate access to learning resources	Regular support, most resources accessible	Comprehensive support, all resources easily accessible and encouraged
Notes					

ASSESSING THE AUDIO-VISUAL MAINTENANCE STRATEGY OF A TERTIARY INSTITUTION

M. Chauke[1]*, S. Chatur[2]* and M. Coetzee[3]

[1,2,3]School of Mechanical, Industrial and Aeronautical Engineering
University of the Witwatersrand, South Africa

[3]maarten.coetzee@wits.ac.za

ABSTRACT

Proper maintenance planning is essential for audio-visual (AV) systems in education to ensure reliable performance, minimise disruptions to learning, and extend the lifespan of equipment. The aim of the research was to evaluate the maintenance strategy of the AV systems at a tertiary institution. This research employed a mixed-method approach, combining qualitative data from semi-structured interviews and quantitative data from structured observations using a process study sheet and observational checklists. The main cause of unplanned downtime resulted from poor maintenance practices, including an over-reliance on reactive maintenance and dependence on international vendors. A balanced maintenance approach as well as partnerships with local vendors, would assist in reducing the lead times for receiving maintenance parts required. A maintenance strategy framework has been proposed that is aligned with the asset care goals and operational goals of the institution.

Keywords: Maintenance strategy, Balanced maintenance approach, Maintenance strategy framework

1 INTRODUCTION

The AV systems have emerged as integral components in a wide range of settings, spanning education, corporate environments, healthcare, and entertainment. By combining visual and auditory elements, these systems create immersive, interactive experiences that enhance communication, facilitate learning, support remote collaboration, and entertain diverse audiences [1]. Common examples include projectors, microphones, video conferencing solutions, digital displays, interactive whiteboards, and sound reinforcement systems. At University X, AV systems form the cornerstone of a dynamic, flexible, and inclusive learning environment. Lecture halls outfitted with advanced projection technology and immersive sound systems enable instructors to seamlessly integrate high-resolution videos, interactive presentations, and live demonstrations into their teaching [1].

This integration fosters an engaging and interactive atmosphere, helping students grasp complex concepts and retain information more effectively. Moreover, high-contrast projectors and large digital displays ensure that visually impaired students can follow along with ease, while specialised audio systems and hearing loops provide auditory-impaired learners with clear, accessible sound. Collectively, these measures exemplify University X's commitment to leveraging cutting-edge AV technology to enhance the educational experience for every student. The maintenance of AV systems is, therefore, a strategic priority to ensure these critical tools remain reliable and consistently available [2]. This approach preserves the quality and accessibility of learning resources. Additionally, it also minimises costs associated with emergency repairs or early replacements. In doing so, the university secures the longevity and dependability of its AV investments, guaranteeing that every classroom and lecture hall continues to provide a seamless, engaging, and technically sound educational experience [2].

However, maintaining these critical AV systems presents significant challenges at University X. With AV systems in over 65 lecture rooms functioning as interdependent units, the failure of a single component, such as a projector, speaker, or microphone, can disrupt the entire system, rendering it ineffective and halting the delivery of lectures. Poor inventory management heightens the issue, as replacement parts, including frequently failing components, are not stocked internally. Instead, parts are ordered from external vendors when needed, leading to significant delays and extended downtimes that disrupt the maintenance schedule. There is a workforce of 10 technicians who are responsible for maintaining AV systems across all venues, forcing the team to rely on reactive maintenance rather than the proactive approach required for predictive strategies.

The organisation of this paper is as follows: The first section, "Introduction," introduces the topic of AV systems and their importance in delivering academic lessons within an educational setting. It also highlights the significance of properly planned maintenance to ensure the reliability and longevity of these systems. The section "Literature Review" discusses secondary research on various maintenance strategies and the integration of these strategies. The section "Method" presents the sampling techniques, research instruments, and data analysis tools used in this study to collect results. The section "Current State Analysis" describes the organisational structure of University X's Information and Communications Technology Organisation, as well as its maintenance processes and procedures, with a focus on reactive and preventive maintenance practices. The section "Framework of a Maintenance Strategy" discusses the development of maintenance strategies at University X based on the results from the current state analysis. The section "Discussion" explains how the short- and long-term goals of the developed maintenance strategies will be achieved using the study's findings. Finally, the last section concludes the study.

2 LITERATURE REVIEW

This review synthesises current academic insights into these strategies and highlights their applications and implications in maintenance management.

2.1 Reactive Maintenance

Reactive maintenance, also known as "breakdown maintenance" or "run-to-fail," is a strategy where repairs and replacements are made only after equipment has failed [4]. This approach is often adopted when the equipment is not crucial to operations or when the cost of preventive maintenance exceeds the potential costs associated with dealing with failures. It is especially effective when the equipment is inexpensive to repair or replace, and the consequences of failure are minimal or manageable [4]. The development of a reactive maintenance strategy involves several key steps. First, identifying critical systems and equipment is necessary to prioritise which failures need to be addressed immediately [5]. Next, a failure response plan must be implemented, specifying the personnel and resources required to quickly address breakdowns. A cost-benefit analysis is crucial for determining if the savings from avoiding preventive maintenance are greater than the costs of reactive repairs [5]. Finally, minimising the impact of equipment failures on operations should be a priority, achieved by keeping spare parts on hand and ensuring staff are trained to respond quickly to breakdowns [6].

Furthermore, reactive maintenance is often viewed as a simpler, more cost-effective approach in the short term, since no resources are spent on routine inspections, scheduled servicing, or predictive tools. As a result, it may appear more budget-friendly for organisations with constrained resources. While reactive maintenance can provide short-term cost savings, it can result in higher long-term costs due to unexpected downtime and emergency repairs [6]. Therefore, it is important to carefully assess its suitability for non-critical systems where the effects of failure are manageable.

2.2 Preventive Maintenance

Preventive maintenance of AV equipment involves regularly scheduled inspections, cleaning, calibration, and firmware updates to ensure reliable and optimal performance. Instead of waiting for problems to occur, technicians proactively address wear and tear, check signal integrity, and maintain proper ventilation and humidity control [7]. By routinely evaluating projectors, cameras, microphones, speakers, and other system components, organisations can prevent unexpected failures, reduce long-term costs, and extend the life of their AV assets. This approach results in consistently high-quality audio and video output, improved user satisfaction, and a more predictable, cost-effective maintenance schedule [7].

The advantages of preventive maintenance are extensive, making it a critical strategy for organisations aiming to optimise asset performance. By addressing potential issues before they escalate, preventive maintenance significantly increases equipment reliability and minimises unplanned downtime, which can be costly for businesses [8]. This proactive approach also extends the lifespan of machinery, reducing the need for frequent replacements and lowering capital expenditure. Moreover, preventive maintenance enhances workplace safety by ensuring that equipment operates within safe parameters, thereby reducing the risk of accidents and injuries [8]. It also supports compliance with industry regulations and standards, as regular inspections help identify and rectify any non-conformities.

However, there are certain disadvantages to preventive maintenance that organisations must consider. One of the primary drawbacks is the cost associated with implementing and maintaining a preventive maintenance programme. Scheduling regular inspections, purchasing spare parts, and hiring additional maintenance staff can increase operational expenses, particularly for businesses with large equipment fleets [9]. Over-maintenance is another

challenge, as performing tasks more frequently than necessary may lead to wasted resources without adding significant value. Furthermore, preventive maintenance does not guarantee the elimination of unexpected breakdowns, as some failures can still occur due to unforeseen factors, such as material defects or extreme operating conditions [9].

2.3 Predictive Maintenance

A predictive maintenance strategy is a proactive approach that uses real-time data, condition monitoring, and advanced analytics to anticipate when equipment failures are likely to occur. Instead of relying solely on scheduled maintenance intervals or reacting after issues arise, this method leverages sensors, performance metrics, and machine learning models to identify subtle signs of wear, component degradation, or inefficiencies [10]. With this insight, technicians can intervene at the most opportune moment just before a potential failure, thereby reducing unplanned downtime, extending equipment life, minimising repair costs, and improving overall operational reliability [11].

Predictive maintenance offers several advantages, including the ability to schedule repairs just before failures occur, thereby reducing downtime, extending equipment life, and optimising maintenance resources [12]. By relying on real-time data and advanced analytics, it can prevent costly, unplanned outages and improve operational reliability. However, implementing predictive maintenance often involves significant upfront investment in sensors, data infrastructure, and analytical tools, as well as ongoing personnel training [13]. Additionally, reliance on complex predictive models can introduce challenges if data quality is poor or algorithms are not properly tuned, potentially leading to inaccurate forecasts and inefficient decision-making [14].

2.4 Integrated Maintenance Approach

The integrated approach to maintenance strategy combines production planning and maintenance strategies to enhance efficiency and sustainability. It emphasises a cohesive system where proactive maintenance (PM) and corrective maintenance (CM) are aligned with production schedules, ensuring minimal disruption and reduced costs [15]. Integration also considers human factors, acknowledging that errors in maintenance tasks can impact equipment reliability and operational efficiency. This holistic approach fosters improved resource allocation, reduced equipment breakdowns, and optimised cash flow, making it a cornerstone for achieving operational excellence [15].

Key elements of an integrated maintenance strategy include developing predictive models that align production and maintenance, considering constraints such as customer demand, budget, and production capacity. These models optimise the frequency and timing of proactive maintenance tasks while addressing human error's impact on operational reliability. Categorising maintenance costs into time-dependent and independent types, the integrated approach provides decision-makers with detailed insights into cost management, enabling a stronger connection between maintenance operations and production outcomes. This approach also incorporates advanced planning methods that account for dynamic conditions and uncertainties [15]. For example, probabilistic models like the Weibull distribution help estimate equipment failure rates, enabling precise scheduling of maintenance tasks. Additionally, the integration of learning curves in PM operations highlights how human expertise evolves, reducing the time and cost associated with maintenance tasks [15]. These advancements support a transition from reactive to proactive strategies, ultimately enhancing sustainability by minimising waste, conserving resources, and reducing emissions.

In conclusion, maintenance strategies can be conceptualised along a continuum from reactive to highly proactive approaches, each with distinct implications for cost, reliability, and equipment longevity. Reactive maintenance, often characterised as a “run-to-failure” model,

addresses problems solely after they occur, potentially resulting in higher long-term costs, frequent interruptions, and diminished asset lifespans. Preventive maintenance shifts the focus toward scheduled inspections, cleaning, calibration, and timely component replacement, thus reducing the incidence of unexpected breakdowns and stabilising operational expenditures over time. The most data-driven approach, predictive maintenance, employs condition monitoring tools, real-time analytics, and predictive modelling to anticipate failures before they occur, enabling Just-In-Time (JIT) interventions that minimise disruption and extend system life [15].

3 METHOD

3.1 Semi-Structured Interview

The research design adopted for this study was a mixed-methods approach, integrating both qualitative and quantitative data to evaluate the AV maintenance strategy at University X. Participants were selected using purposive sampling, targeting staff directly responsible for AV maintenance. Qualitatively, semi-structured interviews were conducted with 5 technicians (comprising two (2) senior and three (3) junior technicians), using a set of open-ended questions developed in accordance with the Wengraf method [16] and the interview protocol can be found in Appendix A. This sample, while small, was appropriate for the qualitative phase as it enabled rich, detailed accounts of maintenance challenges and practices. The interviews sought to examine the key challenges of implementing a proactive maintenance strategy, including the current maintenance processes and procedures, to gain a better understanding of the proactive measures that could be utilised to minimise unplanned breakdowns, ensuring that there are no disruptions affecting teaching. The audio-recorded interviews conducted with the technicians were transcribed using Microsoft Word software. Furthermore, these themes were coded and analysed through thematic analysis, supported by NVivo software, which was used to systematically code the themes and identify patterns within the data. The information on participant characteristics is summarised in Table 1.

Table 1: Participant characteristics information table

Role	Age Range	Gender	Ethnicity
Senior Technician	35–44	Male	Black
Senior Technician	35–44	Male	Black
Junior Technician	24–35	Male	Indian
Junior Technician	18–24	Female	Black
Junior Technician	18–24	Male	Indian

3.2 Observations

Quantitatively, systematic observations were performed for three (3) weeks on 15 working days (Monday to Friday) for 2–3 hours each day. This included routine (preventive) maintenance observations conducted from 7 a.m. to 8 a.m., and emergency (reactive) maintenance observed during 30-minute breaks between lectures. The observation instrument employed calibrated checklists and a five-point (1–5) Likert scale (Excellent to Very Poor) to assess equipment performance, downtime, uptime, and maintenance costs, with descriptive statistics (e.g., frequency counts, means, percentages) and charts were used for analysis. Additionally, a process study sheet was used to take detailed notes based on the maintenance tasks being performed, such as inspection, replacement, and repair. This sheet included a column to record the outcomes of the maintenance tasks. The process study sheet can be found in Appendix B, while the observational checklist can be found in Appendix C. Triangulation, achieved by cross-referencing findings from interviews and observations, ensured the validity and reliability of the results. While these findings are most applicable to

universities or similar institutions with comparable AV maintenance conditions, they may not be universally generalisable across all organisations.

4 CURRENT STATE ANALYSIS

4.1 Organisational Structure

The organisational structure of the Information and Communication Technology (ICT) department is structured into several key areas focusing on service delivery and technical support. At the highest level, the ICT department oversees all management and operations of ICT services, with the ICT desk serving as the primary point of contact for user issues and service requests. The ICT senior service delivery branch, led by senior management and supported by senior technicians, focuses on critical tasks like managing procurement and ensuring efficient vendor relationships to maintain a well-stocked inventory of AV equipment. This ensures that all operational needs are met, and lead times are optimised. On the other hand, the ICT middle senior service delivery branch handles the day-to-day operations, with junior technicians and senior technicians working together to enhance operational efficiency and ensure the smooth functioning of daily tasks. Together, these roles collaborate to ensure the AV systems are well-maintained and operational issues are swiftly addressed.

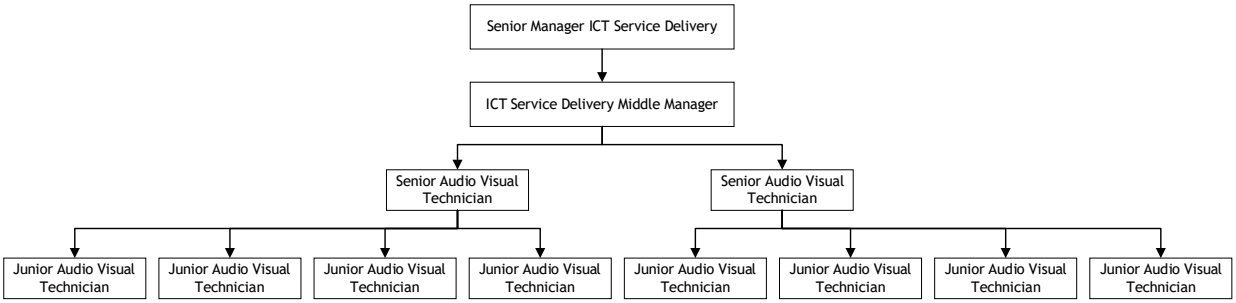

Figure 1: Organisational Structure

4.2 Current Maintenance Processes (Preventive Maintenance)

At University X, the standard routine maintenance for audiovisual equipment is meticulously conducted daily by technicians from 7 a.m. to 8 a.m., before lectures commence. This one-hour window is designed to allow technicians to perform comprehensive checks, including visual inspections, repairs of malfunctioning equipment, and tests on critical components such as cable connections, projectors, sound systems, microphones, and desktop cameras. These steps are intended to ensure that all equipment functions seamlessly, allowing lecturers to deliver their lessons without interruptions. Technicians prioritise lecture venues that are used frequently, focusing on the operational status of projectors, audio clarity, functionality of document cameras, and proper video playback on screens. The maintenance process for AV equipment is illustrated in Figure 2 below.

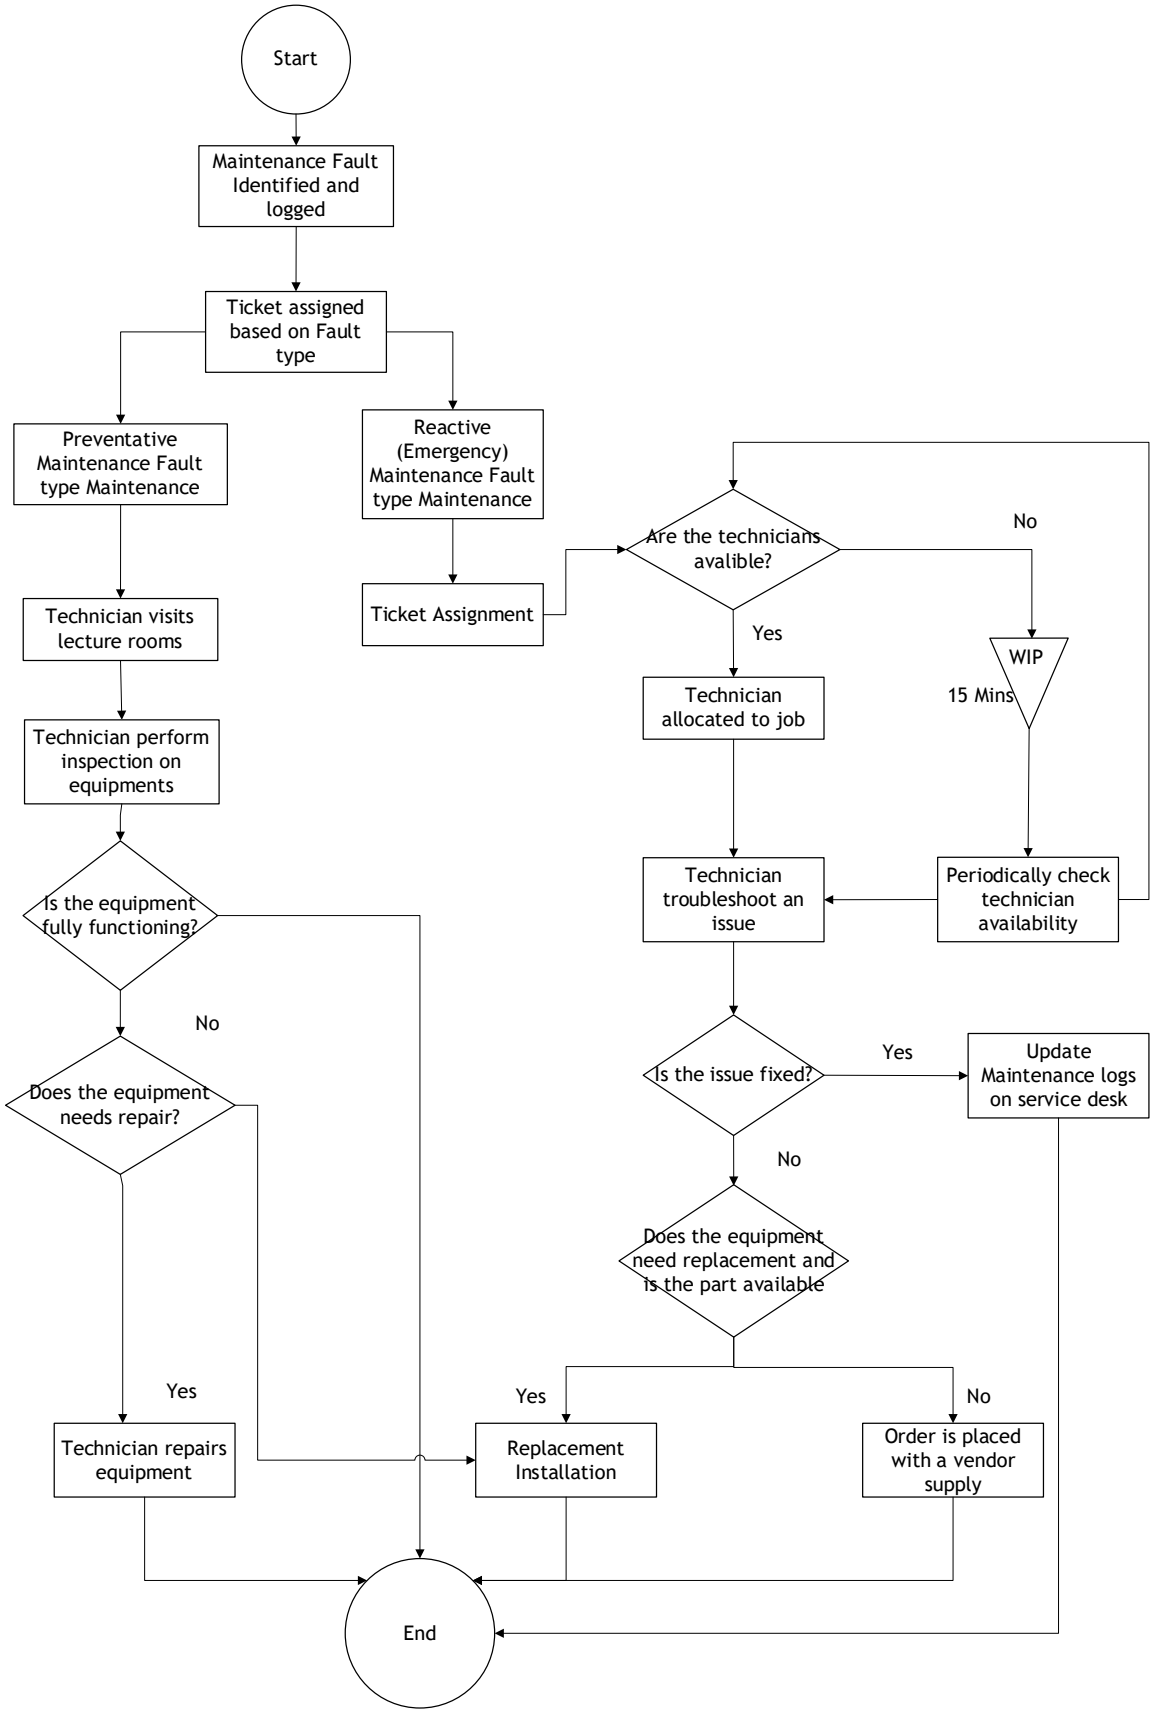

Figure 2: AV maintenance process.

Figure 3 illustrates the impact of routine maintenance on AV equipment uptime and reliability, 60% of technicians believe that daily routine maintenance effectively maximises the uptime of the equipment. On the other hand, 40% of the technicians reported that these maintenance activities minimise the uptime of the AV equipment. Similarly, although only 40% of the participants observe improved equipment reliability due to these maintenance practices, the remaining 60% perceive a reduction in reliability, indicating that the maintenance might be insufficient or improperly targeted, failing to resolve key issues that affect system reliability.

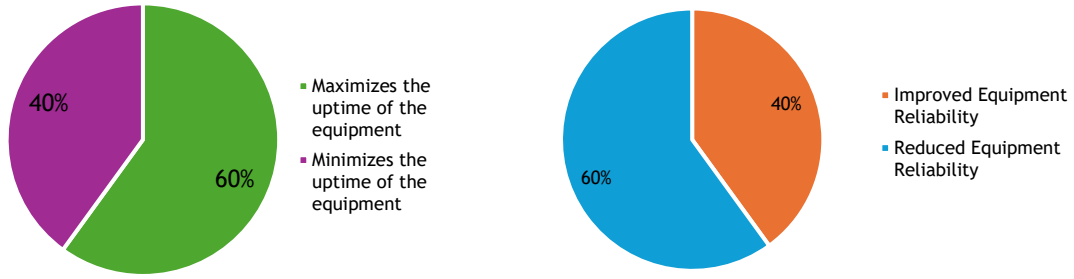

Figure 3: The Impact of Routine Maintenance on AV Equipment Uptime and Reliability

4.3 Emergency Maintenance (Reactive)

Emergency maintenance, often reactive in nature, is strategically scheduled at University X to coincide with the short breaks between lectures, utilising periods such as 9:45-10:15, 12:00-12:30, and the longer lunch break from 13:15-14:15. This scheduling ensures minimal disruption to academic activities while allowing adequate time for necessary maintenance tasks. Replacement tasks are typically carried out during the 30-minute breaks, as they require approximately 24 minutes to complete, fitting well within this window. This allows for efficient use of the short downtime periods to replace any faulty equipment swiftly.

Repair activities, on the other hand, are generally reserved for the lunch break, which provides a one-hour window. This longer period is crucial as repairs tend to be more time-consuming, usually taking between 27 to 33 minutes. The lunch break offers a suitable timeframe for more labour-intensive tasks, such as diagnosing and fixing internal components of the AV equipment. By scheduling complex repair tasks with an extended break, technicians can ensure that repairs are thorough and do not need to be rushed, contributing to the overall reliability and functionality of the equipment for subsequent lectures.

The SWOT analysis in Figure 4 of maintenance practices at University X underscores significant strengths, including fast emergency response times, effective routine maintenance, and in-house technicians' familiarity with AV systems. However, weaknesses such as a limited workforce, reliance on traditional maintenance strategies, frequent breakdowns, long spare part lead times, and poor ventilation highlight areas that need improvement. These limitations often result in increased costs, prolonged downtime, and decreased equipment efficiency and lifespan. By classifying assets into critical, routine, and non-critical categories, resources can be allocated more effectively. Predictive maintenance can be prioritised for critical equipment to anticipate and mitigate potential failures, while preventive maintenance ensures routine assets remain functional through scheduled upkeep. Reactive maintenance can be limited to non-critical assets to reduce resource strain. This approach, alongside staff training, improved inventory management, and user education on proper equipment handling, could significantly enhance system reliability, minimise unplanned downtime, and extend equipment lifespans, creating a more efficient and inclusive learning environment.

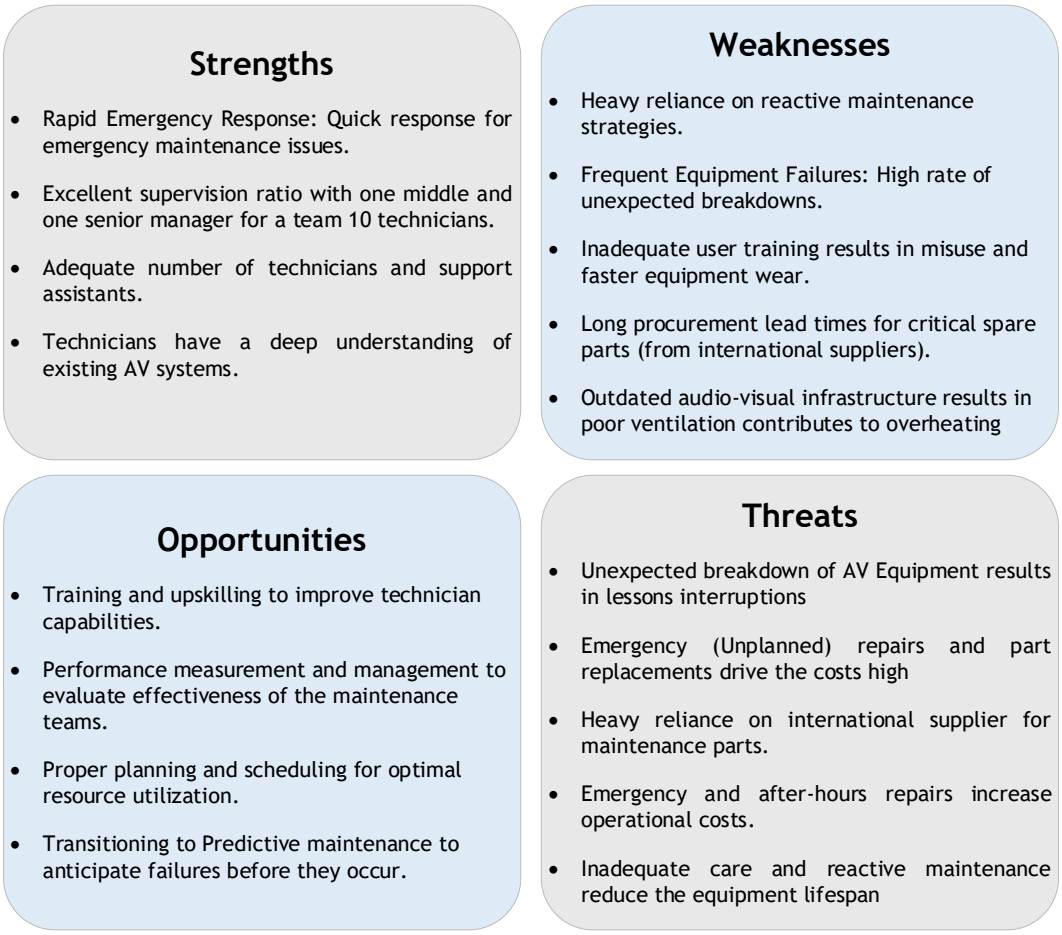

Figure 4: SWOT Analysis for Current Maintenance Approach

5 DISCUSSION

5.1 Maintenance Strategy formulation

The framework for the development of the maintenance strategy begins with asset care goals and operational goals, as shown in Figure 5, aligning maintenance activities with the university's mission and vision. In the selection phase, assets are categorised: predictive maintenance for critical assets, preventive maintenance for routine assets, and reactive maintenance for non-critical, legacy equipment. The implementation phase is driven by strategic enablers such as skilled workforce, inventory management, and cost-benefit analysis, ensuring efficient and effective execution. This integrated approach minimises breakdowns, maximises system uptime, and extends equipment lifespan, establishing a reliable and sustainable maintenance framework.

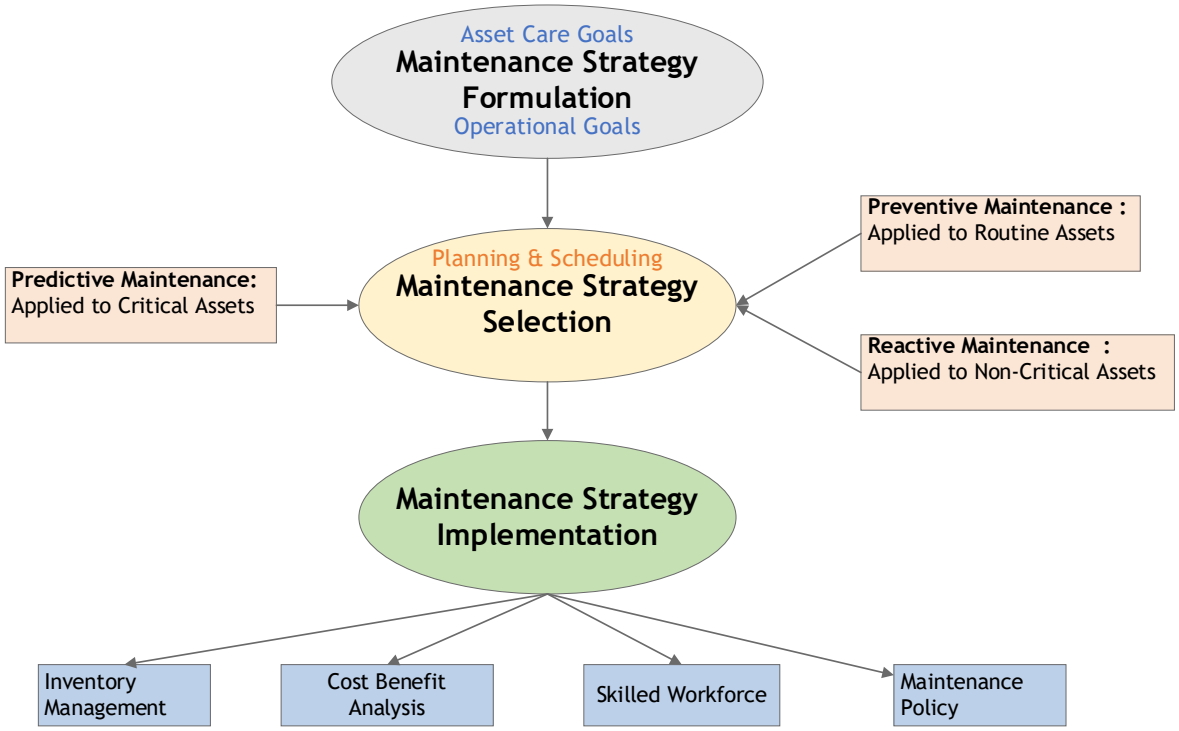

Figure 5: Maintenance Strategy Framework

The formulation of maintenance strategy phase establishes the foundational asset care and operational objectives, ensuring that maintenance initiatives are directly linked to the university's goals of minimising unplanned breakdowns, maximising uptime, reducing maintenance costs, and extending the lifespan of AV equipment.

5.1.1 Asset Care Goals

The asset care goals of University X's maintenance strategy should be focused on maintaining and optimising AV systems to achieve key objectives such as improved equipment reliability, reduced maintenance costs, extended asset lifespan, and minimal disruption to academic activities. By aligning maintenance activities with asset criticality, the strategy ensures that appropriate maintenance actions, predictive, preventive, or reactive, are applied to each asset type. These goals are supported by practices that promote continuous improvement, compliance with operational standards, and efficient resource utilisation across the university's AV infrastructure. Optimising asset utilisation and performance is another key asset care goal. The maintenance strategy prioritises high-use venues and equipment for routine inspections to ensure consistent availability. Performance data collected through daily checks and monitoring is analysed to identify trends, recurring faults, and opportunities to refine maintenance schedules. A data-driven approach supports continuous improvement by enabling the maintenance team to make informed adjustments to frequencies, task priorities, and resource allocations, ultimately improving overall system uptime and maintenance efficiency.

Lastly, managing maintenance costs and ensuring compliance form the third pillar of the asset care goals. The strategy aims to reduce costs by applying proactive maintenance approaches to critical and routine assets, thereby minimising emergency repairs and capital expenditure on replacements. Together, these asset care goals provide a solid foundation for a resilient, cost-effective, and performance-driven maintenance framework that supports the university's mission of delivering high-quality, uninterrupted learning experiences.

5.1.2 Operational Goals

The operational goals of University X's maintenance strategy ensure the seamless integration of maintenance activities into daily operations by focusing on maximising system uptime, minimising disruptions, and enhancing the reliability of AV infrastructure. These goals are supported by key strategic enablers: resource allocation, inventory management, and effective communication. Maintenance activities should be carefully scheduled around the academic calendar to minimise disruptions during lectures and events. Clear communication channels, including an online ticketing system, enable prompt reporting and resolution of AV issues, while regular updates and feedback loops between maintenance teams and stakeholders support continuous improvement. Together, these operational goals and enablers reduce unplanned breakdowns, extend the lifespan of equipment, and align maintenance activities with the university's mission of providing a reliable and inclusive learning environment.

5.2 Maintenance Strategy Selection

For effective maintenance planning, reactive maintenance is crucial as unexpected equipment failures are inevitable. The strategy, therefore, dictates standard procedures for reactive maintenance, ensuring rapid and efficient responses to such failures to minimise downtime and disruption. Additionally, preventive maintenance is vital, involving regular checks of the AV system to extend its operational lifespan and enhance reliability. Predictive maintenance is specifically tailored for equipment known for frequent failures, using data-driven insights to anticipate and mitigate issues before they lead to significant problems.

5.2.1 Reactive Maintenance

In University X's maintenance strategy, the reactive approach was designated for emergencies and primarily involves replacing components rather than repairing them when they fail during operational hours. This strategy should be applied to critical equipment like projectors and speakers, where repair times are known to exceed available short break durations. The designated short breaks for reactive maintenance tasks occur between 09:45 - 10:15 and 12:00 - 12:30. However, given the complexity and time required for certain repairs, which typically take 27-33 minutes, a dedicated time slot from 13:15 - 14:15 was established specifically for these activities.

This scheduling ensures that reactive maintenance does not interfere with the university's operational requirements, such as lectures and presentations, thereby minimising disruption to academic activities. By dictating that replacements rather than repairs occur during these strict timeframes, the strategy optimises maintenance efforts to accommodate the limited time windows and the urgent nature of the failures, ensuring that the AV systems are promptly and efficiently restored to functional status.

5.2.2 Preventive Maintenance

Preventive actions should be scheduled from 7 A.M. to 8 A.M., before the start of daily activities. This window is strategically used to ensure that critical AV equipment is fully operational and will not disrupt upcoming lectures. During this period, technicians should focus on cleaning and maintaining various components, such as microphones, cables, transmitters, and control panels, which can be effectively repaired within this brief timeframe. Attention should be given to the maintenance of projector systems, which are pivotal in the educational delivery process. Technicians must regularly clean the air filters and blow out any dust from the projectors, which is essential for preventing overheating and prolonging the equipment's functionality. Given the frequent failures associated with older, lamp-based projectors, the university should consider upgrading these to laser-based projectors. Laser projectors are favoured for their longer lifespan and reduced maintenance

requirements, which align well with the university's goal to minimise disruptions caused by equipment failures. These preventive measures are part of a comprehensive strategy to enhance the reliability and efficiency of AV resources, ensuring a smoother educational experience.

5.2.3 Predictive Maintenance

This strategy has integrated predictive maintenance. This initiative, driven by data and analytics, aims to predict and prevent equipment failures, optimising the maintenance schedule and reducing downtime. However, the results collected have highlighted that the existing infrastructure is old and not equipped with the necessary compatibility for integrating modern sensors essential for effective predictive maintenance. Therefore, the strategy dictates that the university needs to invest in modern AV equipment to ensure that the benefits of predictive maintenance can be extended beyond the current limitations. Additionally, there is a significant opportunity for the university to invest in training and upskilling its technicians to work effectively with predictive maintenance technologies. This strategic approach not only acknowledges the issues caused by ageing equipment, such as overheating, dust accumulation, and inadequate ventilation, but also emphasises the need for an infrastructure overhaul and professional development to keep pace with technological advancements.

5.3 Maintenance Strategy Implementation

Implementing a successful maintenance strategy involves a proactive and structured approach to ensure equipment reliability, minimise downtime, and enhance overall operational performance. At University X, this process requires careful planning, scheduling, and execution of maintenance tasks tailored to the needs of diverse AV assets across campus. The implementation should start with a thorough assessment of internal maintenance capabilities, existing processes, and resource availability. Critical assets need to be identified and categorised based on their impact on teaching and learning, guiding the selection of appropriate maintenance approaches. Clear maintenance objectives need to be established, including maximising equipment uptime, reducing maintenance costs, and improving response efficiency. A detailed maintenance plan must then be developed, clearly defining task schedules, personnel assignments, and resource requirements to ensure consistent and effective execution of the strategy.

5.3.1 Skilled Workforce

This maintenance strategy relies heavily on the capacity and expertise of a skilled workforce. At University X, technicians must be strategically allocated tasks based on asset classification, ensuring that maintenance responsibilities are aligned with their skill levels and experience. Predictive maintenance requires advanced diagnostic skills and familiarity with data-driven tools. These tasks can be assigned to senior or upskilled technicians who are trained to interpret performance data and conduct condition monitoring. Preventive maintenance tasks such as inspections, component replacements, audio checking, projector testing and calibration, cleaning, cable checks, and system testing are performed by technicians daily using standardised procedures. Reactive tasks that require quick judgment and problem-solving under time constraints should be executed efficiently during short maintenance windows to restore system functionality with minimal disruption.

To support the workforce under this strategy, the strategy includes targeted training programmes to upskill technicians in emerging areas such as predictive analytics, IoT-based monitoring, and AV troubleshooting. This not only boosts technician confidence and job satisfaction but also enhances maintenance quality and system reliability. A proactive investment in human capital ensures that technicians are well-equipped to implement the

strategy effectively, contributing to improved equipment uptime, reduced failure rates, and a more resilient maintenance environment aligned with institutional goals.

5.3.2 Inventory Management

Efficient inventory management ensures that critical spare parts, such as projector lamps, microphones, and cables, are readily available, with usage tracking systems predicting future needs for seamless procurement. A major concern is the over-reliance on international suppliers for maintenance parts, which results in long lead times. To help mitigate these delays, the university needs to build relationships with local vendors to supply critical components, reducing dependency on overseas suppliers and significantly minimising lead times. A JIT inventory management system should be implemented to accurately forecast spare part requirements based on real-time data and predictive insights. This ensures that resources are readily available when needed while avoiding excessive inventory or inventory stockouts.

5.3.3 Maintenance Policy

A structured maintenance policy underpins the implementation, defining clear roles, responsibilities, and processes for executing predictive, preventive, and reactive maintenance. The scope of this policy should include projectors, microphones, speakers, control systems, document cameras, and associated hardware. Maintenance responsibilities must be clearly defined for the execution of routine, reactive, or predictive tasks based on asset criticality. The manager needs to plan task scheduling and compliance, whereas the middle manager must oversee spare parts availability using a JIT approach. Maintenance procedures should be standardised for all tasks.

The policy should ensure all necessary resources are in place, including trained personnel, diagnostic tools, replacement parts, and effective procurement practices. Frequency of maintenance should be defined by the strategy: predictive tasks must be undertaken quarterly, preventive tasks need to be carried out daily before lectures, and reactive tasks should be performed as the need arises so that teaching is not disrupted. Performance measurement and management need to be implemented to ensure the effectiveness of labour force, maintenance procedures, and procurement procedures. Technicians need to perform tasks using standardised checklists and logs, weekly reports are submitted, and monthly reviews assess uptime, breakdown frequency, and cost-efficiency. This structured and responsive maintenance framework ensures long-term system reliability, reduced operational disruptions, and alignment with the University’s educational mission.

5.3.4 Cost-Benefit Analysis

A thorough cost-benefit analysis should be conducted to validate the implementation’s financial sustainability. Despite the initial investments required for predictive maintenance systems and training programmes, costs can be offset by significant long-term benefits. Predictive systems reduce unplanned downtime, extending the lifespan of critical assets like projectors and control systems. Preventive maintenance, although incurring ongoing costs for inspections and part replacements, ensures reliable performance of routine assets like microphones and cables, ultimately reducing disruptions and maintaining operational consistency. Reactive maintenance, applied only to non-critical or ageing assets, minimises unnecessary expenditures where proactive approaches are not financially justified. The transition to local suppliers further minimises procurement delays, lowering the costs associated with emergency repairs and expedited shipments. Furthermore, proactive inventory management through JIT practices ensures optimal stock levels, preventing overstocking or shortages. The resulting financial benefits include lower total maintenance costs, reduced capital expenditure on equipment replacement, efficient resource utilisation,

and enhanced system reliability, contributing to a positive return on investment and a more sustainable maintenance framework.

5.4 Implications of Findings

This study highlights that a strategic shift from reactive to predictive maintenance is essential to reduce downtime, extend AV equipment lifespan, and lower costs. Strengthening local vendor partnerships and inventory management can improve resilience against supply chain disruptions, while targeted workforce training in predictive analytics and AV diagnostics ensures technicians are equipped for emerging technologies. More broadly, the findings show that AV maintenance is a strategic enabler of institutional performance, offering a transferable framework for other universities seeking to enhance operational efficiency and educational continuity.

6 CONCLUSIONS

This research aimed to determine the right balance for an effective maintenance strategy at University X. There was heavy reliance on reactive and preventive maintenance, with a noticeable absence of predictive maintenance. While reactive maintenance was conducted during the short breaks of 30 minutes and the one-hour window during the lunch break between 13:15 and 14:15, this study recognised the significant potential of implementing predictive maintenance. By integrating predictive maintenance, the university can proactively address the issues known to cause frequent failures, thereby optimising the overall maintenance schedule and significantly reducing downtime. The study contributed to the development of a maintenance strategy framework that could aid in providing a cost-effective maintenance approach that ensures minimal disruption to teaching activities resulting from equipment failures.

8 APPENDIX

8.1 APPENDIX A

Interview Protocol

OBJECTIVE: ASSESSING THE AV MAINTENANCE STRATEGY OF A TERTIARY INSTITUTION	
Theory Question (TQ)	Interview Questions
Maintenance Processes and Procedures of Audio- Visual systems	What is the standard procedure for routine maintenance of AV equipment at University X? • Probe: How would you describe the current maintenance practices at University X: are they predominantly reactive, preventive, or predictive? • Probe: What are the most common faults you observe during daily routines?
	What steps do you typically take when you predict a potential failure in AV equipment? • Probe: Have you received any training in predictive maintenance tools or techniques? • Probe: What challenges have you encountered in implementing predictive maintenance?
	How effective do you find the allocated break times for performing reactive (emergency) maintenance tasks? • Probe: What are the typical repair tasks performed during the 13:15–14:15 time slot? • How does the team handle failures that occur outside the predefined reactive maintenance windows?
	What equipment components do you believe benefit the most from routine preventive maintenance? • Probe: How effective is the current preventive maintenance Programme in reducing unplanned breakdowns? • Probe: Have you noticed any recurring equipment failures despite regular preventive maintenance?
	What specific types of AV equipment are known for frequent failures, and what challenges do these issues present in terms of extending their lifespan?
	What is the typical method to assess lifespan of AV equipment used at University X, and which AV equipment have the longest and shortest lifespans? • Probe: What are the common issues that lead to reduced reliability in shorter- lifespan equipment and longer-lifespan equipment?
	What is the typical process for replacing or upgrading AV equipment? • Probe: How do you determine when equipment needs to be replaced rather than repaired?
	How frequently does AV equipment, both with long-lifespan and short-lifespan, require maintenance? • Probe: What are proactive measures to improve the lifespan of the equipment?
	What are the main challenges you face in maximising the uptime of AV equipment at University X? • Probe: How do you evaluate the effectiveness of the current maintenance strategies in increasing AV equipment uptime?
	What are the main challenges you face in improving the reliability of AV equipment at University X? • Probe: What steps are taken to address these reliability challenges?
	Can you describe the common causes of the frequent unplanned breakdowns challenges in AV equipment at University X?

	• Probe: What proactive measures are currently in place at University X to prevent unplanned AV equipment breakdowns?
	Which AV equipment parts are readily available in your inventory, and which are not? • Probe: What criteria do you use to decide which parts to keep in inventory and which parts you decide to order? • Probe: Can you describe a recent situation where a stockout impacted the maintenance of AV equipment?
	For parts not available in inventory, where do you typically order them from? • Probe: How long does it typically take to receive ordered parts from the external vendors? • Probe: Are there preferred vendors or suppliers due to reliability or speed of delivery?
	Do you feel that the current number of maintenance technicians is sufficient to handle the frequency and variety of equipment failures across the campus? • Probe: Are there contingency plans for periods of high maintenance demand, such as the start of an academic term or during special events?
	How is the budget for maintaining AV equipment structured, and does it adequately support equipment maintenance needs? • Probe: Are there budgetary constraints that affect decisions regarding the repair or replacement of equipment with varying lifespans?

8.2 Appendix B

Process Study Sheet

Process study:		Process:			Product:			Observer:				Date/Time
Process Steps	Work element	Observed times										Notes
		1	2	3	4	5	6	7	8	9	10	
Overall AV Equipment Conditions	Visual inspection for physical damage											
	Control panel inspection											
	Checking for signs of projector overheating											
	Cable checking for electrical faults											
	Checking speakers for sound quality											

	Microphones check for sound output levels											
	Lamp / Laser checking for video/image quality											
Maintenance tasks	Repairing											
	Replacement of faulty or worn-out components											
	Cleaning											
	Lubricating											
	Functionality testing for equipment operational reliability											
Tracking Lifespan	Monitoring equipment condition											
	Operating hours and remaining life hours											
	Age and usage											
Documentation	Record-keeping of maintenance activities and outcomes											
	Updating maintenance logs and system status reports											

8.3 Appendix C

Observation Checklists

	Rating scales				
Criteria	1 (Very Poor)	2 (Poor)	3 (Average)	4 (Good)	5 (Excellent)
Standard daily routine maintenance	No established routine: maintenance is poor and unorganised.	Routine is attempted but lacks consistency and effectiveness.	Basic routine established, generally followed with minor issues.	Well-organised and consistent routine that meets most needs.	Optimally managed, adheres strictly to best practices and schedules.
Prioritisation of Maintenance Activities	Poor Prioritisation leads to critical equipment often being neglected.	Some Prioritisation is evident, but critical items can still be overlooked.	Average Prioritisation, with important items usually handled timely.	Good Prioritisation, with important equipment rarely experiencing downtime.	Excellent Prioritisation, perfectly aligned with operational priorities.
Emergency maintenance practices	No plan for emergency maintenance; chaotic responses.	Inadequate emergency procedures, slow response.	Adequate emergency responses but can be improved.	Effective and timely emergency maintenance responses.	Systematic, swift, and highly effective emergency maintenance.
Major maintenance practices	Major maintenance is neglected or poorly managed.	Major maintenance is irregular and often delayed.	Regularly scheduled major maintenance with some delays.	Systematic and timely execution of major maintenance.	Best practice major maintenance, pre-emptively managed with no disruptions.
Efficiency and efficacy of replacement practices	Replacement practices are haphazard and ineffective.	Replacements are delayed, causing extended downtime.	Replacements are timely but could be more strategic.	Efficient replacement practices minimising equipment downtime.	Highly strategic and pre-emptive replacement practices enhancing longevity.
Quality and timeliness of repair practices	Repairs are frequently delayed and poorly executed.	Repairs are somewhat timely but often require rework.	Repairs are performed in a reasonable timeframe and quality.	Repairs are timely and effectively restore functionality.	Repairs are expertly managed, promptly restoring and often improving equipment.

How maintenance methods Maximise equipment uptime	Frequent unplanned downtime significantly impacts operations.	Occasional unplanned downtime causes operational disruptions.	Generally stable uptime with occasional disruptions.	Rarely experiences downtime, maintaining consistent operations.	Nearly zero unplanned downtime, maximising operational availability.
How maintenance methods affect the reliability of equipment	Equipment frequently malfunctions, severely affecting reliability.	Equipment sometimes fails, causing concern for reliability.	Equipment is generally reliable with occasional issues.	Equipment is mostly reliable with infrequent issues.	Equipment reliability is excellent, with issues being exceptionally rare.
How often unexpected equipment breakdowns occur	Breakdowns are frequent and often unpredictable.	Breakdowns are somewhat frequent and occasionally predictable.	Breakdowns occur occasionally and are somewhat predictable.	Breakdowns are rare and usually predictable.	Breakdowns are very rare and almost always predictable.
How maintenance activities impact operational and maintenance costs	Costs are consistently over budget, impacting financial planning.	Costs are often higher than expected, causing budget overruns.	Costs are managed adequately, with occasional budget overruns.	Costs are generally within budget with rare exceptions.	Costs are always within budget, optimised for efficiency.
How time is consumed in maintenance processes	Maintenance processes are excessively time-consuming, stalling operations.	Maintenance often takes longer than expected, delaying operations.	Maintenance duration is reasonable with manageable impacts.	Maintenance is efficient in time usage, minimising impact.	Maintenance is highly efficient, ensuring smooth operations with minimal interruption.
How maintenance scheduling affects the availability of equipment for use	Equipment is often unavailable due to maintenance issues.	Equipment is occasionally unavailable, affecting usability.	Equipment is mostly available with manageable downtimes.	Equipment is generally available, with rare unavailability.	Equipment is always available when needed, maximising usability.
How staffing adequacy meets maintenance needs	Severely understaffed, unable to manage maintenance demands.	Occasionally understaffed, leading to delays in response.	Generally adequate staffing to meet maintenance demands.	Well-staffed, handling demands efficiently.	Optimally staffed, with capacity to handle all needs and emergencies.
Impact of maintenance on	Maintenance practices shorten equipment lifespan significantly.	Maintenance has little positive impact on extending equipment lifespan.	Maintenance practices generally maintain	Maintenance strategies extend equipment lifespan	State-of-the-art maintenance Maximises equipment lifespan, greatly exceeding norms.

equipment lifespan			equipment lifespan at industry standard.	beyond typical expectancy.	
Equipment Lifespan vs. Performance	Lifespan significantly shorter than expected, leading to frequent replacements.	Equipment often fails before expected lifespan, increasing costs	Equipment lifespan generally, meets expectations with some exceptions.	Equipment lifespan usually aligns well with expectations.	Equipment always meets or exceeds lifespan expectations, optimising capital expenditure.
Effectiveness of the current maintenance strategy	Strategy is ineffective, leading to frequent equipment failures.	Strategy is somewhat effective but lacks consistency.	Strategy is adequately effective with room for improvement.	Strategy is highly effective, minimising failures and downtime.	Strategy is optimally effective, maintaining maximum uptime and health.

MAKING WAVES OR WIPING OUT? NAVIGATING THE DRIVERS AND BARRIERS OF AUTOMOTIVE SALES PERFORMANCE

ABSTRACT

In the automotive industry, the underperformance of sales executives presents significant challenges, not only affecting overall sales but also disrupting business cohesion. This study aims to identify the factors influencing the performance of sales executives by conducting a systematic literature review (SLR). The SLR method was used to collect, analyze, and report on key barriers and drivers of success within this role. The findings highlight critical success factors contributing to high performance among top sales executives while also identifying the challenges that lead many to exit the industry. Based on these insights, this study develops a comprehensive framework that categorizes the drivers and barriers impacting sales executive performance. This framework serves as a valuable tool for industry leaders seeking to enhance sales effectiveness and reduce employee turnover. Ultimately, the study contributes to a deeper understanding of performance dynamics within automotive sales, offering strategic guidance for improving salesforce management

Keywords: Automotive industry, SLR, Sales executives, success factors

* Corresponding Author

1 INTRODUCTION

The automotive industry is a primary contributor to the gross domestic product (GDP) of various countries globally. The industry encompasses a wide range of sectors that involve all business operations associated with the design, production, marketing, sales, and servicing of automotive vehicles [1]. In South Africa, this sector accounts for 4.3% of the national GDP and is ranked as the country's fifth-largest export sector, contributing 18.1% of the country's total exports [2].

The area of focus for this study will be the sales department of various dealerships belonging to a South African automotive group. Sales executives employed in these departments are selected based on their attained work performance profiles but often fail to meet company KPI targets. An underperforming sales executive can negatively affect a company in many ways, but primarily by wasting time [3] and financial resources [4].

For this reason, it is reasonable to conclude that dealerships suffer different losses caused by underperforming sales executives. By identifying accurate predictors of success, dealerships can appoint appropriate sales executives and be guided to better decision-making in this regard. By leveraging these factors, predictive models can be trained to indicate the success rate of a prospective employee based on certain attributes. Ultimately, this will contribute to an increase in company profits and a reduction in waste.

At the time of writing this paper, however, there is limited literature available on the key drivers and barriers for success in sales executives, particularly within the automotive industry. Furthermore, there are no studies available on the performance of sales executives within the automotive industry in South Africa. This article responds to the call for further research in this field.

This research article aims to identify the key performance indicators and barriers to success among sales executives and to provide guidance to companies in optimizing their sales employee hiring processes.

2 RESEARCH METHODOLOGY

In order to achieve the research objective of this study, the systematic literature review (SLR) process as outlined by Albliwi et al. [5] was chosen as the preferred research methodology. The methodology is outlined below:

- **Step 1:** Develop a research purpose and/or objective – Define the goal of the SLR
- **Step 2:** Develop research protocol – Develop a research protocol that stipulates the purpose, inclusion criteria, exclusion criteria, chosen databases, keywords, and quality assessment criteria
- **Step 3:** Establish relevance criteria – Describe a source's relevance to the study
- **Step 4:** Search and retrieve the literature – Search the selected databases to identify relevant papers

- **Step 5:** Selection of studies – Refine the selection of papers by applying the inclusion and exclusion criteria
- **Step 6:** Quality assessment for relevant studies – Analyse the quality of each paper
- **Step 7:** Data extraction – Identify relevant information from the papers
- **Step 8:** Analysis and synthesis of findings – Identify patterns from chosen papers by analysing themes
- **Step 9:** Report – Detail the results and conclusions
- **Step 10:** Dissemination – Publish the SLR

Steps 1 to 8 are covered within this article, while steps 9 and 10 will be completed by the publication of this paper.

2.1 Step 1 - Develop a research purpose

The purpose of this research article is to analyse the available literature to identify the key predictors and barriers to success in sales executives, in order to predict the success of sales executives.

2.2 Step 2 - Develop a research protocol

Table 1 illustrates the research protocol that this study will follow.

Table 1: Research Protocol

Purpose of the study	To identify and analyse the available literature on the key drivers of and barriers to success of employees in the service industry
Inclusion criteria	- Literature that contains any of the specified keywords in the title, abstract, or keywords. - Literature that describes the factors contributing to success in sales executives. - Literature that describes the factors contributing to failure in sales executives.
Exclusion criteria	- Studies that do not focus on the service industry. - Studies published before 2015. - Studies that have not been written in a language other than English.
Search databases	- Science Direct - Scopus - Web of Science - Emerald Insight
Keywords	("salesperson" OR "sales employees") AND "service industry" AND ("success" OR "performance")
Quality assessment criteria	- All duplicate resources must be removed. - Studies must relate to the proposed research question. - Studies must utilise a robust and appropriate research method. - Samples must have clear and appropriate sampling and data collection methods. - Methods of data collection should be transparent.

2.3 Step 3 - Establish relevance criteria

A relevance criteria has been designed in order to establish a study's relevance to the proposed research question.

- Studies should include the terms ("salesperson" OR "sales employees") AND "service industry" AND ("success" OR "performance") in the title, abstract or keywords.
- The chosen literature should discuss the correlation between employee attributes and their performance, or illustrate the trademarks of good sales employees.
- Chosen literature should focus on employees within the sales industry.
- Non-English studies, as well as studies published before 2015, will not be considered.

2.4 Step 4 - Search and retrieve the literature

The process of identifying relevant literature was performed during this step. Appropriate papers were conducted via searches in four databases, namely Scopus, Science Direct, Web of Science, and Emerald Insights. This initial search resulted in a total of 66 papers. This part of the methodology is captured in the initial search part of Figure 1.

2.5 Step 5 - Selection of studies

All duplicate studies were removed from the search results, reducing the total to 58 papers. Some papers did not relate to the research question and were therefore removed. Some did not have a robust and clear research method and were disregarded. Papers that did have clear sampling and data collection methods were also not considered. Papers that did not have clear methods of data collection were also disregarded.

After removing all inappropriate literature, 18 papers were selected for analysis. Step 5 is detailed in Figure 1's screening and eligibility sections.

2.6 Step 6 - Quality assessment for relevant studies:

All 18 relevant papers were analysed using the criteria established in the sections above, and the criteria for the SLR were satisfied. This selection process is illustrated in figure 1.

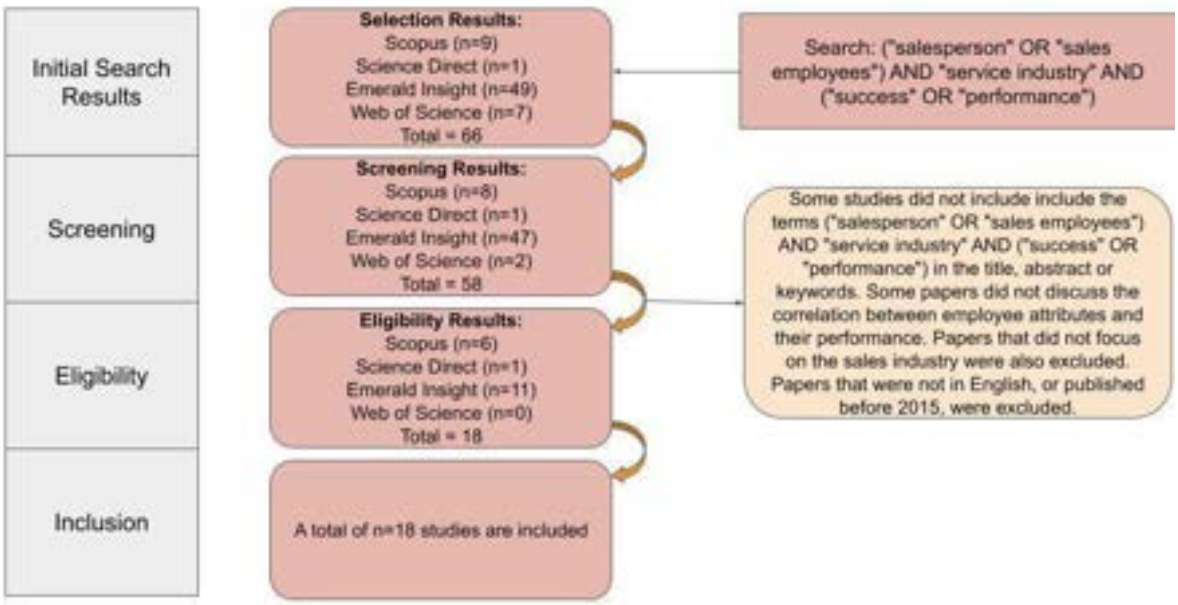

Figure 1: SLR Selection Process

3 FINDINGS

The findings from the analysed and synthesised papers (steps 7 and 8 of the SLR) are discussed in the sections below.

3.1 Step 7: Data extraction

After conducting the thorough analysis detailed above, the 18 relevant papers were studied in their entirety. The information present in each paper is detailed in the table in Appendix A. From this table, it is evident that the studies were conducted in various countries, especially within Europe and Asia. The majority of the studies were done on the financial and retail sectors. This aligns with expectations as the role of sales employees in both the financial and retail sectors is crucial for business success. None of the selected papers were conducted within the automotive sector. This discrepancy justifies the motivation behind this study, especially considering the pivotal role sales executives play in the success of businesses within the automotive industry.

3.2 Step 8: Analysis and synthesis of findings

Following a thorough review of the studies, the extracted data were systematically analysed and ordered into the following sections.

3.2.1 Publications per year

The database search for these papers was limited to a timeframe of between 2015-2025. This is because the results from previous research are repeated in the more recent studies, and it would therefore be redundant to consider them. The majority of the papers were published in 2022, which is likely caused by the return of the workforce to the sales industry following

the COVID-19 pandemic (the sales industry suffered particularly during the COVID-19 pandemic as the nature of the business involves many face-to-face interactions, which were halted during this time). The distribution of studies in this timeframe is Figure 2

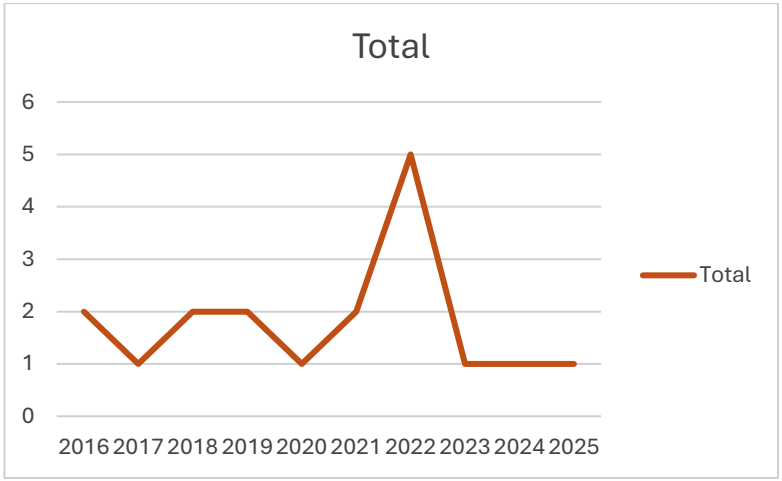

Figure 2: Publications per year

3.2.2 Keywords

A summary of the keywords of each of the 18 analysed papers is illustrated by the word cloud (Figure 3). The word cloud allows the rapid identification of the most recurrent themes in the conducted research, aiding its analysis. The size of the text in the word cloud is representative of the frequency of the keyword's presence across all 18 papers. From this, it is evident that keywords such as "performance", "sales", "customer", and "salesperson" were most prominent. Other keywords such as "adaptiveness", "attitude", "knowledge" and "skill" were also present, highlighting the influence these characteristics have on the performance of sales executives.

Figure 3: Keyword Word Cloud

3.2.3 Country of Study

The following tree map (figure 4) highlights in which countries the samples for the relevant studies were taken.

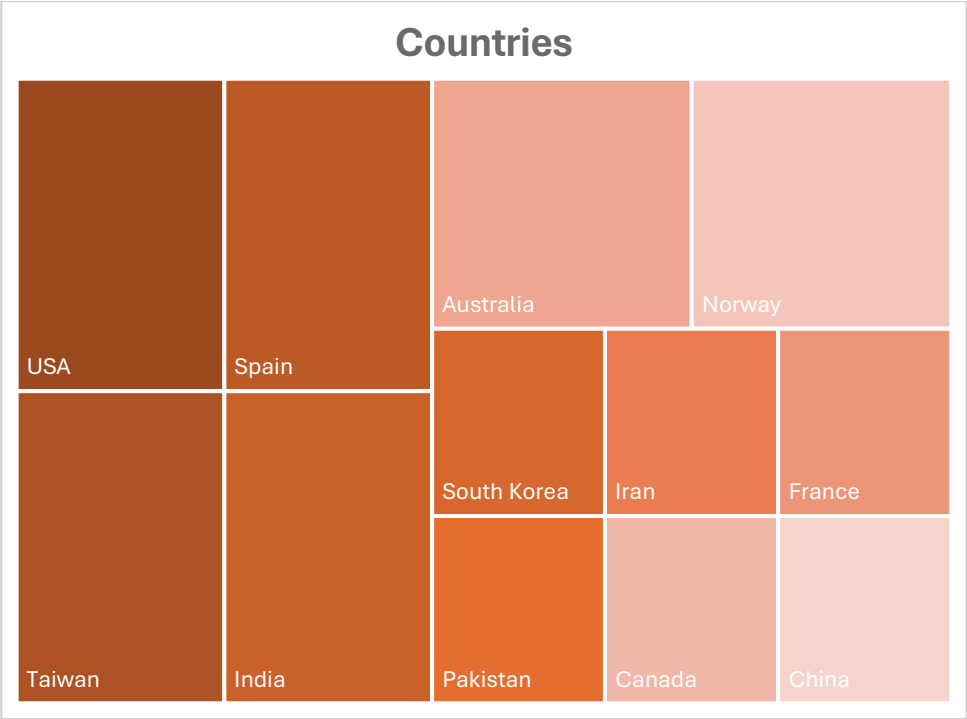

Figure 4: Tree map of Countries

The size of the country's block on the diagram corresponds to the number of studies conducted in that country. This hierarchical view facilitates the detection of imbalances in the evidence base during the analysis of conducted research. From this, it is clear that 2 studies were done in the USA, Spain, Australia, Taiwan, India, and Norway, respectively. Furthermore, 1 study was done in South Korea, Pakistan, Iran, Canada, France, and China, respectively. There is clearly an opportunity for South Africa to contribute to this research conversation.

3.2.4 Internal Drivers of Success in Sales Executives

It is important to have a holistic understanding of the drivers of success contributing to successful sales employee performance, specifically within the service sector [6]. Moreover, it is necessary to distinguish between intrinsic and extrinsic attributes that contribute to their success. This aids businesses in identifying what they can control and optimize versus what they need to mitigate.

Below is a list of characteristics intrinsic to the sales executive as an individual that aid their performance. The sales executive should be/have:

- Adaptable to continuous changes, thus being able to adjust quickly and effectively to evolving environments [7]
- A hard worker, thus putting in consistent effort [7]

- Customer-oriented, being able to prioritise the wants of the customer [8], [9]
- Willing and keen to learn, thus being open to acquiring new skills [8]
- Organised and good at planning, thus efficient in managing time [4]
- Proactive, thus taking initiative [10]
- Good interpersonal skills, thus being able to build positive relationships [10]
- Competitive, thus being driven [11]
- Agreeable, thus being cooperative [11], [6]
- Conscientious, thus being diligent [5]
- Loyal, thus having strong organizational commitment [12]
- Strong personal ethics, thus acting with integrity and honesty [13]
- Good presentation skills, thus clearly delivering information to an audience [14]
- Good communication skills, thus effectively conveying and receiving information in verbal forms [14]
- Self-efficacious, thus believing in their own ability to succeed [15]
- Motivated, thus being goal-driven [15]
- Empathetic, thus understanding and relating to others' emotions [16]
- An ambidextrous selling technique, thus balancing customer acquisition with customer retention strategies [17], [9]
- Extraverted, thus being outgoing [6]
- Good technical selling skills, thus having the skills and knowledge to sell complex products [9]

3.2.5 External Drivers of Success in Sales Executives

As explained in section 3.2.4, it is imperative to distinguish between the intrinsic and extrinsic factors contributing to the success of sales executives. This includes both circumstantial factors and attributes that employees can be trained to have. Below is a list of factors external to the sales executive that aid their performance. The sales executive should:

- Experience high job satisfaction, thus feeling content and fulfilled with their role [7]
- Have high job involvement, thus being personally invested in their work [7], [18]
- Have high product knowledge, thus having received proper training of the products being sold [10]
- Have good department leadership, thus benefiting from supportive and strategic leadership [19], [14]
- Experience meaningfulness in the job, thus viewing their work as significant [20]
- Identify with organizational values, thus feeling aligned with the company's mission [20], [12]
- Experience pay satisfaction, thus feeling that their compensation is fair [20], [21]
- Feel supported in their working environment, thus receiving practical support from colleagues [7]
- Have experience in the field, thus having prior industry knowledge [13]
- Be technologically literate, thus being able to comfortably use digital tools [14]
- Be able to modify the sales approach, thus being to adapt the sales techniques to suit different situations [14]

3.2.6 Internal Barriers to Success in Sales Executives

Understanding the barriers to sales employee success is useful as it highlights factors halting their performance and motivates businesses to proactively remove these barriers in order to improve performance. As with the previous two sections, these factors can also be divided into internal and external factors.

The internal barriers to sales executive performance may be seen as the opposite of the points discussed in 3.2.4. However, it is worth taking note of a few specific factors. Below is a list of characteristics intrinsic to the sales executive.

- Poor communicator, thus struggling to convey ideas clearly [14]
- Poor planning capacity, thus lacking the ability to manage time [14]
- Prone to negative affectivity, thus frequently expressing negative emotions like pessimism [22]
- Emotional dissonance, thus being conflicted between true emotions and the emotions expected to be displayed at work [22]
- Neurotic, thus feeling emotionally unstable [6]
- Cynic, thus being distrustful of others' motives [23]

3.2.7 External Barriers to Success in Sales Executives

The external barriers to sales executive performance may be seen as the opposite of the points discussed in 3.2.5. However, as with 3.2.6, it is worth taking note of a few specific points. The characteristics external to the sales executive that decrease their performance are mentioned below.

- Poor pay satisfaction, thus feeling underpaid [20], [21]
- Poor leadership, thus experiencing unsupportive management [6]
- Poor training, thus lacking proper skill development [20]
- Lack of team morale, thus having a demotivated team [22]
- Exhaustion and burnout, thus feeling mentally or physically drained from prolonged work stress [22]
- Uncivil customers, thus dealing with disrespectful clients [6]
- Organizational cynicism, thus feeling distrustful of the company's motives [23]
- Negative perception of marketing messages, thus believing the marketing materials are misleading [23]

3.2.8 Benefits of Successful Sales Executives

Businesses might also be interested in understanding the benefits of sales executives, as it helps them recognise their strategic value. Additionally, it would motivate them to selectively appoint their employees and also to encourage a work environment conducive to work performance.

- Increased profits, thus achieving higher revenue [4], [18]
- Improved customer loyalty, thus fostering strong, lasting relationships [13]
- Improved customer satisfaction, thus meeting or exceeding customer expectations [13]
- Improved customer retention, thus keeping customers engaged and satisfied [22]
- Competitive advantage, thus standing out from competitors [16]

- Improved collaborative work within the sales department, thus encouraging better teamwork [16]
- Improved sales team morale, improved motivation within the team [16]
- Improved company value, thus improving the business's overall worth and market position [18]

4 FRAMEWORK FOR SALES EXECUTIVE PERFORMANCE DRIVERS AND BARRIERS

The findings summarised in section 3 of this article highlight the various drivers of and barriers to the performance of sales executives in the service sector. In order to highlight and emphasize the findings a framework was designed. This is illustrated in the graphic below (figure 5).

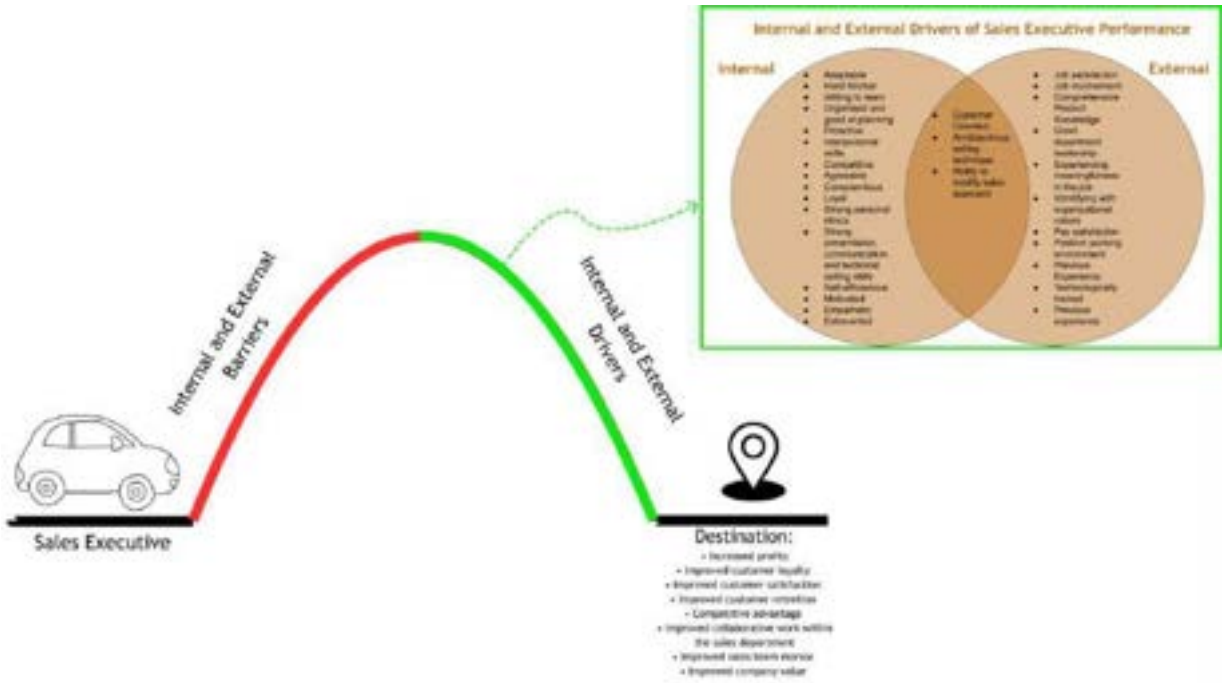

Figure 5: Drivers and Barriers Infographic

Available studies show that comprehensive research has been conducted on the characteristics of performing sales executives, and there is sufficient evidence to suggest that the barriers would be the opposite of these drivers. This article has made a distinction between the characteristics intrinsic and extrinsic to the sales executive, to highlight what a company may control versus what they might mitigate. However, it is worth noting that some of these factors are not mutually exclusive and that they could be categorized as both an intrinsic and extrinsic variable.

From the Venn diagram in Figure 5, it is clear that being customer-oriented, having an ambidextrous selling technique, and the ability to modify a selling approach are categorized

as being both internal and external drivers. These three attributes can also be seen as the primary drivers towards increased sales performance [8].

Customer orientation refers to the extent to which a sales executive aids a customer in making a purchase decision that satisfies the customer's need. This requires, amongst other things, strong interpersonal and communication skills, as well as strong personal ethics [9]. However, for a sales executive to be customer-oriented, they would also have to be trained to have a comprehensive knowledge of available products. For this reason, it is reasonable that this element is derived from both internal and external drivers.

For a salesperson to be ambidextrous means they can simultaneously engage in both customer service and sales activities. By implication, they should integrate addressing customer needs with persuading customers to buy. To perform this effectively, a salesperson should be self-efficacious and have strong technical selling skills, whilst also being trained to have holistic product knowledge. Previous experience is also necessary as it improves the salesperson's situational awareness, which has a direct relationship with their ability to balance sales ambidexterity [17].

The ability to modify a sales approach is critical to the success of sales executive performance. This refers to having a good understanding of a customer's needs and preferences and then modifying the applied sales approach to address them and create long-term value for the customer [8]. For example, some customers may require technical explanations and relationship building, whilst others might require quick solutions. By being adaptable and having good interpersonal skills, a salesperson is more likely to successfully execute this technique. Notwithstanding, a salesperson should be allowed enough job involvement to understand how to effectively profile a customer in order to know when to customize their sales technique [7].

5 CONCLUSION

The automotive industry contributes almost 5% to the South African GDP and is one of the largest export sectors in the country. As profits in the automotive sector and largely propelled by salespersons, understanding the characteristics of successful salespersons is valuable to any company operating within this sector.

This study utilised an SLR to identify relevant literature; however, it was limited to the four databases stipulated in 2.2 of this paper. Furthermore, the keywords that were used as input to these databases did not yield any studies done in the automotive sector. This could be indicative of a need for more research on the performance of sales executives in this field. This implies that the findings from this article might not directly translate to the automotive sector, leading to discrepancies in relevance. The scope of this study is limited to the creation of a conceptual framework, however future research should expand of the implementation and testing of the framework.

This article analysed available literature on the drivers and barriers of sales executive performance and categorised them as internal and external, respectively. From this it was deduced that being customer-oriented, having an ambidextrous selling technique, and the ability to modify a selling approach are the most prominent techniques to improve sales performance. Notably, all three of these attributes are influenced by a combination of both internal and external drivers.

Although there is ample research available on the characteristics of successful sales executives, there is limited knowledge on how these attributes can be utilised to predict sales performance outcomes on both an organizational and individual level. This would be a useful insight that would improve the company value of organizations in this sector, as well as give them a competitive advantage. By utilizing the findings from this article, such a tool could be accurately designed and trained.

ABSTRACT

This study aims to mitigate the impact of human reliability factors on the safety culture within a manufacturing company that offers turnkey security solutions. The primary instrumentation for data collection included an observational checklist and a survey questionnaire that was administered to management and employees. A gap was identified in the current safety procedures relating to employee training, work environment and conditions, workload and scheduling, and employee wellbeing. A device-dependent safety model was created to mitigate this. The model incorporated six key safety management elements, including improved access to standardized procedures, personal protective equipment request forms, hazard reporting forms, an emergency alert platform, daily training material, and a daily reporting checklist (for training, wellness, workload, and work conditions). The safety model addressed risks faced by all stakeholders while providing a feasible, sustainable, and adaptable solution that promotes employee and leadership involvement.

Keywords: Human reliability factors, Safety culture, Safety model, Employee and leadership involvement

1 INTRODUCTION

The health and safety risks inherent in manufacturing operations are notorious, significantly affecting the well-being of the workforce at all levels. In South Africa, the manufacturing sector, accompanied by the agriculture, construction, forestry, and fishing sectors, are deemed the most hazardous sectors, resulting in 200,000 fatal injuries per year – 63% of all fatal occupational injuries, according to the chief inspector of the Department of Employment and Labour in 2024 [1]. This justifies why Occupational Health and Safety (OHS) is a significant addition to the International Labor Organization (ILO) framework as a fundamental right for workers, in 2022 [2].

Beyond the alarming injury, damage, and fatality rates that exist with unsafe manufacturing environments, other negative effects include reputational damage, lowered staff morale, regulatory consequences, and economic losses. Multiple studies on the relationship between work environment and employees suggest that unsafe work environments often cause employee stress, demotivation, and dissatisfaction, resulting in a reduction of employee performance, ultimately increasing company costs [3] [4].

This is particularly relevant to the Gates department at company X, which is primarily driven by a human workforce utilizing heavy machinery in a manufacturing setting since 1993. In this department, employees transform steel parts into gates of various sizes and designs, exposing employees to dangerous equipment, heavy machinery, and toxic fumes. This exposure affects the safety culture, encompassing a shared set of beliefs, values, behaviors, and attitudes that influence the commitment to safety within an organization. [5] [6].

Human reliability factors (HRF) influence behaviors and performance of tasks, in turn impacting safety culture within the company. [7] [8] This comprises aspects like fatigue, inadequate training, unclear procedures, amongst others, that often can be solved on an organizational level. The development of a multi-criteria safety model can be an organizationally driven solution to not only combat these HRFs but also build employee trust, increase cost efficiency, and improve company X's reputation, ultimately securing the organization's long-term viability.

This report aims to identify, investigate, and mitigate the impact of human reliability factors (HRFs) within the Gates Department at Company X. The first section of the paper examines existing literature, particularly regarding the existing safety models. This research then investigates the current safety state in Company X through triangulated data collection from surveys and observational checklists. The results section thematically categorizes the HRFs to feed into the development of the multi-criterial safety model – S.A.F.E.D (Secure, Automated, Feedback-Driven, Engagement-Based, Device-Facilitated). The paper concludes by examining the targeted approach of the safety model to minimize the HRF's impact on the current safety culture.

2 LITERATURE REVIEW

This section reviews existing literature related to common safety models and the intricacies of their functionality. The operations of the following four well-known safety models are investigated: Heinrich's Triangle Theory, Reason's Swiss Cheese Model, Safety Management Systems (SMS), and Behavior-Based Safety (BBS). Exploring and contrasting key elements that define these models can be found below.

Heinrich's Triangle Theory, introduced in 1931, is based on the connection between various safety incidents existing in the workplace. [9] The main takeaway is that high-severity safety accidents resulting in major injuries and fatalities are preceded by low-severity incidents and near misses. [9] [10] Frank E. Bird expanded on this theory, developing a four-tiered pyramid, where 1 serious injury is the result of 10 minor injuries, 30 property damage situations, and

600 near misses. [9] The conclusion is that prevention-focused environments that identify, report, and mitigate risky behavior (at all levels of the safety triangle) to prevent serious OHS incidents (at the top of the triangle). [11]

Existing arguments against this theory state that it is too optimistic and simplistic for modern situations, and that the sole focus of Heinrich's model needs to shift from man (and their failure) to the system of operation. [12] [13] Despite these criticisms, this theory is useful in a modern context as a communication and awareness tool for the main purpose of intervention at early stages. Even though the triangle's role in safety programs is complementary, not stand-alone, it encourages a proactive safety reporting and mitigation system to ultimately prevent the escalation of minor incidents into catastrophic injuries and fatalities.

Nearly 60 years later, James Reason's Swiss Cheese Model (SCM) was introduced and is now used in multiple industries. It is metaphorically presented as sequential layers of cheese with holes, that when momentarily aligned, open a passage for risks to pass through. [14] This implies that safety incidents are a result of various unsolved limitations [15]. This model has been critiqued by other researchers who describe the model as an oversimplification of system components, their interactions with each other, and their evolution over time [14]. Other criticisms entail the unrealistic blame placed on primarily senior management, neglecting the contribution of lower-level employees, regarding accidents. [14] Despite these limitations, this model has shaped safety initiatives by encouraging the strengthening of every layer to improve overall safety with a strong emphasis on redundancy. [15]

The next safety model reviewed is Safety Management Systems (SMS), starting in high-risk industries, and has now made its way across various sectors. Involving employee and management contributions, this framework depends on four pillars: [16] [17] [18]

1. Safety policy: official declaration and documentation of responsibilities and goals, illustrating safety commitment
2. Safety risk management: processes of identifying, assessing, and mitigating risks and hazards.
3. Safety assurance: activities related to monitoring and continuously improving safety.
4. Safety promotion: teaching and communicating to support safety values and attitudes

The key challenge with the SMS model is how much it limits flexibility and creates a bureaucratic environment. [19] The system heavily depends on both organizational commitment and employee engagement. [16] [17] It aims to achieve continuous improvement by integrating safety into organizational processes, rather than an independent system, ultimately improving the safety culture.

Despite the critical contribution of management, environment, and systems to the safety of an organization, another major safety contributor is human factors, entailing people's thoughts, attitudes, and behaviors. [20] [21] The final model reviewed, Behavior-Based Safety (BBS), has a focus on improving employees' attitudes and behavior to lessen their unsafe actions. [20] To develop a strong safety culture, this model is focused on identifying, analyzing, and reinforcing safe behaviors daily while discouraging risky actions. [22] The core elements include behavioral observations, feedback and coaching, behavioral checklists, data collection and analysis, and employee involvement. [23] [24]

Like the previous models in literature, the biggest critique is that the model is insufficient on its own and needs to include broader aspects to combat systemic concerns. [22] The model does not place enough responsibility on design flaws, poor management, or organizational limitations. [24] However, BBS is a powerful tool that improves employee accountability and overall safety stemming from attitudes and behaviors.

Heinrich's Triangle Theory, Reason's Swiss Cheese Model, Safety Management Systems (SMS), and Behaviour-Based Safety (BBS) all have different approaches to safety management. Heinrich's Triangle emphasizes the connection and consequential relationship between minor and major accidents. Meanwhile, Reason's Swiss Cheese Model introduces a layered theory of multiple systemic failures that align to allow accidents to occur. SMS provides a structured framework consisting of 4 pillars – safety policy, assurance, promotion, and risk management. Contrastingly, BBS is based upon employee participation, by building and reinforcing safety beliefs from the bottom up. The most common aspect among these models is the idea that proactive strategies prevent unsafe cultures. Additionally, all the models are prevention-focused and require systematic thinking with structured continuous improvement. After the models have been compared, the key takeaway is that no single model can fully address all the layers of safety. To combat high-risk environments, an integrated approach that combines these perspectives is more reliable.

3 RESEARCH METHOD

A mixed-methods approach was adopted to investigate the impact of HRFs on the safety culture in this manufacturing environment, yielding both quantitative and qualitative data. The specific data collection methods entailed a structured survey questionnaire and a systematic observational checklist to identify perceived and observable HRFs and their safety effects. Participants for both data collection methods consented to be a part of the study; the sample group included employees and managers within the Gates department.

Data regarding the attitudes and behaviours of workers and employees was retrieved through a survey questionnaire. This was developed based on Dillman's Tailored Design Method (TDM), which ensures a reliable and clear survey that focuses on user-friendliness through pilot testing. [25] The design of the survey measured participants' extents of agreement (Strongly Disagree, Disagree, Neutral, Agree, and Strongly Agree) to safety and HRF-related statements. This resulted in the attainment of measurable data that was subjected to statistical analysis. Once responses were analysed using Microsoft Excel, the quantified data detected significant patterns and relationships to paint a clear picture of the current safety culture at company X.

By introducing a structured observational checklist to complement and validate the survey data, behavioural and contextual data were obtained. Day-to-day operations were observed using a reliable checklist designed from the Systematic Observation Method, which involves the use of a predetermined coding system to reduce observer bias. [26] Using a Likert scale, numerical values were associated with observations, where higher values correspond to greater agreement. [27] [28] Additionally, qualitative field notes were captured, documenting contextual factors, interactions, and safety concerns, which were later translated into thematically analysed qualitative results.

The mixed-method approach was utilized, resulting in data triangulation that ensured results that are valid. This clearly outlined the human reliability challenges affecting the facility, directly influencing recommendations for the targeted safety model.

4 RESULTS

The survey conducted on 14 participants yielded results that exposed the workplace dynamics of Company X, with data emphasizing trends, contrasting perceptions, and potential areas of improvement. Much of the survey data showed a clear disparity between the perceptions of the 10 employees and the perceptions of 4 managers, emphasizing a disconnect in safety culture, which can undermine safety effectiveness, morale, and trust. Table 1 displays managers' responses independently from those of employees to account for the contrast between the two groups. This is emphasized by survey responses regarding leaders' commitment to safety; most of the employees view that leaders in company X do not place great importance on the safety culture, and rather, the focus is on profitability.

Both survey data and the observational findings have been arranged within six subthemes, namely, training and expertise, work environment and conditions, workload and scheduling, employee wellbeing, procedure and plans, and safety culture indicators.

The Gates department's operations require uncomplicated skills where on-the-job training is often the only training required, making it simple to ensure employees are adequately prepared for their tasks, as displayed in Table 1 100% of survey participants viewed employees as having good overall skills. This is reinforced in Table 1, where 100% of management and 70% of employees agreed to the statement that training programs are complete and up to date. Management has thus enforced a skill-improving environment by promoting a versatile workforce capable of executing various tasks to ensure operational flexibility, with the department having a strong focus on learning and skill improvement. Additionally, safety incidents related to poor task execution are minimal since employees execute their tasks well, despite the ease of their operations. Contrastingly, safety incidents related to inadequate safety knowledge play a larger role since safety-related training is passive, unstructured, and inconsistent – optional and often outdated posts on a noticeboard. Management adopted an on-the-spot training approach following near-miss injuries, and the designated, yet undifferentiated, safety officer did not see modelling or enforcing safety practices. Therefore, employee responses to the survey question regarding the regularity of safety training were scattered, revealing a standard deviation of 1.179, indicating that the effectiveness of training is not adequate across the participant group, as illustrated in Table 1.

The observational checklist revealed blatant disorganization – pathway obstacles, unstructured WIP (work in progress) storage, damaged and B-grade products poorly secured within commonly used spaces. Additionally, evidence of neglecting annual deep cleaning operations was presented, and post-shift clean-ups merely entailed completing work in progress. This is reinforced in survey data shown in Table 1, by 70% of employees rejecting the statement: "The workspace is clean, bright, and organized." Furthermore, severely insufficient safety signs were observed considering the hazardous manufacturing environment in Company X, which justified the large standard deviation of 1.337 when employees were surveyed regarding the adequacy of safety signage. Employees had complaints regarding their PPE quality, maintenance, replacement, and procedures, resulting in ineffective PPE practices. The survey also revealed that despite the inadequacies mentioned above, Company X was excelling regarding the maintenance of equipment and tools in the facility, when 75% of managers and 80% employees had positive responses in this category, as seen in Table 1.

The effect of shift patterns and hours on employee performance and fatigue is minimal for all managers and only 30% of employees, revealing a large discrepancy in the survey data (Table 1). Whether the workload is distributed evenly is viewed differently by employees and management. This is caused by a clear contrast in how 'workload' is defined – management sees it as the contribution of employees to the production process, and employees view it as the difficulty that they experience in accomplishing their tasks. Explained by a welder who experiences strain from collecting and carrying all components from across the facility, yet according to the managers, he only joins small components.

The observational data revealed that there are two 12-hour shifts, over 60 hours of work per week. During each shift, employees are permitted three breaks (at even intervals, equating to 1 hour), and employee fatigue peaks toward the end of each shift. Employees' time management allows for safe execution of their tasks; furthermore, they are seen to abuse this safety time with phone over-usage, slower product movement, and break extensions.

Table 1: Survey questionnaire notable responses

		Participant response					
Statement	Participant role	Strongly disagree	Disagree	Neutral	Agree	Strongly agree	Standard deviation
Leaders care about and work to keep a strong safety	Managers				2 (50%)	2 (50%)	0.577
	Employees	2 (25%)	4 (50%)	1 (12%)	2 (25%)		1.118
Training programs are complete and up to date.	Managers				2 (50%)	2 (50%)	0.577
	Employees		2 (20%)	1 (10%)	4 (40%)	3 (30%)	1.135
All employees get regular safety training.	Managers				2 (50%)	2 (50%)	0.577
	Employees	1 (10%)	1 (10%)	1 (10%)	6 (60%)	1 (10%)	1.179
Employees have good skills overall.	Managers				4 (100%)		0
	Employees			1 (10%)	5 (50%)	4 (40%)	0.675
There is a focus on learning and skill improvement.	Managers				1 (25%)	3 (75%)	0.5
	Employees	2 (20%)	2 (20%)	3 (30%)	3 (30%)		1.16
The workspace is clean, bright, and organized.	Managers				3 (75%)	1 (25%)	0.5
	Employees	2 (20%)	4 (40%)	1 (10%)	3 (30%)		1.179
Safety signs and warnings are easy to see and understand.	Managers				4 (100%)		0

Company procedures and plans have a significant effect on the safety culture in an organization, which entails SOP management, emergency plan execution, and safety reporting. Table 1 reveals survey data with a large standard deviation of 1.302 regarding employees' perception of SOP access and clarity, suggesting difficulty for employees in this regard. The observational checklist clarifies this; SOP physical documentation is nonexistent at company X, with only practical adjustments. Additionally, emergency plans are drawn up without sufficient equipment, communication, practice, or emergency drills being executed. This was also supported by the alarm system's failure to reach the entire facility, and the survey results validate this, with 56% of employees strongly disagreeing that 'Emergency plans are reviewed and practiced regularly'. Furthermore, safety reporting from management to employees and vice versa is unclear, reactive, and lacks structure, as agreed upon by 80% of

employees who took part in the survey seen in Table 1. Many of the employees don't know how to report, and safety meetings and briefings are infrequent, almost non-existent.

Company efforts to ensure employees' well-being, physically and mentally, are important in the safety culture of any organization. Company X has no existing mental health support available, justifying the 86% of employees either disagreeing or being neutral regarding their access to mental health resources in Table 1. Proactive physical health measures exist, but are inadequate, with PPE provided but poorly managed, resulting in inconsistent usage. Reactive physical health measures include: a minimally equipped first aid room that does not have 24-hour accessibility, and a 2-member health and safety department that does not offer adequate support to employees, resulting in 75% of employees feeling the health and safety measures are inadequate, as seen in Table 1.

There are no formal safety meetings, engagements, activities, or feedback channels in the Gates department in company X. This has created an environment where employees feel reluctant to have safety discussions despite their eagerness to improve their situation. 75% of employees feel as if their safety feedback is not welcome, despite all management expressing that it is, as seen in Table 1. There is a lack of consistency and communication regarding the production manager's approach to risk assessments, strategies, and mitigation, and based on urgency after an incident. The overall safety culture, specifically from management, prioritizes production over safety.

The data collected from the survey and observational checklist revealed an overall need for improvement in safety culture at company X. Urgent areas of improvement can be viewed in the polar diagram in Figure 1 that illustrates a gap analysis. It shows how the current level of safety culture aspects is viewed against the improved level that the model aims to achieve. This figure shows that 'enforcing a skill-improving environment' is an area that which Company X is excelling and requires minimal intervention. However, urgent improvement is required in aspects like employee and management communication, SOP accessibility, emergency plans and alerts, hazard reporting, employee health efforts, and safety signage. Whereas the PPE Request system/procedure and safety training have existing systems in place that would benefit from improvements.

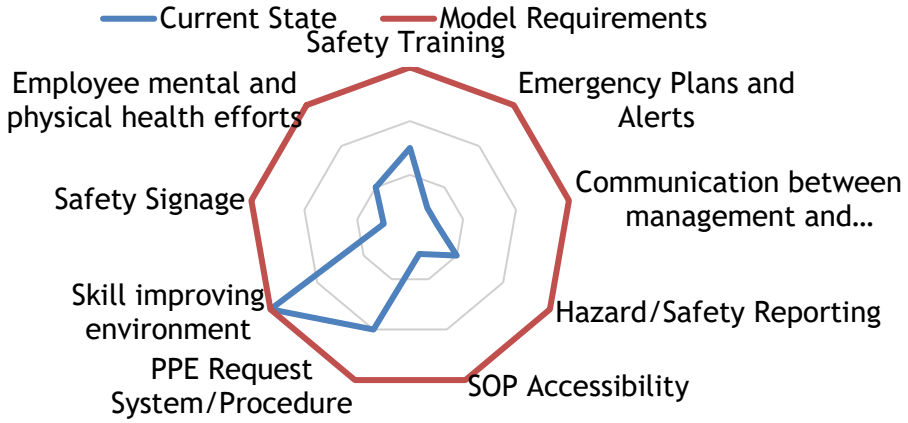

Figure 1: Current state of safety culture at Company X vs. model goals

5 S. A. F. E. D MODEL AND FEEDBACK FORMS

The gap analysis in Figure 1 illustrated the need for a safety model that addresses all the human reliability factors impacting the safety culture of the Gates department in company X. Therefore, the S.A.F.E.D. (Secure, Automated, Feedback-Driven, Engagement-Based, Device-

Facilitated) safety model was developed. The goal of this model is to foster a device-reliant and feedback-driven system where the above-mentioned concerns are counteracted collaboratively by management and employees daily. Employee engagement, leadership commitment, and alignment between the two parties are at the core of this model.

Without disrupting production, tablets facilitate feedback loops that are used to aid mitigation and continuous improvement. The Amazon Fire HD 10 tablet is chosen for its cost-effectiveness, battery life extending over an entire shift (over 12 hours), visibility and durability, and multiple accounts facilitation with management control. For each shift, 4 devices are needed, with each device having private accounts for 5 employees and a manager to encourage honest and personal feedback. Downtime storage and primary charging occur in the production manager's office during the alternative shift. When in use, the tablets will be mounted in low-risk areas where the Wi-Fi connection is strongest, with access to a secondary charging port to promote organization, safety, and ease of use. Device protection on various levels is accounted for with a military grade, ruggedized case, TASSKTO protective cover, and 9H hardness screen protector. In terms of theft, cameras monitor the facility, device location tracking is installed, and facility security performs checks on everyone entering and exiting Company X. The interface for the model is shown below in Figure 2.

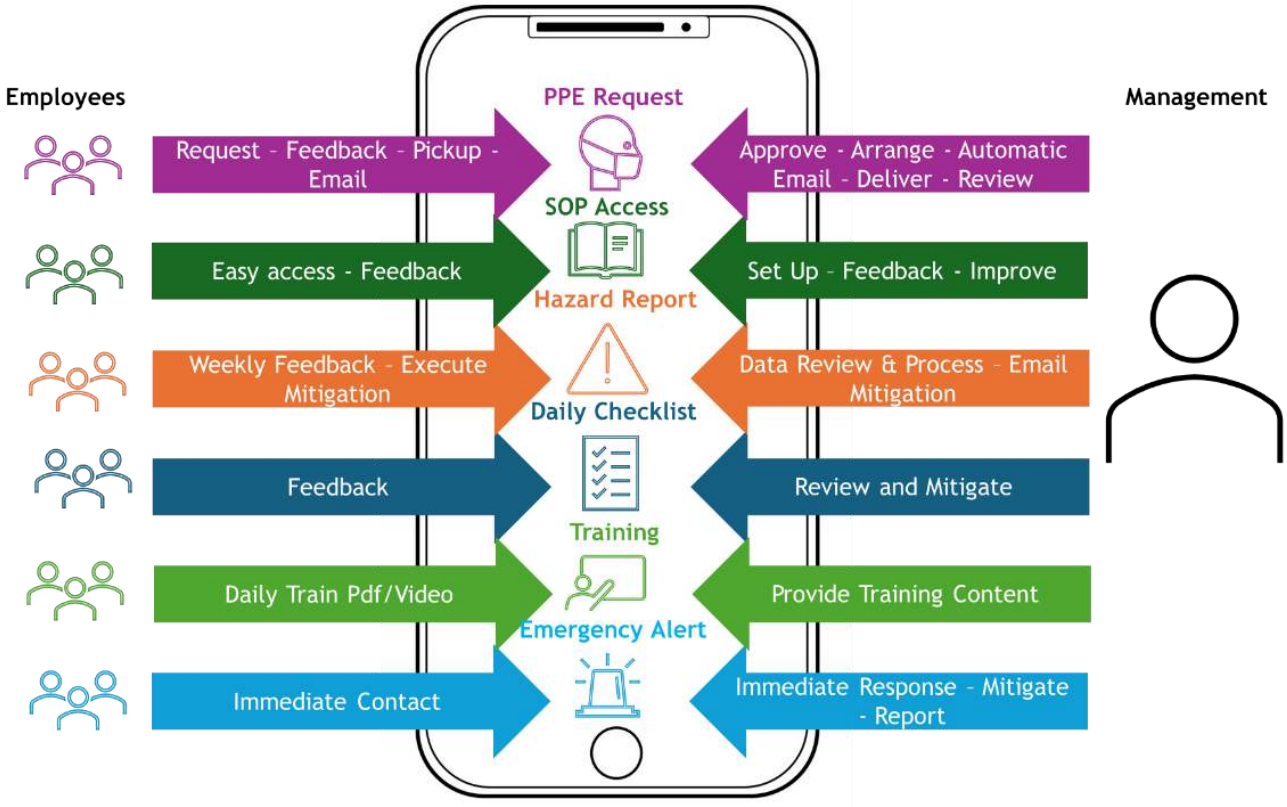

Figure 2: Final Safety model

This model has the added advantage of being scalable and adaptable – it can accommodate possible expansions of the Gates department and include other departments in Company X. It promotes employee accountability and empowerment with monitored safety processes and a platform for their voices to be heard. Furthermore, it encourages flexible leadership engagement when management communicates safety updates and mitigation instructions at a convenient time. Overall, by introducing a system where employees and management collaborate to improve safety, and by encouraging employees to report on incidents

anonymously creating a culture of openness is created. The data being transferred between management and employees promotes a constant safety feedback loop for continuous risk identification and mitigation. On a long-term basis, collected data feeds into monthly reports for management to monitor safety statistics.

The model has 6 key features that help connect employees and managers to improve safety culture. The PPE procurement system optimizes and controls the process of obtaining PPE while minimizing the effect on production time. Employees can privately report hazardous incidents with risk assessments and suggestions for solutions for management to analyze and respond with mitigation instructions appropriately. In addition to having a device-based alert system for emergencies, the model has daily micro-training content that can be covered by employees at any flexible time. The device also enables SOP access and a SOP feedback platform for employees. Managers obtain feedback from daily checklists regarding training, wellness and workload, work conditions, PPE, and device management. The model's features are discussed in more detail in this section.

In emergencies like fires and evacuations, the emergency alert aspect of the model consists of an SOS Alert app that ensures fast, clear and coordinated notification to relevant safety personnel, especially those outside of the gates department in Company X. This is an ideal solution to the current inadequate functional emergency equipment such as the alarm system that does not reach all areas of the facility. This provides a user-friendly and easy interface that, with 1 tap, enables immediate support to the hazard at the location of the tablet, from managers outside the facility. Additionally, emergency instructions and evacuation plans, which were previously not disclosed to employees, will now be accessible on every user's home page for quick and easy reference.

The next criterion of the model aims to automate and streamline the PPE procurement process. On the managerial side, the system includes a screening process to regulate and monitor distribution and potential misuse of PPE supplies (accessing more equipment than necessary), which are some of the managers' concerns. The model automates communication with PPE applicants using coded emails while collecting application data for inventory tracking, forecasting, and continuous improvements in quality and quantity. The goal of this feature is to enhance safety culture by improving the issuance process of PPE while facilitating consistent replacement practices to encourage standard PPE compliance.

5.1 S. A. F. E. D Model Request Forms

The online PPE request form for submitting requests is shown in Figure 3.

PPE Request Form

For PPE Requests, Complaints and Suggestions

1. Email _____
2. Employee Name _____
3. Work Position _____

☐Tube cutter
☐Bender
☐Driller
☐Small component maker
☐Welder
☐Knitter
☐Painter
☐Forklift Operator
☐Overhead Crane Operator

4. Type of PPE needed (only 1 item can be selected for each request form)

☐Helmet/Hard hat
☐Goggles
☐Hearing protection
☐Weld Mask
☐Weld Gloves
☐Paint Mask
☐Boots
☐Gloves (☐small ☐medium ☐large)
☐Overall pants (☐small ☐medium ☐large)
☐Overall top (☐small ☐medium ☐large)

5. Justification of Request

☐Lost
☐Damaged
☐Worn Out
Other: _____

6. Where and how did this occur

_____

7. What can stop it from happening again?

_____

8. Date of Last Issue: _____Example: 7 January 2019
9. Image Upload of damaged PPE (note: image authenticity may be reviewed by supervisors)
10. Suggestion Box! Do you have any suggestions, comments, complaints, questions, worries regarding PPE? All feedback is welcome

_____

Figure 3: PPE Request Form

Research data revealed the inaccessibility and possible nonexistence of SOPs, including ones related to safety, such as emergency plans. The model introduces easy and direct access to general and safety-specific SOP PDFs on the homepage of every device. This is not only a guide for existing employees to perform tasks safely and correctly, but also material for new trainees to learn from. This system eliminates workflow disruptions and time wastage attached to physically searching for SOPs, especially in emergencies. Lastly, the system consists of links for employee input to encourage employee feedback on tasks they have the most experience in, which can be seen in Figure 4. The overall benefits consist of lowering training costs and streamlining SOP accessibility to promote a proactive safety culture, while increasing employee initiative for the betterment of processes in the department.

SOP Suggestion Form

1. Employee Name: _____
2. Work Position:
   - □Tube cutter
   - □Bender
   - □Driller
   - □Small component maker
   - □Welder
   - □Knitter
   - □Painter
   - □Forklift Operator
   - □Overhead Crane Operator

   Other:
3. Which SOP are you suggesting a change for?

   _____
4. What can be included in the Sop to reduce the risk?

   _____
5. Does the SOP pose a safety risk? How?

   _____
6. Which Specific Step would you like to see improved?

   _____
7. What changes do you recommend for this SOP?

   _____
8. How do you believe this change would improve the SOP or process?
   - □Improves safety
   - □Saves time
   - □Increases accuracy

   Other:

   _____
9. How frequently do you use this SOP?
   - □Daily
   - □Weekly
   - □Monthly
   - □Rarely
10. Any additional Comments or Suggestions

    _____

Figure 4: SOP Suggestion Form

The risk management system of the S.A.F.E.D. safety model includes the hazard reporting form seen in Figure 5. This facilitates real-time safety and hazard reporting on the homepage of every device. This criterion of the safety model can be viewed as an indirect safety meeting that does not disrupt production time. By allowing employees to be heard, utilizing an easy-to-use interface, employees can develop safety-driven mindsets. Once employees identify and classify risks, management has valuable color-coded data for safety mitigation instructions for the relevant employees to execute, as well as proactive safety management to prevent recurring and worsening of unsafe situations.

Hazard Reporting Form

Section 1: Incident or Hazard Identification and Definition

1. Type of Hazard (only 1)

- ☐Spill or slippery surface
- ☐Equipment malfunction
- ☐Fire Hazard
- ☐Electrical hazard
- ☐Trip/fall hazard
- ☐Chemical Exposure
- ☐Medical
- ☐PPE issue
- ☐Facility ergonomic (unsafe obstructions)
- ☐The building inadequacy
- ☐The production process
- ☐Unhygienic
- ☐Maintenance
- ☐Peer review
- ☐Management review
- ☐Safety signage

Other: _____

2. Location of Hazard**:** _____

3. Date and Time of Incident: _____

4. Upload Evidence

Section 2: Severity and Frequency Assessment

5. How would you classify the risk according to the categories below

☐Unsafe Act ☐Near Miss ☐Minor Injury ☐Lost time/serious injury ☐Fatality

6. Potential Impact on operation

☐No impact ☐Minor ☐Moderate ☐Significant

7. Frequency of Occurrence

☐First time ☐Rare ☐Occassional ☐Frequent

Section 3: Reaction

8. Immediate Action Taken, if needed

☐No action taken ☐Warned others nearby ☐Marked or blocked off area ☐Notified supervisor

9. Suggested Countermeasure (What action/s do you recommend preventing or reduce this hazard?)

_____

Section 4: Safety Pillars

10. Does the hazard relate to existing safety policy non-compliance? Yes☐ No☐ Maybe☐

11. What Further Action Needed to Manage Risk?

_____

12. Would further training or awareness sessions help mitigate this risk? Yes☐ No☐

Figure 5: Hazard Reporting Form

This formalizes safety strategies that allow management to commit to safety procedures at a flexible time. Throughout this process, data is archived for trend analysis for big safety improvements on a large scale. This structured report system generates data for regular, long-term, and proactive safety monitoring that works towards an improved safety culture. Employees are continuously taught to perform their daily operations sufficiently, reducing the chances of error due to incompetence. However, this is not the case for safety tasks. Despite the employees' general idea of safety rules, there are no intentional or proactive lessons given by Company X; on-the-spot training reacting to near-miss injury, the safety marshal does not perform her duties (safety rule enforcement, informal training, and discipline), and a clear gap between policy and practice regarding safety.

The S.A.F.E.D. safety model counteracts this by incorporating micro safety training content while abiding by the constraint set by management of not disrupting production time. Therefore, short training PDFs, documents, and other resources are available daily on each device, to be reviewed flexibly by employees. To monitor employee interaction with the content, a daily checklist is filled out by each employee to reflect on safety lessons learnt. In conjunction with monitoring training, this checklist also investigates employees' perception of their work environment – conditions, wellness, and workload, with the intention of mitigating facility issues and trying to improve employee well-being.

The work conditions need improvement from their current unsanitary and disorganized state, which can be improved in stages based on feedback from employees and instructions from management. Decluttering positively influences employee performance and minimizes operational chaos, limiting the hazards and distractions that compromise safety. [29] [30] Daily clean-up sessions can be enforced and monitored properly, and this data can influence the timing of the annual deep clean. Additionally, employees can directly or indirectly alert management to safety signs that need to be included and equipment that needs to be maintained.

Regarding workload and scheduling, the current state involves an average employee's work week exceeding 60 hours. At the same time, studies have shown that surpassing 40 hours of work per week can cause performance deterioration, an increased injury rate, and poorer overall health. [31] These work hours exceed the maximum (9 hours per day) in South Africa, set out by the Basic Conditions of Employment Act (BCEA). [32] Moreover, the current perception of uneven workload distribution can lead to perceived unfairness, decreased morale, and potentially impact overall safety performance. [33] Using this checklist, employees have a platform to report their concerns regarding fatigue, unfair work distribution, and insufficient time to avoid compromising employee alertness, resulting in accidents and risks. The checklist introduces mental health initiatives and facilitates a proactive physical health system. This checklist is presented in Figure 6 below, it encourages an environment of continuous improvement and accountability

Daily Checklist

1. Work Position

□Tube Cutter
□Tube Bender
□Driller
□Small component maker
□Welder
□Knitter
□Painter
□Forklift Operator
□Overhead Crane Operator
Other: _____

2. I completed my daily training today: Yes☐ No☐
3. I learnt the following in my training today:

Section 2: Work Environment and Conditions

4. I performed my post shift clean up yesterday: Yes☐ No☐
5. My workstation was clean when I got here today: Yes☐ No☐
6. The lighting and electricity are working in my workstation: Yes☐ No☐
7. There is a leak or spills near my workstation: Yes☐ No☐
8. Do you have any comments, suggestions, complaints, etc. with your work environment and

_____

Section 3: PPE

9. I'm wearing my overalls today: Yes☐ No☐
10. I'm wearing my safety boots today: Yes☐ No☐
11. I'm wearing my gloves today: Yes☐ No☐
12. I'm wearing my hard hat today: Yes☐ No☐
13. I'm wearing my safety goggles today: Yes☐ No☐
14. I'm wearing my welding mask today (welder): Yes☐ No☐

Workload And Scheduling

15. Did you experience fatigue today? Why?

_____

16. Was your break sufficient today? Why?

_____

17. Did you feel you like you performed you tasks safely today? Yes☐ No☐
18. Do you have any comments, suggestions, complaints, etc. with your workload and scheduling

_____

Employee Well being

19. Are you experiencing any difficulties or disruptions in your emotional, psychological, or social well-

_____

20. Do you have any comments, suggestions, complaints, etc. with how the company can assist with

_____

Figure 6: Daily Checklist

6 CONCLUSION

The research highlights the importance of effective safety management in manufacturing to help prevent incidents that can cause harm to employees as well as negatively affect the reputation of Company X. Data was analyzed from surveys and observational checklists to evaluate the human reliability factors that need to be mitigated within: training plans, work environment, safety procedures, work scheduling, and employee well-being. The contribution of the study includes the design of a safety model (S.A.F.E.D) aimed to resolve these using a device-based model with PPE acquisition digitization and automation, easily accessible SOPs and emergency plans, virtual safety meetings and briefings through feedback forms, safety micro-training, an emergency alert system, and daily checklists to monitor wellness, workload, training, and work conditions. Additionally, the model serves as a tool to maintain quality management and ensure production runs smoothly. This proactive approach to safety management fosters open safety discussions, employee engagement, and leadership commitment, all while minimizing disruptions to production. There is room for this model to improve by condensing the device-based approach into a singular and comprehensive app or software that has all the features in one place. The model is scalable and can be adapted to all departments within Company X to help facilitate long-term safety improvements by creating avenues for open communication between the employees and management.

How long have you been doing this work?					
Do you set safety rules or follow them?					
Tick your view on the following statements:	**Strong disagree**	**Disagree**	**Neutral**	**Agree**	**Strongly agree**
1. Training programs are complete and up to date.					
2. All employees get regular safety training.					
3. New employees get good safety training when they start.					
4. Employees have good skills overall.					
5. Employees know how to follow safety procedures.					
6. Skills checks help find areas to improve and make safety better.					
7. There is a focus on learning and skill improvement.					
8. The workspace is clean, bright, and organized.					
9. Work areas are free from dangers like spills or obstacles.					
10. Safety signs and warnings are easy to see and understand.					
11. Equipment and tools are well-maintained and in good condition.					
12. Employees correctly use personal protective equipment (PPE).					
13. Shift patterns and work hours do not cause problems with performance or tiredness.					
14. Standard procedures (SOPs) are clear & easy to find.					
15. SOPs are updated often.					
16. Reporting safety concerns is clear and simple.					
17. Emergency plans are reviewed and practiced regularly.					
18. Safety meetings happen often and are of high quality					
23. Leaders care about and work to keep a strong safety culture.					
24. The organization listens and responds to safety concerns from employees.					
28. Work is spread out evenly among employees.					
29. There are ways to prevent employees from getting too tired (breaks, shift changes).					
30. Employees manage their time well.					
31. Employees have enough time to do tasks safely.					
36. There are ways to keep workers physically healthy.					
37. Workers have access to mental health resources.					
41. Employee feedback is welcomed and taken seriously.					

42. Risk assessments are done regularly.					
44. Safety performance is regularly checked and analyzed.					

8.2 Appendix B: Instrument 2: Observational Checklist

Observational Checklist for Human Reliability Factors Influencing Safety Culture, Rated by: Researcher Asilah Ellahi

Table 3: Observational Checklist Table

			Effectiveness of ratings				
			1	2	3	4	5
1. Training and Expertise	1.1 Training Programs	1.1.1. Are training programs comprehensive and up-to-date?	Not comprehensive, outdated.	Partially comprehensive, partially updated.	Comprehensive, but needs updates.	Mostly comprehensive and mostly UpToDate.	Fully comprehensive and fully UpToDate.
		1.1.2. Are all employees provided with regular safety training?	Rarely provided.	Occasionally provided.	Regularly provided but with gaps.	Regularly provided with minor gaps.	Consistently provided without gaps.
		1.1.3. Are new employees given a comprehensive safety orientation?	Not provided.	Partially provided.	Provided but lacking in detail.	Mostly comprehensive.	Fully comprehensive.
	1.2 Skill Level	1.2.1. How do you perceive the overall skill level of employees?	Very low skill level.	Minimal skill set	Average skill level.	Above average skill level.	Very high skill level.
		1.2.2. Do employees demonstrate competence in safety procedures?	Rarely competent.	Occasionally competent.	Generally competent.	Mostly competent.	Fully competent.
		1.2.3. How effective are the skills assessments in identifying areas for improvement and enhancing safety culture?	Not effective at all in identifying areas for improvement or enhancing safety culture.	Somewhat ineffective in identifying areas for improvement or enhancing safety culture.	Moderately effective in identifying areas for improvement and enhancing safety culture.	Effective in identifying areas for improvement and enhancing safety culture.	Highly effective in identifying areas for improvement and enhancing safety culture.

	1.3 Continuing Education	1.3.1. Is there an emphasis on continuing education and skill development?	No opportunities.	Few opportunities.	Some opportunities.	Many opportunities.	Extensive opportunities.
2. Work Environment and Conditions	2.1 Physical Environment	2.1.1. Is the workspace clean, well-lit, and organized?	Very poor conditions.	Below average conditions.	Average conditions.	Above average conditions.	Excellent conditions.
		2.1.2. Are work areas free from hazards (e.g., spills, obstructions)?	Very hazardous.	Some hazards.	Generally, hazard-free.	Mostly hazard-free.	Completely hazard-free.
		2.1.3. Are safety signs and warnings prominently displayed and understood?	Not displayed.	Displayed but not understood.	Displayed, but some confusion.	Mostly displayed and understood.	Fully displayed and understood.
	2.2 Equipment and Tools	2.2.1. Are equipment and tools regularly maintained and in good condition?	Rarely maintained.	Occasionally maintained.	Generally maintained.	Mostly maintained.	Fully maintained and in excellent condition.
		2.2.2. How well are personal protective equipment (PPE) protocols followed by employees, including correct usage, wear, and replacement?	PPE protocols are not followed at all by employees.	PPE protocols are rarely followed, with frequent misuse or neglect.	PPE protocols are somewhat followed, with occasional misuse or neglect.	PPE protocols are generally followed, with minor instances of misuse or neglect.	PPE protocols are strictly followed by all employees, with correct usage, wear, and timely replacement.
	2.3. Work Hours and Shift Patterns	2.3.1. How do shift patterns and work hours affect employee performance and fatigue levels?	Severely negatively impact employee performance and lead to high fatigue levels.	Negatively impact employee performance and contribute to significant fatigue.	A moderate impact on employee performance and fatigue levels.	Generally, support good employee performance, with manageable fatigue levels.	Optimize employee performance and minimize fatigue levels effectively.
3. Procedures and Plans	3.1 Standard Operating Procedures (SOPs)	3.1.1. Are SOPs clearly defined and	Not defined or accessible.	Partially defined or accessible.	Defined but not easily accessible.	Mostly defined and accessible.	Fully defined and easily accessible.

		accessible to all employees?					
		3.1.2. How often are the SOPs updated?	Never	Every 5-10 years	Every 1-5 years	Every year	Every month
		3.1.3. How clear and well-defined is the protocol for reporting safety concerns?	There is no clear protocol for reporting safety concerns.	The protocol for reporting safety concerns is poorly defined and rarely followed.	The protocol for reporting safety concerns is somewhat clear but inconsistently followed.	The protocol for reporting safety concerns is clear and generally followed.	The protocol for reporting safety concerns is very clear, well-defined, and consistently followed by all employees.
	3.2 Emergency Plans	3.2.1. Are emergency plans regularly reviewed and practiced?	Never reviewed or practiced.	Rarely reviewed or practiced.	Occasionally reviewed or practiced.	Mostly reviewed and practiced.	Regularly reviewed and thoroughly practiced.
		3.2.2. How frequently are safety briefings conducted?	Safety briefings are never conducted.	Safety briefings are conducted very infrequently (e.g., once a year).	Safety briefings are conducted occasionally (e.g., once every few months).	Safety briefings are conducted regularly (e.g., once a month).	Safety briefings are conducted very frequently (e.g., weekly or more often).
		3.2.3. How would you rate the quality of safety briefings?	Safety briefings are not informative or engaging, and do not contribute to safety culture.	Safety briefings are somewhat informative but lack engagement and impact on safety culture.	Safety briefings are moderately informative and engaging, contributing to safety culture to some extent.	Safety briefings are informative and engaging, contributing positively to safety culture.	Safety briefings are highly informative, engaging, and significantly enhance safety culture.
	3.3. Communication of Procedures	3.2.6. How effective is the emergency communication system in ensuring timely and accurate information dissemination?	Not effective at all, leading to delays and inaccuracies.	The emergency communication system is somewhat ineffective, with frequent delays and inaccuracies.	The emergency communication system is moderately effective, with occasional delays and inaccuracies.	The emergency communication system is effective, with minor delays and inaccuracies.	The emergency communication system is highly effective, ensuring timely and accurate information dissemination without any issues.
		3.2.2. How well do employees understand and follow communication	Employees do not understand or follow communication protocols	Employees have a limited understanding of communication	Employees have a moderate understanding of communication protocols and	Employees generally understand and follow communication	Employees have a thorough understanding and consistently follow communication protocols

		protocols during emergencies?	during emergencies at all.	protocols and rarely follow them during emergencies.	follow them inconsistently during emergencies.	protocols during emergencies, with minor lapses.	during emergencies without any lapses.
		3.2.5. How clear and accessible are the reporting protocols for safety concerns?	Reporting protocols are not clear or accessible at all.	Reporting protocols are somewhat clear but difficult to access.	Reporting protocols are moderately clear and accessible.	Reporting protocols are clear and accessible, with minor issues.	Reporting protocols are very clear and easily accessible to all employees.
	3.4 Supervision and leadership	3.4.1. How committed is leadership to promoting and maintaining a strong safety culture?	They show no commitment to promoting or maintaining a safety culture.	They show minimal commitment, with occasional mentions of safety culture.	They show moderate commitment, with some efforts to promote and maintain a safety culture.	They show strong commitment, with regular efforts to promote and maintain a safety culture.	They show exceptional commitment, with continuous and proactive efforts to promote and maintain a safety culture.
		3.4.2. How responsive is the organization to safety concerns raised by employees?	Safety concerns are ignored or dismissed.	Safety concerns are acknowledged but rarely acted upon.	Safety concerns are acknowledged and occasionally acted upon.	Safety concerns are acknowledged and usually acted upon promptly.	Safety concerns are promptly acknowledged and consistently acted upon in a timely and effective manner.
5. Workload and Scheduling	5.1 Workload Distribution	5.1.1. Balance and Fairness of Workload Distribution: Is the workload evenly distributed among employees?	Very unevenly distributed.	Somewhat unevenly distributed.	Neutral distribution.	Mostly evenly distributed.	Very evenly distributed.
		5.1.2. Adequacy of Measures to Prevent Worker Fatigue: Are there measures in place to prevent worker fatigue (e.g., adequate breaks, shift rotations)?	No measures are in place to prevent worker fatigue.	Measures to prevent worker fatigue are minimal and often ineffective.	Some measures are in place to prevent worker fatigue, but they are inconsistently applied or moderately effective.	Effective measures are in place to prevent worker fatigue, and they are usually applied consistently.	Highly effective measures are in place to prevent worker fatigue, and they are consistently applied and regularly reviewed for improvement.
	5.2 Time Management	5.2.1. Efficiency in Time Management: How well do employees manage their time?	Very inefficient.	Somewhat inefficient.	Neutral efficiency.	Mostly efficient.	Highly efficient.

		5.2.2. Sufficiency of Time Allotted for Task Completion: Are employees given enough time to complete tasks safely?	Consistently not given enough time to complete tasks safely, leading to rushed and unsafe practices.	Frequently not given enough time to complete tasks safely, often resulting in rushed work.	Sometimes, given enough time to complete tasks safely, but there are occasional periods of rushed work.	Usually given enough time to complete tasks safely, with rare instances of rushed work.	Consistently given more than enough time to complete tasks safely, with no instances of rushed work.
	5.3. Task Prioritization	5.3.1. Effectiveness of Task Prioritization for Safety and Efficiency: Are tasks effectively prioritized to ensure safety and efficiency?	Tasks are not prioritized, leading to frequent safety hazards and inefficiencies.	Tasks are rarely prioritized effectively, often resulting in safety risks and inefficiencies.	Tasks are sometimes prioritized effectively, with occasional safety risks and inefficiencies.	Tasks are usually prioritized effectively, minimizing safety risks and inefficiencies.	Tasks are consistently prioritized effectively, ensuring maximum safety and efficiency.
6. Team Dynamics and Collaboration	6.1 Team Communication	6.1.1. Clarity and Frequency of Team Communication: Is team communication clear and effective?	Very unclear.	Somewhat unclear.	Neutral clarity.	Mostly clear.	Very clear and effective.
	6.2 Problem-solving	6.2.1. Effectiveness of Collaborative Problem-solving: How well do teams collaborate to solve problems?	Very ineffective.	Somewhat ineffective.	Neutral effectiveness.	Mostly effective.	Very effective.
	6.3. Team Cooperation	6.3.1. Support and Cooperation Among Team Members: Do team members support and cooperate?	No support or cooperation among team members, leading to frequent conflicts and inefficiencies.	Rarely support or cooperate, which results in occasional conflicts and inefficiencies.	Sometimes support and cooperate, but there are still some conflicts and inefficiencies.	Usually support and cooperate, with minimal conflicts and high efficiency.	Consistently support and cooperate, fostering a highly efficient and harmonious work environment.
7. Employee Wellbeing	7.1 Physical Health	7.1.1. Availability and Effectiveness of Health Measures: Are there measures in place to ensure the physical health of employees?	No measures.	Few measures.	Some measures.	Many measures.	Extensive measures.

	7.2 Mental Health	7.2.1. Access to Mental Health Resources: Are mental health resources available to employees?	No access.	Limited access.	Some access.	Good access.	Excellent access.
		7.2.2. Attentiveness and Alertness During Work: How attentive and alert are employees during work?	Employees are consistently inattentive and frequently display a lack of alertness, leading to numerous safety risks and errors.	Employees are often inattentive and occasionally display a lack of alertness, resulting in some safety risks and errors.	Employees are sometimes attentive and alert, but there are occasional lapses leading to moderate safety risks and errors.	Employees are usually attentive and alert, with few lapses that rarely lead to safety risks or errors.	Employees are consistently attentive and alert, minimizing safety risks and errors, and contributing to a highly safe and efficient work environment.
8. Safety Culture Indicators	8.1. Employee Engagement and Participation	8.1.1. Do employees actively participate in safety meetings and initiatives?	Rarely attend or contribute to safety meetings, showing little to no engagement.	Attend some safety meetings but rarely contribute or show interest.	Generally, attend meetings and sometimes participate, but engagement is inconsistent.	Usually attend and actively participate in safety meetings, with considerable engagement.	Consistently attend, are highly engaged in safety meetings and initiatives, frequently contributing valuable input.
		8.1.2. Are employees encouraged to provide feedback on safety issues?	Employees are very rarely encouraged to provide feedback, with little to no avenues for input.	Employees are occasionally encouraged, but feedback mechanisms are limited or ineffective.	Employees are sometimes encouraged to provide feedback, with some systems in place to collect input.	Usually encouraged to provide feedback, effective systems collect and respond to input.	Employees are consistently and actively encouraged to provide feedback, with robust systems ensuring all input is considered and acted upon.
		8.1.3. Encouragement and reception of employee feedback	Feedback from employees is ignored or discouraged, with no visible action taken.	Feedback is sometimes acknowledged but rarely acted upon.	Feedback is generally received, with some actions taken, but improvements are inconsistent.	Feedback is usually welcomed and leads to visible improvements.	Feedback is actively sought, highly valued, and consistently results in improvements.
	8.2. Risk Assessment and Management	8.2.1. Are regular risk assessments conducted?	Rarely conducted, leading to	Conducted infrequently	Generally conducted but	Regularly conducted and are usually thorough.	Conducted frequently, thoroughly, and

			significant safety risks.	and are often incomplete.	may lack thoroughness.		effectively, identifying all potential risks.
		8.2.2. Are risk mitigation measures implemented effectively?	Rarely implemented, leaving many risks unaddressed.	Sometimes implemented, but are often ineffective.	Generally implemented but may not be fully effective.	Effectively implemented and addressing most risks.	Consistently implemented & highly effective in addressing identified risks.
	8.3. Safety Performance Metrics	8.3.1. Are safety performance metrics regularly monitored and analyzed?	Rarely monitored or analyzed, leading to poor safety performance.	Occasionally monitored, but analysis is inconsistent or incomplete.	Generally monitored and analyzed, but improvements are needed.	Regularly monitored and analyzed, contributing to good safety.	Often monitored, thoroughly analyzed, and continuously improved safety.

NATURE-INSPIRED STRATEGY FROM WAVE MASTERS: A BIOMIMICRY EXPLORATION ON SOUTH AFRICAN AQUATIC LIFE

M.Roopa[1*] and O.C. Koekemoer[2]

ABSTRACT

Over time, wave-exposed marine species have evolved behaviours that harness wave dynamics for survival. Biomimicry is the disciplined emulation of nature to achieve desired outcomes. This research identifies strategy-oriented characteristics that support sustainable innovation by extracting traits from South African marine species that use waves to their advantage. Strategic elements are distilled from published observations via a literature review and categorisation. Species were selected if they (i) are indigenous to South African waters, (ii) exhibit documented wave-adaptive behaviours, and (iii) have peer-reviewed behavioural descriptions that allow abstraction of strategy-oriented principles. Not only does this boast strategies that can boost sustainable innovation, but it warrants recognition for the accomplishments South African aquatic life has made over many years. Using the nature-inspired strategies presented in this research, organisations are able to challenge their status quo, redefine their modus operandi and innovate beyond existing competitors in a way that nature suggests.

Keywords: Biomimicry, Strategy, Sustainability, Innovation, Framework, South Africa.

1 INTRODUCTION

Strategy has served as the cornerstone of societal advancement and gain. According to Carr [1], strategy is often seen as action in space and time. This deliberately configured dimension and careful balance have made the execution of strategy a business survival imperative. The most blatant source of survival instincts can be observed in nature.

Nature has persisted throughout complex and disruptive change. The mastery of any strategy requires patience and disciplined practice. In the natural world, many species exhibit precise, repeatable behaviours shaped by persistent turbulence and constraint. Similar to Jedi masters from the popular Star Wars franchise, the Jedi invest many years honing their abilities of the force to eventually become Jedi masters that demonstrate traits of leadership, strategy, wisdom and skill. In fact, leadership skills from Urick [2] demonstrated management styles that can be distilled from the franchise.

The concept of mastery is also evident in our natural world. Nature boasts solutions that demonstrate high levels of strategy carried out with precision. This organic solution space offers a resolution to many challenges today, as showcased by its track record in the literature [3]. Biomimicry is concerned with seeking inspiration from and designing solutions that are nature-inspired. This growing field fosters creativity, sustainability and innovation that can feature in any industry [4, 5].

South Africa faces many societal challenges. Those associated with innovation include a decline in employment-intensive sectors, low productivity and various forms of socio-economic disparity, as mentioned by Booyens and Hart [6]. Using sustainable innovation and national systems, one can help resolve these socio-economic challenges [7].

The application of nature-based solutions has also been explored by Botha [8] in South Africa as a form of nature-inspired leadership facilitated by the design of a thought model. This artefact effectively showcases the ability to turn to nature for inspiration. The findings were derived from studying nature in South Africa to improve leadership.

Water is among the most powerful forces in nature. It is commonly understood that Earth's surface comprises around 70% water [9]. It is here where waves become strong and formidable for species in nature. Arguably, the species that continuously interact with waves demonstrate high levels of strategy, leadership and resilience. Their operations require them to interact with unpredictable wave conditions. Consequently, these "wave masters" exhibit deep adaptation to the ocean environment and provide insights that can aid the way strategies are developed and executed in developing countries such as South Africa.

1.1 Research opportunity

Although biomimicry is well documented at the organism/form and process levels, reviews note that system- and strategy-level applications remain comparatively scarce and fragmented, with inconsistent terminology and methods [36–38]. Barriers to organisational uptake, including limited taxonomies for strategy, weak translation pathways from biology to managerial action, and a lack of evaluation frameworks are also reported [39]. In developing-country contexts, scholars argue for nature-inspired policy and strategy to leverage biodiversity for socio-economic development [40]. These gaps motivate the present study's strategy-level approach grounded in ecosystem principles and tailored to South African conditions.

An opportunity exists to learn from nature to better address sustainable innovation challenges in developing countries at a strategic level. It is for this reason that various strategies can be harnessed from the characteristics of South African aquatic life.

1.2 Research aim

The aim of this research is to identify strategic traits derived from wave-adaptive aquatic species in South Africa that support sustainable innovation.

1.3 Research objectives

The purpose of this research is tied to the following objectives:

1. Contextualise the scope of the study by defining the core subject matter
2. Apply Biomimicry to extract strategic elements from species in nature
3. Design a nature-inspired strategic framework for sustainable innovation
4. Validate the framework by assessing its alignment with Life's Principles

The literature review in section 2 provides a contextualised understanding of pertinent concepts associated with this research. Furthermore, the Biomimicry design spiral is proposed in section 3 as the methodology employed. The sea of literature is explored, and various strategies are captured and discussed in section 4 alongside the aforementioned artefact. Section 5 details the implications of the artefact from this research. Ultimately, the conclusions and recommendations are used to provide the core takeaways and way forward.

2 LITERATURE BACKGROUND

2.1 Biomimicry

The notion of nature-inspired or nature-based solutions in engineering is strongly believed to have been pioneered by the innovator Leonardo Da Vinci. The groundbreaking advancements in engineering are seen as the early onsets of Biomimicry [10]. Much of his accolades stem from his drawings that detail futuristic concepts such as flapping machines inspired by the anatomy of birds [11].

After many more nature-based inspirations were employed, the term Biomimicry was coined and simply defined as emulating nature's genius [12]. This practice solves human problems by intricately combining technology and biology to create sustainable designs and innovations [13]. The success stories of Biomimicry have also formalised the field of Biomimetics, which explores biologically inspired technologies. Biomimetic solutions sampled from Bar-Cohen [14] include applications of controlled adhesion, structures, defence and attack mechanisms, bio-sensors and robotics, only to highlight a few. These advances welcome waves of innovation that have brought about change to society. Yet, there remains the issue of the sustainable trajectory of this, which is often challenged by a lack of prioritisation for sustainability investments.

The use of Biomimicry can feature at the product (micro), process (meso) and systems (macro level). As elaborated by Botha [8], the application of Biomimicry on a systems level has been termed as "system mimicry". This term speaks to the interconnected nature of challenges that persist in developing countries.

2.2 Sustainable Innovation

The term sustainability seeks to ensure that the current needs are met without compromising future prosperity in an inclusive society [15]. The dimensions of sustainability are economy, society and the environment, which have varied forms of interaction that can be seen as siloed, mutually inclusive or embedded within each other [16].

Innovation is often seen as the process of combining various functions within organisations to develop and implement new or improved products, processes or ideas [17]. Innovation is also not always new, and may take the form of technological, process, product, service, business model, disruptive and radical, design-driven, social and responsible innovation [18]. In effect,

it is innovation that ensures business competitiveness and responsiveness to a dynamic environment [19].

According to Booyens and Hart [6], South Africa is confronted with challenges of underdevelopment, poverty and skewed spatial patterns of innovation and research focus. This innovation asymmetry not only affects the innovation cycle but also implicates all relevant stakeholders in maximising their value capture. As for the sustainability considerations, it is only if this is sustainable that it will promise an equitable and prosperous societal gain.

This innate relationship between sustainability and innovation has led to the dual perspective on sustainable innovation. As defined by Hautamäki and Oksanen [20], sustainable innovation considers the far-reaching and long-term impacts synchronised with the innovation process by balancing the economic, social and environmental factors at play. This high interconnection creates multiple goal adherence that meets the environmental targets of the organisation while creating or maintaining its competitive advantage [21].

Similar convoluted interactions exist between technological innovation, process innovation and environmental strategy. The research from Čater, *et al*. [22] suggests that by greening the processes, the environmental strategy and overall outcome of an initiative remain beneficial to the organisation. Advice from literature suggests inculcating high sustainability mindsets and sustainability performance and deliberately searching for sustainability-based opportunities [23]. This feature is also able to compliment ecological modernisation theory.

2.3 Strategy

Strategy concerns itself with the selection process of the activities an organisation will execute according to well-defined goals, competitive forces and cost [24] . Porter [25] defines early answers as a crucial determinant of firm success amidst challenges in theory building, the chain of causality, time horizon and empirical testing.

Carr [1] argues that strategy is “action in space and time”. The author continues to argue that strategic behaviour is built on the fabric of time, even though this phenomenon is neglected in the literature. Four strategic behavioural concepts for strategies are proclaimed, namely order, duration, significance and transition.

3 RESEARCH METHODOLOGY

Variations of the Biomimicry models exist in the literature. The most prominent forms are the Challenge to Biology and Biology to Design models from the Biomimicry Institute [26]. Problem-oriented research typically warrants the use of the Challenge to Biology model, whereas opportunity or more exploratory research calls for the Biology to Design model. The former seeks to design a biomimicry solution using a defined problem where functions are abstracted from nature. In contrast, the Biology to Design approach turns to nature for intuitive impressions since it is more solution-oriented than the Challenge to Biology approach. This research will therefore employ the Challenge to Biology model since natural models in the ocean will be studied to retrieve strategic elements to solve for sustainable innovation. The steps have been visualised in Figure 1.

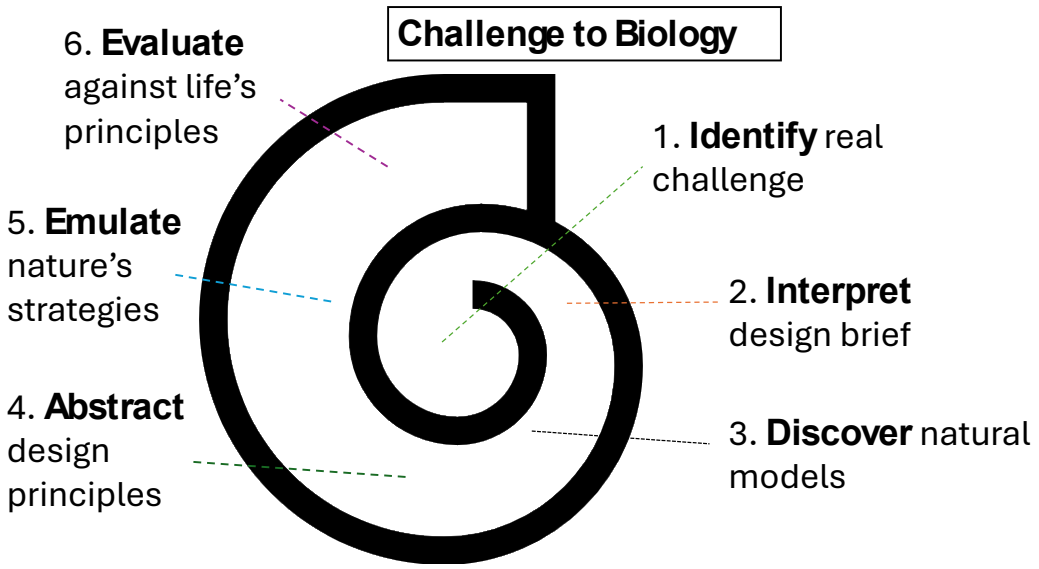

Figure 1: Challenge to Biology methodology from Biomimicry Institute [26]

This research is structured according to the Challenge to Biology methodology, deliberately casting the structure of section 4. It is because of this design spiral that the explicit stages are used to ensure that the nature-inspired solution promotes sustainable innovation. This real challenge is first formulated using the research components details in section 1. The design brief is more closely associated with the aim and speaks to the specifications needed for the design (strategic framework). Thereafter, the discovery stage tasks the researcher with familiarising and contextualising themselves with the natural models. The abstract phase extracts design principles that can be used as sources of inspiration from the natural models explored using literature and AskNature. For the purposes of this research, the abstraction will be done specifically using South African aquatic life. Using these sources of inspiration, nature is emulated by designing a strategic framework for sustainable innovation. The last stage requires evaluation of the Biomimicry solution using Life's principles. This validation framework allows biomimicry solutions to be evaluated against nature-inspired traits and explore the degree to which the solution conforms to the notions of Biomimicry.

4 BIOMIMICRY APPLICATION: NATURE-INSPIRED STRATEGY

4.1 Identify the real challenge

Based on the literature overview and research opportunity, developing countries are challenged with pathways to sustainable innovation. Hence, the real challenge is that there are limited strategic elements for sustainable innovation.

4.2 Interpret the design brief

The design brief is to develop a strategic framework that embodies elements for sustainable innovation using nature as a source of inspiration. Different solution spaces are thus needed. The discovery phase first needs to consider sustainability and sustainable innovation Biomimicry solutions before abstracting directly from South African aquatic life.

4.3 Discover natural models and abstract design principles: strategies from nature

4.3.1 Sustainability

Biomimicry instinctively aspires to ensure sustainability in the notions and content of its solution [13, 27]. The work of Llieva, et al. [28] provides a Biomimicry framework on

sustainability focus areas plotted on a Cartesian plane. This has been further distilled and clustered into Table 1.

Table 1: Biomimicry for Sustainability Framework summary crafted from Llieva, et al. [28]

Biomimicry dimension	Sustainability focus	Biomimicry Solution
Innovation	• Techno-centric aims • Novel solutions • User-product interactions • Commercial interests	• De Mestral's Velcro • JR West's Bullet Train • Neri Oxman's Silk Pavilion
Net-Zero Optimisation	• Optimise performance • Technical focus on reducing impact	• JR West's Bullet Train • Neri Oxman's Silk Pavilion • ITKE's Flectofin
Societal Transformation	• Changes in societal scale • Redesign within planetary boundaries • Systemic perspective	• Yaniv Peer's Mobius Project • BioHaven's Floating Islands
Biosynergy	• Human-nature interactions • Rethink human ends • Generative impact on nature	• BioHaven's Floating Islands

The various Biomimicry solutions speak to set sustainability focus areas with a fixed or flexible mimesis that are either nature passive or active. The sustainability focus areas seeks to rehabilitate and improve ecology and environmental gain by being regenerative and conscious of the environmental impact. The innovation-related Biomimicry solution entails answers that have been commercialised into products readily available and popular today. It is therefore suggested that a Biomimicry innovation that is sustainable sparks commercial interest and is novel. Furthermore, the solution must be techno and user-centric in its design.

Nature has long since proven that it can be sustainable, and so it is often believed that Biomimicry solutions are naturally sustainable [12]. The biomimicry solutions tied to sustainability focus areas all demonstrate efficient and effective sustainability enabling through specific Biomimicry dimensions formulated in Table 1. This application is not purely associated with sustainability, but also various forms of innovation are motivated by Metz, et al. [23].

De Pauw, *et al.* [29] emphasise that strategies which learn from nature entail Biomimicry, Nature Capitalism and Cradle to Cradle strategies which positively impact business processes, product design, as well as the type and the number of materials used.

4.3.2 Sustainable Innovation

AskNature is a Biomimicry solution that contains a repository of numerous natural species where functions can be observed and searched for [30]. AskNature queries were seeded from its function taxonomy (i.e., reduce drag, manage shear, dampen oscillations, channel flow, co-ordinate) and from behaviours typical of wave-exposed species (i.e., porpoising, hydrodynamic efficiency, co-operative herding sensory navigation), synonyms were iteratively expanded with Boolean operators and retained when pilot searches returned South African occurrences. This platform has been used to search for sustainable innovation which was by default segmented into innovation and strategy species. The search only revealed two forms of species known for their biological strategy. The core strategy from the bottlenose dolphin entails peer-to-peer learning which aids in spreading innovations rapidly. This learning directly embodies effective knowledge management through the innovation process for it to be sustainable. On the other hand, grazing animals demonstrate the sustainable use of land. This directly translates to strategic and careful use of resources that reduces material consumption. The segmented forms of functions for innovation and strategy directly extracted from Ask Nature were the following [30]:

- Break down (5)
- Get, Store, or distribute resources (4)
- Maintain community (2)
- Make (12)
- Modify (7)
- Move or stay put (4)
- Process information (1)
- Protect from physical harm (18)

Using AskNature [30], the functions of sustainable innovation were searched in order to identify natural systems with the number of case studies in parentheses above. These natural systems included the composite technologies inspired by the Mantis Shrimp, cement supplements from the oceanic mineralisation of calcium, material design using marine sponge, marine phytoplankton inspiring optimisation software, chemical additives and coatings from seaweed and Salvinia water fern.

A two-level codebook (Level-1 Function codes aligned with AskNature taxonomy nodes; Level 2 Strategy codes expressing abstract principles) was developed. Axial coding was then applied to cluster the Level 2 Strategy codes into the three Whirlpool strategy types: Stabilise & Simplify; Co-ordinate & Shape; Adapt & Amplify. Strategies can now be abstracted from the functions provided from AskNature by searching for sustainable innovation. Break down speaks to work breakdown structures, resource use into utility and resource utilisation. Maintaining community is tied to social cohesion. Aspects associated with make, modify and move are implicitly associated with manufacturing or service activities that can be strategically managed using operations management. Information processing can be made metaphorical with IT and information support structures, with measuring and monitoring as strategic elements. Health and safety are hinted at by the protect from physical harm function in nature.

4.3.3 Strategy from South African aquatic life

Adhering to the application of Biomimicry, the solution should be contextual and situated within the same environment as the problem. This means that this research will need to consult South African aquatic life for inspiration on strategies to aid with sustainable innovation. Therefore, a literature review was conducted and led to the formation of the following strategic elements that are inspired by South African aquatic life and feature in Table 2.

Table 2: Strategic elements abstracted from nature

Aquatic life	Skill	Strategic element
Tigerfish	Rapid movement	Quick Strategic decision making
	Predatory skills	Red Oceans mindset on competitiveness
Yellowtail	Hydro-dynamic design for high speed and efficient swimming	Reconfigure and enhance resources according to environmental and technological landscapes [22]
Cape fur Seal	Co-operative hunting	Teamwork and social cohesion
	Individual foraging	Delegating to subject matter experts
Common bottlenose dolphin	Wave-riding	Strategic coasting to be conservative and build capacity
African penguin	Porpoising	Low leverage point execution (using existing momentum)
		Leapfrogging
Great white shark	Electroreception-driven sensing	Reliance on monitoring systems for decision making
	Breaching to disorient prey	Effective marketing strategy

Strategy abstractions follow a conservative logic: first, each behaviour is grounded in a well-described biomechanical or ethological function; second, that function is translated into a managerial analogue that preserves the constraint–response structure (e.g., energy minimisation → resource-efficiency pacing; co-ordinated foraging → role clarity and synchronised execution); third, a strategic element is ascribed only where the managerial analogue can be operationalised (e.g., measurable change in cycle time, resource intensity, or co-ordination latency). This discipline avoids loose metaphors and ensures a traceable line from observation → function → strategic principle → managerial lever.

Tigerfish possess rapid movement which is analogous to speed. This has been further associated with the notion of quick decision-making. Their predatory skills can be seen as. Red oceans mindset. The careful use of resources are emphasised by yellowtail swimming. Social cohesion and task delegation are retrieved from the South African seal's hunting and foraging behaviour. The intent of wave-riding is synonymous with the notions of strategic coasting. Interestingly, porpoising surfaced as a result. This act of propelling finds mammals leaping into the air at high speeds to breathe air through highly resistive surface regions before entering the surface layer with less resistance [31]. This can be seen as leapfrogging past infrastructure requirements and using low leverage point capabilities in business execution.

4.4 Emulate: Biomimicry wave-inspired strategic framework for sustainable innovation

Wave mastery has been showcased by South African aquatic life. These strategic traits are not particular to South African species, since many similar species have the same genetics in the same way that sustainable innovation challenges exist in other parts of the world. In order to emulate, this would be rather complex since more than one species provides strategic elements. To sidestep this design challenge, it becomes apparent that the forces of water can be consulted for further inspiration. This led to the design inspiration of a whirlpool embodying the nature of the solution. A whirlpool is a formidable force that can amplify waves, refract or diffract and also interact with existing waves. The preceding results from section 4 have been modified and pieced together in the Whirlpool framework for sustainable innovation as illustrated in Figure 2.

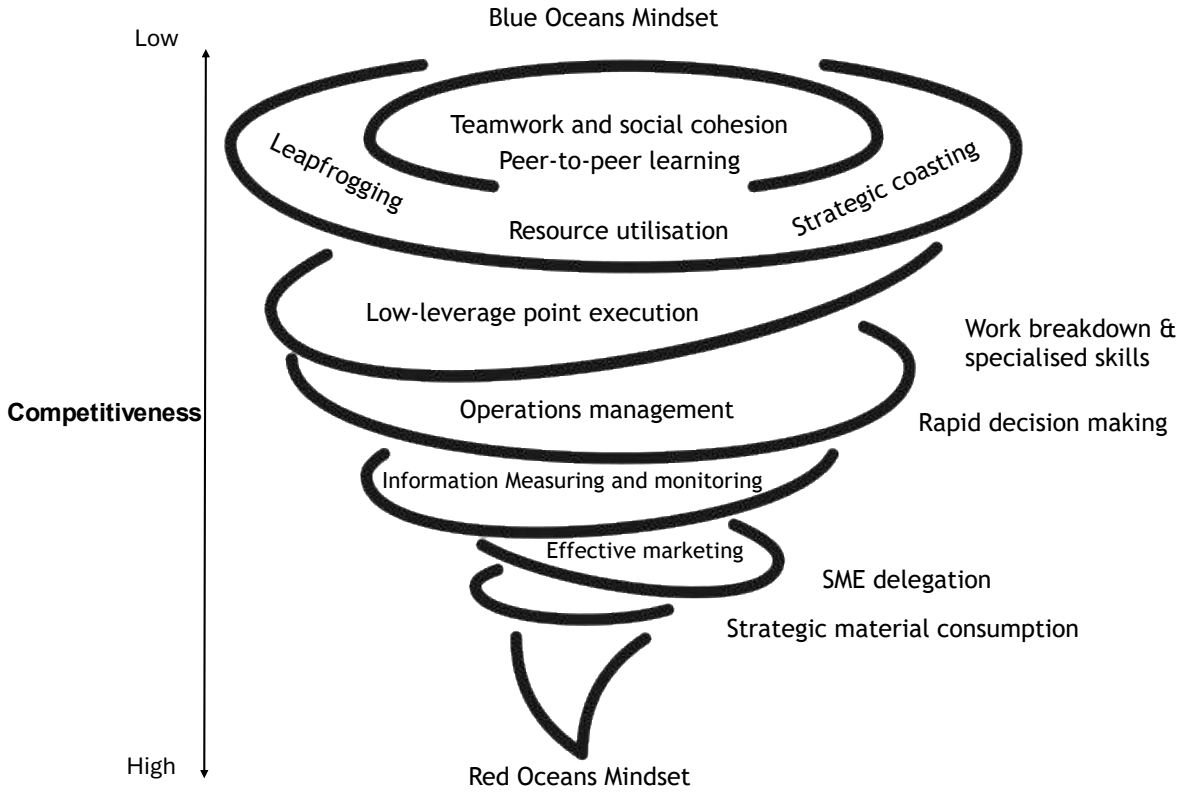

Figure 2: Whirlpool framework for sustainable innovation

The velocity of a whirlpool is such that the centre has increased velocity. The depth of this framework is such that high competitiveness features lower down where gravity and pressure (competition) are at their highest. The beginning of the whirlpool has less pressure, more flexibility and a high risk appetite. Certain strategies lie outside the whirlpool, which are seen as aspects which are unspecific to the type of strategy would ensues. Similar to the flow of water in a whirlpool, it increases over time and is almost linear. However, this framework welcomes varied sequencing with non-specific duration in accordance with the strategy components for strategic behaviour using space and time from Carr [1]. The strategies are nature-inspired and communicated using the whirlpool phenomenon in nature which has a direct impact on waves. It is also important to highlight that this model is from a systems level which aligns with the systems level strategic implementation needed to ensure sustainable innovation. The framework incorporates a simple monitor–review–adjust loop to support short, low-risk learning cycles.

To ensure this promotes sustainable innovation, the innovation sustainability focus areas from Llieva, *et al*. [28] are revisited. The design has a techno and user-centric focus since it considers human interaction, information measuring and monitoring elements. Commercial interests are considered since this promotes sustainability and innovation as a novel solution.

Using the wave-mastery from aquatic life, developing countries similar to South Africa can compete in a red oceans or blue oceans space, innovate, market effectively, leapfrog, improve operations and resource consumption and measure and monitor their performance which allows them to improve their modus operandi and redefine their status quo.

The Whirlpool Framework is a heuristic, not a universal prescription. Its effectiveness depends on context—particularly baseline process telemetry, the capacity to run short, low-risk experiments, and sufficient partner density for coalition pilots. It does not replace domain-

specific constraints (for example, regulatory, safety, or environmental requirements) and may be inappropriate in high-reliability settings where variation is tightly controlled. Elements should be tailored to organisational maturity and sector conditions; mis-analogy risks are mitigated by limiting each mapping to a single mechanism to principle to strategy element and by monitoring KPIs for unintended effects.

4.5 Evaluate: Framework validation using Life's Principles

Biomimicry 3.8 presents its Life's Principles model, which serves as a validation mechanism ensuring that a Biomimicry design creates conditions conducive to life [32]. It also helps ensure that the design or artefact contains the core traits of a Biomimicry solution. Table 3 details the principle, description and justification provided by applying the framework.

Table 3: Framework validation using Life's Principles from Biomimicry3.8 [32]

Life's Principle	Descriptors	Justification
Adapting to changing conditions	Maintain integrity through self-renewal	Uses adaptive aquatic life that mimic adaptive strategies
	Incorporate diversity	Includes a diverse range of South African marine life
	Embody resilience	Built using resilient aquatic life.
Be locally attuned and responsive	Use readily available materials and energy	Not catered for in framework
	Cultivate cooperative relationships	In need of field testing but contains aspects tied to social cohesion
	Leverage cyclic processes	Cyclic nature of spiral inspired from Biomimicry design spiral
	Use feedback loops	Monitor-review-adjust loop
Integrate development with growth	Combine modular and nested components	Combines and consolidates various strategic elements.
	Build from the Bottom-up	Not catered for in framework since the solution functions across the entire strategic level without creating hierarchy
Be Resourceful with material and energy	Use multi-functional design Use low energy processes Recycle all materials Fit form to function	Not catered for in framework explicitly since it encourages resource efficiency from a strategic level
Use life-friendly chemistry	Employ elegant processes Use a small subset of elements Do chemistry in and with water Break down into Benign and useful constituents	No explicit link with chemistry
Evolve to survive	Replicate strategies that work	Evidenced by the success of species and their performance in nature
	Integrate the unexpected	The sequential piecing of strategic elements considers adaptive traits that help with unpredictable environments
	Reshuffle Information	Unfortunately, not since the strategies are sequenced

The Life's Principles validation can be read alongside the sustainability pillars to clarify impact pathways. At the Stabilise & Simplify ring, strategies that "reduce drag before adding power" primarily drive economic efficiency (cycle-time and defect reduction), while simultaneously improving environmental performance by lowering material and energy intensity, and supporting social outcomes through safer, standardised work practices. At the Co-ordinate & Shape ring, coalition pilots and shared infrastructure enhance economic value via market-shaping and risk-sharing, strengthen environmental performance by avoiding duplicated assets and enabling higher utilisation, and advance social outcomes through partner inclusion, supplier development, and fair value splits. At the Adapt & Amplify ring, short learning cycles and modular scale-out foster economic resilience (risk-adjusted ROI across a portfolio of small

bets), improve environmental fit through local attunement and circularity measures, and reinforce social performance by embedding feedback loops with workers, partners, and communities. Representative indicators include: economic—resource productivity, cycle-time, partner retention, risk-adjusted ROI; environmental, material/energy intensity, waste diversion, emissions intensity; social—safety incident rate, knowledge-diffusion/learning participation, partner equity/retention.

This framework abstracts strategy principles from published behavioural observations; as such, it inherits the biases and gaps of the underlying literature (e.g., charismatic-species bias, uneven observational depth). Ecological functions are simplified to yield managerially useful principles; this risks over-generalisation outside wave-exposed or coastal operating contexts. The Whirlpool rings indicate sequencing logic but are not prescriptive and do not guarantee performance without local attunement. Finally, validation used Life's Principles as an alignment check rather than an outcomes evaluation; empirical testing in specific sectors and locations is required to quantify effect sizes across the economic, environmental, and social pillars.

5 IMPLICATIONS ON STRATEGY AND BIOMIMICRY

The findings from this research reveal an array of strategic elements which can be pieced together to build an effective and sustainable business strategy for an organisation. Nature serves as a model, measure and mentor [32]. This framework can cascade into mathematical or mental models which distil strategic elements into more actionable, specific methodologies, tools and techniques. It can be used to benchmark and set KPIs that speak to sustainable innovation. The strategies can serve as a mentor to other organisations, sites within the organisation or even industries.

Considering that these strategic elements have been formalised generically, the solutions appear non-specific to any sector within South Africa. Nevertheless, the findings and strategic elements are able to spur on sustainable innovation.

When revisiting the phrasing of systemsmimicry, Troncale [33], the manner of being nature sensitive to its interaction and response to its environment is emphasised. Despite the artefact from this research exploring sustainable innovation using South African marine life, systems mimicry could explore larger natural systems that mimic systemic behaviour and problem analogies that can be made with sustainability, innovation and sustainable innovation as distinct problem areas.

Considering that this research divulged strategic-level aspects from nature, future research could consider the lower business execution levels, namely, tactical and operational aspects from nature. Similar to the cascading application stream suggested Roopa, et al. [34] for a sustainable competitive advantage using industrial engineering and environmental sustainability knowledge, one could define a Biomimicry application stream with explicit forms of theory and practice within organisations.

One aspect not explicitly addressed was the prospect of frugal innovation, which is most commonly adopted in developing countries. Frugal innovations seek to make affordable solutions available for sustainable development by generating more value with fewer resources [35]. Nature can be resourceful, and so a noteworthy research avenue can explore the concept of frugal innovation within Biomimicry contexts.

6 CONCLUSIONS AND RECOMMENDATIONS

This study identified strategy-oriented traits from wave-adaptive South African aquatic species and abstracted them into a Whirlpool framework that sequences principles across Stabilise & Simplify, Co-ordinate & Shape, and Adapt & Amplify. In line with the research aim and

objectives, the work (i) contextualised the strategic challenge of sustainable innovation in developing-country settings, (ii) extracted strategy elements from documented behaviours using a transparent search and coding approach, (iii) designed a nature-inspired strategic framework, and (iv) validated its alignment with Life's Principles, highlighting strengths and explicit gaps. Practically, the framework offers a structured pathway to reduce resource intensity, improve co-ordination, and accelerate learning while remaining locally attuned.

Future work should focus on sector-specific pilots in South Africa that co-design indicators for each ring, quantify economic, environmental, and social outcomes, and iterate the framework using longitudinal feedback.

Industrial Engineers are not only future system-mimics, but masters of strategic time and space. Similar to the proposition of wave mastery, the Industrial Engineer is already seen as a master of integration, but now, too, may become a master of strategy.

ABSTRACT

Aftersales service centers hold significant profit potential for the automotive industry, yet this opportunity remains underutilized. This study investigates the role of facility design in optimizing aftersales service centers to enhance efficiency and profitability. A systematic literature review (SLR) was conducted to collect, analyze, and report on the key drivers and barriers influencing effective facility layouts in this sector. The findings highlight the advantages and limitations of various facility designs, showcasing case studies of successful implementations. By identifying best practices and critical success factors, this study provides valuable insights into optimizing spatial planning, workflow efficiency, and customer experience in aftersales service centers. The results contribute to the development of improved facility layouts, offering strategic guidance for future design considerations in the automotive aftersales industry. Ultimately, this research underscores the importance of facility design as a key enabler of operational excellence and revenue generation.

Keywords: Facilities design, SLR, Aftersales service centers, Automotive industry

1 INTRODUCTION

Aftersales service operations, although not the traditional primary service provided within the automotive industry, is still a major contribution to profitability. Essential maintenance, repairs and part replacements are done at aftersales service centres, with a goal to foster long-term customer relationships, leading to recurring revenue. Providing consistent quality services builds trust and loyalty between a dealership and a customer [14]. However, inefficiencies within these service centres can be detrimental to profitability and customer satisfaction.

Facility design is a key factor in the performance of aftersales service centres. A layout which is well designed can enhance productivity and improve workflow, while a poorly designed facility can lead to bottlenecks and wastage of time and space. Poor after-sales support can prevent companies from achieving a good customer satisfaction record and therefore growth [15].

Despite the recognised importance of facility design in manufacturing and service environments, there is a lack of research that specifically addresses aftersales service centres in the automotive sector. However, analysis will be done on existing literature available in this field, as well as research on facility layout optimization in related sectors. In doing so, this review will identify key drivers and barriers influencing key requirements of aftersales service centres.

Ultimately, this research seeks to provide valuable insights and strategic guidance for future facility design considerations in the automotive aftersales industry. The contribution of this literature review is to synthesize the fragmented research available on facility design in this sector, to create a framework for linking facility design concepts to operational requirements of automotive service centres, and to outline a research agenda as direction for future work.

2 RESEARCH METHODOLOGY

A Systematic Literature Review was conducted, to collect data in pursuit of achieving the research aim. The SLR method formulated by Albliwi et al [12], providing a step-by-step method to writing such a paper, was used as guidance for this SLR. These steps are summarised as follows:

- **Step 1: Develop a research purpose and/or objective** – Define the aim and focus of the SLR.
- **Step 2: Develop research protocol** – Create a research protocol defining the objectives of the SLR, criteria for the inclusion and exclusion of studies, databases, keywords and quality
- assessment criteria
- **Step 3: Establish relevance criteria** – Provided reasoning to decide whether a study is applicable or not.
- **Step 4: Search and retrieve the literature** – Find literature by searching on applicable databases.
- **Step 5: Selection of studies** – select studies based of the inclusion and exclusion criteria.
- **Step 6: Quality assessment for relevant studies** – Assess the quality of each paper
- **Step 7: Data extraction** – Extract relevant information from the papers
- **Step 8: Analysis and synthesis of findings** – Analyse and synthesise the data from the papers to find themes and patterns
- **Step 9: Report** – Report the review in detailed results
- **Step 10: Dissemination** – Publish the SLR

2.1 Step 1 - Develop a research purpose

The purpose of this research was to investigate the role of facility design in optimizing aftersales service centres

2.2 Step 2 – Develop a research protocol

Table 1 defines the research protocol used to search, select and assess existing research in literature relevant to facility design in aftersales service centres. Inclusion criteria, keywords and quality assessment criteria are defined.

Table 1Research review protocol (Structure adapted from Xiao et al. [13]

Purpose of the study	The purpose of this research was to investigate the role of facility design in optimizing aftersales service centres.
Inclusion criteria	• Literature that includes "automotive industry" or "service", and "facility layout" in the title, abstract or keywords. • Literature that explores the key drivers and barriers influencing • effective facility layouts in this sector
Exclusion criteria	• Literature published before 2015 (greater than 10 years old) • Non – English studies
Search databases	• Scopus • Science Direct • EBSCOhost • IEEE Xplore
Keywords	("facility layout" AND ("automotive industry" OR "service"))
Quality assessment criteria	• All duplicates removed • Literature must be relevant to automotive industry • Literature must be relevant to facility layout • Studies must be scientific

2.3 Step 3 - Establish relevance criteria

Studies specific to the facility design of aftersales service centres were not found, thus, to broaden the net and to ensure that studies are relevant to the aim, the following criteria was used:

- Literature that includes "automotive industry" or "service", and "facility design" in the title, abstract or keywords.
- Literature that explores the key drivers and barriers influencing effective facility layouts in this sector.
- Studies focusing on the facility layout or design of closely related service industries (e.g., heavy vehicle maintenance, equipment servicing).
- Research addressing the impact of facility design on operational efficiency, profitability, and/or customer experience
- Studies published before 2015 should be excluded.

2.4 Step 4 - Search and retrieve the literature

During step 4, the search and retrieval of literature was conducted using the databases

stipulated in Table 1, which resulted in a total of 151 papers. This is illustrated in the identification section of Figure 1.

2.5 Step 5 - Selection of studies

After the initial database searches and identification process, the retrieved papers were screened for relevance to the research purpose. Duplicates and non-English studies were removed, which left 135 papers in consideration. The titles and abstracts of each study were reviewed to assess alignment with facility layout design, production system design, and applications in service, repair, or aftersales environments. Due to very few articles being

relative to the automotive industry, many studies were removed – resulting in only 7 studies remaining. Even for studies within this industry, many were irrelevant to facility layout, due to their focus being on concepts not relevant to facility layout or aftersales services.

Many of the papers had words relating to healthcare within their titles or abstracts. These papers were omitted, as their content would not be relevant to the automotive industry. Furthermore, when reading the abstracts of certain papers, it became evident that their content would not be relevant, and these papers were omitted. The process of narrowing the number of studies down from 151 originally, to 7, is clearly illustrated in Figure 1, in which PRISMA guidelines are used to filter studies.

2.6 Step 6 - Quality assessment for relevant studies:

Each of the 7 selected studies were assessed using the quality criteria presented in Table 1 and met the requirements to be included as part of the SLR, as illustrated in Figure 1. All the studies included the keywords in the abstract. Furthermore, the studies were relevant to facility redesign and were deemed helpful in solving problems surrounding this subject. Although not all the selected studies were based within the automotive industry, their concepts were relevant to this SLR. Interestingly, the paper about a carpet manufacturer [7] provided key concepts to be referenced throughout this review. The studies selected were scientific and were all published journal papers.

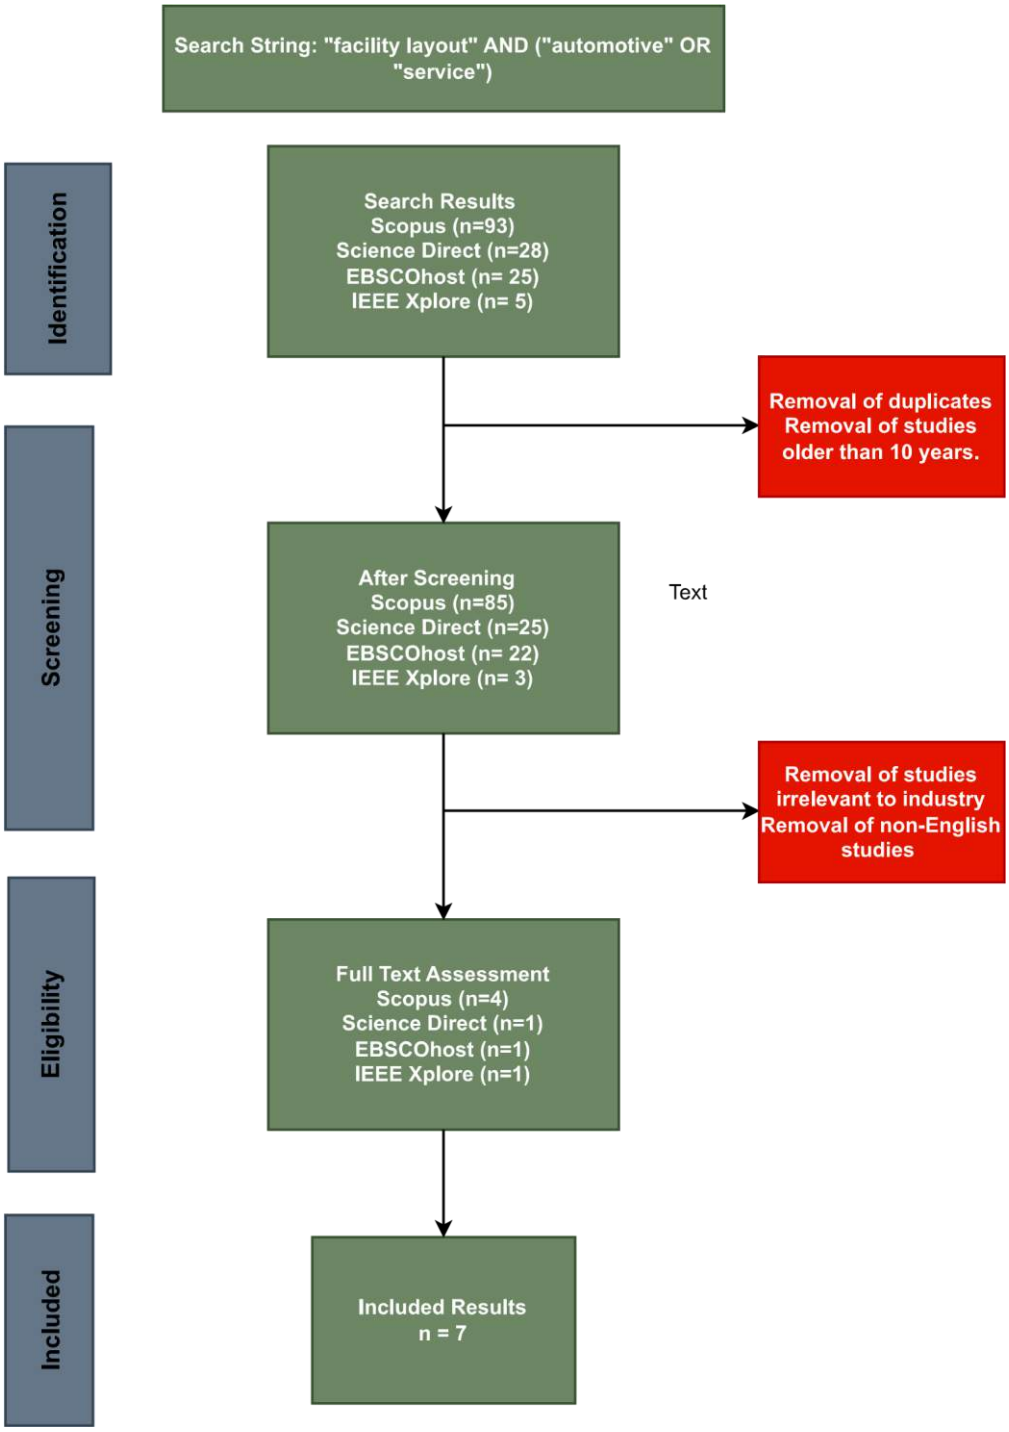

Figure 1 Selection process chart (As per PRISMA guidelines)

3 FINDINGS

3.1 Step 7: Data extraction

The list of studies to be included was finalised, and their full texts were studied in search of relevant concepts and data. In appendix A, the selected studies are shown, along with an indication of the data present in each study.

While not specifically based on the aftersales service centres, the studies are heavily centred around the automotive industry. This highlights the research gap in this field, and provides an opportunity for future research to fill this gap.

3.2 Step 8: Analysis and synthesis of findings

After the selected studies were read and analysed in full, and data was collected, the following was found:

3.2.1 Annual distribution of studies

The distribution indicates a slight increase in interest in recent years, particularly in 2023, which saw two studies published, possibly reflecting a renewed focus on advanced facility layouts due to increased digitization and post-COVID-19 operational re-evaluation.

The 2025 study, although futuristic in publication date, suggests the field remains active and is exploring cutting-edge approaches such as matrix manufacturing and Multi objective optimization techniques.

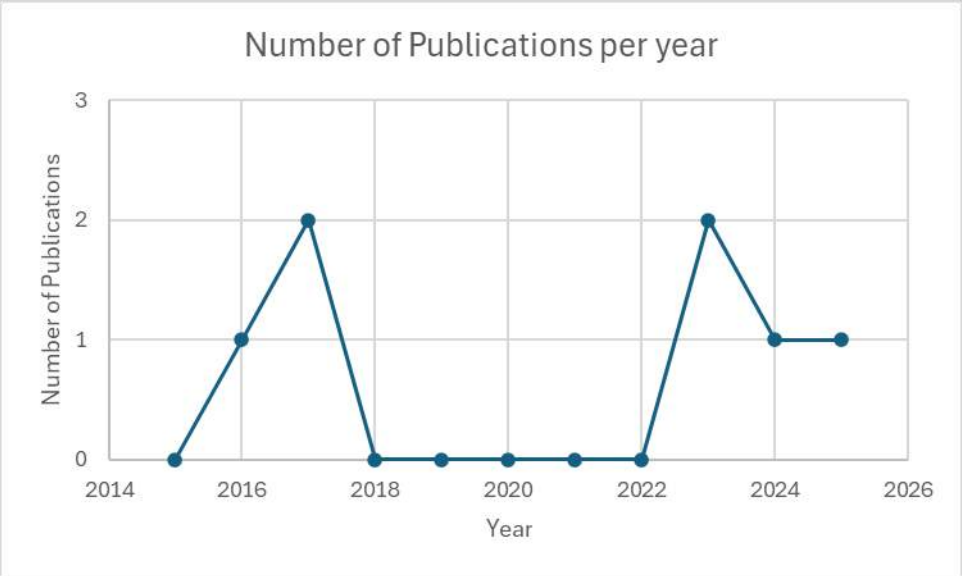

Figure 2 Annual distribution of studies

3.2.2 Facility layout concepts

The following concepts, derived from the selected papers, is relevant to facility design. Although the literature does not directly refer to aftersales environments, below is an explanation of how these concepts can affect aftersales service centre facility layouts:

- **Optimization techniques**
  Methodologies like Genetic Algorithms and Simulated Annealing, which have proven effective in optimizing manufacturing layouts, could be adapted to find efficient layouts for aftersales service centres. The primary focus of using optimization techniques is to measure the maximum or minimum value of a function depending on the circumstance [6]. In the context of an aftersales service centre, values to be

maximized include profit, operator efficiency, operator productivity, and capacity, while values such as costs, time wastage due to ineffective facility layout, and processing time should be minimized.
Such techniques can be used to identify the most suitable location for service bays, waiting areas, parts departments, and customer interaction zones within an aftersales service centre.

- **Simulation**
  Discrete event simulation, used to analyse and improve manufacturing processes by identifying bottlenecks and evaluating different layouts [11], can be applied to model the flow of vehicles and customers through a service centre, helping to optimize resource allocation and space utilization.
  Through simulation, key performance indicators such as waiting times, number of vehicles in WIP, total task times and utilization can be measured. In the context of aftersales service centres, such metrics apply directly when evaluating efficiency regarding vehicle flow, service bay utilization, and operator workload.
- **Systematic Layout Planning**
  The use of this methodology, created by Muther and Hales [9], provides a structured, step-by-step approach for developing efficient facility layouts. Through SLP, material flow with minimal handling will be emphasized, while from-to charts and activity relationship diagrams will assist in determining the desired proximity between departments.
  In the context of an aftersales service centre, Systematic Layout Planning will allow for optimized part- and tool flow between bays, and locations for departments, which include service bays, tolls, parts and reception areas, which will maximize productivity within the facility.
- **Importance of Flow and Adjacency**
  Throughout the selected studies, there is a common theme of emphasizing the importance of material flow and adjacency between different departments. The creation of a continuous flow is achieved by having a constant flow between processes. [9].
  In an aftersales service centre, a continuous flow from when the vehicle enters the facility, is repaired, has parts replaced, and any other actions performed on the vehicle until it departs the facility. A well-planned flow of vehicles, technicians and parts will increase efficiency.

3.2.3 Relation of layout types to aftersales service centres

Russel and Taylor [10], define the different types of facility layout types. In the selected literature, types like which are mentioned include multi-facility layouts, dynamic layouts, and collaborative layouts. In Table 2, all applicable layout types are compared by their ability to meet the key requirements of an aftersales service centre.

These columns were specifically chosen due to their alignment with the dominant facility configurations discussed in the reviewed literature, while discussing the operational dimensions most relevant to aftersales service environments. By comparing these requirements with the layout types, areas of alignment, as well as potential mismatches that warrant further research are identified.

Multi-facility layout is omitted from the table, as it is not relevant due to the assumption that aftersales service centres are operated at a single location.

Table 2 Concept relation to aftersales service centres

Layout Type	Reduces Turnaround Time	Enhances Customer Experience	Improves Space Utilization	Supports Flexibility
Dynamic	✓		✓	✓
Collaborative	✓	✓		✓
Cellular	✓		✓	✓
Functional		✓	✓	
Process		✓		
Fixed-Position				

3.2.4 Methods used

Majority of the methodologies discussed were computational approaches to facility layout optimization, namely Genetic Algorithms and Simulated Annealing. These methods are well-suited for solving complex layout problems involving multiple objectives and constraints, which are prevalent in aftersales service centres.

Additionally, multi-objective optimization techniques were also discussed – these methodologies are particularly useful when trade-offs must be made between competing factors like cost, space usage, and flow efficiency.

Simulation techniques were used in a minority of the papers, generally to validate or test the performance of a proposed layout in a controlled virtual environment. The use of simulation added value by allowing the researchers to test how layouts performed under varying demand conditions or process times.

Notably, no study applied hybrid methodologies that combine simulation and optimization in the same model. This represents an opportunity for future work, to improve realism and decision-making in layout problems that focus on service centres.

3.2.5 Barriers to effective facility layout in aftersales service centres

The various facility layout concepts discussed in the literature may provide limitations when applying these concepts in an aftersales service environment.

Firstly, the physical constraints found in service centres and different to those found in manufacturing plants. Layout changes may be restricted by architectural limitations, safety regulations, or legacy infrastructure. Unlike production lines, which are often housed in purpose-built industrial spaces, service centres must accommodate customer-facing functions, such as reception areas, waiting zones, and delivery bays. These factors provide a set of considerations which are different to manufacturing facilities.

Human interaction also plays a much larger role in service operations than in manufacturing. The flow of people (both customers and technicians), vehicles, and parts must be coordinated while maintaining a high level of service quality and safety. Layout changes that enhance efficiency must not compromise the customer experience or technician ergonomics.

Lastly, a high level of variability is prevalent within service tasks, due to vehicle condition and customer requests, which makes standardization more complex. For example, scheduling and space requirements may vary drastically between a routine service and a complex repair job. Dynamic or reconfigurable layouts offer adaptability but must be supported by real-time data and flexible work procedures to be truly effective in such contexts.

3.2.6 Key drivers affecting effective facility layout in aftersales service centres

The principles of facility design, when applied to automobile aftersales centres, must adjust its focus from manufacturing traditions like efficiency and utilization, and rather incorporate those with the added uncertainty, and as well as customer-facing operations that accompany service centres.

The minimization of material and workflow handling is a key priority. Service centres must manage the movement of vehicles, tools, parts and technicians, instead of solely raw materials and components. Travel distance between service bays, storage areas and even customer reception zones must be kept to a minimum – this drives the need for efficient facility layout. By doing so, the flow within the service centre can be streamlined, allowing for reduced turnaround times per vehicle – another key driver affecting facility layout.

Due to the high variance in different customer requirements, and even more so with the number of different vehicles and models, service centres must be flexible and must prepare for dynamic demand. Thus, modular layouts which can be reconfigured is a key consideration in such facility layout design. This would enable quick conversion of service bays into special lanes for special tasks, or the addition of extra workstations depending on demand, without much structural adjustment.

A factor which is unique to service centres, is the consideration of customer-facing requirements and zones. With the knowledge that the customer will likely see the service centre, the layout needs to create a positive perception within the customer's mind. Thus, reception areas should be accessible and comfortable and clearly, away from noisy work zones.

These drivers must be taken into consideration when designing the facility layout of aftersales service centres.

4 FRAMEWORK AND FUTURE RESEARCH AGENDA

The framework in Figure 2 was developed to consolidate the findings from the literature, while providing a structured guide for facility layout development in aftersales service centres. Key layout concepts, aftersales service centre requirements, and corresponding layout types identified throughout the review are connected and their interactions are displayed visually.

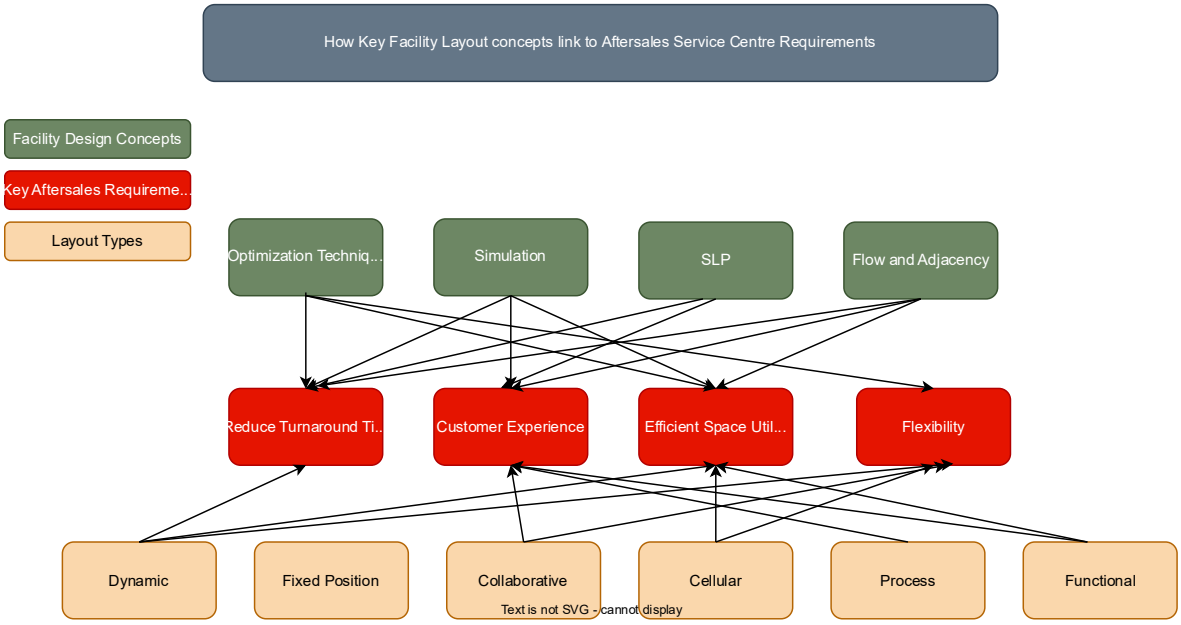

Figure 2 Framework

4.1 Framework

This framework visualizes the key facility design concepts derived from the literature and portrays how these concepts support critical aftersales service centre requirements. In turn, the requirements of an aftersales service centre play a role in the choice of layout type, and the relationships between those concepts are also portrayed.

Figure 2 is a visual representation of how both theoretical and practical insights can be integrated in such facility design processes. The arrows in the figure indicate linkages between the extracted concepts such as simulation, optimisation, etc, and the identified operational requirements of aftersales centres.

Clearer decision-making during design or redesign stages is made possible, by mapping theoretical principles such as simulation, optimization techniques, Systemic Layout Planning and flow principles to requirements vital to aftersales service centres, which include reduced turnaround time, customer experience, space utilization and flexibility.

Furthermore, arrows are also used to indicate the relatedness of these requirements to existing layout types shows the adaptability of these layout types (e.g. dynamic, cellular, etc.) based on the needs of such service environments. These linkages highlight how a particular facility layout approach can address the targeted performance requirements.

Ultimately, the framework bridges the gap between literature and application in the field of facility design, specifically for aftersales service centres.

4.2 Future Research Agenda

Several opportunities for furthering research on facility design in automotive aftersales service centres are introduced and highlighted through this review.

Areas that lack studies in this field include the integration of digital technology and Industry 4.0 tools, the consideration of customer-centric design approaches, and empirical studies in real-world contexts, instead of conceptual or simulation-based research.

This research areas identified provide a roadmap for bridging current gaps in the literature, to ensure that facility design contributes to profitability in the aftersales service sector.

5 CONCLUSION

This Systematic Literature Review set out to investigate existing literature relevant to the role of facility design in aftersales service centres, and how this can affect profitability. Although resources already available specifically applicable to this topic, through this review, it was evident that existing facility layout concepts, many from other fields, are relevant to aftersales service centres.

Considering the key requirements within aftersales service centres, which include the need for reduced turnaround time, improved customer experience, flexibility, and efficient space utilization, existing methods often used in facility redesign can address this. These methods include simulation, SLP and optimization techniques. In addition to these methods, facility layout types were compared and linked to the needs of aftersales service centres. All the abovementioned concepts, requirements and layout types are integrated into a framework which can assist as a basis for the redesign of aftersales service centre layouts.

This research contributed to closing the research gap within this niche and allows for further exploration, to ultimately show how improved facility layout of aftersales service centres can be key to profitability.

ABSTRACT

Aftersales service centres present a significant yet underutilised profit opportunity for the automotive industry. However, the physical demands of service centre tasks may have long-term effects on employee health and performance. Despite this, targeted ergonomic research in automotive aftersales environments remains limited. This study conducts a systematic literature review (SLR) to examine ergonomic practices across service-intensive industries, identifying transferable strategies that address physical strain and operational inefficiencies. The findings highlight the benefits and limitations of ergonomic interventions, identifying key tools and concepts applied across various studies. Drawing from this synthesis, the study proposes a conceptual framework for aftersales service centres, offering guidance for future empirical research and practical implementation. Ultimately, the research highlights the critical role of ergonomics in enhancing workforce sustainability and unlocking operational value in the automotive aftersales sector.

Keywords: Aftersales service center, Automotive industry, SLR, Ergonomics

1 INTRODUCTION

The automotive industry includes vehicle and component manufacturing and retail. Automotive retail includes vehicle and parts sales and the aftersales service market. The after-sales service industry is a key aspect of the automotive industry. It provides repair and maintenance for a product after purchase. Therefore, it is an essential factor in relation to the brand's reputation. This drives the industry to be customer-focused, prioritising customer satisfaction and retention. A brand with satisfied customers is more likely to maintain loyalty to a product with which they have a positive experience. This enhances the brand or company's competitiveness, subsequently impacting their profit [1].

Vehicle servicing includes various activities related to the car. Although tools and equipment have advanced, technicians still perform tasks that require repetitive motions, awkward posture, and sustained effort. Consequently, the physical and mental effort creates a labour-intensive environment, often affecting the efficiency and well-being of the employees. This is where the principles of ergonomics become relevant, as companies recognise that the human factor in operations is essential for prosperity. Literature often refers to ergonomics as human factor engineering and human-systems integration[2].

Ergonomics intends to fit the work environment to the capabilities of humans [2, 3]. Therefore, to drive comfort in the workplace, organisations must optimise the interaction between the human and the system.

This study investigates ergonomic interventions employed in physically demanding work sectors. It examines activities relevant to the automotive service sector and evaluates the benefits and drawbacks of these interventions. Finally, the ergonomic tools and concepts from the literature will guide the research's objectives.

2 RESEARCH METHODOLOGY

The research methodology follows the steps below to reach the goal of the systematic literature review (SLR) [4].

Step 1: Develop a research purpose and/or objective – The goal of the SLR must be stated

- **Step 2: Develop research protocol -** A research protocol must be created that incorporates the purpose, inclusion and exclusion criteria, search databases, keywords and quality assessment criteria
- **Step 3: Establish relevance criteria -** Give reasons for what makes a resource relevant to your study
- **Step 4: Search and retrieve the literature** – Search scientific databases to find the relevant literature
- **Step 5: Selection of studies** – Utilise the inclusion and exclusion criteria
- **Step 6: Quality assessment for relevant studies** – Evaluate the quality of each resource
- **Step 7: Data extraction** – Relevant data to be extracted from the resources
- **Step 8: Analysis and synthesis of findings** – Analyse and synthesise the data to find common patterns and themes
- **Step 9: Report** – Provide a review of detailed results
- **Step 10: Dissemination** – Produce the SLR

2.1 Step 1 - Develop a research purpose

The purpose of this research was to collect and report on the literature about the benefits and limitations of ergonomic interventions, identifying key tools and concepts.

2.2 Step 2 - Develop a research protocol

A research protocol, table 1, is designed to guide the review process, consequently achieving the desired outcome.

Table 1: Research review protocol

Purpose of the study	• To collect and record available literature on the benefits and limitations of ergonomic interventions, identifying key tools and concepts applied across various studies.
Inclusion criteria	• Literature that contains "Ergonomics" and "Service" in the title, abstract or keywords. • Literature that discusses the benefits and limitations of ergonomic interventions, identifying key tools and concepts.
Exclusion criteria	• Non-English studies • Ergonomic concepts are not transferable to the automation service industry, as they may be too industry/domain/task specific.
Search databases	• Scopus
Keywords	• "Ergonomics" AND "service"
Quality assessment criteria	• Duplicate resources must be removed. • Check if the literature is relevant. • Check if the literature conveys ergonomic principles correctly. • Studies must be scientific • Studies must have transparent data collection.

2.3 Step 3 - Establish relevance criteria

Ergonomics in the aftersales service sector is unique, and the relevance criteria will cater to this area of literature:

- Literature that contains "Ergonomics" and "Service" in the title, abstract or keywords.
- Literature that discusses the benefits and limitations of ergonomic interventions, identifying key tools and concepts.
- Non-English studies must be excluded.
- Literature where the ergonomic concepts are not transferable to the automation service industry, as it may be too industry/domain/task specific.

2.4 Step 4 - Search and retrieve the literature

Initially, this study used four databases: Science Direct, Web of Science, Emerald Insight and Scopus. The keywords did not provide sufficient results on Science Direct, Web of Science, and Emerald Insight, however, Scopus provided an abundant amount. It was decided that Scopus alone would be the main database. We searched using the keywords, "Ergonomics" and "Service" in the title, abstract or keywords. It resulted in 3645 documents. Filters were then applied to reduce the results to a manageable number. Included filters: Year: 2015-2025; Document Type: Conference Document, Review and Article; Study Field: Engineering and Social Studies; Language: English; Keywords: Ergonomics. This resulted in 767 documents that will undergo the screening process. Figure 1 below illustrates this in the identification process.

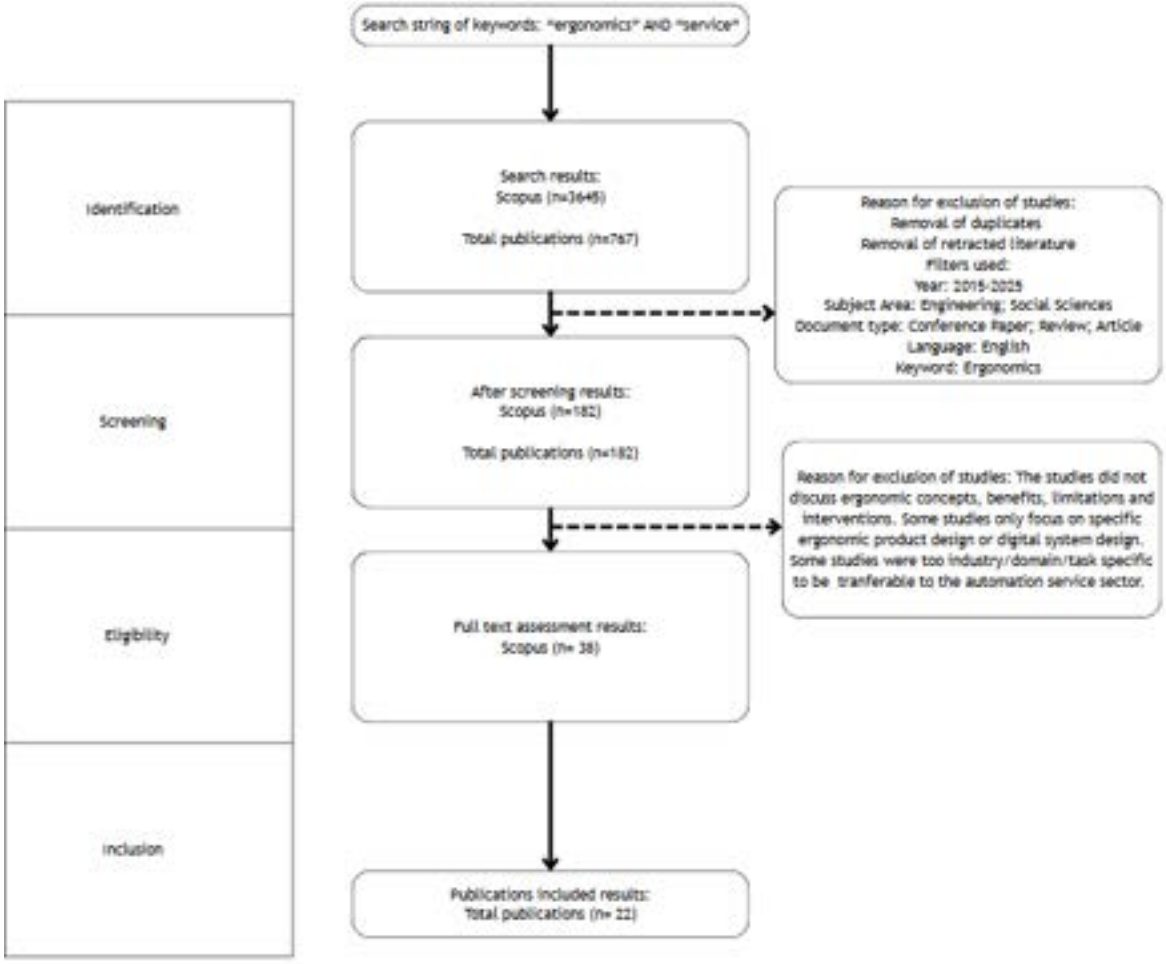

Figure 1: PRISMA guidelines

2.5 Step 5 - Selection of studies

The screening process removed duplicates and retracted documents. The authors selected literature if the title and abstract included relevant terms indicating the benefits and limitations of ergonomic interventions, as well as identified key tools and concepts. Any literature with ergonomics as the focus in the title. This resulted in 182 documents advancing to the eligibility stage. Next, a full-text assessment occurred. We excluded literature that only focused on specific ergonomic product design or digital system design. The authors also excluded any literature that was too industry/domain/task specific to be transferable to the automation service sector. Figure 1 illustrates the 38 eligible studies that are fit for inclusion.

2.6 Step 6 - Quality assessment for relevant studies:

The authors assessed the 38 studies according to the quality assessment criteria presented in Table 1. We removed duplicate resources and verified the relevance of the literature. We also analysed the literature to ensure the accurate representation of ergonomic principles and ideas. Finally, the studies must be scientific and convey transparent data collection. Figure 1 illustrates that only 22 studies met the requirements and will be included in the SLR.

3 FINDINGS

Steps 7 and 8 follow below. The findings will be described through the data extraction, analysis, and synthesis.

3.1 Step 7: Data extraction

Appendix A illustrates the table of papers. The table shows the data that the literature discusses, and in the specific industry it took place. The table displays a mixture of industries. Although most of the data is not automotive service-specific, the ideas found were transferable to this industry. However, the health industry is a very prominent sector for ergonomics, followed by manufacturing. This shows the research gap of ergonomic studies in the automotive service sector and motivates the opportunity for future research.

3.2 Step 8: Analysis and synthesis of findings

The following subsections discuss the analysis and synthesis of the included literature.

3.2.1 Number of publications annually

The graph in Figure 2 displays annual publications. It is apparent that in 2020, the most publications were made. The decline after 2020 could be attributed to the COVID-19 pandemic, as researchers could not collect data in 2020 itself. However, we see an increase towards 2025, hopefully meaning a recovery in research activity.

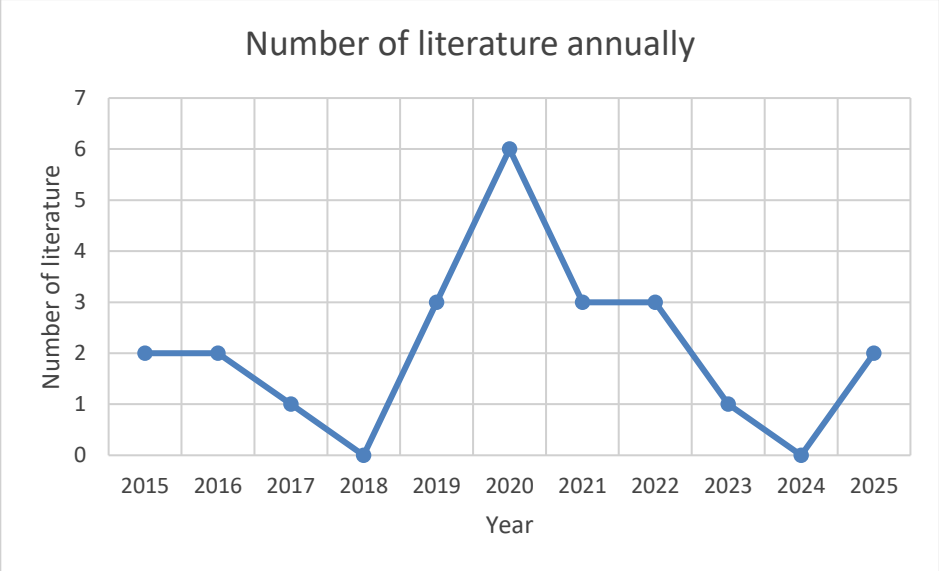

Figure 2: Graph of annual publications

3.2.2 Keywords

Figure 3 illustrates a word cloud of all the keywords from the eligible and included literature. The most frequently used word is “Ergonomic”, indicating the research aim of the SLR. Following this are musculoskeletal, occupational disorder, risk, assessment, safety, manual handling, training, and lifting. These words represent typical ergonomic language. A crucial aspect of ergonomics is occupational health and work-related musculoskeletal disorders. Ergonomic concepts offer stakeholders solutions that enhance their health and safety. Researchers generally evaluate this through risk assessments and other tools. Practitioners employ ergonomic tools to address organisational practices through interventions. Training is

also a common approach as it enhances stakeholders' knowledge regarding ergonomics in the workplace.

Figure 3: Keywords word cloud

3.2.3 Ergonomic theme: Intervention types

Figure 4 illustrates that each study used specific intervention types as the main intervention. The most commonly used ergonomic intervention is workplace and workstation redesign. However, studies usually apply multiple interventions simultaneously. Training programs are also prevalent, regardless of the lack of evidence, as they may be the most inexpensive option. Digital tools are used less frequently since they may be too expensive to implement and require expertise.

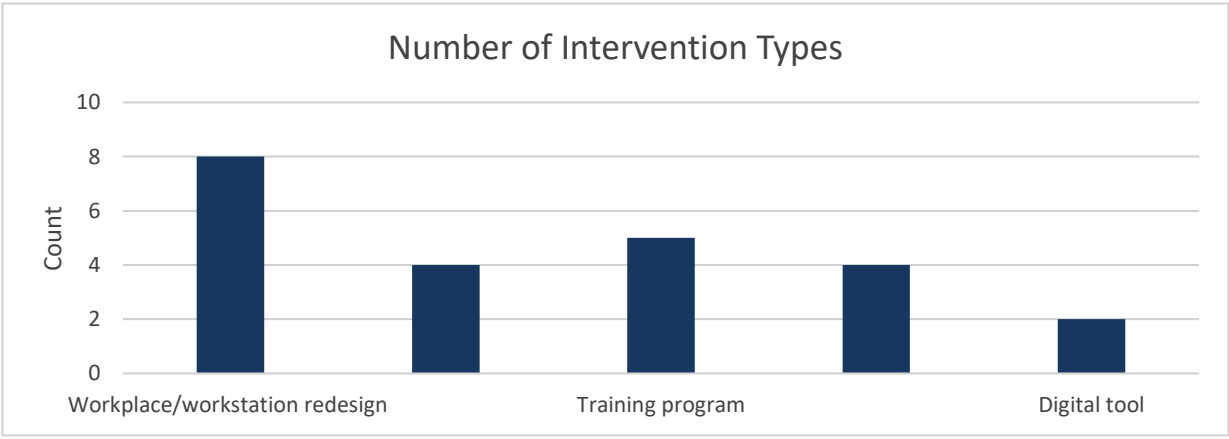

Figure 4: Number of Intervention Types

3.2.4 Ergonomic tools and concepts

Table 2 showcases the ergonomic tools and methods used in the studies. Researchers employed each ergonomic tool, which is either an observational method, a direct measurement, or computer-based. Table 2 displays the various applications and key features of each tool. Many studies utilised the Rapid Upper Limb Assessment (RULA), Rapid Entire Body Assessment (REBA), and NIOSH Lifting Equation. Additionally, numerous studies incorporated surveys to

gather subjective data for evaluating ergonomic risk factors. A notable ergonomic tool that was prevalent is the use of surface electromyography (sEMG), which is a direct method of measurement for muscle fatigue, activation and recovery. Multiple studies featured simulation software , highlighting its relevance and practical value. Furthermore, it is clear that each study employed multiple ergonomic tools to assess the workplace or specific tasks.

Table 2: Ergonomic tools

Ergonomic tool/Method	**Type (Observational; Direct measurement; Computer-based)**	**Application**	**Key Features**	**Study using the tool**
Rapid Upper-Limb Assessment (RULA)	Observational checklist	Upper limb tasks	Upper extremity evaluation	[5], [6],[7],[8]
Rapid Entire Body Assessment (REBA)	Observational checklist	Manual material handling	Whole body posture evaluation	[5], [9],[10], [7],[8],[11]
NIOSH Lifting Equation	Direct calculation/checklist	Manual lifting tasks	Recommended Weight Limit for lifting tasks	[5],[10],[12], [11]
Ovako Working Posture Analysis System (OWAS)	Observational checklist	Work tasks	Posture evaluation	[7]
Nordic Musculoskeletal Questionnaire (NMQ)	Observational (subjective checklist)	Any industry	Questionnaire for body part pain/discomfort/duration/location	[5],[13]
Maynard Operation Sequence Technique (MOST)	Direct measurement	Repetitive tasks	Pre-determined time standards are used to predict operation duration	[14]
Methods-Time Measurement (MTM)	Direct measurement	Complex task/non-repetitive	Task motions breakdown to set standard task times	[6]
Posture checklist	Observational checklist	Work tasks	Checklist for optimal posture	[14]
Surface electromyography (sEMG)	Direct measurement	Manual tasks	Measurement of muscle electrical activity (muscle activation/fatigue/recover)	[15],[16],[12],[17]
ILO/IEA Ergonomic Checkpoints tool/Hazard assessment	Observational checklist	Any industry	Whole workplace evaluation and solutions	[18, 19]

NASA-TLS (Task Load Index)	Observational checklist (subjective questionnaire)	Any industry, task-based	Perceived workload demand (mental, physical, temporal, frustration, performance, effort)	[11]
Virtual Element Method (VEM) for posture modelling	Computer based	Manufacturing (can be adapted to any industry)	Modelling; analysis; optimisation	[9]
Rodgers Muscle Fatigue Analysis	Observational checklist	Repetitive tasks	Risk for muscle fatigue evaluation	[7]
Moore and Garg method (strain index)	Observational checklist	Task-based	Distal upper extremities evaluation (wrist, hand, elbow)	[7]
3D Static Strength Prediction Program™ (3DSSPP) model biomechanical	Computer-based	Manual tasks	Predicts static strength requirements for tasks	[20]
Other simulation software (Jack)	Computer-based	Manual tasks/operations	Human-modelling for biomechanical loads (spinal loads)	[10]
3d motion capture (VICON)	Computer-based	Manual operations	Analysis of movement	[16]
Borg scale	Observational checklist (subjective)	Manual operations	Perceived exertion	[16],[10]
3d modelling (Sketchup pro)	Computer-based	Any industry	Visualisation of the workplace	[19]
Sensor network	Computer-based	Work tasks	Step tracking and ergonomic monitoring of movement and posture	[6]
Cost/benefit analysis	Direct measurements	Any industry	Ergonomic intervention justification	[14]
Adapted surveys	Observational checklist(subjective)	Any industry	Extracting subjective worker data	[21],[13],[8],[22],[11],[20],[23],[24]

Cause-and-effect diagram	Observational	Any industry	Root cause analysis of ergonomic risks	[8]

Concepts

The review of included studies revealed the core concepts of ergonomics. The most prevalent concepts related to posture and its impact on musculoskeletal disorders (MSDs)/pain/discomfort/injury. Therefore, researchers addressed risk factors commonly associated with awkward postures. Several studies linked manual material handling risks, such as repetitive tasks and lifting, to an increased incidence of MSDs [25].

Closely related to posture is the concept of workstation or task design. Workspace design would consider the anthropometric dimensions of the working population to implement ergonomic changes. Principles such as reachability, which ensures that tools and equipment are placed within a comfortable range to minimise awkward postures [19]. Additionally, ensure the layout has enough space for body movement and equipment operation. Researchers often explored these ideas with office ergonomics and manual material handling, where a poorly designed workstation increased the risk for injury and caused bad posture.

Many studies frequently used participatory ergonomics. The focus of engaging the workers seemed to motivate them to adapt to ergonomic changes or recommendations [26]. Here, researchers frequently applied safety-related concepts. Oakman, et al. [27] discuss the novel application of the Stage of Change (SOC) participatory ergonomics approach, which includes readiness to change. SOC shows how effective the implementation of the change will be.

Ideas like workload, fatigue and productivity were interrelated topics. Suokko, et al. [14] concluded that continuous ergonomic development decreased physical workload and simultaneously increased productivity. Ergonomic task development lessens fatigue, thus doing work more efficiently. Therefore, the well-being of the worker improved. Psychosocial factors like stress improved through sustainable ergonomic implementation, and also led to increased productivity[8].

3.2.5 Benefits of the interventions

All the studies in the systematic literature review (SLR) reported the following benefits. Table 3 highlights the benefits of the interventions that researchers employed in the studies. The implementation of interventions such as workplace, workstation, or task redesign, assistive devices, or digital tools offers advantages that enhance the physical effects of the tasks that workers perform. The interventions that decrease fatigue and discomfort often lead to the improvement of productivity and performance of workers. Experts recommend that these interventions be implemented, as they provide substantial results. Meanwhile, training and participatory ergonomics primarily increase ergonomic awareness and engagement. Participatory ergonomics introduces actionable improvements and increases the adoption rate. The implementation of various interventions will lead to multifaceted improvements.

Table 3: Intervention benefits

Workplace/workstation/task redesign	Reduction in MSD risks Healthier physical ergonomics Increased performance and productivity Decreased spinal loads Lower cognitive workload Reduced postural strain Reduction of perceived discomfort Reduction in muscle strain/activity Reduction in fatigue
Assistive devices	Reduction in manual lifting and pushing forces Reduction of musculoskeletal strain/risk Improved safety Increased productivity Reduction in fatigue Reduction in postural risks Reduce peak spine shear forces Reduction of strain
Digital Tools	Virtual Element Method (VEM): Real-time feedback for postural/behaviour correction Sensor networks for step tracking: Real-time ergonomic feedback
Training programs/Posture program/Stretch program	Promotes ergonomic practice sustainability Promotes a safety culture Increase ergonomic knowledge Increased productivity Promotes behaviour change Increased flexibility Strengthens posture Promotes teamwork Increased managerial support
Participatory ergonomics	Promotes worker engagement Promotes management engagement Promotes ergonomic awareness Higher adoption rate Promotes low-cost solutions/practical improvements Increases focus on priority areas needing ergonomic improvement Actionable improvement suggestions Increases self-initiated improvements

3.2.6 Limitations of the interventions

All the studies in the systematic literature review (SLR) reported the following limitations. Table 4 highlights the limitations of the interventions that researchers applied in the studies. The most prevalent limitations were concerns regarding the generalisability of the interventions and the cost of implementing them. Additionally, some interventions lacked long-term validation, which affects their credibility. The training of ergonomic practices revealed a potential lack of implementation. Practitioners should implement training alongside other strategies to enhance effectiveness. The studies showed that management and organisational readiness can pose a barrier to the implementation of interventions. Therefore, one of the main challenges in introducing interventions is the need to convince stakeholders to change existing practices.

Table 4: Intervention limitations

Workplace/workstation/task redesign	Convincing management of ergonomic practices Resistance to change Inconsistent implementation

	Lack of continuous development is less beneficial Some practices are not generalisable Budget/feasibility constraints Some practices lack long-term validation
Assistive devices	Cost/feasibility constraints Requires workforce training Accessibility Generalisability Task-specificity
Digital tools	Generalisability Specific technology needed Long-term validation needed
Training programs/Posture program/Stretch program	Training lacks task/work context Lacks generalisability Lacks scientific evidence of effectiveness on injury/discomfort reduction Lacks integration with the organisation Cost/time Incentive programs may influence injury reports Work variability makes a standardised program difficult Reliance on perceived/self-reported discomfort Additional intervention necessary
Participatory ergonomics	Ego/pride issues Inconsistent implementation Limited generalisability Management considerations Organisational readiness

4 FRAMEWORK

This systematic literature review (SLR) discusses the findings that offer a foundational framework for conducting ergonomic assessments and interventions. Although the studies did not focus on automotive after-sales service, the utilisation of ergonomic tools and methods applies to this service industry. Practitioners in this industry can follow the framework to achieve the necessary outcomes. The framework offers a conceptual pathway for automotive service centres to assess ergonomic risks and implement improvements. Although empirical validation in this specific domain is necessary, the tools and strategies presented are based on evidence from comparable service environments.

As illustrated in Figure 5, the process involves evaluating the interaction between the workplace and the worker, utilising ergonomic tools, and identifying appropriate interventions to enhance worker well-being. The process begins with the identification of ergonomic risk factors, which may span across physical, environmental, and organisational domains. Researchers employ various ergonomic assessment tools and methods to verify and quantify these risks. As shown in Table 2, practitioners select these tools based on the nature of the tasks under analysis. Researchers use multiple tools to generate comprehensive and reliable data. The data provides evidence for change and the root cause of risks. Following the assessment phase, practitioners select, design and implement suitable interventions. The benefits and limitations mentioned in Tables 3 and 4 can guide the interventions, which help clarify potential outcomes. The studies broadly define the mentioned interventions and will require further refinement based on specific tasks or workplace context. Ultimately, the goal of these interventions is to achieve various outcomes pertinent to the health, safety and overall performance of the workers. Reducing the pain and discomfort of the worker will lead to a reduction in musculoskeletal disorders and fatigue, which in turn increases productivity and morale. These are merely some of the potential results.

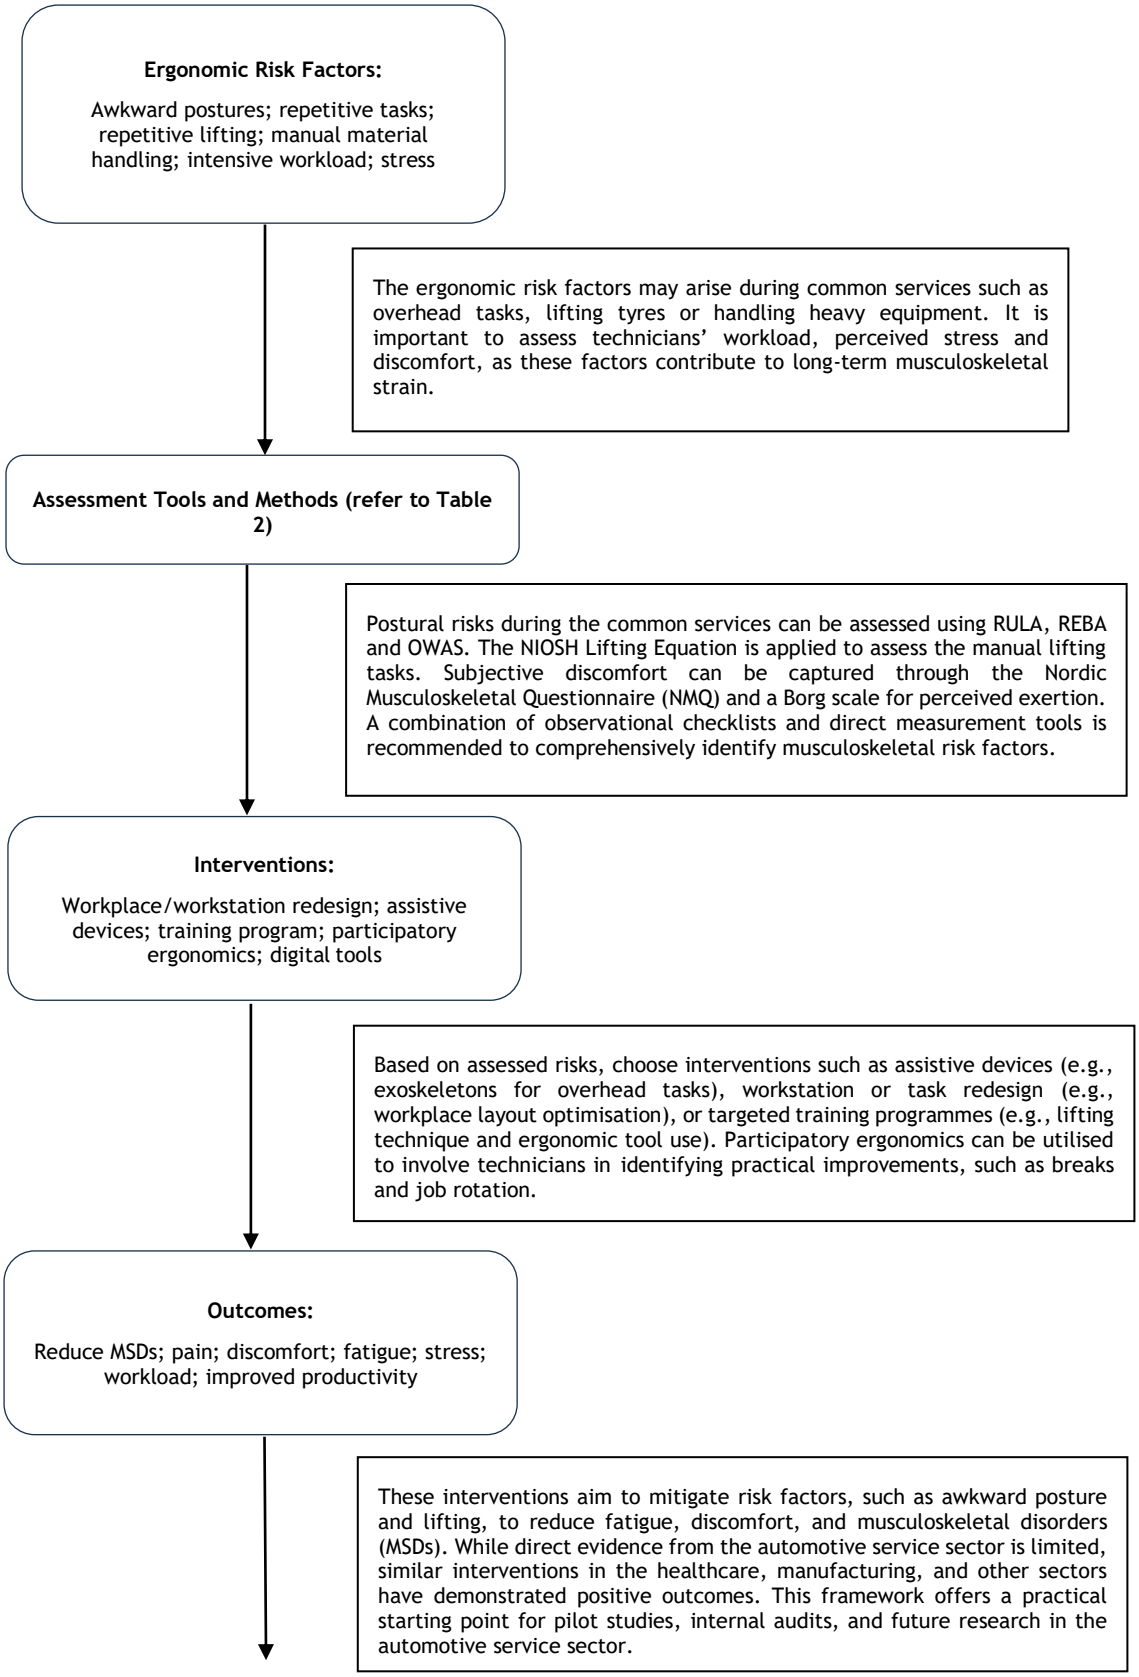

Figure 5: Ergonomic Assessment Framework

5 CONCLUSION

This review synthesises transferable ergonomic practices from broader sectors because of the limited availability of literature on ergonomic studies specific to automotive after-sales service centres. The proposed framework provides a conceptual guide for researchers and practitioners to evaluate and enhance the ergonomic conditions of automotive service environments, particularly emphasising the key gaps and opportunities for future empirical validation.

This review sought to synthesise existing evidence regarding ergonomic interventions for manual material handling to identify effective strategies and gaps in the literature. The results continue to emphasise the significance of posture, workstation design, and participatory ergonomics in mitigating the risks associated with musculoskeletal disorders. Training initiatives alone showed limited effectiveness if not integrated with other interventions; however, they did improve ergonomic knowledge and participation. This review highlights the need for complex ergonomic interventions that include technical, organisational, and behavioural elements by combining evidence from diverse industries. It establishes a foundation for more comprehensive ergonomic initiatives in the workplace. Few studies provided scientifically-based proof of improvement and instead utilised perceived discomfort as evidence. Studies also lacked long-term follow-up of health. Notably, there was a shortage of studies incorporating both physical and psychosocial factors, particularly in the automotive service sector. Future studies should include physical and psychosocial factors in evaluations, and scientific tools should be employed to measure the outcomes of interventions. Additionally, more studies are necessary within the automotive service sector. This systematic review offers vital insights to those aiming to improve workplace ergonomics and reduce musculoskeletal disorders, thereby contributing to increased productivity and healthier, safer work environments. The systematic literature review provided a guideline for the design of a framework. The framework follows the steps to analyse the risk factors using ergonomic tools. The interventions are then selected, designed and implemented to improve the health and safety of workers.

Appendix A

Title	Authors and year	Intervention type	Ergonomic tools/Methods used	Measured outcomes	Industry	Reference
Identifying ergonomics practices currently used by grocery distribution centers	Lavender et al. (2025)	Workplace; Organisational	Participatory ergonomics; Ergonomic practice checklist	Self-reported use of practices; perceived success in reducing MSDs	Grocery distribution centers	[18]
Productivity and employee well-being in manufacturing process development – Comparison study of two departments	Suokko et al. (2025)	Workplace/workstation redesign (continuous ergo development)	Maynard Operation Sequence Technique (MOST); Workload analysis via video recording; posture checklist; cost-benefit analysis; productivity metrics(macro and micro ergo frameworks)	Standard times from MOST; perceived discomfort; workload measurements; cost	Manufacturing	[14]
A Feasibility Study on the Conversion from Manual to Semi-Automatic Material Handling in an Oil and Gas Service Company	Saptari et al. (2023)	Technological intervention (Physical task design; equipment redesign; workflow improvement)	REBA/RULA/NIOSH lifting equation/ Nordic Body Map	Ergonomic risk scores improved with the proposed system; Demonstrated acceptability and practicality of transition to semi-automation	Oil and gas service company warehouse	[5]
A Virtual Element-Based Postural Optimization Method for Improved Ergonomics During Human-Robot Collaboration	Makrini et al. (2022)	Digital ergonomics intervention using real-time postural optimisation (task-level)	Virtual Element Method (VEM) for posture modelling; Real-time posture feedback interface; REBA for ergonomic risk scoring	Positive user perception; Quantified improvements in posture (ergonomic load reduced); Demonstrated feasibility in polishing task with cobot	Manufacturing	[9]
The Effect of an Active Upper-Limb Exoskeleton on Metabolic Parameters and Muscle Activity during a Repetitive Industrial Task	Blanco et al. (2022)	Assistive devices	Electromyography; Heart rate and oxygen consumption measurements; heart rate variability (HRV)	Reduce oxygen consumption; reduce muscle activity	Industrial	[15]
Chronic lower back pain in aquaculture clam farmers: adoption and feasibility of self-management strategies introduced using a rapid	Dunleavy et al. (2022)	Participatory ergonomics with rapid prototyping of self-management strategies	Surveys; Video demonstrations, team discussions, weekly reminders, patient-specific functional scale (PSFS), Oswestry Disability Index (ODI), focus groups	Decreased lower back pain; Increased productivity	Clam farmers	[26]

prototype participatory ergonomic approach						
Wrapping technique and wrapping height interact to modify physical exposures during manual pallet wrapping	Maciukiewicz et al. (2021)	Assistive device (novel)	Surface electromyography (sEMG) 3D motion capture (VICON) Borg scale for perceived exertion/discomfort Analysis of posture, muscle activation, and ergonomic risk	Muscle activity (sEMG) of the shoulder and back muscles. Kinematic data (posture/angles) of torso and upper extremity. Ratings of perceived discomfort and exertion (Borg scale).	Industrial	[16]
Improving Working Conditions Using the Ergonomic Checkpoints Tool: Application in a Colombian Meat Processing Plant	Pérez et al. (2021)	Participatory ergonomics	ILO/IEA Ergonomic Checkpoints tool 3D modelling for workstation redesign Participatory approach involving workers	Identification of 24 checkpoints requiring improvement (17 prioritised) Engineering and organisational solutions developed and modelled	Industrial	[19]
A cross-sectional survey of musculoskeletal disorder hazard exposures and self-reported discomfort among on-shore wind turbine service technicians	Fischer et al. (2021)	Participatory ergonomics (ergonomic design improvements)	Uses a structured MSD hazard survey tool adapted from the Ontario Worker Discomfort survey, Perceived Exertion Survey, and Staff Feedback Survey; Promotes ergonomics-informed tool design, workstation layout, and task redesign	Data from the hazard survey	Wind turbine service technicians	[21]
Human-oriented maintenance and disassembly in sustainable manufacturing	Siew et al. (2020)	Work design	Sensor networks for step tracking; MTM; modified RULA Real-time ergonomic feedback Mathematical modelling of ergonomic factors Human-computer interaction	Outcomes provided are the task tracking data that suggest improved ergonomic movement sequences.	Manufacturing	[6]
Paramedic equipment bags: How their position during out-of-hospital cardiopulmonary resuscitation (CPR) affect paramedic ergonomics and performance	Harari et al. (2020)	Work design	Simulation (jack); REBA (Rapid Entire Body Assessment); CPR performance metrics; Borg scale; NIOSH	Equipment position significantly influenced both physical ergonomics and CPR performance - Supports redesign of field procedures and training setups; Spinal loads using Jack	Paramedics	[10]

Safety Voice for Ergonomics (SAVE): Evaluation of a masonry apprenticeship training program	Hess et al. (2020)	Training program	Structured ergonomics training tool (SAVE); Modified Nordic Questionnaire (MNQ); Questionnaire	No change in MNQ after training; Increase safety voice use (speak up), safety participation and ergonomic practices, safety compliance and communications of hazards, and ergonomic knowledge scores	Masonry	[13]
Questioning the value of manual material handling training: a scoping and critical literature review	Denis et al. (2020)	Training program	Manual Material Handling Training (MMHT) analysed; Scoping review of 77 studies (from 5 meta-analyses, 2007–2019)	Effectiveness of MMHT in reducing musculoskeletal injuries and improving safe handling behaviours; Content and structure of training programs; Training limitations and improvements to be made	Multiple	[25]
The implementation of digital ergonomics modeling to design a human-friendly working process in a postal branch	Drašković et al. (2020)	Workstation redesign	Ergo Fellow software suite: Rapid Upper Limb Assessment (RULA); Rapid Entire Body Assessment (REBA); Ovako Working Posture Analysis System (OWAS); Moore and Garg method; Suzanne Rodgers method; Visual observation and video analysis of tasks; Literature review of ergonomic risk and posture standards	Ergonomic risk scores for each workstation/task; Identification of high-risk postures and tasks (e.g., prolonged sitting, awkward upper limb positions); Recommendations for workstation redesign and improved work organisation	Office	[7]
A biomechanical evaluation of potential ergonomic solutions for use by firefighter and EMS providers when lifting heavy patients in their homes	Lavender et al. (2020)	Assistive devices	EMG; NIOSH	Biomechanical results indicating violation of NIOSH	Paramedic	[12]
Assessing the effectiveness of integrating ergonomics and sustainability: a case study of a	Munguía Vega et al. (2019)	Workstation redesign; training and breaks	Rapid Entire Body Assessment (REBA); Rapid Upper Limb Assessment (RULA); Worker	Reduction in ergonomic risk scores (REBA/RULA); Worker-reported decrease in	Manufacturing	[8]

Mexican maquiladora			perception and ailment surveys; Cause and effect (Ishikawa) diagram; Participatory brainstorming and benchmarking	musculoskeletal discomfort; Improved awareness of ergonomic risks; Qualitative feedback on intervention effectiveness		
Effect of flooring on lower extremity discomfort during food service tray-line jobs	Mahesh et al. (2017)	Workplace/workstation redesign	Anti-fatigue mats; Muscle temperature measurement (infrared thermography); Leg volume changes (bioimpedance); Fatigue and discomfort scales (subjective ratings); Biomechanics	Reduced muscle temperature decline; Reduced leg swelling and lower discomfort/fatigue scores compared to hard floors.	Food service tray line	[22]
Intervention development to reduce musculoskeletal disorders: Is the process on target?	Oakman et al. (2016)	Participatory ergonomics: Tailored ergonomic interventions based on the **Stage of Change (SOC)** model	SOC model; participatory ergonomics; tailored intervention reports; ergonomist-led site assessments	Tailored advice led to the implementation of 80% of recommended interventions. - 4 additional self-initiated interventions by the company	Ergonomics+case study done in manufacturing plant	[27]
Biomechanics and Kinematic Responses of the Upper Extremity during Isotonic and Isokinetic Wrench-Turning Tasks	Wiyor et al. (2016)	Work design	Biomechanics, Kinematics, Muscle activity, surface electromyography (sEMG) and motion tracking	Lower muscle activity at 0° work surface inclination; The forearm joint posture should be 45° inclined to induce less activity.	Any tool use industry	[17]
Use of the Meta-postureTM Program in the Construction Industry	Blankenheim et al. (2015)	Training program	Meta-Posture™ Program; postural training/stretches; functional tests; surveys	Improvement of lifting mechanics; Increased productivity in awkward positions; Decrease in musculoskeletal complaints	Construction	[23]
If you've seen one construction worksite stretch and flex program ... you've seen one construction worksite stretch and flex program	Goldhar et al. (2015)	Training program	Stretch/flex program; interviews; surveys	Interviews and surveys: perceived reduction in WRMDS, strain and pain, improved safety climate, reduced fatigue, and teamwork	Construction	[24]
Risk factors for musculoskeletal injuries among airport customer	Asadi et al. (2019)	Workplace/workstation redesign	REBA (Rapid Entire Body Assessment); NIOSH lifting equation analyses; NASA-TLX (task	REBA scores; NIOSH lifting task results; reduction of strain, and improvement in productivity	Airport baggage service	[11]

service employees			Load Index); Surveys			
Evaluation and comparison of lift styles for an ideal lift among individuals with different levels of training	Abdoli-Eramaki et al. (2019)	Training program	3D Static Strength Prediction Program™ (3DSSPP) model biomechanical simulation software for 3D static posture evaluation; Kinematic and kinetic analyses; motor learning, deliberate practice, augmented feedback; individualized training; Questionnaire	Preferred verbal cues: 'Bend your knees' and lifting style: squat lift; Quantitative biomechanical data: trained group showed less low back loading, lower knee and shoulder loading but not substantially.	Manual handling	[20]

ASSESSING THE NET-ZERO READINESS OF SOUTH AFRICA'S MINING SECTOR: A SYSTEMATIC LITERATURE REVIEW

S.R. Ngwaku[1*] and S. Nhleko[2]

[2]Centre for Sustainable Mining
North-West University, South Africa

ABSTRACT

The accelerating demand for net zero emissions is transforming the business landscape, compelling companies to reassess their strategies. This study investigates the extent to which South Africa's mining sector is aligning with environmental, social, and economic sustainability objectives, particularly in the context of achieving net-zero emissions. Using a systematic literature review (SLR) methodology, 23 peer-reviewed studies were critically analysed. The review focused on themes such as acid mine drainage, ESG reporting, mining economics, and renewable energy transitions. Findings reveal that while regulatory and policy reforms are accelerating, environmental sustainability remains the most prioritised dimension, with social and economic considerations often treated as secondary. Barriers such as inadequate data infrastructure, high decarbonisation costs, and legacy environmental damage persist, though there is growing corporate adoption of ESG frameworks. The study concludes that, although progress is evident, South African mining companies are not yet on a clear path to net-zero. Targeted policy alignment, technological investment, and stronger governance are urgently needed.

Keywords: Sustainable mining, Net-zero emissions, ESG reporting, Decarbonisation, South Africa, SLR

* Corresponding Author

1 INTRODUCTION

South Africa's mining industry remains a vital component of the national economy, contributing approximately 8% to the country's Gross Domestic Product (GDP) and directly employing over 450,000 people as of 2021 [1]. The sector is also a key source of foreign exchange earnings, particularly through the export of precious metals like gold, platinum, and palladium [2]. Beyond direct employment, mining supports thousands of indirect jobs in transport, equipment manufacturing, and services, making it indispensable to regional development in mining-heavy provinces such as Mpumalanga, Northwest, and Limpopo [3]. Additionally, mining companies often invest in local infrastructure, health, and education, playing a broader socio-economic role [4].

Despite its economic significance, the environmental toll of mining activities in South Africa is substantial and growing. The country faces long-standing challenges related to acid mine drainage (AMD), which results from the exposure of sulfide minerals to air and water, producing sulfuric acid that contaminates waterways [5], [6]. In regions like the Witwatersrand Basin, AMD continues to degrade groundwater and river systems, posing health and ecological risks [7]. Moreover, heavy metal contamination from tailings and the generation of fine particulate matter contribute to soil and air degradation [8]. The sector also contributes significantly to greenhouse gas emissions due to energy-intensive extraction and processing methods, particularly in deep-level gold and platinum mines [9].

To mitigate these impacts, South Africa has implemented a series of environmental regulations aimed at improving sustainability in the mining sector. The National Environmental Management Act (NEMA) and the Mineral and Petroleum Resources Development Act (MPRDA) require environmental impact assessments and mine closure plans before operations commence [10], [11]. However, enforcement remains inconsistent, and many legacy mines continue to pollute due to historical under-regulation and insufficient rehabilitation funding [12]. The introduction of the "polluter pays" principle and the establishment of the Department of Mineral Resources and Energy's Environmental Mineral Resources Inspectorate aim to strengthen accountability [13].

International and domestic pressure on South Africa to reconcile mining development with environmental stewardship has increased. Multinational corporations operating in the country face rising demands from investors and stakeholders to adopt Environmental, Social, and Governance (ESG) frameworks [14]. Society, including non-governmental organisations and affected communities, has also become more vocal, challenging environmentally harmful practices through legal means [15]. Additionally, South Africa's commitment to the Paris Agreement necessitates a gradual transition to low-carbon economic activities, further compelling the mining sector to reduce its environmental footprint [16].

Achieving net-zero in mining is complex and expensive. Companies must tackle Scope 1 (on-site), Scope 2 (electricity), and Scope 3 (value-chain) emissions [17], [18]. South African mines face compounded challenges: steep upfront investments, inadequate emissions data, outdated infrastructure, and continued reliance on Eskom's coal-powered grid [19], [20]. Additionally, geographic isolation of many mining sites hampers deployment of renewables, and weak alignment between local and national climate policies further slows decarbonisation efforts [21], [22].

South Africa's Climate Change Act (No 22 of 2024) mandates carbon budgets and requires companies to develop mitigation plans [23], [24]. This legal architecture is complemented by updates to the Carbon Tax Act, where allowances are being phased out and offset credit use tightened [15]. The carbon tax aims to incentivise emission reductions by directly imposing costs on carbon emissions, thereby encouraging companies to adopt cleaner technologies and improve operational efficiency.

The Carbon Tax rate started at R120 per tonne of carbon dioxide equivalent, and the price continues to increase annually, directly impacting operation costs for emitting companies. However, the Tax offers several advantages, including encouraging companies to innovate and adopt cleaner technologies for a sustainable future.

Moreover, initiatives like the Renewable Energy Independent Power Producer Procurement Programme (REIPPPP) and Risk Mitigation IPP Programme have expanded renewable capacity, offering strategic relief for off-grid mining operations [26], [27]. The broader Just Energy Transition Framework, backed by international funding, also aims to manage social impacts in coal-heavy regions [28].

Balancing economic development with environmental protection in South Africa's mining sector requires integrated policy approaches and sustainable business models. While the economic value of mining is undeniable, unchecked environmental degradation could compromise the sector's long-term viability and the well-being of surrounding communities [29]. Innovations such as mine-water reuse, green mining technologies, and circular economy practices offer pathways to reducing negative externalities [30]. However, these require substantial investment, technical capacity, and coordinated governance. As the global mining industry undergoes a green transition, South Africa must align its mining practices with international standards while addressing domestic socio-economic realities [31].

To evaluate whether South Africa's mining sector is on track to meet net-zero emissions targets, and to also identify if there is a balance between the three pillars of sustainability, Environmental, economic and social, this study adopts a systematic literature review (SLR) methodology. Unlike traditional narrative reviews, SLRs follow a structured, transparent, and reproducible process for identifying, assessing, and synthesising relevant studies, thereby minimising bias and enhancing the reliability of conclusions [32]. This approach is especially valuable in sustainability research, where interdisciplinary trade-offs and context-specific factors often complicate the design and implementation of effective policies [33]. By systematically coding and analysing sustainability themes - economic, environmental, and social-this review identifies which dimensions of the triple bottom line are prioritised in current mining strategies.

Understanding this distribution will allow policymakers and industry stakeholders to determine whether corporate practices are aligned with South Africa's development priorities and global sustainability frameworks such as the United Nations Sustainable Development Goals (SDGs) [34], [4]. The review also synthesises data from academic studies, government publications, and industry frameworks to highlight key barriers—such as high decarbonisation costs, limited technical capacity, and insufficient emissions data as well as enabling factors like regulatory evolution, renewable energy uptake, and global market incentives [33], [34], [35]. Moreover, the analysis evaluates recent policy interventions and the financial feasibility of renewable energy integration, offering a comprehensive assessment of the sector's trajectory and identifying best practices for aligning with national and international climate objectives [36], [37].

2 METHODOLOGY

As indicated above, SLR will be used in this study because it follows a predefined protocol that minimises selection bias and increases the credibility and reproducibility of findings [38], [39]. The following steps were followed to adhere to the SLR search protocol.

- Clearly defined research questions
- Eligibility criteria
- Structured search strategy across academic databases such as Scopus, Google scholar, and ScienceDirect

- Articles are screened at both abstract and full-text levels based on inclusion and exclusion criteria to ensure that only relevant, high-quality studies are included [40].
- By incorporating only peer-reviewed academic literature, credible government publications, and authoritative industry reports, the study ensures the robustness and contextual relevance of its dataset [41], [42].

A comprehensive search strategy was developed using specific keyword combinations. The search terms were derived from a combination of core keywords and modifiers. Core keywords represent the central focus of the research, while modifiers are additional terms used to refine and tailor the core keywords to a specific industry context. Table 1 summarises the keywords searched.

Table 1: Keyword combinations for the literature search

Pre-modifier	Core keyword	Post-modifier 1	Post-modifier 2
South Africa	Mining	Environmental	Sustainability
		Socio-Economic	Considerations
		AMD	
		ESG	Reporting

The selected literature is then subjected to data extraction and thematic coding. In this study, themes will be analysed through the lens of the triple bottom line economic, environmental, and social sustainability. This classification will help identify which sustainability dimension is most emphasised in current mining strategies in South Africa [43], [44]. It is important to note that mining operations outside South Africa are excluded in this research due to difference in regulations, which may lead to results being skewed. Table 2 summarises the search protocol with specific exclusion and inclusion criteria.

Table 2: SLR search protocol

Aspect	Detail
Databases searched	Google Scholar, ScienceDirect
Search terms	South Africa, Net zero, sustainability, triple bottom line, ESG reporting, mining economics
Inclusion criteria	Peer-reviewed articles Published 2010–2024 Focus on South African mining English language
Exclusion criteria	Opinion pieces without data Mining operations outside South Africa

From Table 2, the SLR research protocol outlines the search of Google Scholar and Science Direct for peer-reviewed articles published between 2010 and 2024 that focus on South African mining using specific search terms, while excluding opinion pieces, and studies on mining operations outside of South Africa. The thematic synthesis also enables the identification of barriers (e.g., high decarbonisation costs, weak data infrastructure) and enablers (e.g., policy reforms, renewable energy uptake) in the sector's transition toward net-zero [42], [45].

Moreover, the analysis will assess how mining firms are aligning their strategies with global frameworks such as the United Nations Sustainable Development Goals (SDGs) and South Africa's Climate Change Act [45], [46]. By organising and interpreting this body of knowledge, the SLR will provide a consolidated view of the mining sector's sustainability trajectory, inform future policy development, and highlight opportunities for targeted intervention and innovation [41], [45]. The next section discusses the results of the SLR.

3 RESULTS

The process began with the formulation of clear research questions focusing on the sustainability practices and net-zero progress of South Africa's mining sector.

The keywords search in Table 1 were executed across multiple academic databases, primarily Google Scholar and ScienceDirect, to capture peer-reviewed articles and authoritative publications.

The review applied stringent inclusion and exclusion criteria to ensure relevance and quality as highlighted in Table 2. The inclusion criteria mandated that studies be peer-reviewed, published between 2010 and 2024, focused on South African mining contexts, and available in English. Exclusion criteria removed opinion pieces lacking empirical data and studies not related to South Africa. Figure 1 shows the PRISMA chart of the search processes and Results.

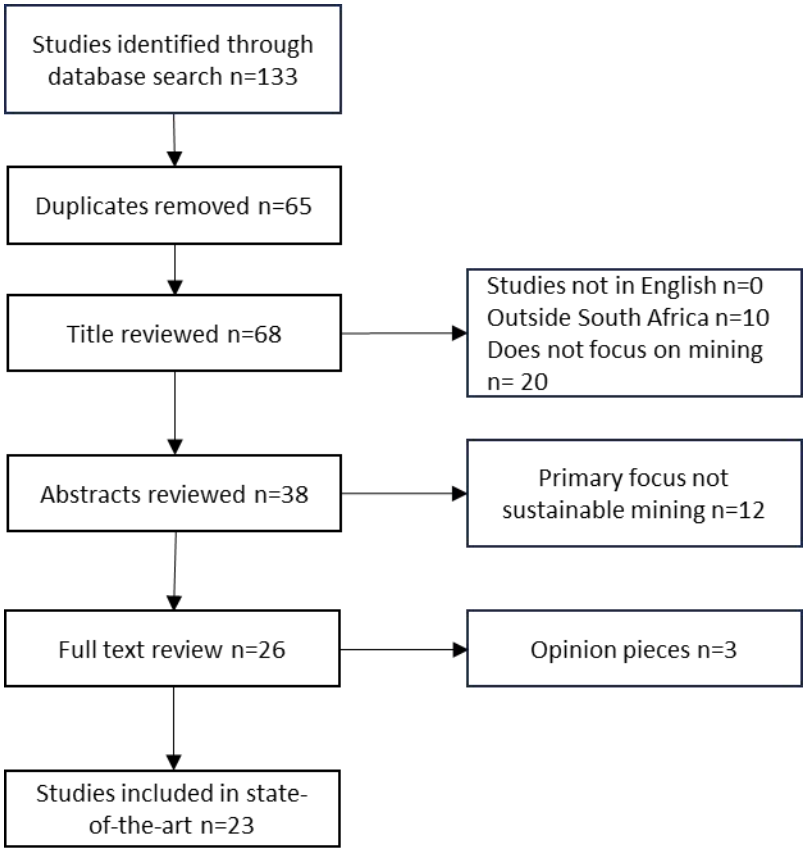

Figure 1: SLR PRISMA chart

As indicated in Figure 1, following initial screening of titles and abstracts, full-text reviews were conducted to confirm eligibility. This systematic approach resulted in a final selection of 23 studies that collectively represent a robust and comprehensive dataset for thematic analysis.

The selected studies were then categorised and analysed according to their focus on the triple bottom line of sustainability economic, environmental, and social dimensions. Data extraction involved coding key themes such as barriers to net-zero, policy impacts, technological innovations, and ESG implementation. A tabulated summary Table 2 was developed to organise the studies by reference, industry relevance, study type, and primary sustainability focus. This enabled a holistic understanding of current progress and challenges in South Africa's mining sector's transition towards net-zero emissions.

Table 3 summarises 23 peer-reviewed studies on South African mining, indicating a brief article summary, and its primary sustainability focus (environmental, social, or economic). Each study was critically evaluated based on inclusion criteria from 2010–2024. The table enables identification of thematic trends and gaps in sustainability research in South Africa's mining sector. In Table 3, X means that the study contributes to the theme while, O means it does not.

Table 3: Summary of findings from SLR search protocol

Study No.	Reference	Summary	Environmental	Economic	Social
1	[48]	Explores the role of mining in GDP and employment using statistical data.	O	X	O
2	[49]	Analyses export contributions of precious metals.	O	X	O
3	[50]	Describes regional development impacts in mining-heavy provinces.	O	X	X
4	[51]	Discusses mining company investment in community infrastructure.	O	O	X
5	[52]	Reviews AMD and environmental degradation.	X	O	O
6	[53]	Discusses contamination from AMD and tailings.	X	O	O
7	[54]	Details AMD impacts in the Witwatersrand Basin.	X	O	O
8	[55]	Reports on air and soil pollution from mining.	X	O	O
9	[56]	Assesses GHG emissions from deep-level mines.	X	O	O
10	[57]	Reviews environmental laws like NEMA and MPRDA.	X	O	O
11	[58]	Investigates ESG score correlations in JSE-listed miners.	O	X	O

Study 1 by Statistics South Africa reported GDP contributions from mining, indicating the sector's continued dominance in South Africa's economic structure [48]. Using national accounts and statistical modelling, the report highlights that mining still underpins export earnings and job creation, despite global shifts towards renewables [48]. While the study is purely economic, it underscores the challenge of balancing growth with environmental degradation. It lacks integration of sustainability metrics but provides a critical baseline for policy evaluation.

Study 2 compiled sectoral data on mineral production, exports, and revenue, illustrating the mining sector's fiscal role [49]. The methodology was descriptive and quantitative, relying on industry-reported outputs. The study focuses on economic performance but does not assess social or environmental costs, thereby reinforcing the perception of mining as an economic driver without critically engaging with sustainability trade-offs [49].

In study 3, provided an industry-level review of mining's contributions to employment, infrastructure, and regional development [50]. While framed as a factual industry report, it implicitly promotes the sector's economic and social value. The report highlights regional disparities, noting that mining-heavy provinces benefit disproportionately. However, it downplays negative environmental externalities, revealing a gap in holistic sustainability reporting.

Study 4 empirically analysed the socio-economic impact of mining on local communities, using case studies to assess employment, infrastructure, and livelihoods [51]. Findings showed mixed outcomes while mining brought short-term socio-economic benefits, communities faced long-term dependency and vulnerability after mine closure. This study contributes significantly to the social dimension of sustainability but is weaker in addressing environmental impacts [51].

Study 5 produced a CSIR technical report assessing mining impacts on water resources in the Zambezi, Limpopo, and Olifants catchments [52]. Their hydrological and water quality analysis showed severe contamination from acid mine drainage (AMD) and mineral processing. This study strongly advances the environmental sustainability discourse, providing robust empirical evidence on mining's ecological costs, though it does not fully integrate socio-economic trade-offs.

Study 6 reviewed AMD impacts nationally, synthesising field data and prior studies [53]. The article emphasised AMD as South Africa's most pressing mining-related environmental threat, with implications for water scarcity, ecosystem degradation, and public health [53]. While the study is environmentally focused, it indirectly links to social and economic dimensions by noting high treatment costs and community health risks.

Durand in study 7 investigated the long-term hydrological and ecological effects of gold mining in the Witwatersrand Basin [54]. Using geological surveys and water quality assessments, the study demonstrated irreversible impacts on rivers and karst systems. The findings stress the intergenerational consequences of mining, underscoring the need for long-term remediation. Its primary focus is environmental, though implications for social resilience are evident.

Study 8 adopted a chemical engineering perspective to review AMD treatment technologies [55]. Their critical review identified both technological challenges and potential opportunities for resource recovery. The study highlights the dual nature of mining waste: as a liability and as a potential economic resource. Thus, it bridges environmental and economic dimensions by discussing remediation costs and valorisation prospects.

In study 9 Wagner [56] examined energy efficiency in the South African mining sector using case studies and energy consumption modelling. The study identified significant inefficiencies in deep-level gold and platinum mines, with opportunities for energy savings through

modernisation. While framed as an environmental issue (energy and GHG reduction), the findings also have economic implications in reducing operational costs.

Study 10 consolidated environmental governance frameworks under the National Environmental Management Act (NEMA) [57]. The study provides the legal basis for sustainable mining operations, embedding the precautionary principle and polluter-pays approach. While not empirical, it directly contributes to environmental and social sustainability by enforcing corporate accountability. However, gaps remain in implementation and enforcement capacity, which weakens its practical impact.

From study 11 the authors assessed ESG disclosures among JSE-listed mining companies and found an uneven uptake of environmental metrics [58]. The methodology involved regression analysis correlating ESG score performance with profitability, revealing that most companies prioritised economic returns over environmental transparency. Although companies recognised the strategic value of ESG reporting, there was limited commitment to net-zero pathways, particularly in Scope 3 emissions. This study contributes to the economic and social dimensions but highlights a significant gap in environmental integration.

Study 12 adopted a mixed-methods approach to examine institutional dynamics in ESG implementation [59]. They found that internal resistance, limited technical capacity, and inadequate stakeholder engagement hinder environmental compliance in mining firms. The study demonstrated that although corporate strategies increasingly mention net-zero ambitions, operational changes are lagging due to inconsistent policy interpretation and fragmented accountability mechanisms [59]. This study contributes heavily to the social and environmental dimensions by exposing organisational barriers that delay climate commitments.

Study 13 scenario modelling was applied to platinum mining operations, identifying feasible decarbonisation pathways under existing constraints [60]. Their findings showed that despite technological availability, cost pressures and infrastructure limitations such as Eskom's unreliable coal-dominated grid—make short-term net-zero attainment improbable [60]. While this study is focused on the environmental and economic dimensions, it reinforces the notion that systemic challenges, rather than ambition, are the core hindrance in achieving net-zero targets.

Study 14 offers a highly empirical geohydrological analysis of acid mine drainage (AMD) in the Witwatersrand Basin [61]. The methodology is rooted in environmental sciences, including field sampling and modeling of subsurface water systems. It makes a significant contribution to the environmental dimension by detailing the spatial extent and persistence of AMD damage [62]. However, its socio-economic implications are underexplored, revealing a disciplinary silo. Nonetheless, this work forms the scientific backbone for later policy debates and interventions surrounding AMD mitigation.

Study 16 examines the feasibility of recovering rare earth elements from AMD, using a techno-economic assessment model [63]. Their work straddles the economic and environmental domains, offering a circular economy perspective rarely addressed in mining literature. By quantifying the cost-benefit potential of AMD reuse, the study brings innovation into the sustainability conversation [64]. However, the economic models assume ideal extraction conditions and do not account for the fragmented ownership and governance of abandoned mines in South Africa, thus limiting real-world applicability.

Turning to study 18, the authors conduct an SDG alignment assessment in communities around the West Wits goldfields [65]. Using spatial analysis and household surveys, they map disparities in education, health, and infrastructure. The study is methodologically strong and directly contributes to the social dimension by offering post-closure community diagnostics.

However, it falls short on environmental and economic integration failing to connect these local deficits to broader industry practices or policy responses [65]. Still, its evidence is vital for understanding the human cost of poorly planned mine closures.

In examining the socio-economic impacts of mine closure in the West Wits goldfields, as discussed it is vital to consider the broader implications for Corporate Social Responsibility (CSR), ESG monitoring, and the SDGs [65]. The closure of mines often results in significant challenges for local communities, including job losses and economic decline, which often lead to ghost towns. To mitigate these impacts, mining companies should enhance their CSR initiatives by developing transition plans that prioritise community engagement and support for affected workers. The mining companies should strengthen investment in local infrastructure, education, and alternative livelihood programs that can foster economic resilience and social equity beyond mining. Effective ESG monitoring and reporting are essential because mining companies can assess their social and environmental impacts, ensuring accountability through regular reporting on community engagement and environmental rehabilitation initiatives.

Furthermore, the socio-economic impacts of mine closure align with SDG Goal 8, which emphasises the need for sustained economic growth and employment opportunities, and Goal 11, advocating for sustainable urbanisation. By addressing these aspects, stakeholders can foster a holistic understanding of the long-term implications of mine closures, guiding the mining industry toward more sustainable and responsible practices that benefit communities and the environment.

Study 19 applies a SWOT analysis (strengths, weaknesses, opportunities, threats) to critically assess the future trajectory of South Africa's mining sector [66]. It highlights the country's strengths, such as its rich mineral endowment, established infrastructure, and skilled workforce, while also noting weaknesses including regulatory uncertainty, high operational costs, and declining ore grades [66]. Opportunities are identified in the form of beneficiation, value addition, and potential global demand growth, while threats include environmental degradation, social unrest, and increasing global competitiveness. The paper concludes that South Africa's mining future depends on balancing profitability with sustainable governance and environmental responsibility, making it an early contribution to debates around mining-sector resilience and sustainability.

Finally, study 20 provides a strategic review of threats to South Africa's mining sector using SWOT analysis [67]. It identifies six macro risks: infrastructure constraints, HIV/AIDS, labor unrest, declining ore grades, policy volatility, and global competitiveness. This multi-dimensional approach effectively bridges the social and economic pillars. However, while environmental risks are acknowledged, they are not deeply examined. The study's strength lies in its holistic view, which makes it a useful strategic reference for industry policymakers, especially in framing resilience against future disruptions.

Additional insights from study 21 [68] revealed discrepancies in net-zero commitments between large multinational corporations and junior miners. Large firms were more likely to have defined emission targets and sustainability frameworks, attributed to investor pressure and reputational risk [68]. However, junior miners, which constitute a large portion of the sector, lacked resources for long-term planning. This points to a dual-speed transition in the sector—where a small subset may meet net-zero targets, but the broader industry remains behind schedule. This study offers a valuable contribution across all three sustainability dimensions, particularly highlighting socio-economic inequities in climate strategy adoption.

Study 22 employed scenario analysis to test the feasibility of mining companies meeting net-zero emissions under various policy and technological assumptions [69]. Their findings confirmed that, under current regulatory and financial conditions, most companies will fall

short of their 2050 targets [69]. However, accelerated policy alignment, renewable energy uptake, and carbon pricing could help reverse this trend. This study aligns strongly with environmental and economic themes, providing a forward-looking critique on sector readiness.

Lastly, study 23 conducted interviews with community stakeholders and mining executives to explore perceptions of climate action [70]. They found a disconnect between corporate declarations and local impact, where community members often viewed sustainability efforts as superficial. The research highlights the need for participatory climate planning and greater transparency to build social legitimacy. It enriches the social dimension and stresses the importance of integrating community voices in the transition to net-zero.

Table 3 shows that the studies highlight the multifaceted impacts of the mining industry in South Africa, focusing on economic, environmental, and social aspects, with a major emphasis on environmental impacts such as acid mine drainage, pollution, and the adoption of sustainability practices, while addressing the role of mining in regional development and community investment.

4 CONCLUSIONS

This systematic literature review has critically examined the sustainability trajectory of South Africa's mining sector in the context of net-zero emissions. Drawing from 23 peer-reviewed and empirically grounded studies, the findings indicate that while there is a growing discourse around environmental, social, and governance (ESG) integration, meaningful progress towards net-zero remains fragmented and inconsistent. Larger corporations with access to international capital and investor scrutiny have begun aligning their practices with global climate frameworks. However, smaller mining entities, which represent a significant proportion of the sector, continue to struggle with limited technical and financial capacity, regulatory ambiguity, and infrastructural barriers such as reliance on Eskom's coal-powered grid.

The review revealed that most studies emphasise environmental sustainability—particularly acid mine drainage, air pollution, and greenhouse gas emissions but there is a relative underrepresentation of the social and economic dimensions in operational strategies. Moreover, policy interventions such as the Climate Change Act (No. 22 of 2024) and the Renewable Energy Independent Power Producer Procurement Programme (REIPPPP) offer regulatory and market-driven opportunities for reform. Nonetheless, weak enforcement mechanisms, legacy liabilities from historical mining, and limited stakeholder inclusion continue to hinder systemic transformation. These findings underscore the need for integrated approaches that align national development goals with sector-specific realities.

While the sector demonstrates partial alignment with net-zero objectives, the pathway forward requires substantive shifts in governance, technology adoption, and community engagement. Future success depends not only on capital investment but also on transparent ESG reporting, capacity-building initiatives, and a just transition framework that ensures vulnerable populations are not left behind. Without accelerated intervention, the mining industry risks failing to meet both domestic and international climate commitments, thereby compromising long-term socio-economic and ecological stability.

5 RECOMMENDATIONS

While the study successfully identifies key trends and challenges in South Africa's mining sector's net-zero readiness, future research would benefit from methodological diversification. Although the systematic literature review (SLR) offers valuable thematic insights, it may not be the most effective tool for capturing the nuanced, real-time dynamics of corporate strategy and implementation. Incorporating interviews with industry stakeholders or analysing company-specific sustainability reports could provide richer, more actionable

data, allowing researchers to assess the authenticity of ESG adoption, uncover internal decision-making processes, and better understand the practical barriers to decarbonisation. Such qualitative depth would complement the existing findings and strengthen the evidence base for policy and industry recommendations.

Additionally, to place South Africa's mining industry firmly on the path to net-zero emissions, it is recommended that government agencies, mining firms, and research institutions collaborate on a national decarbonisation roadmap tailored to sector-specific challenges. This should include targeted subsidies for renewable integration, compulsory and standardised ESG reporting across all company sizes, and increased community participation in environmental decision-making. Moreover, legacy mine rehabilitation must be prioritised through a well-financed national fund, while technical training programmes should support workforce adaptation. A coherent, multi-stakeholder approach is essential to balance economic growth with environmental stewardship and social equity.

In light of the accelerating demand for net-zero emissions and the shifting business landscape described in the study, a robust climate policy framework offers South Africa's mining sector a strategic advantage as a risk management tool. The systematic literature review highlights persistent barriers such as legacy environmental damage, high decarbonisation costs, and inadequate data infrastructure all of which increase operational and reputational risks for mining firms. By embedding carbon budgets, tightening tax allowances, and enforcing ESG compliance, the framework enables companies to anticipate regulatory shifts and mitigate long-term liabilities. This structured approach not only enhances investor confidence but also supports strategic planning for low-carbon transitions, aligning corporate actions with global sustainability benchmarks.

Furthermore, the framework facilitates coordinated, multi-stakeholder action, an essential response to the fragmented prioritisation of environmental goals over social and economic dimensions noted in the review. As the study recommends, a national decarbonisation roadmap tailored to sector-specific challenges can bridge this gap by integrating targeted subsidies for renewable energy, standardised ESG reporting, and inclusive community engagement. Legacy mine rehabilitation and workforce retraining, supported by a national fund and technical programmes, would further address historical damage and future-proof the industry. In this way, the framework not only manages risks but also catalyses systemic transformation, positioning South Africa's mining sector on a more coherent and equitable path toward net-zero emissions.

In this study, SLR was used to identify the Net-Zero readiness of South Africa's mining industry, and while it provides some interesting findings, it does have some shortfalls. To address the shortfall of SLR future work should consider incorporating qualitative methods such as interviews with mining stakeholders and analysis of company annual reports. These approaches could provide a deeper insight into the practical challenges and strategies concerning sustainability efforts, complementing the findings from the SLR. Furthermore, including case studies of mining companies that have successfully implemented the Net-Zero initiatives could offer valuable perspectives and actionable lessons for the whole mining industry.

ABSTRACT

Aftersales service centers hold significant untapped profit potential in the automotive industry. With the rise of Industry 5.0, it is crucial to explore how this paradigm shift could reshape aftersales operations, enhancing efficiency, personalization, and sustainability. This study investigates the applicability of Industry 5.0 concepts in aftersales service centers, focusing on human-centric automation, smart technologies, and collaborative robotics. A systematic literature review (SLR) was conducted to collect, analyze, and report on the tools, concepts, and approaches relevant to Industry 5.0 in this sector. The findings highlight the benefits and challenges of various Industry 5.0 technologies, providing insights into their potential impact on service quality and profitability. This study offers a strategic framework for implementing Service 5.0, outlining a pathway for integrating advanced technologies while maintaining a customer-centric approach. Ultimately, the research contributes to shaping the future of aftersales services in the automotive industry.

1 INTRODUCTION

The global automobile service industry plays a crucial role in ensuring vehicle safety, performance, and longevity, contributing significantly to the overall automotive sector. With over 1.4 billion vehicles on the road worldwide, the demand for maintenance, repairs, and aftersales services continues to rise, making this industry an essential pillar of modern transportation infrastructure [1].

Technological advancements like artificial intelligence (AI), the Internet of Things (IoT), augmented reality (AR), and predictive analytics are transforming the automotive industry as electrified and driverless vehicles become more common [2]. Despite this, the aftersales service centre at Company X still employ outdated manual processes and lack the digital infrastructure needed to meet evolving customer and operational needs [3].

This gap between technology potential and current practice requires a closer look at how innovative concepts like Industry 5.0 can be integrated into automobile aftersales services. Industry 5.0 is an emerging concept that builds on Industry 4.0 and emphasises human-centricity, sustainability, and resilience in industrial systems [5]. Unlike Industry 4.0 that only focused on automation, Industry 5.0 highlights the integration of human creativity with smart technologies such as digital twins, collaborative robots, and artificial intelligence (AI) [8]. While existing literature highlights the benefits of automation, AI, and smart diagnostics in improving productivity and service quality in industrial settings, there are not many studies that specifically address their application in aftersales environments in South Africa. [4].

This study addresses that research gap in understanding Industry 5.0's practical relevance for aftersales service operations in developing countries, by investigating the potential application of Industry 5.0 concepts—specifically, human-centric automation and collaborative technologies—to the after-sales services provided by Company X.

2 RESEARCH METHODOLOGY

A systematic literature review (SLR)[13] was carried out to gather information to investigate the definitions, advantages, challenges, and opportunities of Industry 5.0 in a service centre to accomplish the aim. The SLR approach served as the basis for this investigation and is described in the following steps:

- **Step 1: Develop a research purpose and/or objective** – Define the purpose of the SLR.
- **Step 2: Develop research protocol** – Includes databases, keywords, inclusion and exclusion criteria, and quality assessment criteria.
- **Step 3: Establish relevance criteria** –Explain why a resource is relevant to this research.
- **Step 4: Search and retrieve the literature** –To locate literature, search relevant scientific databases.
- **Step 5: Selection of studies** – To choose studies, use the inclusion and exclusion criteria.
- **Step 6: Quality assessment for relevant studies** –Evaluate each paper's quality.
- **Step 7: Data extraction** –Pull relevant information out of the papers.
- **Step 8: Analysis and synthesis of findings** – Determine themes and patterns by analysing and combining the data from the papers.
- **Step 9: Report** – Give a thorough report on the review's findings.
- **Step 10: Dissemination** –The publication of the SLR

2.1 Step 1 - Develop a research purpose

The purpose of this study is to gather and document an overview of existing literature on the tools, benefits, challenges, and implementation strategies of Industry 5.0 technologies in aftersales service centres to develop a strategic framework for adoption within the South African automotive industry.

2.2 Step 2 - Develop a research protocol

Table 1 shows the research method that was developed.

Table 1 Research protocol

Purpose of the study	• To investigate and document an overview of existing literature on the tools, benefits, challenges, and implementation strategies of Industry 5.0 technologies in aftersales service centres.
Inclusion criteria	• Literature that contains “Industry 5.0” and “Automotive” in the title, abstract, or keywords. • Literature discussing human-centric automation, human-machine collaboration, or smart technologies in the context of aftersales services. • literature on the tools, benefits, challenges, and implementation strategies of Industry 5.0
Exclusion criteria	• Non-English studies • Studies focusing solely on Industry 4.0 without connection to Industry 5.0
Search databases	• Scopus • ScienceDirect • Web of Science
Keywords	• “Industry 5.0” AND “Automotive”
Quality assessment criteria	• Relevance of literature must be checked • Duplicate literature must be removed • Research needs to be scientific • Literature must be reviewed for correct interpretation of Industry 5.0 principles • Research methods and data collection procedures must be transparent

2.3 Step 3 - Establish relevance criteria

Industry 5.0 is a relatively new field of study that has only received significant research attention in the last few years. To ensure an in-depth evaluation of relevant papers, the following relevance criteria were created:

- Works of literature which include "Industry 5.0" and " Automotive " in the title, abstract, or keywords
- Literature that explores the definitions, tools, benefits, challenges, or strategies of integrating Industry 5.0 technology in automotive environments
- Studies that are not in English will not be accepted.

- Studies that solely focus on Industry 4.0 or other unrelated service sectors will be excluded since they do not align with the primary study objective of evaluating Industry 5.0 in automobile aftersales contexts.
- Themes were identified deductively by mapping findings to categories. Validity was supported through reviewer cross-checking, with reliability ensured by PRISMA guidelines.

2.4 Step 4 - Search and retrieve the literature

Using the databases listed in table 1, the literature was searched and obtained in step 4, producing 111 papers in total. The identification part of Figure 1 shows how the papers are broken down in this step.

2.5 Step 5 - Selection of studies

During the initial search, 111 publications were identified. After removing duplicates, 79 unique records remained for screening, as illustrated in Figure 1. At this stage, studies that did not address the definitions, benefits, or challenges of Industry 5.0 were excluded. Papers focusing solely on general Industry 4.0 concepts without linking them to Industry 5.0 or its relevance in service contexts were also removed, as were those limited to historical overviews of industrial revolutions. Non-English articles without available translations were excluded as well.

The screening process prioritized studies that explored system interconnection within the context of Industry 5.0, particularly in automotive aftersales service environments. Research limited to theoretical overviews, highly specialized use cases unrelated to service operations, or isolated technologies (such as additive manufacturing, cybersecurity in general vehicle design, or narrow AI applications without broader system integration) was excluded. Preference was given to papers examining the integration of digital twins, ERP systems, legacy equipment, human-machine collaboration, and cross-platform communication—key enablers of intelligent and interconnected Industry 5.0 ecosystems.

Following this filtering process, 8 studies met the inclusion criteria, as shown in the final stage of Figure 1. While there is a huge body of research on Industry 5.0, there is very little available in the automotive environment currently.

2.6 Step 6 - Quality assessment for relevant studies:

Following evaluation using the quality criteria indicated in table 1, included maintaining scientific credibility, verifying accurate interpretation of Industry 5.0 principles, assessing the literature's relevance to Industry 5.0 and possible advantages to the aftersales services context, and verifying transparent research methods and data collection processes were some of these requirements. In the earlier screening phase, duplicate research were also removed. All eight studies met these requirements and were deemed to be of sufficient quality to be included in the final systematic literature review, as illustrated in figure 1.

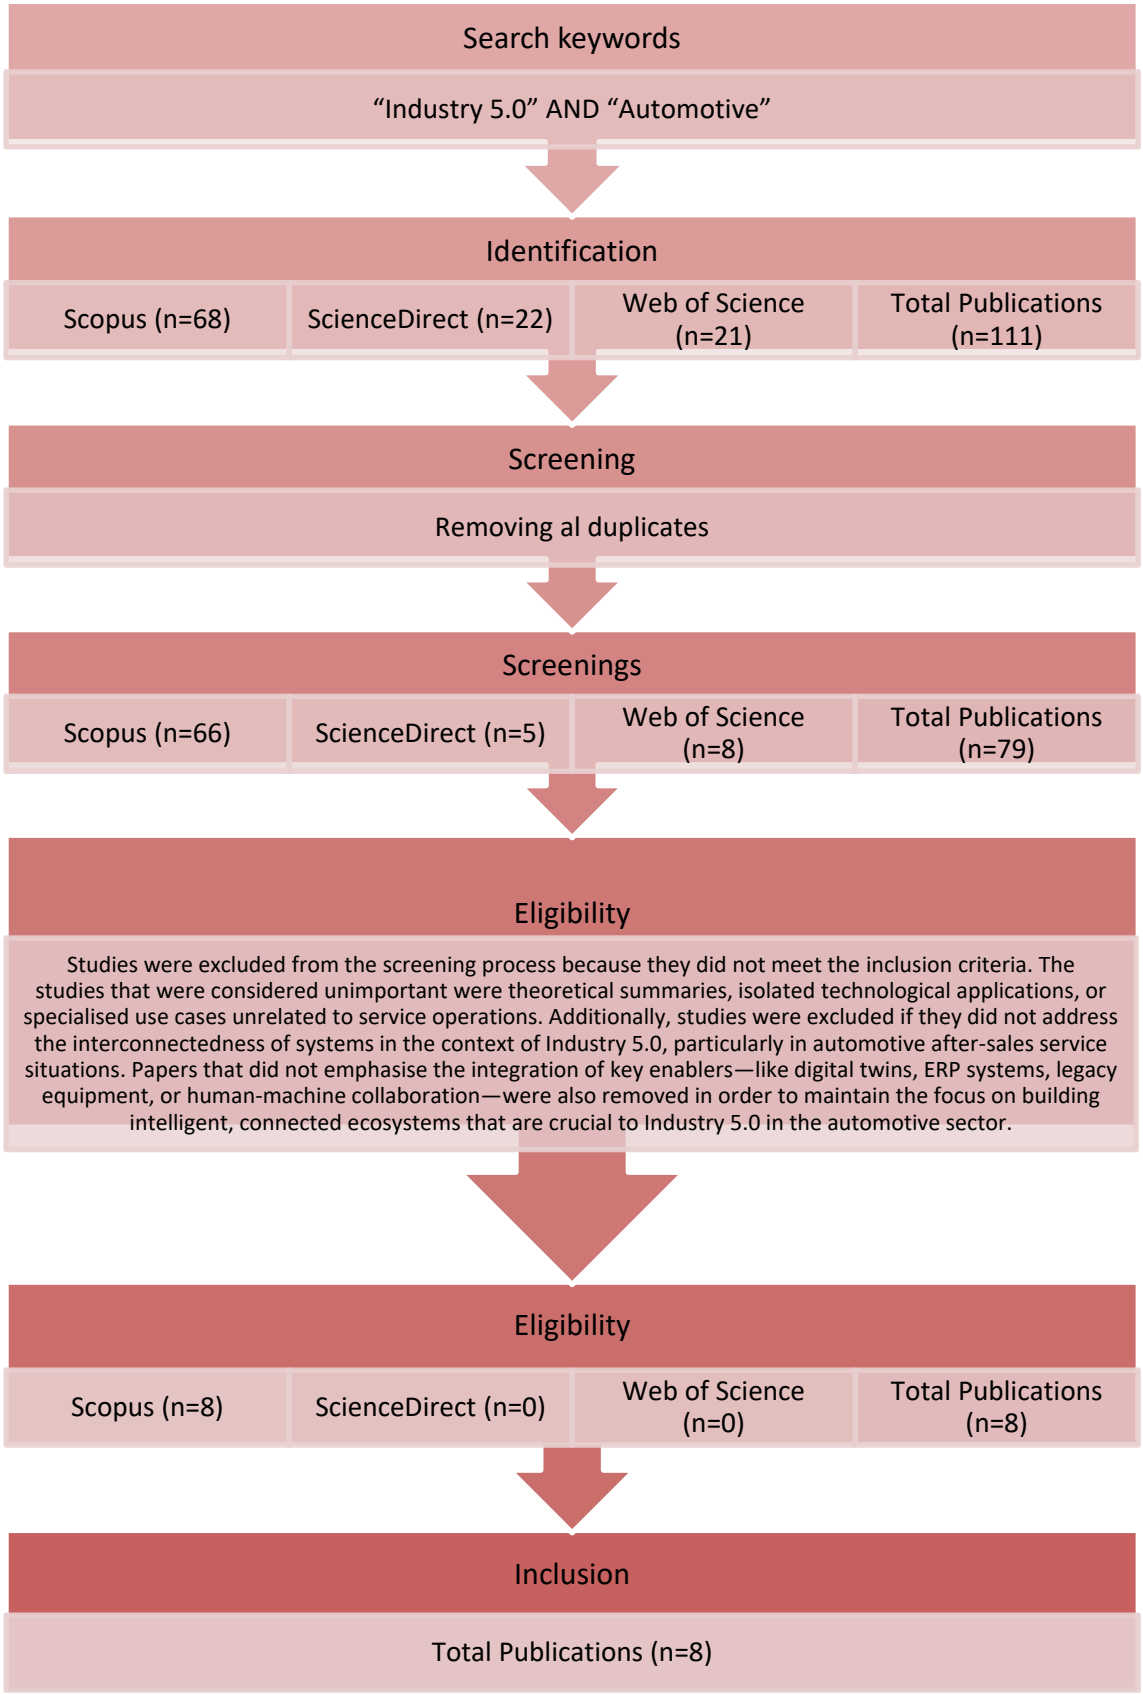

Figure 1 Process of selection chart (As per PRISMA guidelines)

3 FINDINGS

The following subsections cover the results (steps 7 and 8) of using the PRISMA guidelines.

3.1 Step 7: Data extraction

Following the final selection of the studies, all of the articles were closely reviewed, and information about the use of Industry 5.0 technologies was extracted. Appendix A offers a structured summary of the relevant research and highlights the aspects of each study, such as human-machine collaboration, advanced technology implementation, and human-centric innovation. The majority of current research is mostly focused on manufacturing and production contexts. Relatively little study has been done on the integration of Industry 5.0 technologies into automotive service-oriented processes, particularly in aftersales service departments. This observation adds to the importance and uniqueness of this study, which applies Industry 5.0 to the after-sales operations of a leading automotive firm (Company X) in the South African context. The lack of previous research in this area highlights a knowledge gap and a need for further exploration of interactive and human-centred technology in service environments, especially in developing countries.

3.2 Step 8: Analysis and synthesis of findings

The following subsections provide the data that was extracted, examined, and produced after all of the papers were analysed.

3.2.1 General publication trends

There were eight studies included in the final review. The distribution of publications by year is shown in figure 2.

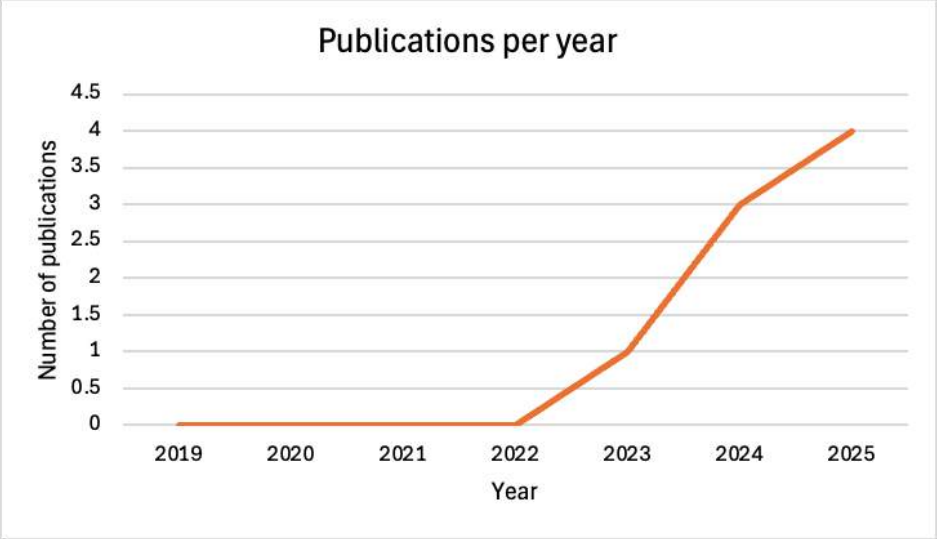

Figure 2 Line graph of the number of publications per year

The increase in research interest in Industry 5.0 within the automotive and related sectors in 2024 and 2025 indicates an increasing academic and industrial focus on the practical application of human-centric, resilient, and sustainable manufacturing processes. Since this topic is emerging and relatively specialized, limited studies is expected, yet sufficient to presents an upward trend and growth in the literature.

3.2.2 Key themes and topics addressed

The included studies address a wide range of Industry 5.0 themes. This can be combined to form the key to unlock the potential of Industry 5.0. Notable themes that emerged from the analysis are shown in figure 3 which include:

- **Organizational readiness and awareness**:
  - One study evaluated the knowledge and readiness of Polish businesses across a range of industries, highlighting the slow adoption, considerable challenges (such as infrastructure upgrading and employee training), and significant benefits (such as higher-quality products). [5]
- **Integration of legacy systems**:
  - Research on integrating older industrial equipment into modern building-management systems has shown that web-based technologies and Internet of Things (IoT) frameworks can provide sustainable and human-centred digital changes without replacing costly equipment. [6]
- **Lifecycle assessment and automation**:
  - One study developed a Python-based ERP integration system for automating transportation-related carbon footprint assessments, addressing a critical aspect of supply chain sustainability and compliance with regulation.[7]
- **Industrial inspection and evidence management**:
  - A software framework for online monitoring and visualisation of inspection failures was created to enhance decision-making and strengthen the integration of human operators through Industry 5.0 concepts.[8]
- **Human digital twins (HDTs)**:
  - Recent studies have focused on the possibility of human digital twins to enhance human interactions with digital ecosystems. The need of integrating human factors into digital design while preserving data management and privacy was emphasised [9]. HDTs bridge the gap between humans and digital systems in automotive aftersales, ensuring that technology improves service efficiency, quality, and personalization without replacing the human element, which is the core principle of Industry 5.0.
- **Artificial Intelligence (AI) for quality assurance**:
  - To achieve Industry 5.0 objectives, a thorough investigation showed how artificial intelligence (AI) methods, such as convolutional neural networks, are transforming live part tracking, predictive maintenance, and defect detection in the automotive sector. [10]
- **Digital twins in engineering**:
  - Reaching higher Technology Readiness Levels (TRL) and integrating with digital threads are two of the primary challenges that digital twins face, according to another report that looked at their use in a range of industries, including the automotive sector. [11]
- **Decentralized and human-oriented vehicle maintenance**:
  - A DAO-based (Decentralised Autonomous Organisation) architecture was introduced for vehicular healthcare to offer safe, customised maintenance solutions that align with human-centric governance models for the automotive future. [12]

Figure 3 The key to Industry 5.0

3.2.3 Common benefits identified

Several reoccurring advantages of Industry 5.0 methods were found in the researched studies:

- **Improved quality of products and services** (which was determined by 73% of businesses surveyed in one study) [9, 10, 11]

Industry 5.0 technologies have made it possible for businesses to monitor, manage, and improve production processes more effectively. This includes using IoT sensors for continuous monitoring, AI for real-time quality inspection, and digital twins for testing and simulation. The ability of these technologies to reduce defects, improve consistency, and enable faster problem identification results in higher quality outputs.

- **Improved operational resilience and sustainability** [8]

Operational resilience is the ability of an organisation to adapt to disturbances (like supply chain delays or energy shortages) while operating as usual. Sustainability's primary objective is to reduce waste, pollution, and resource use. Predictive analytics, energy-efficient systems, and smart technologies are all part of Industry 5.0, which aims to improve responsiveness and reduce environmental impact.

- **Enhanced human-machine collaboration** through automation while maintaining human responsibilities [6, 10]

Instead of replacing humans, Industry 5.0 promotes collaboration between workers and intelligent systems. While technology handles repetitive, data-intensive tasks, humans focus on creativity, decision-making, and oversight. Cobots (collaborative robots) and AI-powered assistants help people, increasing productivity without undermining their value.

- **Reducing production costs and maximising resource utilisation** [5, 8, 9]

By using automation, AI analytics, and real-time feedback to improve processes, businesses may reduce waste, energy consumption, and overproduction. Machine learning also enables better scheduling, routing, and load balancing, ensuring maximum output with minimal inputs.

- **Higher operating efficiency and data accuracy** in maintenance and lifespan inspections [4, 9, 11]

Machine health is continuously monitored by digital twins and Internet of Things (IoT) sensors, which predict problems before they happen. This increases reliability, extends equipment life, and ensures accurate performance tracking. At the same time, digital records and cloud technologies ensure that inspection data is stored securely and accurately.

- **Customisation and personalisation** of services, especially in the automotive industry [5, 6, 8, 9, 12]

Industry 5.0 enables mass customisation, enabling products to be developed to accurate customer specifications without sacrificing efficiency. Artificial intelligence can recommend designs, while flexible industries, can quickly adapt to new designs or customer needs.

- **Enabling preventive maintenance methods** with AI and IoT interfaces [9, 11, 12]

Preventive maintenance aims to fix concerns before they become problems. By looking at temperature, vibration patterns, past data, and other factors, AI models can predict when maintenance is necessary. This approach reduces the need for urgent maintenance and increases the lifespan of machinery.

3.2.4 Common challenges reported

A review of the examined papers revealed several persistent obstacles to the implementation of Industry 5.0 technologies:

- **Training and skill needed:** Several organisations underlined the importance with which employees need to be upskilled to work with cutting-edge systems. [9, 10, 11]
- **Cost challenges and infrastructure modernisation:** It can be challenging to update outdated infrastructure and processes. [7, 9]
- **Cybersecurity and data privacy:** In unmanaged and human-centric systems, data protection remains a top priority. [9, 12]
- **Legacy system interconnection:** A seamless transfer between old and modern technologies requires customised, cost-effective technical solutions. [9, 12]
- **Technological readiness:** Some technologies, like digital twins, are not as developed as they could be because of integration problems that are slowing down the adoption of these technologies. [12]

3.2.5 Implications for practice and future research

According to the findings, Industry 5.0 operations in the automotive and related industries should prioritise the following:

- Integrated transformation strategies that consider both technological and human factors
- Scalable and open-source system integration options
- Investing into employee training and change management to promote effective technology adoption
- Development of safe, interconnected technologies that foster adaptability and consistence
- Increased focus on available AI and sustainable practices to achieve long-term social objectives [8]

Future research is needed to:

- Analyse human digital twin models in more detail in practical, realistic automotive environments.[9]
- Develop defined frameworks for integrating legacy systems with modern Industry 5.0 environments. [6, 7]
- Analyse how organised maintenance models, including those based on DAO, affect operations and the economy over the long run. [12]
- Support development and integration of digital twin technology across numerous complex industrial domains. [9, 11]

4 FRAMEWORK

A structured framework has been developed to effectively and realistically convey the study's conclusions. This framework shows the progression from initial readiness to long-term Industry 5.0 implementation by organising the key elements discovered throughout the evaluation into a layered structure. The framework is shown in Figure 4 as a pyramid, with each layer building upon and supporting the one above it.

At the base of the pyramid, Layer 1 represents Organisational Readiness and Awareness. The first stage to a successful Industry 5.0 adoption, according to Bartuś et al. [5], is a comprehensive understanding of the organization's current technology and human capabilities. This means evaluating the skill levels of the employees, infrastructure limitations, and technological gaps. Businesses must invest early in infrastructure modernisation, change management, and employee training to lay a solid foundation for future developments. Without this essential basis, attempts at higher levels of Industry 5.0 transformation are unlikely to be successful.

This foundation is expanded on by Layer 2, which concentrates on Key Technological Focus Areas. This layer identifies the specific activities and technological advancements that companies must prioritise to get closer to Industry 5.0 goals. Important activities include automating life cycle assessments (LCAs) for sustainability management [7], integrating outdated systems into smart networks [6], and implementing software frameworks for improved administration and inspection of industrial operations [8]. Advanced technologies are also crucial, such as human digital twins (HDTs) [9], artificial intelligence for defect detection and quality assurance [10], and digital twins for increased operational transparency [11]. Additionally, using decentralised autonomous organisation (DAO)-based maintenance models, which combines digital automation with collaborative governance, for intelligent cars is a novel approach to creating reliable and human-centred maintenance systems [12]. By actively addressing these focus areas, organisations can embrace and integrate cutting-edge technology in ways that align with human-centric, resilient, and efficient principles.

Layer 3 of the pyramid focusses on achieving Industry 5.0 benefits through strategic integration. Organisations that effectively combine readiness with strategic technology investments can benefit from the primary advantages identified in the report. These include improved product and service quality, more accurate data in maintenance inspections, better service customisation, improved operational resilience and sustainability, and preventive maintenance enabled by AI and IoT technology. This layer represents the actual value that organisations can unlock when the bottom layers are structured correctly.

At the top of the pyramid is Layer 4, which describes the research and future practical implications. This layer highlights the ongoing need for more thorough research in areas such as the practical application of human digital twins [9], frameworks for integrating legacy systems [6], the long-term effects of DAO-based maintenance models [12], and the maturity and integration of digital twin technologies [11]. Practically speaking, it highlights the importance of putting open-source, scalable solutions into practice, developing safe,

networked technology, and ensuring that human factors remain a crucial component of all technological advancements. By addressing these issues, organisations can maintain their Industry 5.0 changes over time and stay ahead of evolving possibilities and limitations.

As seen in Figure 4, each layer of the pyramid structure is dependent upon the stability and effectiveness of the layer underneath it. Implementing key technologies and being organisationally prepared are both necessary for achieving the expected advantages and guide future research and practice. Businesses in the automotive and related industries can use this multi-layered strategy as a thorough and useful model as they develop their Industry 5.0 initiatives.

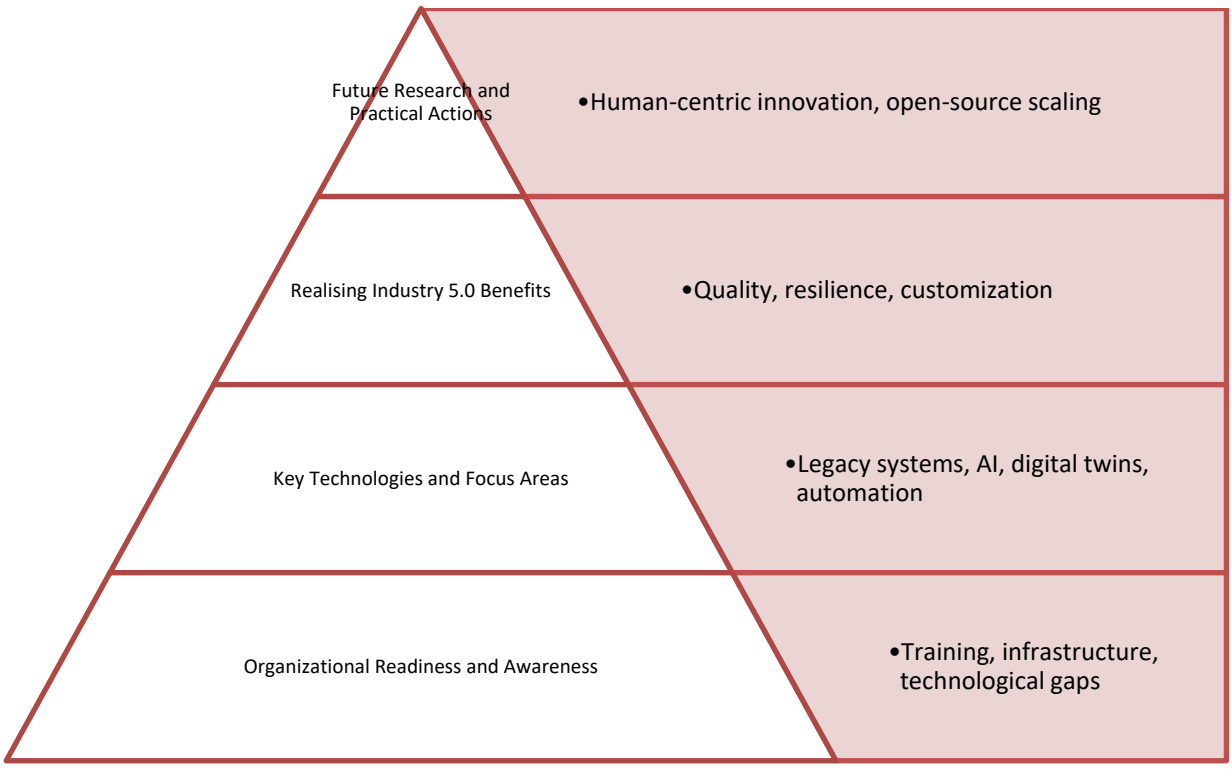

Figure 4 Industry 5.0 for the automotive service sector

5 CONCLUSION

The transition to Industry 5.0, which is defined by the integration of advanced automation, sustainable operations, and human-centric technologies, has significantly changed the manufacturing and automotive sectors. This study developed a structured framework—illustrated in Figure 4—to help organisations make this transition by highlighting the importance of organisational readiness, prioritising key technological focus areas, and strategically integrating innovations to achieve measurable benefits. The examination and review of current research made it clear that successfully implementing Industry 5.0 has both technological and organisational difficulties.

Key findings from the literature show that modernising old systems, implementing data-driven maintenance strategies, and investing in basic staff training are all necessary for long-term success. Additionally, digital twin ecosystems, human digital twins, and DAO-based maintenance models are examples of innovative technologies that promise to create operational resilience, improved service quality, and more customised client experiences. To take advantage of these benefits, organisations must, however, move away from individual technological improvements and towards integrated, human-centred initiatives.

The framework proposed by the study offers a helpful, layered approach to managing Industry 5.0 implementation in the automotive and other industries. It emphasises that organisational development, technological advancement, and research innovation must all go in harmony to produce operations that are sustainable and future ready. In addition to further verifying and enhancing this paradigm across various industrial contexts, future research should focus on investigating the long-term effects of new technologies on employee roles, sustainability results, and organisational competitiveness. Ultimately, Industry 5.0 includes not only smarter factories but also more resilient, adaptable, and supportive industrial ecosystems.

ABSTRACT

High staff turnover in the automotive industry presents a significant challenge, particularly in departments responsible for training new employees in trade skills. The continuous cycle of hiring and training new staff not only impacts operational efficiency but also increases costs. This study analyzes the underlying reasons for high turnover rates in the automotive sector through a systematic literature review (SLR). The SLR was conducted to collect, analyze, and report on key factors contributing to employee attrition. The findings reveal a range of challenges, including workplace conditions, career development opportunities, and organizational culture, while also identifying effective mitigation strategies from case studies in the literature. Based on these insights, this study develops a drivers and barriers framework to better understand and address turnover issues. Ultimately, the research provides valuable guidance for industry leaders seeking to improve employee retention and create a more sustainable workforce within the automotive sector.

Keywords: Aftersales service center, Automotive industry, High staff turnover, SLR

1 INTRODUCTION

The automotive industry is a globally integrated and competitive sector that not only influences transportation but also significantly contributes to economic growth, employment, and technological innovation. The industry involves all companies and activities related to the design, manufacturing, retailing, and aftersales maintenance of motor vehicles. [11] Within this industry, aftersales service plays a critical role in customer retention and brand reputation. Dealerships are responsible not only for vehicle sales, but also for long-term customer support through maintenance, repairs, and part replacements. To remain competitive and efficient, especially in premium automotive brands, the aftersales department must be run by highly skilled and motivated personnel.

The automotive industry is regarded as one of the world's most influential and technologically advanced sectors. The automotive industry is classified under ISIC Rev. 4 Code 2910: "Manufacture of motor vehicles". [12] Globally, the industry plays a crucial role in technological innovation, employment creation, and economic development. In South Africa, the automotive sector contributed approximately 4.3% to the national gross domestic product as of 2024 [13], underscoring its role as a strategic industry for growth and transformation. This industry also employs more than 110 000 people while being the country's fifth largest export sector, 18.1% in 2024. [13]

Company X provides structured upskilling opportunities through training programs for various job positions. Certifications earned through these programs can lead to salary increases and career progression. Despite these upskilling initiatives, the company faces a persistent challenge: retaining trained staff. Employees often leave shortly after completing training programs, either for higher-paying positions elsewhere at industry competitors, alternative work environments, or different industries altogether. This results in a repetitive cycle of recruitment and training, undermining the effectiveness of the company's investment in human capital.

2 RESEARCH METHODOLOGY

The research methodology adopted for this study is a Systematic Literature Review (SLR) [15], a formal structured and replicable approach used to identify, evaluate, and interpret existing research relevant to the underlying factors contributing to high staff turnover within the aftersales service centre of Company X. This method was selected due to its ability to gather evidence comprehensively and accurately from multiple scholarly sources, providing an overview of patterns and proposed solutions within the available literature.

- Step 1: Develop a research purpose and/or objective – Clearly define the aim of the SLR.
- Step 2: Develop research protocol – Formulate a detailed research plan including the purpose, criteria for inclusion and exclusion, databases to search, keywords, and standards for quality evaluation.
- Step 3: Establish relevance criteria – Specify the rationale for determining whether a resource is applicable to this study.
- Step 4: Search and retrieve the literature – Perform searches on relevant scientific databases to gather literature.
- Step 5: Selection of studies – Apply the inclusion and exclusion criteria to choose the appropriate studies.
- Step 6: Quality assessment for relevant studies – Evaluate the quality of each selected paper.
- Step 7: Data extraction – Collect pertinent information from the chosen papers.
- Step 8: Analysis and synthesis of findings – Examine and combine the data from the papers to identify themes and patterns.

- Step 9: Report – Present the review with detailed findings.
- Step 10: Dissemination – Share or publish the SLR results.

2.1.1 Research purpose:

The purpose of the study is to investigate the root causes of high staff turnover in the aftersales service department of a premium automotive dealership and to develop practical strategies to enhance employee retention.

2.1.2 Research protocol:

Table 1 below details the research protocol used to obtain relevant articles that can be used and analysed within the SLR.

Table 1:Research protocol

Purpose of the study	The purpose of the study is to investigate the root causes of high staff turnover in the aftersales service department of a premium automotive dealership and to develop practical strategies to enhance employee retention.
Inclusion criteria	- Studies addressing employee turnover, retention, workplace satisfaction and related factors - Focused within any service-related sector
Exclusion criteria	- Non-article literature - Published beyond 2015-2025 - Non-English literature - Articles where full text was unavailable - Subject of medicine
Search databases	Scopus, Emerald insight
Keywords	“Service” AND “Training” AND “Turnover”
Quality assessment criteria	- All duplicate literature must be removed - Literature must be checked for relevance - Studies must be scientific

2.2 Phase 2 – Conducting the review:

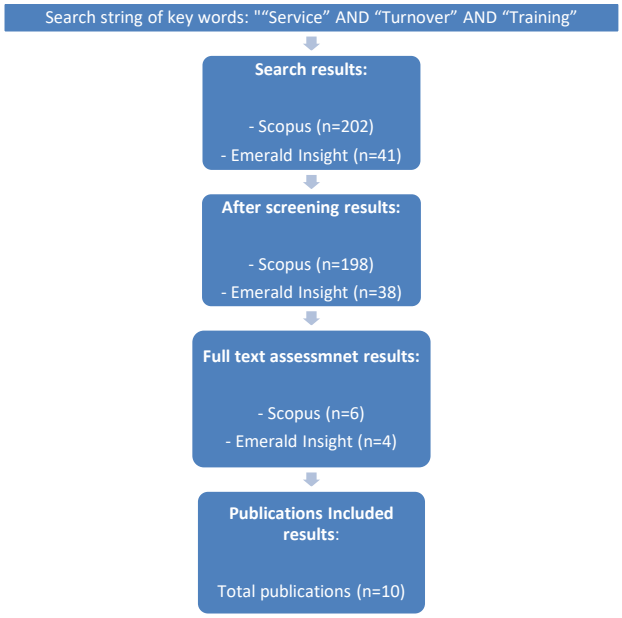

Figure 1: Selection of studies

2.2.1 Establish relevance criteria:

- Direct focus on employee retention or turnover – The study must address staff attrition, turnover or employee retention within its discussion, objective, and findings. Studies without clear reference to turnover or retention were therefore considered irrelevant.
- Considerations related to career advancement, skills development, or training – The research should examine the effects of these opportunities on staff turnover or are used as retention strategies.
- Service sector or service-related organizational context – The study must be carried out within the broader service sector, ideally in the automotive aftersales service sector or comparable service industries such as retail, hospitality, or customer service.
- Empirical research focus – Only empirical studies that presented primary or secondary findings (qualitive, quantitative or mixed methods) were considered relevant. Articles that did not include data-backed conclusions were excluded.
- Publication in peer-reviewed academic journals – To guarantee academic rigor, the research must be published in a peer-reviewed publication that is included in reliable databases such as Emerald insight and Scopus.
- Publication within a certain date – To capture current turnover challenges, trends, and practices, only research published between 2015 and 2025 were considered relevant.

2.2.2 Search and retrieval of the literature:

The literature search for this systematic review was strategically planned to meet the study objectives and relevance standards set in the early phases of the review process. Two credible academic databases, Scopus and Emerald Insight, were chosen to obtain relevant suitable studies due to their extensive coverage of peer-reviewed research. These databases were thought to be suitable for capturing both international and industry-specific perspectives on staff turnover and training procedures in service-oriented industries.

The terms “Service” AND “Turnover” AND “Training” were used to create a structured keyword search strategy. These keywords were chosen to target studies that had a connection between staff turnover and training opportunities within service organizations. The Boolean operator ‘AND’ was used to refine the results and obtain studies that specifically contained all three terms. There were 202 papers on Scopus and 41 papers on Emerald Insight found (as depicted in figure 1). From these results received, all the duplicates and retraction notices were removed to obtain a refined number of results.

2.2.3 Selection of studies

Following the literature search, the 198 papers from Scopus and 38 papers from Emerald Insight (as depicted in figure 1), were screened to assess their relevance to the study’s objectives. To improve the relevance of the search results, filters were applied. Publications were limited to those written in English and in the form of journal articles, and restricting publication data range to 2015-2025. Literature focusing on medical and pharmaceutical related topics were also excluded, as their conclusions were not completely transferable to the service-oriented industry.

After the removal of duplicates, the remaining studies were subjected to title and abstract screening. The predetermined relevance criteria were used to rapidly assess whether a study potentially addresses staff turnover and considers training or skills development as a factor, within the service industry.

Six papers from Scopus and four papers from Emerald Insight, ten papers in total, showed potential alignment to the study and were retained (as depicted in figure 1). This helped to narrow down the literature pool and streamline the review process to avoid the full text assessment of irrelevant topics early.

2.2.4 Quality assessment for relevant studies:

The ten articles that passed the title and abstract screening stage proceeded to the full text assessment stage, where full articles were retrieved and evaluated thoroughly to determine if they met both inclusion and exclusion criteria established. By ensuring an efficient assessment of each study's objectives, context, methodology, and conclusions, the full text review confirmed that only the most relevant and high-quality research was included in the final analysis. Upon closer inspection, none of the ten articles were excluded since their findings did indeed specifically address staff turnover outcomes or retention strategies and they did contain data-driven insights (as depicted in figure 1).

3 FINDINGS

The findings chapter presents the conclusions obtained from the SLR conducted to examine various factors contributing to high staff turnover in service driven industries, with the aim of creating solutions to improve staff retention. Since literature explicitly addressing the automotive aftersales environment, studies from related service industries – such as hospitality, healthcare, and manufacturing – were included to expand the contextual understanding of staff attrition dynamics.

A total of ten high-quality, peer-reviewed journal articles were included in the final synthesis and analysis, each offering unique perspectives and solutions to problems faced in the study. Training efficiency, role stress, work satisfaction, burnout, and organizational support were all frequently evaluated variables in the studies. The studies employed different quantitative methods, such as regression analysis and large-scale surveys, to determine connections between these variables and staff turnover rate.

3.1 Data extraction

As an initial step in the analysis phase of the SRL, a structured data extraction table was developed to arrange and categorize important information from the chosen studies. This table served to simplify the comparison of key study features, providing a foundation for the full text assessment that follows.

To assess each study's relevance to research objectives, the three keywords used to search for literature, "Service", "Training" and, "Turnover", was identified and tracked within each study. It was noted that all ten articles that were examined addressed the concept "Turnover" which is the foundation of the study, while other articles included both the other two concepts or only one of them.

The extracted data enabled the identification of recurrent patterns and gaps within the literature. Table 4, in Appendix A, illustrates the discussed extraction table.

3.2 Analysis and synthesis of findings

3.2.1 Thematic synthesis in relation to research purpose

<u>Job stress, burnout, and emotional exhaustion as key predictors:</u>

Work related stress and emotional exhaustion are among the most significant possible contributors to staff turnover within service-oriented industries. A study done in South China used a questionnaire on hospitality employees, which revealed that role-stress as a four-dimensional construct (conflict, ambiguity, qualitative overload and quantitative overload) has a statistically significant impact on burnout. [2] It is believed that the burnout concept has two aspects: physical and behavioural symptoms. Physical symptoms referring to the person's perceived state of fatigue, and behavioural symptoms describe the difficulty to control emotions, eventually leading to poor performance. [2] The positive effect of burnout

on turnover intention has been proved by scholars, highlighting that burnout correlates with job dissatisfaction, absenteeism and turnover. [2]

Job satisfaction, career growth, and advancement opportunities:

Employee attrition is frequently caused by limited opportunities for career advancement and personal growth. A study of turnover in behaviour analysis examined 96 behaviour technicians across agencies in California and found that different satisfaction measures were significant predictors of their intention to leave. [3] Low organizational commitment has been found to be related to low job satisfaction.

[9] found that higher turnover intention was a result of unsatisfied fundamental needs, such as the desire for meaningful work and professional identity in union staff. Despite training investments, the absence of advancement pathways and a misalignment between organizational direction and employee purpose led to emotional disconnection from work. These results are further contextualised by psychological contract theory. [8] Employee trust in the company declines and their intention to leave increases when they believe that the implicit contract of growth or recognition has been broken.

Service climate and organizational culture

Positive, supportive, and communicative work environments can buffer the effects of job stress, which directly influences turnover intention. When employees think management sincerely cares for their well-being, they experience advanced levels of job fulfilment and display more dedication to the organization, resulting in reduced turnover intention. In the hospitality industry, the number one listed cause listed for employee turnover was the employees' perception of the quality of supervision. [7]

This is supported by [7] which found that employees who perceived their managers as well-trained, empathic and communicative significantly reduced intention to leave organization. Organizational culture also determines whether employees feel that their efforts are recognized. In [4] high turnover was not only linked to employee compensation but also perceived neglect and disrespect from their management.

Compensation, benefits, and financial satisfaction

Inadequate pay and unsatisfactory benefits packages remain strong predictors of staff turnover. This is evident by referring to the large increase in turnover within a ship repair organization where compensation was the most cited reason for turnover. Lack of transparency and budgetary constraints limited the company's ability to improve pay, creating a feedback loop of dissatisfaction and turnover. It was noticed that the under-appreciation from the company led to low work habits displayed by employees, including tardiness, low job quality and unannounced absences. [4]

[8] confirmed that compensation, along with training, directly influenced turnover intention among hotel workers. The study found that the impact of psychological contract breaches could not be balanced, even with effective human resource management. If employees expected better financial recognition than they received, their trust in the organization declined.

The role of training in employee retention:

Traditional human capital theory argues that the value of employees increase after employers provide general skills training. Once possessing appropriate general skills for gaining employment in other organizations, employees are likely to become attracted to working for other organizations, which leads to increased staff turnover. [6] This is supported by [9] , cautioning that training alone is insufficient if not aligned with organizational values and employee expectations.

Organizational support theorists (OST) argue from a different viewpoint and believe that general skills training can perceived organizational support (POS), enhancing emotional commitment between employees and their organization. Based on equal value exchange relationship, OST assumes that employees should rewards organization with high work engagement and reduced turnover [6]. This is supported by [1], which found that field-based training for new caseworkers led to reduced turnover rate. According to the study, burnout slightly mediated the association between retention and training, but work satisfaction entirely mediated it.

3.2.2 Statistical overview of reviewed papers

The ten reviewed studies used a variety of statistical and analytical techniques to investigate the predictors and mediators of staff turnover in service oriented industries. Although turnover intention was a dependent variable in all ten of the studies, there were notable differences in the sophistication and data coverage, which revealed more trends in the methodological practice within the research field.

Sample size and data diversity:

Sample sizes across studies ranged from small, focused populations to large national datasets. The largest study, conducted by [1], analysed 2,365 newly hired caseworkers in the U.S. public service sector. Similarly, [9] examined turnover intention among over 1,000 recent graduates in Korea, using government-collected survey data. These studies provided greater statistical power, allowing for more reliable identification of patterns.

Conversely, the other studies were more limited in scale but contributed valuable insights. For example, [6] examined 147 Chinese graduate employees using PLS-SEM, and [3] analysed just 96 behaviour technicians in a highly specialized U.S. healthcare context. While smaller samples may limit generalizability, they allow researchers to collect nuanced psychological data, particularly on satisfaction, burnout, and perceived support.

Geographically, the research predominantly focuses on Asia ([2], [6], [8], [10]) and North America ([1], [3], [7]), with one study each from Australia [9], Pakistan [5], and Malaysia [4]. Despite the relevance of employee turnover in Africa's growing service economy, no studies were conducted in African or South African settings. This lack of representation limits contextual relevance and highlights an urgent need for region-specific analysis, particularly in the automotive aftersales sector.

Methods and analytical techniques:

The reviewed studies employed different standard and advanced statistical techniques, with multiple regression being the most frequently used. Studies ([2], [6], [8], [9]) went further, incorporating moderation and mediation models to identify indirect and conditional effects. One study, [10], adopted machine learning, marking a significant methodological innovation and differentiating itself from other articles.

Table 2: Methods and analytical techniques

Ref	Method used	Tools/Techniques	Key turnover predictors identified
[1]	Logistic regression	Pre/post intervention modelling	Training, job satisfaction, burnout
[2]	SEM (Mediation)	Structural equation modelling	Role stress, burnout, service climate
[3]	Multiple regression	Likert-scale analysis	Job satisfaction, organizational commitment
[4]	Thematic analysis (qualitative)	Narrative from case interviews	Compensation dissatisfaction, poor management
[5]	Descriptive and correlation	Mixed-method survey, business strategy analysis	Staff engagement, strategy-training alignment
[6]	PLS-SEM	POS, mediation via job satisfaction	General skills training, POS

[7]	EFA and regression	Factor loadings, multivariate analysis	Manager training, perceived supervisor support
[8]	Moderated regression	Contract breach and HR practices	HRM practices, compensation, contract breach
[9]	Hierarchical regression	Moderation by value alignment	Unsatisfied career expectations, value dissonance
[10]	Machine learning	Classification prediction models, logistic regression	Job security, compensation, career mismatch

Cross-study observations:

A synthesis and review of ten studies reveals recurring predictors of turnover intention and highlights key psychological and organizational factors. Although study contexts varied across industries and countries, five themes were consistent.

Burnout emerged as one of the most powerful mediators between workplace stress and turnover. Burnout was found to be either a direct predictor or an indirect pathway linking job demands with intention to leave in studies [1], [2], [3], [6], and [8]. In these cases, burnout magnified the emotional strain of job stress, contributing to disengagement and eventual exit.

Job Satisfaction was correlated with turnover intention in six studies: [1], [3], [6], [7], [8], and [9]. Employees reporting higher levels of satisfaction with their roles, recognition, and growth opportunities were significantly less likely to consider leaving. Job satisfaction was constantly found to be both a direct predictor and an intervening variable impacting turnover in both structural equation and regression models.

Training displayed a dual role in turnover dynamics. In [1], [6], and [7], training was shown to reduce turnover when it was perceived as a form of organizational investment—enhancing commitment and emotional engagement, in line with Organizational Support Theory. However, [6] and [10] highlighted a contrasting outcome: general skills training may increase external employability, leading to higher turnover and facilitating attrition by upskilling employees who later pursue higher compensation roles elsewhere.

Perceived Organizational Support (POS) was identified in [3], [6], and [9] as a critical buffer against turnover. When employees believed their organization cared about their well-being and career development, their intention to stay increased. POS acted as a mediator in various models, reinforcing its role in translating training and managerial support into long-term retention outcomes.

Financial Dissatisfaction was reported as a strong turnover driver in [4], [8], and [10]. Employees facing inadequate compensation—particularly when coupled with a lack of pay transparency, limited benefits, or budget constraints—were more likely to leave. Studies revealed that perceived underappreciation or inequity in compensation eroded employee morale and contributed to tardiness, absenteeism, and job disengagement, all precursors to resignation.

These findings suggest that turnover intention is influenced by a complex set of interrelated factors. A frequency breakdown of the most commonly reported predictors is provided in Table 3 below.

Table 3: Frequency breakdown

Predictor	Number of studies	% of Studies
Job satisfaction	6	60%
Burnout	5	50%
Training	4	40%
Financial dissatisfaction	3	30%
Perceived Organizational support (POS)	3	30%

Emerging trends and gaps

The methodological landscape of turnover research is evolving, with two notable shifts and omissions identified across the reviewed studies.

Mediated and Moderated Modelling is becoming more prevalent in the literature. Researchers increasingly acknowledge that workplace dynamics are complicated, multi-layered interactions rather than isolated processes. Studies [2], [6], [8], and [9] utilized mediation and moderation techniques to uncover how stress, training, organizational support, and psychological contract breaches influence turnover intention under different conditions. These models revealed not only whether variables influence turnover but also how and under what circumstances these effects occur. For instance, [8] discovered that psychological contract violations affected the efficiency of HR procedures, while [6] showed that perceived organizational support (POS) mediated the connection between general training and turnover.

Predictive Analytics represents an emerging frontier with substantial potential. With a predictive accuracy of 78%, [10] is the only study in the review to apply machine learning techniques—specifically XGBoost, K-Nearest Neighbours (KNN), and logistic regression—to classify turnover intention. This transition from traditional explanatory modelling toward predictive forecasting suggests a promising direction for data-driven human resource management. Through real-time employee data, organizations may be able to detect turnover risk early and intervene proactively. However, the absence of predictive models in the other nine studies underscores a significant methodological gap that future research could address by leveraging artificial intelligence and big data approaches.

3.2.3 Limitations of the reviewed literature

Although the ten reviewed studies provide valuable insight into predictors of staff turnover in service-driven industries, five methodological and contextual limitations are evident. These limitations affect the strength, generalizability, and practical application of the findings.

Over-reliance on Cross-Sectional Designs

The majority of studies used cross-sectional survey designs ([2], [3], [6], [7], [8], [9]), limiting the ability to establish causal relationships between predictors and turnover intention. Without longitudinal data, it is difficult to determine whether changes in stress, satisfaction, or training precede turnover intention or are simply correlated with it. Only [1] incorporated a before-and-after training design, offering stronger temporal insights into causality.

Limited Use of Longitudinal and Predictive Models

Despite the increasing availability of HR data, only [10] employed predictive modelling techniques using machine learning. The absence of time-series or longitudinal modelling in the other studies restricts our understanding of how turnover intention develops over time, and how interventions (e.g., improved training or compensation) influence it in the long run.

Geographic and Sectoral Bias

The studies are geographically concentrated in Asia (e.g., [2], [5], [6], [8], [10]), the USA ([1], [3], [7]), and Australia [9], with no representation from African countries, including South Africa. Additionally, while hospitality, manufacturing, and public service sectors are covered, none of the reviewed studies focus specifically on the automotive aftersales

environment, which is the contextual interest of this review. This limits the applicability of the findings to that sector.

Inconsistent Theoretical Frameworks

Although studies reference established theories—such as Organizational Support Theory (OST) in [6], Human Capital Theory in [6] and [10], and Psychological Contract Theory in [8]—many do so superficially. Others fail to position their findings within any theoretical framework at all. This weakens the ability to generalize findings and compare results across studies using a consistent lens.

Inconsistent Operationalization of Constructs

Finally, constructs such as burnout, satisfaction, and support were operationalized differently across studies. For instance, burnout was measured as a mediator in [2] and [6], while in [3] it was treated as a direct predictor. Some studies used multi-item validated scales, while others relied on single-question metrics. This variation limits comparability and weakens the possibility of synthesizing results quantitatively.

3.2.4 Gaps identified for future research

Building on the limitations identified in Section 3.2.3, four important research gaps emerge that present opportunities for advancing the literature on staff turnover, particularly within automotive service-driven sector.

Lack of Context-Specific Research in Automotive Aftersales

Despite the focus of this review, none of the included studies investigated turnover dynamics within the automotive aftersales industry, a sector with unique stressors such as technical expertise requirements, performance-based pressure, and customer-facing conflict. Future research should target this context specifically—especially in countries like South Africa—where skilled labour shortages and employee retention are critical to operational continuity.

Underexplored Use of Predictive Analytics

Machine learning models was introduced in [10] to predict turnover intention with high accuracy, this method remains largely absent from the rest of the literature. Future work should explore data-driven predictive models using tools like XGBoost, decision trees, and neural networks to develop early warning systems for high-risk employees. These approaches can transform retention strategies from reactive to proactive.

Need for Multilevel and Team-Based Modelling

All studies relied on individual-level analysis, despite growing evidence that turnover is also shaped by team dynamics, supervisor relationships, and local unit culture. Future studies should apply multilevel modelling to account for nested data structures (e.g., employees within departments), enabling more accurate interpretation of organizational effects.

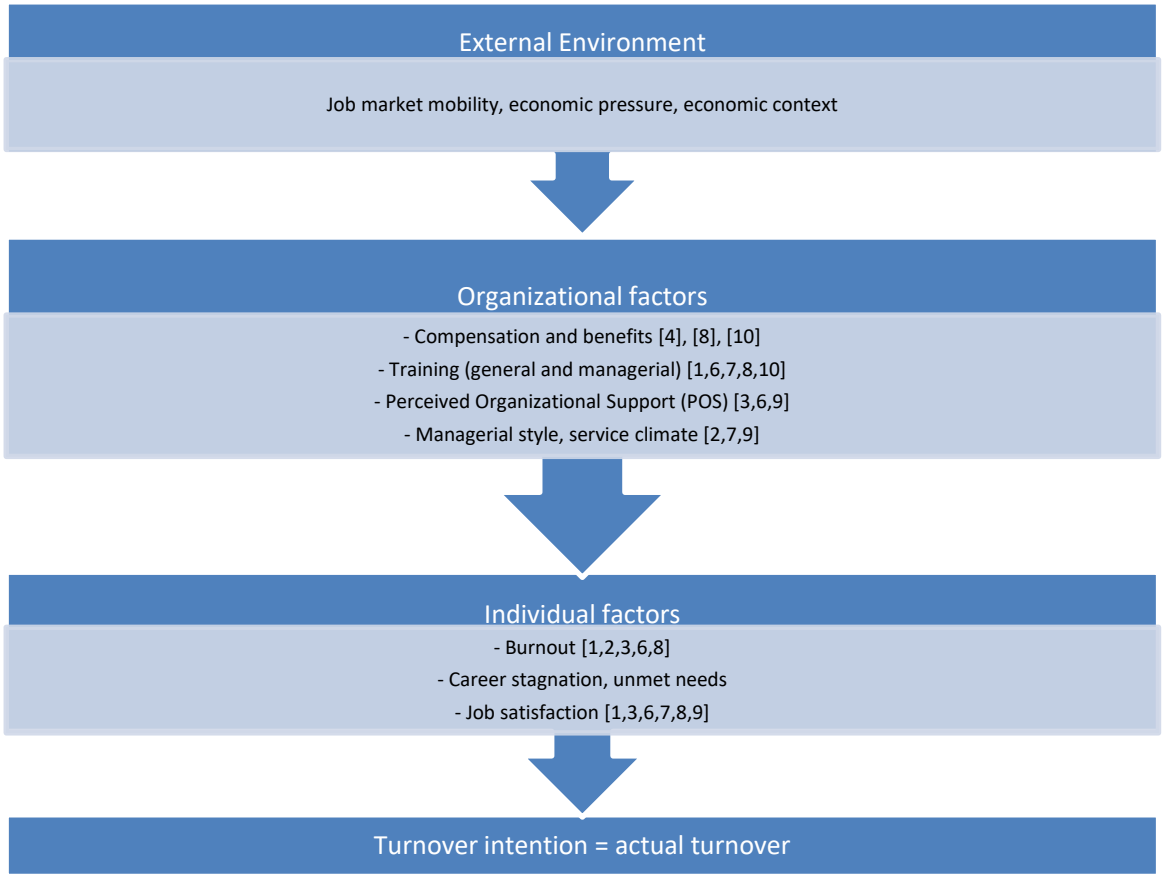
Cultural and Regional Representation

With most studies conducted in Asia, the USA, and Australia ([2], [3], [6], [9], [10]), there is a notable absence of African or Middle Eastern contexts. Cross-cultural studies are needed to understand how turnover drivers differ in regions where job mobility, economic opportunity, and cultural attitudes toward work vary significantly.

4 FRAMEWORK

The analysis in Section 3 highlighted recurring predictors of staff turnover, including burnout, job satisfaction, perceived organizational support, compensation, and training. To integrate these themes into a coherent model, a conceptual framework is proposed that graphically illustrates how organizational, individual, and external factors interact to influence turnover intention. The framework draws on Organizational Support Theory, Human Capital Theory, and Psychological Contract Theory, ensuring that the recurring predictors identified in the literature are theoretically grounded and systematically connected.

Figure 2: Influence of external, organizational and individual factors



From figure 2, the cascade of interactions between organizational, individual, and external factors that affect turnover intention, and then finally translate to actual turnover, is graphically depicted. The framework starts with the external environment, where organizational realities are shaped by elements such as economic pressure, job market mobility, and the larger economic context. These external circumstances subsequently affect organizational factors such as managerial style, perceived organizational support, training opportunities, and compensation and benefits. These organizational components then influence results and performance at the individual level. The model proposes a sequential link, emphasizing that organizational and external factors influence internal employee reactions, which in turn influences whether employees intend to leave.

5 CONCLUSION

To identify effective measures to improve employee retention, this systematic literature review analysed various factors contributing to high staff turnover in service-driven industries. The findings show that turnover intention is shaped by a dynamic interplay of individual-level psychological factors, organizational practices, and external environmental influences. At the individual level, job dissatisfaction and burnout emerged as the most frequent and influential predictors of turnover. These factors often act as mediators between workplace stressors and the final decision to leave.

From a practical perspective, organizations should implement comprehensive retention strategies that go beyond financial incentives. Effective retention requires addressing both the professional and emotional needs of employees. This includes promoting career growth opportunities, reducing role stress, ensuring fair and transparent compensation practices, and creating a supportive and engaging workplace culture.

Future research should address the identified gaps by conducting industry-specific studies, particularly in the automotive aftersales sector, applying predictive analytics to create early turnover risk identification systems, and integrating longitudinal intervention studies to evaluate the long-term effectiveness of HR practices. Although this study is consolidative in nature, by identifying these gaps it provides a foundation upon which more progressive and context-specific research can be developed.

ABSTRACT

In operations management, it is crucial to monitor and regulate downtime to prevent negative effects on revenue, production time, and unhappy stakeholders. A fly ash processing plant is one of the strategic operations that requires effective management for the cement industry. The cement industry is under pressure to find manufacturing strategies for reduction of carbon dioxide (CO_2), as for every 1 tone of cement clinker produced is associated with 0.87 tone CO_2. To achieve this, one of the key raw materials is fly ash and for every quantity of fly ash used for cement production is associated with similar of CO_2 emission reduction. The fly ash processing plant had downtimes assessed over four months period, which affected fly ash availability. Pareto chart was used to categories the downtimes, calculations of Mean Time To Repair (MTTR), Mean time between failures (MTBF), availability and Overall Equipment Effectiveness were made. Subsequently the cost associated with downtimes was also calculated. Pareto chart indicated that 80% of the downtime outcomes were due to breakdown on pipe conveyor belt, pipeline and fly ash hopper. This subsequently indicated an overall MTBF, MTTR and OEE for the four months period was 7.20, 3.14 and 29.32% due to the unavailability of equipment affecting potential production output. respectively. This was correlated with the uptime of 56.42%, with 43.58% accounted by downtime mainly from pipe conveyor belt and pipeline breakdowns with high MTBFF and MTTR. The overall cost associated with carbon tax payable over the four months period was ZAR1.72 million in better case of at better case tax rate of ZAR165.30/ton and ZAR7.68 million in the case of ZAR37.00/ton payable at better case scenario. Meanwhile in the case of CEM II/A-V cement type production at carbon tax better payable rate case of ZAR131.10/ton and ZAR28.49/ton at worse and better case, the carbon tax payable was ZAR1.32 million and ZAR6.09 million respectively. Corrective maintenance was planned and scheduled through Gantt chart. It was carried out over 29 days period to install new pipe conveyor belt, idlers, and rollers on the belt system to avoid old ones wearing the belt thus making the entire system to be affected. The pipe conveyor belt contributed the highest duration at 48.28% and 82.49% total cost of components procured. Post maintenance event on repair and installation of new equipment or component in the manufacturing system, a maintenance program needs to be designed and followed. This is to a monitor and control the equipment, and the entire system of manufacturing to gain the

expected life out of the components maintained. Further research is needed to review future fly ash availability in South Africa in-line with the power utility's driver on Just-Energy-Transition (JIT) strategy. The research should also look at each coal fired power station's electricity generation units' retirement plan which will substituent reduce availability of fresh from older power stations that are best positioned to supply the cement industry for decarbonization initiatives.

Keywords: Carbon dioxide, carbon tax, decarbonization, downtime and Just-Energy-Transition (JIT) strategy

1 INTRODUCTION

1.1. Background

Production uptime is of great importance in manufacturing facilities to fully utilize the equipment on-site for conversion of raw materials into finished goods. Most manufacturers are striving for world class manufacturing with Overall Equipment Effectiveness (OEE) target of 85%. Fakhri et al. [1] indicated that 85% OEE is achieved at three factors, namely availability rate of 90%, performance rate of 95% and quality rate of 99%. OEE has an objective to make an equipment that is constraint to run more efficiently in a manufacturing line [1]. Monitoring of equipment performance in manufacturing processes is an everyday responsibility in production management. Jeong and Phillips [2] decades ago indicated that successful data that gives reflection on real utilization of equipment aids managers with identification of causes of lost time and attempt to reduce the loses, so equipment is available for the required production hours. Thus, minimization of downtime on equipment within a production line is important for meeting this key performance indicator. Haque et al. [3] described downtime as the length of time that a process of manufacturing is interrupted due to unexpected circumstance.

Reduction of downtime as corrective action by first defining priorities through pareto analysis and secondly by creation of projects that ensure a solid approach to solving the issue Haque et al. [3] has been the approach in manufacturing facilities as indicated by much research. Minimization of downtime in a fly ash processing plant is of great importance to cement and concrete industry for decarbonization objectives. Coal fired power stations in South Africa are the dominant source of electricity production. One of the Coal Combustion Products (CCP) from a power station is ash. Eskom [4] indicated that, during power station operations, about 50 000 tons of coal is consumed daily by a typical 3708MW power station which generates 20 000 tons of ash per day.

The coal procurement strategy at the power station operations with respect to category of coal supply contracts being issued, for example, long-Term cost-plus contracts; long term fixed price contracts, medium term or short-term fixed price contracts affects the landed coal cost per ton to the power station due to the pros and cons associated with each contract being used. Contract duration for Long term contracts (cost plus and fixed price) are generally between than 10 years and 40 years with a pre-determined coal price escalation formula. The unit cost of coal is around ZAR397.00 per Megawatt hour as at year 2021, which is higher by 14.61% in comparison to year 2020 pricing. These added to the cost of coal of ZAR66.6 billion which was 59.4% of the primary energy cost of ZAR112.1 billion spent for the 2019/20 fiscal year. This further indicated an increase of 16.3% on average cost per ton coal purchase year-on-year (Parliament of the Republic of South Africa and Eskom Research Unit 2021). Furthermore, Ratshomo (2021) stated that the Department of Mineral Resources and Energy (DMRE) indicated year 2020 average price per ton of local sales based on Free-On-Road (FOR) for bituminous coal and anthracite coal is ZAR 443.09 and ZAR 1037.50 respectively, with value-added tax excluded.

These subsequently have an influence on ash availability and cost thereof, with an assumption that average selling price of fly ash is determined as a function of per-centage fly ash content in the coal. The per-centage is then used to calculate the expected average selling price of fly ash based on the price per ton of coal. The ash produced from coal combustion is split into daily production of 17 000 tons (85%) fly ash and 3000 tons (15%) bottom ash, thus with hourly production rates of 708.33 tons and 125 tons respectively. This means expected estimated average selling price of fly ash is ZAR150.65/ton in the case of bituminous coal combusted at the power station (i.e. Average fly ash selling price = %fly ash in coal× coal price ; Average fly ash selling price = (17 000tons/50 000 tons) × ZAR443.09/ton)).

The cement industry has been embracing fly ash as a raw material categorised as supplementary cementitious material for manufacturing of cement for decades. Most recently, sustainable development targets has been with an emphasis on climate change whereby manufacturing sector contributes. The cement industry contributes carbon dioxide as a greenhouse gas being emitted, such that, Dong et al. [5] indicated that every 1-ton Portland clinker produced is associated with 0.9 tons CO_2 produced and Beltran and Arnesh [6] indicated that it categorises the cement industry as the second largest pollutant in the world. However, depending on manufacturing strategies of a cement plant, this quantity of CO_2 can potentially be minimized from being emitted to the environment at 100% or at a partial percentage depending on production system in reducing the emissions. The Carbon Tax Act 2019 drives the cement industry to invest in decarbonization techniques within their manufacturing processes or systems. This is through charging of a carbon emission environmental levy known as Carbon Tax, which according to Kotze et al. [7] it has commenced on 1 June 2019 at a rate of ZAR120/ton CO_2 emitted. Kotze et al. (2023) further indicated that this tax was planned to be escalated yearly at consumer price inflation (CPI) +2% until 31 December 2022. Thereafter, the tax rate will be escalated by CPI only. The 2024 carbon tax is ZAR190.00/ton CO_2 emitted, and this is payable passed on cement type produced such that the higher the clinker content in the final cement is associated with high carbon content payable and vice versa. This further amounts to ZAR165.30/0.87ton clinker per 1 ton CEM I cement type produced or ZAR165.30/ton CEM I cement type produced, while a typical cement manufacturer can pay-out carbon tax rate of ZAR37.00/ton CEM I cement produced based on the baseline discount based on Carbon Tax Act. The carbon tax typically payable for production of Portland fly ash extended cement, CEM II/A-V 52.5N with 18% fly ash, 3.5% gypsum and 78.5% clinker on better carbon tax payable scenario using ZAR37.00/ton CO_2 emission is therefore at ZAR29.67/690kg CO_2 emitted.

In April 2016, South African government indicated commitment to participate in the Paris Agreement on climate change. Reduction of greenhouse gas emissions by up to 42% is of great need to mitigate the rate of change in climate. For these reasons, availability of fly ash is of strategic value to substitute clinker usage thereby reducing its consumption per ton cement produced which subsequently reduces CO_2 emissions.

Tau et al. [8] described fly ash manufacturing process where a pipe conveyor is utilized for wet handling of fly ash rejects streams as depicted by Figure 1.

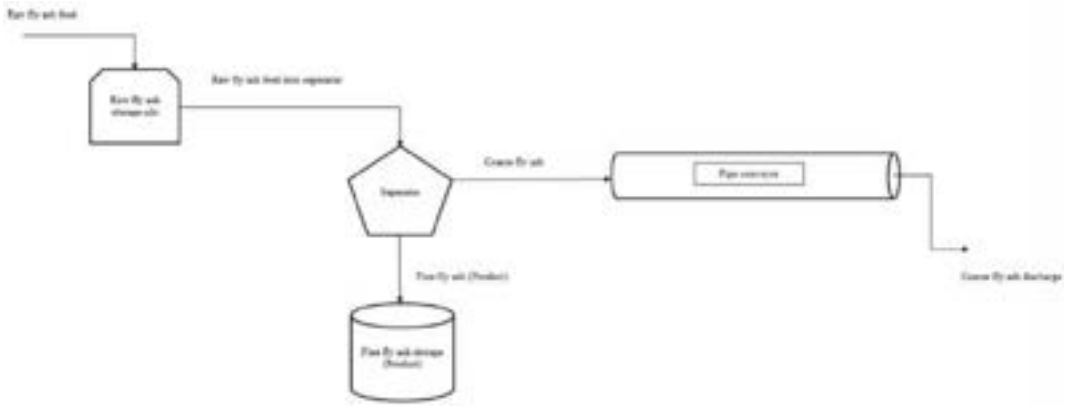

Figure 1: Coal fly ash processing description.

Source: Tau et al. [8]

Downtimes in such strategic plants need to be kept as minimal as possible to avoid supply chain interruptions for decarbonization initiatives, in this case, in the cement and concrete industry.

1.2. Problem statement

Materials handling systems in manufacturing sectors through utilization of belt conveyors are of great importance for movement from point A to B in an efficient and effective manner. Tau et al. [8] analyzed the equipment failure in a production line of a fly ash processing plant. The key findings were that the pipe conveyor belt breakdown/stoppage contributed about 44% of the frequent breakdowns as analyzed over 31 days production period. The average time spent by maintenance personnel to rectify pipe conveyor breakdown was at 192 hours which further indicated 74% of breakdown time spent on attending to breakdown due to pipe conveyor belt. Thus, this was the highest compared to time spent on rectify other breakdown types. The study then recommended frequent inspection and replacement of all idlers that are torn on the infrastructure of the belt station. This was for minimization of wear and tear rate on the pipe conveyor. Furthermore, the study recommended the installation of additional idlers at the back of station idlers to maintain the folding shape of the pipe belt conveyor while running. Further recommendations indicated was that the counter weigh required to be at the design requirements for the belt to ran properly. Thus, the current belt has worn and need to also be replaced to minimize the high number of times spent on no production due to the belt nor running productively. This constraints OEE and fly ash availability to the cement and concrete sector for decarbonization purpose on very ton/cubic meters of cement/concrete produced due this belt system creating constraint. The impact of downtime in such operations as fly ash processing plants are of great importance to be researched as they have direct effect on the entire cement and concrete industry as fly ash is a strategic raw material for decarbonization.

1.3. Objective

1.3.1. Overall objective

The primary objective was to conduct corrective maintenance on Japanese pipe conveyor belt of a fly ash production line for minimization of downtime to increase production uptime for fly ash as a strategic cement raw material for decarbonization.

1.3.2. Specific objective

1.3.2.1. To determine downtime contribution and impact on equipment availabilities, OEE, lose in production hours and quantities.

1.3.2.2. To determine downtime impact on production revenue, lose and carbon tax payables.

1.3.2.3. To conduct corrective maintenance on pipe conveyor belt, pipeline and fly ash hopper to increase production uptime.

1.4. Significance of the study

Coal fired power station operations are under tremendous pressure to manage solid waste such as ash and gypsums from coal combustion in from generation units and gypsum from flue gas desulphurization systems respectively. Disposal of this daily produced waste to ash dams and landfills is not a preferred solution due to environmental risk it possesses such as underground water contaminations with disposal sites be lined or unlined, while with South Africa being a water scarce country and need to protect the little was sources available. Better management of fly ash processing plants is of strategic value to power station ash management strategies for disposal avoidance, however, for beneficiation in the cement and concrete industry. The cement and concrete industry also depend strategically on fly ash for clinker factor reduction in cement associated with 0.9 tons CO_2 production for every 1-ton clinker produced. As it is known that fly ash utilization in cement production reduces CO_2 production by same quantity used as recently investigated by Tau et al. [9]. Availability of fly ash from power station fly ash extraction plants is of great importance for both these industries for sustainable operations on land pollution and climate change due to CO_2 as one of the greenhouse gas emissions. Ali et al. [10] indicated that flue gas streams from clinker production is composed of concentrations of CO_2, nitrogen dioxide (NO_2), nitrogen oxide (NOx), Sulfur dioxide (SO_2) and Oxygen (O_2) with CO_2 constituting the highest share by weight as maximum as 33%. Thus, CO_2 is great concern for reduction by the cement industry.

2 LITERATURE REVIEW

OEE is the concept of Total Productive Maintenance systems that was developed and pioneered by Seiichi Nakajima as noted by Nakajima [11]. Availability factor of OEE is considered as the time available for activities of production by machines and downtime affects this factor [1]. OEE is the measurement of value that is added to production by a specific machine in a certain period, thus for maximisation of equipment effectiveness (Haque et al. 2022) and it is the product of three factors: availability, performance efficiency and quality rate calculated as follows as indicate by several studies (12, 13): OEE= Availability rate × Performance rate × Quality rate. These factors are calculated as: (i) Availability rate = (Total operating time / Available operating time) × 100 (ii) Performance rate = ($Total$ output/ Potential output) × 100 (iii) Quality rate = (Quality production/ $Total\ production$) × 100.

Haque et al. [3] indicated that availability factor of OEE associates the time an equipment could be in operation theoretically thus when the demand for utilisation is available versus the actual time there was output or utilisation from it. Kusumo and Ishak [12] indicated that downtime on equipment often occurs which then results with slowed down process of production, resulting with not meeting the predetermined targets of production output on product. Govender and Dewa [13] also indicated that operational availability is described as the time percentage that an equipment or line of assembly can properly operate when is required for production. Kusumo and Ishak [12] further indicated that to resolve this, companies make efforts to carry out maintenances that are aimed at implementation of program of total productive maintenance.

Nakajima [11] aimed at OEE development to be used as an indicator for identification of losses which are associated with resource consumption without value addition on the final product being manufactured. Thus the bottom approach around OEE deployment involves the entire workforce in a manufacturing process to contribute for the elimination of six big losses which

are (i) unexpected failures of equipment that stop it from contributing to production (ii) set-up and adjustment that is associated with exchanging of tools or production line adjustments for production start-up on every equipment (iii) minor machine stoppages (iv) reduction in operating speed of equipment compared to standard requirement (v) scrap and reprocessing of product produced that does not meet the quality specification required and (vi) losses as a result of start-ups.

Cabezas-Fulca and Muelle-Macchiavello [14] implemented lean manufacturing to maximise the availability of machine in a metal working company. Quantitative analysis of production process of a steel coil cutting machine (Slitter) of a Peruvian metalworking company was conducted. The scope included improvements proposal and implementation as lean manufacturing tools to increase machine availability. Single minute exchange of die (SMED), which is aimed at reduction of setup time of machine through rearrangement of internal to external activities. Kaizen and 5s methods were also applied to continuously improve, standardise processes, improvement of cleanliness and workstations. These were associated with an outcome of improved monthly available time of production by 95.73 hours which indicated 17.36% improvement in machine availability. Furthermore, 16% and 16.5% reduction in setup times and operation cycle times was achieved respectively.

Todmal et al. [15] indicated that machine failures or breakdown results with production interruption which affects the availability of the entire system of production, expenses on maintenances and affecting end customers. Breakdowns and implementation of optimal maintenance of engine cylinder block machines was analysed to improve operational availability [15]. Analysis were made with Operational availability (up time), Failure Mode Effect Analysis, Root Cause Analysis and Why-Why analysis, while parameters like Mean Time To Repair (MTTR), Mean time between failures (MTBF) and Machine Uptime %. The following equations were used to calculate these parameters:

Operational availability (up time) = Number of working days in a month × Available hours in a month [1].

Availability = MTBF/(MTBF + MTTR) [2] ; MTBF = Total available hours/Total number of breakdown (Count); Available hours = Working time – Breakdown time; MTTR = Total breakdowns hours/ Total number of breakdown (Count) [16]

The production quantity achieved were used as key performance indicators whereby they were compared with previous year data in a computerized maintenance management system. The outcome of the study indicated that percentage uptime or availability of machine is critical for achievement of production goals and breakdown must be reduced to increase the percentage uptime.

Predictive maintenance and corrective maintenance are one of the levers of maintenance strategies or types for the improvement of future availability of equipment in a manufacturing plant as shown on Figure as recently reported by Martinus et al. [17] from Rastegari and Salonen [18].

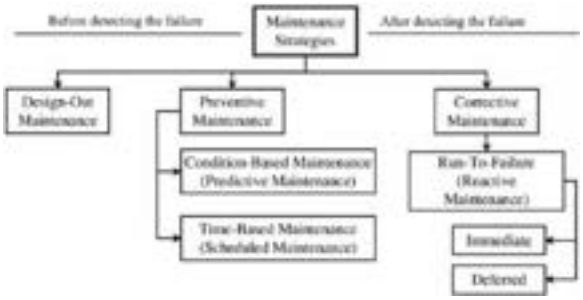

Figure 2: Maintenance strategies.

Source: [17]

Lind and Muyingo [19] stated that Dunn in 2003 defined maintenance strategy as plan for long operational control which covers maintenance management aspects associated with direction settings and with clear actions for achievement future state that is desired in the maintenance function. Furthermore, Zaim et al. [20] also stated that maintenance strategy entails a choice between corrective, preventive and condition-based maintenance. Blanchard [20] indicated that corrective maintenance operates on the basis that an equipment is repaired when it failed or is about to fail. Thus it is not scheduled and has repair actions associated with increased number of equipment downtime resulting with reduction in production output and high cost of resources. Lind and Muyingo [19] further stated that corrective maintenance is also known as breakdown or failure-based maintenance is subdivided according to either being able to be done immediately as failure is detected or deferred to a later date which might perhaps be part of the longer run of maintenance plan.

Martinus et al. [17] conducted predictive maintenance as a means for improvement of centrifugal slurry pump availability of Ergo city deep plant. The study used monitoring techniques of preventative maintenance and it proved that predictive maintenance is better than reactive maintenance for centrifugal slurry pumps due to pump availability being able to be increased by 49%, while the downtime and cost of maintenance have also been simultaneously reduced by 58%. This further improved production losses thereby maximising profit margins of the plant. Pasipatorwa et al. [22] indicated that the manufacturing industry's ability to produce goods at a quality and quantity that satisfy existing customer base, expansion of share in the market, remaining competitive and profitable is dependent on reliability of machines in the line of production. Pasipatorwa et al. [22] explored the impact of machine reliability in a line of production through analysis and interpretation of information of operations sourced from machine database of computerised maintenance management system (CMMS). This was conducted by comparison of Adcock Ingram Critical Care (AICC) and Adcock Ingram Health Care (AIHC) same lines of production. The machines performed bellow benchmarking points, however, post implementation of preventive maintenance there was improvements.

Rahman [23] stated that in year 1906, a mathematical formular was created by an Italian economist, Vilfredo Pareto, for description of distribution of wealth that was unequal in his country. The observation made was that, 20% of people owned 80% of the country's wealth. Additionally, in year 1940s later, Dr Joseph M. Juran attributed the 80/20 Rule to Pareto inaccurately, calling it Pareto's principle. Furthermore, Rahman [23] stated that this technique is helpful in identification of causes of problems that are predominant that are required to be first resolve majority of the problems. The assumption, always, is that 20% of causes are determined by 80% of problems. Wilianto et al. [24] most recently also stated that Pareto chart simply implies that, 80% of outcomes (or outputs) results from 20% of all causes (or inputs) for any given event. Grosfeld-Nir et al. [25] decades ago described pareto chart as frequency block diagram depicting the relative frequency of attributes that are different, in

a descending order. This method of classification should be preceded by taking corrective actions of differentiation and allocation. Burga-Dominguez et al. [26] successfully used pareto chart for the identification of reasons for unproductive times for data collected in the study for management of production model based on lean manufacturing and SLP for optimisation of unproductive times in a SMEs in the plastics industry.

3 METHODOLOGY

Figure 3 depicts step by step flow of activities being carried out for execution of the research.

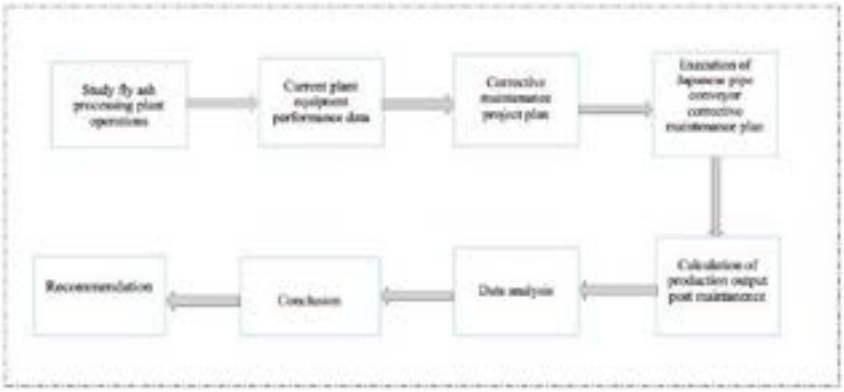

Figure 3: Step by step research flow

The following formula were used to calculate the required variables or factors:

Potential production quantity (tons)

Fly ash production quantity lose (tons) = Hourly production rate (ton/hr) × Downtime duration (hr) ; Production rate is consistent at an average of 38 tons/hr as reported by [3].

Total available production time (hours) = Number of days in a month × hours in a day

Total available none-productive time (hours) = Number of days in a month × daily allocated none-productive hours

Total available productive time (hours) = Number of days in a month × daily allocated productive hours

Total available none-productive time contribution (%) = (Total available none-productive time/ Total available production time) × 100

Total available productive time contribution (%) = (Total available productive time/ Total available production time) × 100

Production capacity utilization (%) = (Actual production quantity / Potential production quantity) × 100

Production capacity under-utilization (%) = (Fly ash production quantity lose / Potential production quantity) × 100

Breakdown time and number of breakdown counts were gathered through daily production log sheet during each month period.

MTBF = Total available hours/Total number of breakdown (Count)

MTTR = Total breakdowns hours/ Total number of breakdown (Count)

Availability = MTBF/(MTBF + MTTR)

Uptime = Available working time − Breakdown time

% Uptime = (Uptime/ Available working time) × 100

% Downtime = (Breakdown time/ Available working time) × 100

Downtime cost, revenue lose (ZAR) at fly ash plant = Average fly ash product selling price × Fly ash production quantity loses

Downtime cost, due to carbon tax payable at worse case at fly ash user cement operations (ZAR) = Cement quantity usage × Worse case carbon rate payable ; Worse case carbon rate payable = South Africa 2024 carbon rate which ZAR190/ton CO_2 emitted as reported by Kotze et al. [28]

Cement quantity usage = Fly ash production quantity loses

Average fly ash selling price = %fly ash in coal × coal price

Downtime cost, due to carbon tax payable at worse case/better case tax = Fly ash production quantity lose × carbon tax rate

Carbon tax payable saving on CEM II/A-V cement type production compared to CEM I based better case tax rate of ZAR37.00/ton cement produced (%)= ((A – B)/A) ×100 ; Where A is downtime cost due to carbon tax payable at better case tax rate of ZAR37.00/ton CEM I cement type produced without fly ash usage, B is the downtime cost due to carbon tax payable at better case tax rate of ZAR37.00/ton CEM II/A-V 52.5N cement type produced with fly ash usage at fly ash user cement operations

4 RESULTS AND DISCUSSION

4.1. Determination of downtime contribution and impact on equipment availabilities, OEE, lose in production hours and quantities.

Table 1 indicates that the total amount of none-productive time spent on production have been increasing by a margin of 3.73%, 3.62%, and 1.40% between month one and two, month two and three, and month three and four respectively. Even though the total available time of production have been different on some months. The big effect is the additional unplanned non-productive hours, added as downtime. This affected the overall productive time by achievement of only 46.19%, while 55.32% was not productive due to downtimes.

Table 1: Targeted time versus actual time on Japanese pipe conveyor production line over four months period with reference to appendix A

Parameters	*Unit of measure*	*Month 1*	*Month 2*	*Month 3*	*Month 4*	*Total*
Target						
Total available production time	**hour**	600,00	696,00	696,00	744,00	2736,00
Total available none-productive time	**hour**	125,00	145,00	145,00	155,00	570,00
Available productive time	**hour**	475,00	551,00	551,00	589,00	2166,00
Total available none-productive time contribution	**%**	20,83	20,83	20,83	20,83	20,83
Total available productive time contribution	**%**	79,17	79,17	79,17	79,17	79,17
Actual						
Achieved productive time (relative to available productive time)	**hour**	299	321	296	306	1222
Achieved none-productive time (relative to available productive time)	**hour**	176	230	255	283	944
Total achieved none-productive time (relative to total available production time)	**hour**	301	375	400	438	1514
Total achieved productive time contribution	**%**	63,01	58,29	53,72	51,95	56,4
Total achieved none-productive time contribution	**%**	240,56	258,50	275,86	282,59	265,53
Total achieved productive time contribution at total available production time	**%**	49,88	46,15	42,53	41,13	46,19
Total achieved none-productive time contribution at total available production time	**%**	50,12	53,85	57,47	58,87	55,32

Table 2 indicates the available time of production which was split between uptime and downtime due to equipment breakdown on the production lines. It is noted on Table 2 that the uptime has been decline from month one to month two by a margin of 4.69%, from month two to month three by a margin of 4.54% and from month three to month four by a margin of 1.77%. The target is to achieve a world class availability of 90.00%. This lose in uptime is

gained by per-centage downtime at the same pace. The overall MBTF for months 1, 2 and 4 were higher than for month 3 which indicated that the rate of breakdown or failures were not taking place within a short duration. Meanwhile at month 3, the MTBF value was low which indicated that failures were taking place within short time. Furthermore, the MTTR for months 2, 3 and 4 were the lowest compared to month which indicated improvement in mean time to recovery post the downtime to ensure production resumes having a fair interruption. In overall over the total four months, an uptime of 56.42% was experienced which is far by 33.57% from the world class availability of 90%. The overall breakdown time of 944 hours associated with 43.58% downtime within the four durations, affecting the production output from the fly ash plant.

Table 2: Equipment MTTR, MTBF and uptime in a fly ash processing plant over four months period with reference to appendix A

Equipment	*Available working time (hrs)*	*Breakdown time (hrs)*	*No. of breakdown counts*	*MTBF*	*MTTR*	*Uptime (hrs)*	*% Downtime*	*% Uptime*

Month 4								
Fly ash hopper	589.00	51.00	18.00	32.72	2.83	538.00	8.66	91.34
Compressor		48.00	23.00	25.61	2.09	541.00	8.15	91.85
Classifier		3.00	2.00	294.50	1.50	586.30	0.51	99.49
Pipe conveyor belt		93.00	29.00	20.31	3.21	496.0	15.79	84.21
Pipeline		88.00	27.00	21.81	3.26	501.00	14.94	85.06
Total	589.00	283.00	99.00	5.95	2.86	306.0	48.05	51.95
Sum over four months	2166.00	944.00	301.00	7.20	3.14	1222.00	43.58	56.42

These downtimes are better categorized by Table 3 and Figure 4 which indicates that pipe conveyor belt has high number of breakdown count followed by pipeline, meanwhile divetor valves due to not sealing properly contributed less. The Pareto chart on Figure 4 generated using results on Table 1 and Table 2 indicated that breakdowns on pipe conveyor belt, pipeline and fly ash hopper contributed 80% of the downtimes in the fly ash processing plant. Thus, these were the factors of improvement for increasing the uptime.

Table 3: Collected data for pareto chart with reference to appendix A

Breakdown causes	*Count of breakdown instances*	*Cumulative total*	*Cumulative percentage (%)*
Pipe conveyor belt	101.00	101.00	34.00
Pipeline	74.00	175.00	58.00
Fly ash hopper	47.00	222.00	74.00
Compressor	41.00	263.00	88.00
Valve	19.00	282.00	94.00
Classifier	10.00	292.00	97.00
Divetor valve not sealing properly	8.00	300.00	100.00

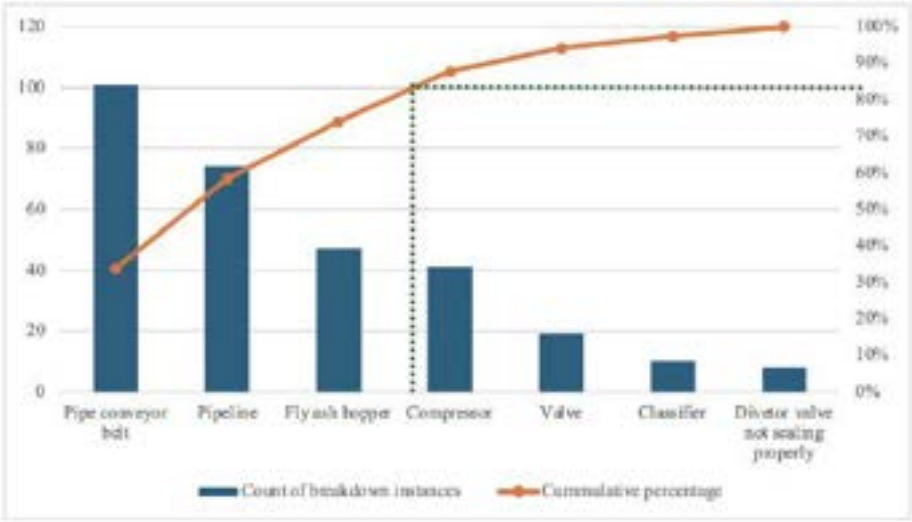

Figure 4: Overall pareto chart for the four months Duration using data on Table 1 and Table 2.

Table 4 indicates that, the downtime due to equipment breakdown, resulted with lower availability and performance rate. This is due to the reduced productive time and production output compared to potential quantities respectively. This subsequently reduced monthly OEE month compared to world class standard. A variance of - 55.68% was achieved when comparing actual OEE with world class OEE target on average for the four months.

Table 4: Downtime impact on OEE

Month	*Availability rate (%)*	*Performance rate (%)*	*Quality rate (%)*	*Actual OEE (%)*	*World class OEE target (%)*	*Variance on actual OEE versus world class OEE target (%)*
1	62.95	62.95	93.10	36.89	85.00	- 48.11
2	58.26	58.26	91.90	31.19	85.00	- 53.81
3	53.72	53.72	90.60	26.15	85.00	- 58.85
4	51.95	51.95	88.90	23.99	85.00	- 61.01
Average	**56.72**	**56.72**	**91.13**	**29.32**	**85.00**	**- 55.68**

Furthermore, Figure 5 indicates that OEE was negatively impacted by an increase in downtime as noted on the four months on month duration. This further justified the impact of downtime on OEE for the need to address the 20% challenges that affected the 80% of the outcome in accordance with Pareto principle.

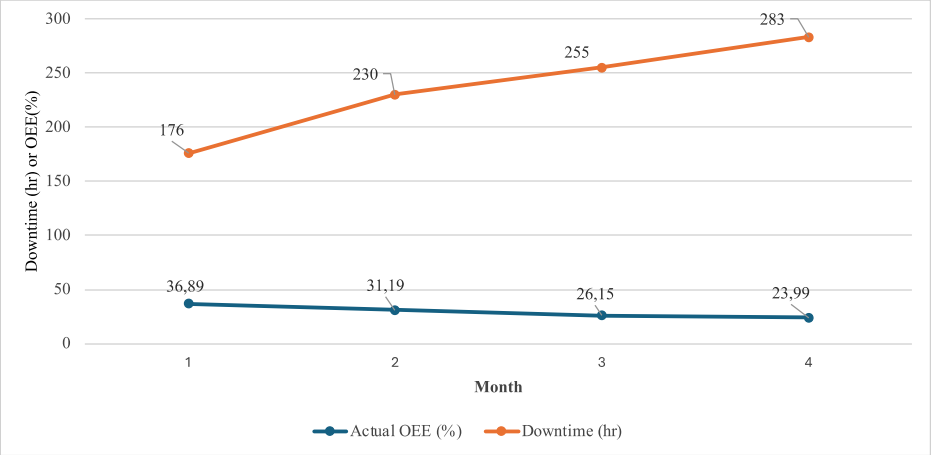

Figure 5: Monthly downtime versus OEE

4.2. Determination of downtime impact on production revenue, lose and carbon tax payables.

Power station operations make use of bituminous coal or anthracite depending on availability and operational needs of the power plant at a point in time. Table 5 indicates the assumed calculated fly selling price as a function of coal being combusted. It is noted that fly ash derived from anthracite is high in price compared to fly ash derived from bituminous coal by a ZAR/ton difference of 202.10 vat exclusive based on Free-On-Road (FOR) coal cost. Even though the fly ash content is assumed to be equal in the coal. However, the selling price in the general market is not variable as a function of type of coal being combusted, but importantly, this gave a fair pricing points in the fly ash market as a quantifiable assumption.

Table 5: Average fly ash selling price as a function of coal type being combusted at a Power station.

Coal type	*Coal amount consumed (tons/day)*	*Fly ash produced (tons/day)*	*Fly ash content in coal (%)*	*Free-On-Road (FOR) coal cost (ZAR/ton) VAT excl.*	*Fly ash average selling price (ZAR/ton) VAT excl.*
Bituminous	50 000	17 000.00	34.00	443.09 [4]	150.65
Anthracite	50 000 *(high grade coal, consumption practically less than bituminous)*	17 000.00	34.00	1037.50 [4]	352.75

Table 6 indicates that , the downtime associated with underutilization of the equipment as a function of production output since the combination of all these equipment forms a production system. Month 1 had the highest utilization of 62.95%, while month 4 had the lowest utilization of 51.95% due to highest downtime. The lower utilization of production capacity, the higher is the underutilization. In total over the four period, utilization of production capacity was 56.42% which required to be improved through minimization of the downtime. The underutilization per-centage can be reduced if the downtime is also reduced. The increase in downtime month on month was associated with an increase in revenue lose at fly ash plant using average selling price of bituminous coal combustion and anthracite. In the case of fly ash selling price as a function of bituminous coal, the loss was 31.00%,11.45% and 10.99%

between month 1 and 2, month 2 and 3, and month 3 and 4 respectively. Similar trend has been noted in the case of anthracite coal usage. This is also indicated by Figure 6.

The carbon tax payable that the cement manufacturer had to incur for production of cement without usage of fly ash also have been increasing month on month for both better and worse case carbon tax rate payable. This indicated an overall cost increase on carbon tax payable by 23.81%, 22.22%, 23.81% and 23.26% on month 1,2,3 and 4 respectively in the case of better case carbon tax rate payable. In the case of worse case, the associated carbon tax payable increased monthly by 21.16%, 20.79% 20.98% and 20.83% for month 1, 2, 3 and 4 respectively. This is also indicated by Figure 7. Although this cost increases in carbon tax, will be passed to the customer as an environmental emission levy, the carbon emitted is not acceptable for environment. Thus, fly ash is a strategic raw material in production of cement with lower clinker, fly ash operations management is of great importance to the cement industry.

Table 6: Downtime production impact and cost

Factor	***Month 1***	***Month 2***	***Month 3***	***Month 4***	***Total***
Available productive hours	475.00	551.00	551.00	589.00	2166.00
Actual productive hours (hours)	299.00	321.00	296.00	306.00	1222.00
Downtime duration (hours)	176.00	230.00	255.00	283.00	944.00
Potential production quantity (tons)	18 050.00	20 938.00	20 938.00	22 382.00	82 308.00
Actual production quantity (tons)	11 362.00	12 198.00	11 248.00	11 628.00	46 436.00
Fly ash production quantity lose (tons)	6 688.00	8 740.00	9 690.00	10 754.00	35 872.00
Production capacity utilization (%)	62.95	58.26	53.72	51.95	56.42
Production capacity under-utilization (%)	37.05	41.74	46.28	48.05	48.05
Downtime cost, revenue lose (Million ZAR) at fly ash plant using average selling price of bituminous coal combustion	1.00	1.31	1.46	1.62	5.40
Downtime cost, revenue lose (Million ZAR) at fly ash plant using average selling price of anthracite coal combustion	2.36	3.08	3.42	3.79	12.65
Downtime cost, due to carbon tax payable at better case tax rate of ZAR37.00/ton CEM I cement type produced without fly ash usage, at fly ash user cement operations (Million ZAR).	0.42	0.45	0.42	0.43	1.72
Downtime cost, due to carbon tax payable at worse case tax rate of ZAR165.30/ton CEM I cement type produced without fly ash usage, at fly ash user cement operations (Million ZAR).	1.89	2.02	1.86	1.92	7.68
Carbon tax payable at better case tax rate of ZAR37.00/ton CEM II/A-V 52.5N cement type produced with fly ash usage, at fly ash user cement operations (Million ZAR) ; Reduced to ZAR28.49/ton cement produced payable due to fly ash usage.	0.32	0.35	0.32	0.33	1.32
Carbon tax payable at worse case tax rate of ZAR165.30/ton CEM II/A-V cement type produced with fly ash usage, at fly ash user cement operations (Million ZAR) ; Reduced to ZAR131.10/ton cement produced payable due to fly ash usage.	1.49	1.60	1.47	1.52	6.09
Carbon tax payable saving on CEM II/A-V cement type production compared to CEM I cement type based better case tax rate (%).	23.81	22.22	23.81	23.26	23.26
Carbon tax payable saving on CEM II/A-V cement type production compared to CEM I cement type based worst case tax rates (%).	21.16	20.79	20.98	20.83	21.09

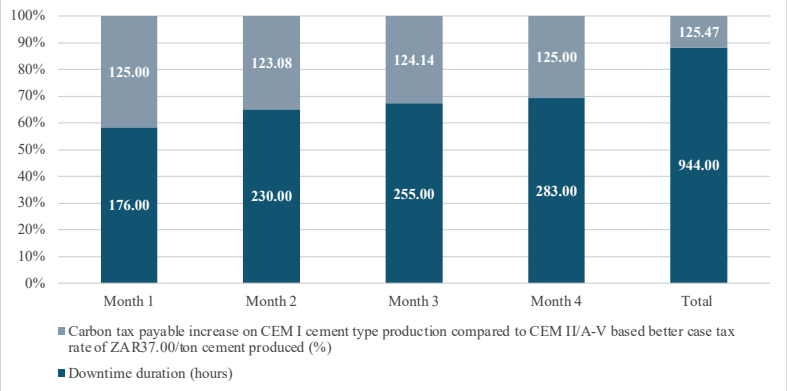

Figure 7: Downtime duration versus carbon tax payable increase on CEM I production than CEM II/A-V

4.3. Corrective maintenance on pipe conveyor belt, pipeline and fly ash hopper to increase production uptime.

4.3.1. Bottleneck identification.

Pareto analysis as depicted on Figure 4 indicated that pipe conveyor, pipeline and fly ash hopper are the biggest losses that contributes to downtime. Thus if debottlenecked, equipment availability and production uptime can increase. Maintenance was conducted over 29 period as scheduled through Gantt chart in order as a key guideline based on the principle of Theory of Constraints (TOC). Ramasu et al. [30] indicated that TOC philosophy requires deployment of additional resources where bottlenecks exist to debottleneck the process area for maximization of capacity utilization.

Table 7 indicates the key activities that was scheduled and executed during the kaizen event in conducting the corrective maintenance. It can be noted that the planned duration pipe conveyor belt, pipeline and fly ash hopper have been achieved at 17.65%, 25.00% and 10.00% less than the initial planned duration. This then reduced the total estimated project duration by 17.14%, thus achieving it at 82.86% of the planned duration. The optimization of the time duration was achieved through running of some of the activities co-currently on which activities that was not affected by other tasks prior. This was to reduce the cost associated with downtimes as calculated on Table 6.

Table 7: Scheduled activities on corrective maintenance

Bottlenecked equipment system as per Pareto chart	*Component worked on*	*Planned duration of activities (days)*	*Actual duration of activities (days)*	*Cost of items (ZAR)*
Pipe conveyor belt	Installation of new idlers and repairing of damaged plates	17	14	90000
	Pulley lagging			25000
	Replacement of bearing counters			150000
	Replacment of counter weight			310000
	Installation of new pipe conveyor belt			650000
Pipeline	Replacement of old 900 metres steel pipeline with new one	8	6	210000
Fly ash hopper	Installaition of new pipes and corrosion prevention at bends	10	9	50000

The activities are being carried out on pipeline conveyor belt as shown on Figure 9 did not only contribute the highest actual duration contribution of 48.28% , but also the highest monetary cost contribution at 43.77%. The lowest monetary cost activity was around pulley lagging with activities shown by Figure 10. It contributed about 1.68% of the entire cost items being procured to debottleneck the equipment and increase uptime.

Figure 8: Replaced pipeline.

Figure 9: New pipe conveyor belt.

Figure 10: Lagged pulley.

5 CONCLUSION

Downtime at the fly ash processing plant as a strategic raw material for substation of clinker to minimize CO_2 emission. Cement type, CEM II/A-V is manufactured using fly ash instead of CEM I cement type which is associated with 0.87 tons CO2 emission. The total downtime over the four months period was 944 hours in comparison to 2166 hours available. According to pareto analysis, 80% of the downtime was associated with breakdown of pipe conveyor belt, pipeline and fly ash hopper. The downtime resulted with underutilization of overall plant at 46.19% which was improved by working on the conveyor belt which was replaced with a new belt, pipeline leaks resolved through installation of 900 meters pipeline and the fly ash hoppers repaired on leaks and pumping vessels from temporary storage equipment. The overall uptime was 56.42%. The achieved OEE was 29.42% due to downtime affecting availability rate and performance rate. Month 2 had the highest MTBF at 10.20 compared to other months which indicated that breakdowns were severe, while month 3 had the lowest MTBF at 2.16.The highest MTTR was noted during the month of January which meant that mean time to recovery post breakdown was longer. The revue loses that fly ash plant had to incur as a function of downtime increased monthly over the four months period. The overall revenue loss was ZAR5.40 million and ZAR12.65 million in the case of fly ash from bituminous and anthracite respectively. The user of fly ash produced cement without fly ash and incurred extra carbon tax cost by 23.26% and 21.09% for tax payable at better case and worse case respectively.

6 RECOMMENDATIONS

6.1. To operations management

Post maintenance event on repair and installation of new equipment or component in the manufacturing system, a maintenance program needs to be designed and followed. This is to a monitor and control the equipment, and the entire system of manufacturing to gain the expected life out of the components maintained.

The existing maintenance strategy need to be reviewed to refocus on section of the plant that requires consistent attention. Preventative maintenance schedules need to be followed on time to avoid responding on corrective maintenance which is costly. Furthermore, computerised maintenance management system (CMMS) can be used as a tool to management the assets, schedule maintenance and for tracking of work orders for the enhancement of reliability of the life of the equipment in the plant.

6.2. Future research

The study revealed the cost associated with carbon tax payout as an environmental levy for the emission of carbon dioxide as greenhouse gas by the cement industry. This subsequently indicated the extent to which the South African cement industry relies on fly ash from coal fired power station to reduce clinker content in cement produced associated with carbon dioxide. Thus, due to these, further research is needed to review future fly ash availability in South Africa in-line with the power utility's driver on Just-Energy-Transition (JIT) strategy. The research should also look at each coal fired power station's electricity generation units' retirement plan which will substituent reduce availability of fresh from older power stations that are best positioned to supply the cement industry for decarbonization initiatives.

Further research is also required for the evaluation of dumped effluent conditioned fly ash from disposal sites for suitable use in cement production for decarbonization purpose in case of scarcity of fresh fly ash in the future.

ABSTRACT

The power industry evolves due to technical, socioeconomic, and environmental factors, with a key focus on managing transmission and distribution assets such as transmission lines, transformers, boilers, and substations. Asset management in power plants includes decision-making, monitoring, and evaluation to ensure adequate maintenance, fault detection, and component replacement. These operations generate vast amounts of data that industrial systems collect and contain critical insights into processes, alarms, and failures. Machine learning models support proactive decision-making, enhancing operational efficiency and improving component lifetime assessments. Through a systematic literature review, this study investigates machine learning applications for optimising asset maintenance management in coal-fired power plants. The research contributes to academia and industry by assessing how machine learning has been applied in this context and identifying future research opportunities for improving asset maintenance management strategies.

Keywords: Systematic Literature Review, Machine Learning, Asset Maintenance Management, Power Industry

1 INTRODUCTION

Asset management within the context of power plants is defined as the decision-making, monitoring and evaluation of assets and equipment [1]. Maintaining control operations, lifespan, and the working conditions of various components within a power plant ensures the quality of distribution systems [2]. Subsequently, asset management within power plants ensures that a strategy is followed to make the right decision at the right time of operation, maintenance, fault detection and component replacement [3, 4]. In coal-fired power plants, asset management is further complicated by challenges such as high-temperature corrosion, abrasive ash deposits, and accelerated component wear from harsh environmental and operational conditions.

The significance of asset management is highlighted in academic literature and industry since it improves profits, reputation and reduces costs [5, 6]. Various researchers, including Napoleone *et al*. [7], have highlighted the benefits of implementing asset management strategies. These benefits include increased operation efficiency and improved lifetime assessment of components, low-cost consumption, reduced failure rate and improved component availability and safety. This paper will focus on overall asset management, including maintenance planning and execution, health monitoring, lifecycle maintenance, predictive data analytics, and inventory management. The asset maintenance management model is presented in **Figure I**, as obtained from Cheng *et al*. [8].

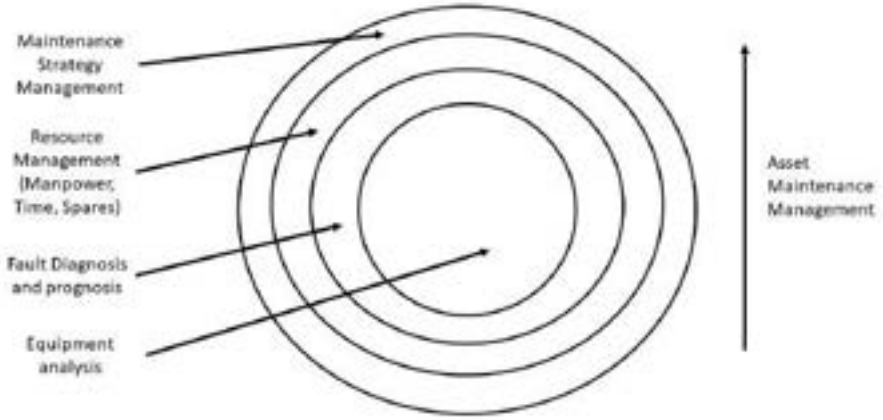

Figure I: The asset maintenance management model, as adopted by Chin *et al*. [8].

Chin *et al*. [8] stated that asset maintenance management has become a large area of operational research since it is based on mathematical models in which the costs and benefits of various maintenance strategies are quantified [8]. Replacing equipment becomes worthwhile when maintenance programs prove ineffective. Subsequently, if the cost-benefit ratio of long-term maintenance outweighs the benefits due to frequent equipment failures, replacement offers more significant advantages. However, effective maintenance and reliability schedules aim to do the correct maintenance at the correct time on the right assets to prevent equipment replacement. For this reason, maintenance management is applied to prevent or reduce the number of equipment failures.

According to Khuntia *et al*. [9], time-domain asset management is divided into time-based and activity-based. Time-based asset management consists of long-term, mid-term, and short-term asset management. Activity-based asset management consists of technical, economic, and societal factors. **Figure II** provides an overview of asset management, as obtained from Khuntia *et al*. [9].

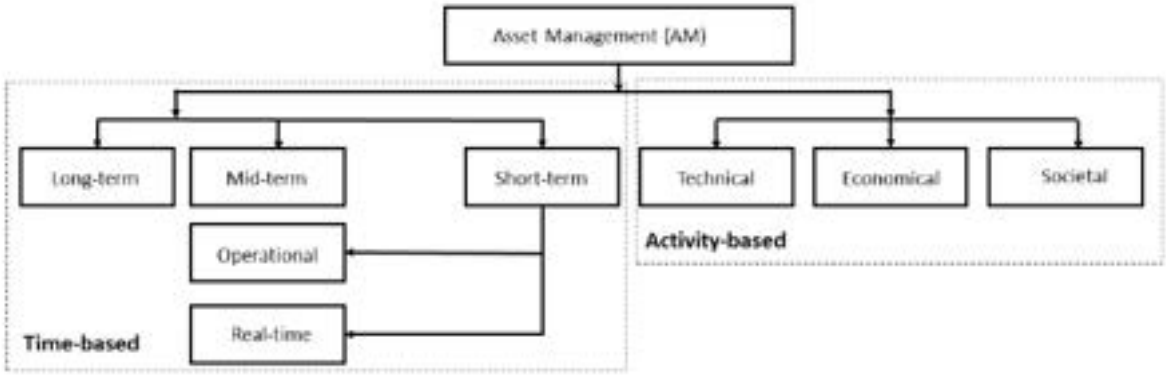

Figure II: Classification of asset management models, as adopted from Khuntia *et al*. [10]

Long-term asset management (one year and more) encompasses upgrading existing transmission and distribution assets. This type of asset management consists of future planning and the investment in new assets, including transformers, reactive devices, capacity expansion and upgrading substation equipment. Mid-term asset management ranges over a more extended period and consists of optimal equipment maintenance scheduling and resource allocation within power plants. Furthermore, accurate maintenance plans may reduce unplanned power outages, costs, financial and physical risks, and the expansion of the life span of assets. *Short-term asset management* is defined as operational asset management that minimises asset risks subject to load demand and hourly prices, and real-time asset management assesses the unexpected outages due to unexpected events, including weather change, a sudden breakdown and load fluctuations [10].

On the activity level, Smit *et al*. [11] indicated that asset management can be categorised into three sections: Technical, economic, and societal asset management. First, technical asset management concerns the physical condition of assets and inventory. For example, the components' ageing, failure and inventory must be considered using historical data for future planning. Economic asset management is concerned with the financial aspect of asset management, including but not limited to maintenance costs, spare part costs and equipment tests and assessments. Societal asset management is concerned with how equipment utilisation impacts the environment, for example, power outages within hospitals and schools [11].

Effective asset management reduces operational and capital expenditures by improving the return on investment and optimising the life cycle of electrical equipment [12]. One of the power industry's biggest challenges is the interruption of the power supply. For this reason, implementing effective predictive maintenance and business strategies is essential. Predictive maintenance strategies also include data analysis tools that enhance effective maintenance management, risk assessment, decision-making and condition monitoring [12]. Khuntia *et al*. [10] stated that asset management involves obtaining a maintenance strategy for the assets, which is essential since it will determine the link between maintenance and renewal actions, resulting in various new strategies.

These strategies include corrective maintenance (run-to-failure), preventive maintenance, reliability-centred maintenance (RCM) and time-based maintenance. *Corrective maintenance* is defined as maintenance and work done on equipment after the point of failure, whereas preventive maintenance is done before the point of failure. RCM is where the most critical components are prioritised, and time-based maintenance is where the component status is observed during the last visit. One advantage of time-based maintenance is that components

can be maintained simultaneously. However, if the time interval is not used correctly, it may result in technical failures or economic losses.

Condition-based maintenance is followed when a fault is detected on the equipment [10]. However, it is essential to note that condition-based maintenance requires systematic oversight of all components. Predictive maintenance is also an essential part of asset management and consists of using predictive tools, including machine learning, to determine which maintenance tasks should be executed. Predictive maintenance identifies early fault detection and improves equipment's overall asset health [13]. All these maintenance strategies form part of effective asset management at coal-fired power plants.

Carvalho *et al*. [13] stated that a large amount of data is collected by industrial systems, which contains valuable information about occurrences, processes and alarms. However, the data must be correctly processed and analysed to obtain valuable information and knowledge that might assist with strategic decision-making regarding maintenance strategies, machine fault detection, inventory and safety. Milić *et al*. [14] indicated that early fault detection of equipment and prediction is possible due to the rapid development of computer and communication systems, which increased the development of complex machine-learning algorithms. Machine learning, which is defined as a subdivision of artificial intelligence, is a powerful tool to develop and assist with strategic decision-making, specifically maintenance.

Ahmad *et al*. [15] added that machine learning algorithms could process energy distribution data quickly and efficiently; machine learning algorithms can also assist with improved energy efficiency, energy demand side response and energy planning under uncertainty. Furthermore, machine learning can process high-dimensional and multivariate data and identify hidden patterns. It is also essential to note that the performance of these algorithms depends on the type of algorithm and the application domain. A large number of studies have been published focusing specifically on maintenance management. A review conducted by Fraser *et al*. [16] investigated various maintenance management models in various sectors. The main application areas were manufacturing, power plants and oil refineries. These studies mainly utilised preventive and predictive maintenance strategies.

Furthermore, Alrabghi and Tiwari [17] also contributed by reviewing simulation-based approaches for maintenance systems. Subsequently, most of these papers used discrete event simulation and genetic algorithms as optimisation tools. To contribute to research, this study aims to investigate machine learning applications for optimal asset management in coal-fired power plants.

The following objectives are defined:

1. To provide an overview of all theoretical aspects regarding machine learning.
2. To investigate machine learning applications for optimal asset management in power plants.
3. To provide valuable future recommendations based on the findings of the systematic literature review.

This study contributes towards research and industry by analysing the current state of machine learning algorithms and their applicability to asset management at coal-fired power plants. The studies are evaluated in detail by providing insight into how these models were developed and how machine learning models can be applied for effective asset management by considering various equipment, including but not limited to distribution networks and coal-fired boilers.

The paper is outlined as follows: Section 1 and Section 2 provide an overview of machine learning, followed by an overview of how some of these algorithms are applied for asset

management. Section 3 conducts a systematic literature review, and the results are discussed in Section 4. Conclusion and valuable future recommendations are presented in Sections 5 and 6, respectively.

2 A LITERATURE SURVEY

The electric power industry is experiencing various changes due to technical, socioeconomic, and environmental developments including the increase in emissions. Subsequently, the primary focus is on transmission and distribution assets, including substation equipment, transmission lines, and transformers. For this reason, *asset management* is defined as an essential activity for transmission and distribution system planning and operation.

Maintaining components and policies is widely applied and investigated within the academic literature. For example, authors Bartlett [18], Abu-Elanien and Salama [19] and Heggset *et al*. [20] demonstrated the maintenance of power transformers. Further studies conducted by Bartlett [18] and Kalinowski and Anders [21] investigated maintenance on lines and cables, and Heggset *et al*. [20] and Lindquist *et al*. [22] have also investigated maintenance on protection devices.

Studies conducted by Zhang and Gockenbach [23], Abu-Elanien *et al*. [24], Mkandawire *et al*. [25], and Heo *et al*. [26] have focused on extensive research regarding power transformers, specifically health monitoring, ageing and oil-indicators. Other extensive research was conducted on circuit breakers within power plants and underground cables by Mackinlay and Walton [27].

Khuntia *et al*. [10] indicated that data management integrates power plants' physical and non-physical asset management domains. Large amounts of data are available due to the advanced computational tools and smart meters. This data is typically used to improve the performance of assets and policies. Data within this domain concerns the inspection rates, mean time to failures, etc. [28]. For example, Aldhubaib and Salama [29] studied the impact of maintenance on transformers, precisely the replacement time, using genetic algorithms and RCM.

Within the last decade, multiple studies focused on integrating information technology and human-machine interfaces within the asset management domain. For example, Kostic [30] integrated IT in asset management using process data and other analysis tools, including supervisory control and data acquisition, data management services, and a computerised maintenance management system. The development of algorithms and tools using optimisation and machine learning has been widely studied in the literature. Before these studies can be explored, an overview of machine learning is provided.

Machine learning enables data-driven models to detect anomalies, predict failures, and optimise maintenance schedules in power plants. Furthermore, machine learning teaches machines how to handle data efficiently and more effectively. For example, after viewing the data, there is still uncertainty about what the data means and what information can be taken from these datasets. Due to this uncertainty, machine learning algorithms are applied to interpret this information effectively.

Machine learning is divided into four subsets: supervised, semi-supervised, unsupervised, and reinforcement learning. This paper focuses on applying machine learning for effective asset management. For this reason, a high level will be provided on these algorithms' theoretical aspects, focusing on how these algorithms are applied in academia and industry.

1. **Supervised:** Supervised learning algorithms enable a model to predict certain outputs based on specific inputs, using labelled examples that understand the patterns and relationships between the input and output variables. Supervised learning requires external assistance to train and test the models. The data is typically divided into training and test data. The model is trained using hyperparameter tuning. The

parameters are tuned until acceptable performance metric values are obtained. Once the best hyperparameter values are obtained, the model is tested using the unseen test data. Supervised algorithms include decision trees, support vector machines, Naïve Bayes, and Supervised Neural Networks.

2. **Unsupervised:** Unsupervised learning algorithms do not depend on predetermined answers or an external assistant. These algorithms work and operate independently and investigate patterns and relationships between various variables. These algorithms use previous knowledge to process unfamiliar data and identify the features and hidden patterns within the data. Unsupervised algorithms include and are not limited to Principal component analysis, K-means clustering, and Unsupervised neural networks.
3. **Semi-supervised:** Semi-supervised machine learning combines aspects of both supervised and unsupervised techniques. These algorithms use labelled data to make predictions and unlabelled data to investigate the patterns within the data and the data distribution. Semi-supervised algorithms include Transudative SVM and Generative Models.
4. **Reinforcement learning:** Reinforcement learning is concerned with agents and the actions of these agents based on the environment. The purpose is to maximise the notion of reward. Reinforcement learning algorithms include Multitask learning, Ensemble learning and boosting.

Machine learning techniques are widely applied to solve data-driven problems while comprehensively reducing complexity and time consumption [31, 32]. A study by Aminifar *et al*. [33] evaluated the performance of various machine-learning techniques used for asset management. The application of these techniques plays a vital role in power distribution/transmission systems [12]. Lal Rajora *et al*. [12] investigated different machine learning algorithms and how these techniques were applied to asset management within power systems. Afrasiabi *et al*. [34] applied a deep neural network for fault detection in power transformers. Subsequently, the internal faults were identified by first estimating the computational burden and model dependency. Regarding the deep neural network, the advantage identified was that this technique has high robustness; however, it has difficulty processing large datasets.

Bacha *et al*. [35] applied the support vector machine for fault diagnosis in power transformers. Subsequently, different types of faults were identified, and it was concluded that the support vector machine's computational complexity is high; however, it can minimise the risk and error rate. Another study conducted by Spatti *et al*. [36] applied expert systems to optimise asset management. The authors stated that the electrical system must be prevented from unknown failures. For this reason, this study evaluated the fault history of the equipment using an asset management strategy. It was concluded that expert systems have better reliability and improved safety levels. Mirhosseini *et al*. [1] applied a multi-criteria decision-making model for asset management, specifically power distribution systems. In conclusion, this technique is highly accurate in terms of evaluation. However, it has a high time complexity. Based on the existing literature and the limitations of the application on machine learning, this study aims to further investigate the application of machine learning by conducting an SLR.

In **Section 2**, an overview was provided of asset management and the application of machine learning within the academic literature. In the following section, a systematic literature review is conducted to investigate the application of machine learning algorithms for asset management at coal-fired power generation utilities.

3 A SYSTEMATIC LITERATURE REVIEW: RESEARCH METHOD

There is a significant gap in the academic literature between the number of published papers and the time it takes for academics to review them [37]. For this reason, various methods exist to address this gap, including a systematic literature review. This type of review originated in the medical industry and is primarily defined as an evidence-based search where a specific number of studies are selected from the academic literature related to a specific research field [38]. A systematic literature review follows a rigorous method that distinguishes it from other reviews, such as literature reviews [38]. This study aims to investigate the application of machine learning algorithms for asset management at coal-fired power generation utilities. The research method followed in this study is based on the method proposed by Kitchenham *et al*. [38], Garg and Kumar [39] and Xiao and Watson [40] (presented in Table 1). The study by Kitchenham *et al*. [38] conducted a review to identify the status of Evidence-based Software Engineering (EBSE) papers. Furthermore, the study by Garg and Kumar [39] conducted a systematic literature review on sentiment analysis within the social multimedia industry. Xiao and Watson [40] provide detailed guidelines on how to conduct a systematic literature review. This review was also conducted following the same process as the review conducted by Bisset *et al*. [41]. Table 1 demonstrates the research methods followed in the first two studies and identifies the research method followed in this study.

Table I: Examples of research methods

#	Research method	Study examples
1.	The systematic literature review method conducted in the study consisted of seven stages. These include the following: 1. The formulation of the research questions 2. A formulated search process 3. Inclusion and exclusion criteria 4. Quality assessment 5. Data collection 6. Data analysis 7. Deviations from the protocol.	Kitchenham *et al*. [38]
2.	The systematic literature review method conducted in the study consisted of seven stages. These include the following: 1. The formulation of the research questions 2. A formulated search strategy 3. Study selection 4. Quality assessment 5. Data extraction 6. Data synthesis	Garg and Kumar [39]
3.	The systematic literature review method conducted in the study consisted of seven stages. These include the following: 1. The formulation of the research questions 2. Search Process 3. Study selection: Inclusion and Exclusion Criteria 4. Quality assessment 5. Data extraction 6. Data synthesis	N/A

3.1 RESEARCH METHODOLOGY

The research methodology is present in **Table II**.

Table II: Research methodology

1. RESEARCH QUESTIONS

Research Question
What is the current maturity of machine learning algorithms or models for asset management specific to coal-fired power generation utilities?

2. SEARCH PROCESS

Step 1	Step 2	Step 3	Step 4
Literature Identification	Screening for inclusion	Quality and Eligibility Assessment	Iterations

Keywords (Set 1)	Keywords (Set 2)	Databases
"Machine Learning" AND "Asset Management" AND "Coal-fired power plants"	"Machine Learning" AND "Asset Management" AND "Boiler"	Science Direct

Inclusion Criteria	Exclusion Criteria
1. The study only included published journal articles. 2. The study only included the journals with the relevant keywords. 3. The study only included articles published between 2013 and 2023.	1. Non-English Articles

3. DATA COLLECTION AND ANALYSIS

Data Extraction	Data Analysis
The data extracted from each study were the following: 1.The type of machine learning algorithm applied.	Each study identified is summarized in Table III to show: 1. The title of each study 2. Journal and year 3. Reference 4. The year of publication. 5. Reference.

4. RESEARCH RESULTS

The quality assessment criteria followed were obtained by Xiao and Watson [40]. Each phase with a description is described in the table below.

Research Protocol	Research Results
Step 1: Literature Identification Xiao and Watson [40] indicated that the search starts with identifying the literature. Typically, the keywords are used to identify which studies apply to the search and the timeframe. The total number of studies published per database is recorded.	The databases were searched. The following results were obtained: Keywords set one: • Science Direct = 13 Keywords set two • Science Direct = 60 **Total: 73**
Step 2: Screening for inclusion The next step is known as screening for inclusion. This step aims to scan the abstracts of all the studies identified in phase one for relevance. More than one researcher must evaluate the studies. The studies not applicable must be excluded from the search, and those applicable must be kept and analysed further in step three.	The following results were obtained by screening the studies according to the inclusion and exclusion criteria. Keywords set one: • Science Direct = 8 Keywords set two • Science Direct = 39 **Total: 47**
Step 3: Quality and Eligibility Assessment Step 3 three consists of the quality and eligibility assessment. The full articles must be skimmed to evaluate the relevance of these selected studies identified in phase two. It is also essential that the duplicates are removed to ensure that no study is selected twice in the search.	All duplicates were removed. The following results were obtained: Keywords set one: • Science Direct = 3 Keywords set two • Science Direct = 39 **Total: 42**
Step 4: Iterations In phase four, a detailed analysis is conducted to investigate the method used in each paper. The paper is also evaluated to obtain the required information to achieve the review's aim.	A full-text assessment was done on all **42 studies** to investigate the application of machine learning algorithms for asset management at coal-fired power generation utilities.

4 A SYSTEMATIC LITERATURE REVIEW: THE REVIEW RESULTS

4.1 Search Results

The study results are demonstrated in Appendix A. The study conducted by Milić *et al*. [14] investigates the primary roles of data science and machine learning in various parts of power plants, including the edge, fog, and cloud levels of vertical IIoT. Data pre-processing, specifically data analysis, is discussed on all levels. The proposed concepts presented in this paper may provide valuable management and maintenance improvements with minimum production downtime. The authors provided an overview of different IIoT concepts, including the following: Data pre-processing subject to supervised, unsupervised, semi-supervised and reinforcement learning. The data is usually split into 70% / 30% for supervised learning. The model's training is done on 70%, and the model is tested using 30%.

Sierla *et al*. [53] developed a virtual power plant that can enhance renewable energy generation. Furthermore, a virtual plant may have the functionality to forecast loads and market prices and manage assets related to distributed energy resources. Machine learning algorithms have been developed to realise some of the functionalities of these systems. For this reason, this article aims to present a 3-tier taxonomy of all these functionalities identified: Optimising, forecasting and classification. The authors of this paper followed a scientometric research methodology and developed a central database where all the articles referenced in this paper were captured. The paper concludes by discussing the topics of specific fields expected to gain many publications in the future and identifying unresolved challenges.

This study, conducted by Cheng *et al*. [8], addresses restrictions in reactive and preventive maintenance strategies for building maintenance management. This paper proposes a predictive maintenance strategy using advanced technologies, including but not limited to Building Information Modelling (BIM) and the Internet of Things (IoT). The proposed framework includes data collection and integration, and an application layer with modules for condition monitoring, fault alarming, assessment, prediction, and maintenance planning. Machine learning algorithms, including ANN and SVM, are developed and employed to predict the future condition of MEP components. The example presented in this paper demonstrates the framework's effectiveness in predicting component conditions for efficient maintenance planning. Research paper – This study addresses restrictions in reactive and preventive maintenance strategies for building maintenance management. This paper proposes a predictive maintenance strategy using advanced technologies such as Building Information Modelling (BIM) and the Internet of Things (IoT). The proposed framework includes data collection and integration, and an application layer with modules for condition monitoring, fault alarming, assessment, prediction, and maintenance planning. Machine learning algorithms, including ANN and SVM, are developed and employed to predict the future condition of MEP components. The example presented in this paper demonstrates the framework's effectiveness in predicting component conditions for efficient maintenance planning.

The authors explained that machine learning can be used within asset management, specifically for predictive maintenance. The authors discussed the relevance of data collection and how all this data will be used for condition prediction. For this study, the ANN and the support vector machine models are developed to predict the future condition of MEP (mechanical, electrical and plumbing components. The models are developed using 300 datasets for condition prediction with 15 variables collected from the BIM, FM and IoT sensor networks. The models are trained using real-time sensor data, so the training phase is an ongoing process. The dataset is split into three (80% training, which consists of 240 data sets; 10% cross-validation, which consists of 30 data sets; and 10% testing, which also consists of 30

data sets). The model is trained by adjusting the parameters and using the 10% cross-validation set, and the model is tested using the 10% unseen data. The authors predicted two main variables, including the condition index of MEP components in buildings and the triggers for the required maintenance actions. The prediction accuracy for the SVM was 95.55%, which was better than the ANN, which was 96.42%. The Average Mean Error for the ANN was 3.58%, more significant than the SVM, which was 3.43%. The prediction coefficient was 0.993 in both methods. The SVM outperformed the ANN based on the error indexes using MAE and RMSE. The authors also concluded that ANN required twice as much time as an SVM in computational solving ability. Lastly, the authors performed t-tests, and it was concluded that the larger the value of t, the more significant the difference between the actual and predicted values. The authors also estimated the P-values for both models. It was concluded that the results were statistically acceptable, and the predictive values can be used for predictive maintenance. Overall, the SVM outperformed the ANN [8].

Data analysis has become more popular due to increased machine learning and artificial intelligence applications [42]. Thus, these methods are considered helpful in increasing the efficiency of energy systems. This paper, conducted by Vialetto and Noro [42], proposes an innovative approach using extensive data analysis to design cogeneration systems. This approach aims to meet energy demand by selecting the correct type of cogeneration technology and strategy. First, the method to perform clustering to analyse data is described, followed by an analysis of a case study based on a cogeneration plant. In this paper, an alternative congeneration system is designed and thermodynamic and economic benchmarks are used to evaluate the two alternatives.

The study conducted by Khare *et al*. [43] states that fossil fuels still account for 80% of global energy. In recent years, the importance of renewable energy sources has been highlighted and recognised to reduce pollution and improve environmental sustainability. This study will review microgrid systems, focusing on their design and the evaluation of the control systems. This paper also investigates energy management, economic analysis, and reliability assessment within microgrid systems. Furthermore, artificial intelligence, data analysis, and various other factors are explored in their application to microgrid systems.

FMECA, known as Failure Mode, Effects and Criticality Analysis, is a versatile tool that addresses engineering problems and often integrates with multi-criteria decision-making processes. For this reason, the study conducted by Dabous *et al*. [44] reviews the integration of the methods above, specifically in the manufacturing industry. Some of the findings of this review include, but are not limited to, the electronics environment, mainly applying these two methods within the manufacturing industry. The most used MCDM method is the technique for order of preference by similarity to the ideal solution. This paper contributes towards research by providing valuable insight into these methods and their respective applications.

The authors, Chin *et al*. [45], critically analyse all approaches to asset maintenance within the chemical industry. Various maintenance strategies are also discussed: corrective, time-based, risk-based, and condition-based maintenance. This paper provides more insight into which type of maintenance is ideal for specific conditions and provides valuable future research opportunities. The authors conducted a review since they indicated that the various maintenance strategies adopted were research; however, their application was still questionable [45].

The importance of big data in the energy sector is highlighted, specifically smart energy services, including intelligent energy management, energy consumption prediction, and leveraging Internet of Things (IoT) solutions [46]. This paper's authors propose introducing a high-level architecture for a big data platform to facilitate the creation, development, maintenance, and use of these innovative energy services. This platform simplifies collecting

data from multiple sources and transforming it into valuable information. The paper also describes the development of a web-based Decision Support System (DSS) based on this architecture, which uses data from different sources to create energy management action plans. The DSS has been tested in three European cities. The results demonstrated that this system can potentially assist managers in optimising building energy performance using data-driven insights [46].

Performance-centred maintenance (PCM) considers operational performance and degradation conditions when maintaining systems [47]. In some cases, systems can still perform well even as they degrade; alternatively, new systems may not perform as expected. Subsequently, challenges arise where different decision-makers have different strategies to prioritise either performance or condition at the expense of the other. For this reason, this paper proposes a theoretical framework for PCM and discusses the critical aspects of this modelling approach. The study is motivated by a real-world industrial system where it is crucial to optimise maintenance decisions. The authors use a Markov decision process and demonstrate an exact solution through dynamic programming. Further, a less computationally intensive heuristic is explored using a reinforcement learning algorithm, showing its accuracy for a large-scale industry model. The results highlight that PCM models can offer valuable decision support for maintainers and operators while considering all decision-makers' perspectives. The authors of this study developed a reinforcement learning algorithm, specifically Q-learning, to explore a heuristic for a sizeable industry-developed model. The different states and actions at each period were determined using the Q-learning method [47]. The accuracy of this heuristic was measured and compared to an exact solution obtained using dynamic programming [48]. They are learning from delayed rewards. Applying machine learning, an optimal maintenance policy was developed to guide the decision-makers, including maintainers and operators [47].

Before the research question is addressed, the studies identified are evaluated. The journals in which each study was published are demonstrated using a pie chart, as depicted in **Figure III.**

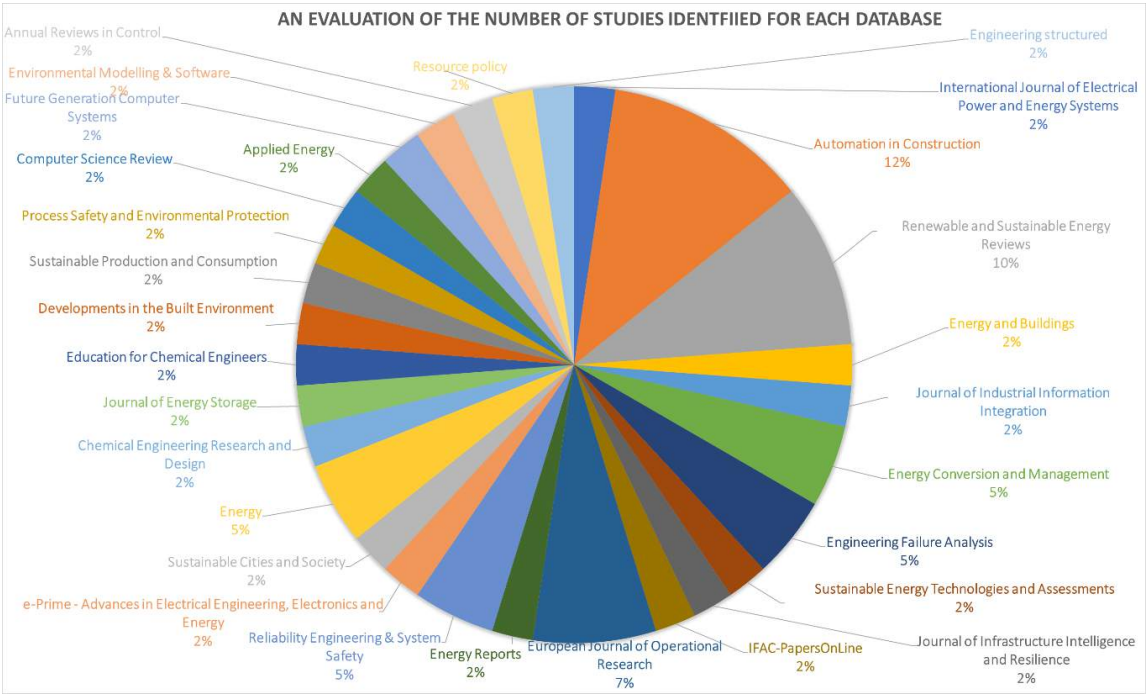

Figure III: A demonstration of the studies published in each journal

Figure III shows that Automation in Construction has 12% publications, renewable and sustainable energy has 10%, and the European Journal of Operational Research has 7% publications. Other journals include and are not limited to Engineering Failure Analysis, Energy Conversion and Management and Reliability Engineering and Systems. **Figure III** demonstrates an overview of the applicable journals that publish studies related to machine learning and asset management and can assist industry and researchers in finding functional studies to assist with these types of problems. **Figure IV** demonstrates the number of studies published per year.

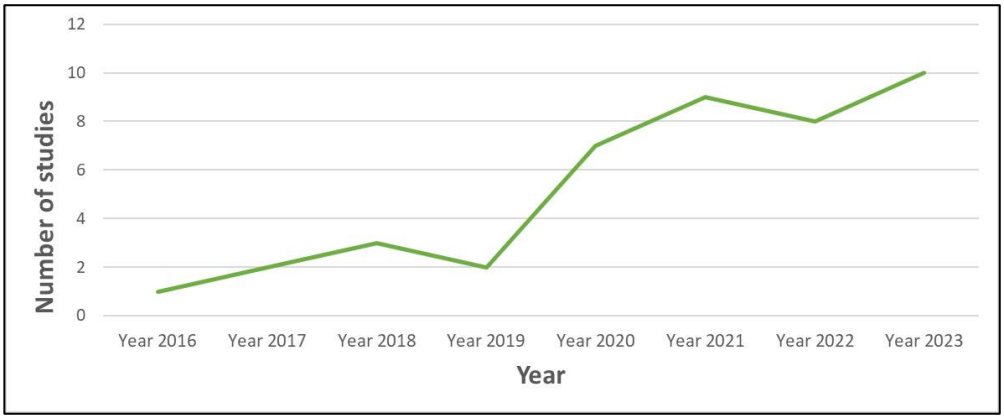

Figure IV: A demonstration of the number of studies published per year

There is an increase in publications per year regarding asset management and the application of machine learning within power plants. The year 2023 has a higher publication rate than previous years. This highlights the popularity of these articles published in the academic literature. **Figure IV** emphasises the need for machine learning, and the popularity and contribution of these algorithms for optimal asset management are emphasised in this study. From the titles of all the studies identified, a word cloud has been generated to showcase

which types of words are among the most popular. Research question 1 is addressed in Section 4.2.

4.2 Research Question 1: What is the current maturity of machine learning algorithms or models for asset management specific to coal-fired power generation utilities?

The review emphasised the popularity of integrating digital twins with machine learning algorithms. Studies conducted by Sharma *et al*. [49], Tuhaise *et al*. [50] and Liu *et al*. [51] highlighted that combining machine learning and digital twins will enable decision-makers to test assets using various scenarios and monitor asset health using real-time data. Subsequently, this will enable real-time decisions, prevent asset failure, and assist with asset maintenance management. The study by Xie *et al*. [52] concluded that applying machine learning will assist with optimal asset management. Liu *et al*. [51] further contributed that digital twins have a lot of data limitations, one of which is the limitation of large volumes of data. For this reason, the application of machine learning will assist in overcoming these challenges.

One clear trend among the studies identified is the data limitations experienced with asset management. Xie *et al*. [52] stated that machine learning algorithms could analyse large volumes of data from different domains, enabling proactive responses to uncertainty and market changes in the energy market. Furthermore, the authors added that these algorithms can predict loads and market prices and manage assets related to distributed energy resources. Subsequently, this will address the lack of data and enable proactive decision-making. Sierla *et al*. [53] further stated that applying machine learning can assist in mitigating grid failure and improve energy materials' design and deployment at the energy distribution level [51].

The authors Sierla *et al*. [53] and Sleiti *et al*. [54] had similar findings in their studies that contributed towards applying machine learning for optimal asset management. These studies suggested that machine learning can help investigate non-linear relationships between system inputs and outputs and predict future conditions of assets. Subsequently, by applying machine learning, practitioners and academics can understand all maintenance practices on an asset's overall sustainability score, leading to more efficient and effective asset management.

It is worthwhile noticing that some studies focused on sustainability and the environmental impacts of various assets and maintenance strategies. The study conducted by Ghaleb *et al*. [55] assessed the effect of maintenance interventions on the environment. A method, including the best-worst, was applied to quantify scores and demonstrate the sustainable performance of various maintenance strategies. Razmjoo *et al*. [56] also contribute towards sustainability by developing intelligent energy systems to achieve a decarbonised, renewable energy-based environment. A few other studies also focused on sustainability within asset management: Wu *et al*. [57], Çetin *et al*. [58], Wong *et al*. [59] and Barlow *et al*. [47].

The studies conducted by Chin *et al*. [45] and Solmaz *et al*. [60] integrated FMECA with multi-criteria decision-making techniques within the manufacturing and predictive maintenance fields, respectively. Authors, including Patriarca *et al*. [61] and Wong *et al*. [59], focused on innovative local energy and smart systems. The popularity of smart grids is also highlighted among the studies identified. Studies conducted by Faheem *et al*. [62], Razmjoo *et al*. [56], and Couraud *et al*. [63] integrated IoT technologies with smart grids and energy systems. Other studies conducted by Marinakis *et al*. [46] and Wong *et al*. [59] utilised IoT devices and big data analytics for energy management and optimisation.

The significance of various machine learning algorithms is highlighted among the identified papers. Milić *et al*. [14] indicated that reinforcement learning could be applied to predict the cost associated with the upper cloud (enterprise) levels. Sierla *et al*. [53] stated that various studies identified in the authors' paper were focused on combining forecasting with

optimisation using reinforcement learning. Furthermore, the value of reinforcement learning techniques has been highlighted in this study by demonstrating the value as a potentially disruptive technology for optimising home energy management systems, building energy management systems and VPP systems. Reinforcement learning can obtain heuristic solutions to complex problems with uncertainty [53]. For example, the study conducted by Barlow *et al*. [47] showcased the statement made by Sierla *et al*. [53] by demonstrating a less computationally intensive heuristic using a reinforcement learning algorithm, showing its accuracy for a large-scale industry model [47].

Cheng *et al*. [8] developed artificial neural network and support vector machine models to predict the future condition of MEP (mechanical, electrical, and plumbing) components. The study explains the details of the models' development. From this study, it is essential to note that the support vector machine outperformed the artificial neural network using various performance metrics based on the error indexes. The significance and specific contributions of these models to optimal asset management are highlighted.

Wu *et al*. [64] also indicated that the artificial neural network and support vector regression machines could be employed for demand forecasting, specifically short-term load forecasting. The application of machine learning in various sectors is highlighted in this review. A breakdown of the application of machine learning in different domains is identified: Energy system optimisation (Wu *et al*. [57], Faheem *et al*. [62], Wu *et al*. [64], Barlow *et al*. [47]), facility management and BIM (Stewart *et al*. [65], Wu *et al*. [57], and predictive maintenance and asset management (Ahmed *et al*. [66]).

The review identifies various limitations and challenges of applying machine learning for asset management within power plants. These include the following:

1. **Data quality and availability** [64] - The inconsistent data and quality of data across all sources are identified. Furthermore, the insufficient availability of quality historical data, specifically for the cases of rare events, is also witnessed.
2. **Interpretability and explainability** [63] - Machine learning models are sometimes complex to develop. It is also challenging to interpret the results and make decisions thereof. Furthermore, the lack of transparency and explainability is also seen as a barrier, specifically with critical systems where understanding the decision is crucial.
3. **Operational integration** [46] - Integrating machine learning models into existing operational workflows and systems is a challenge. Also, ensuring real-time data is processed efficiently and incorporated into decision support systems is seen as a barrier. Also, limitations identified include and are not limited to regulatory complaints, dependency on historical data and resource and expertise constraints.

5 CONCLUSIONS AND FUTURE RECOMMENDATIONS

Asset management is widely recognised in both academic literature and industry for its role in enhancing profitability, strengthening reputation, and reducing costs. Maintenance management has emerged as a major focus within operational research, largely driven by mathematical models that quantify the costs and benefits of various maintenance strategies. Equipment replacement becomes justifiable when maintenance programs are no longer effective. In cases where the long-term cost of maintenance exceeds the benefits—particularly due to frequent failures—replacement offers greater value. Nonetheless, well-designed maintenance and reliability schedules seek to perform the right maintenance, at the right time, on the right assets to minimise the need for replacement.

This study aimed to investigate machine learning applications for optimal asset management in coal-fired power plants. This study contributes towards research and industry by analysing the current state of machine learning algorithms and their applicability to asset management

at coal-fired power plants. The studies are evaluated in detail by providing insight into how these models were developed and how machine learning models can be applied for effective asset maintenance by considering various equipment, including but not limited to distribution networks, transformers and coal-fired boilers.

Maintaining components and policies is widely applied and investigated within the academic literature. The primary focus is on transmission and distribution assets, including transmission lines, protection devices, transformers, and substation equipment. From this study, it is evident that various machine-learning algorithms were developed. These models include a support vector machine for fault diagnosis in power transformers, expert systems to optimise asset management, a multi-criteria decision-making model for asset management, specifically power distribution systems, reinforcement learning, and an artificial neural network and support vector machine models to predict the future condition of MEP (mechanical, electrical and plumbing) components. Some studies focused on FMECA with multi-criteria decision-making techniques in manufacturing and predictive maintenance. Other studies focused on innovative local energy systems and intelligent systems. These studies also identified a few limitations: Data quality and availability, interpretability and explainability and operational integration.

Multiple valuable research opportunities have been identified. These include the following:

1. **Enhanced Data Quality and Utilisation:** To improve the quality, consistency, and availability of data used for asset management, enabling more accurate machine learning models and predictions.
2. **Advanced Predictive Maintenance:** Investigating machine learning algorithms, including deep learning and reinforcement learning, specifically for predictive maintenance in power plants, decreasing downtime, and increasing efficiency. Furthermore, researching the integration of predictive maintenance with IoT devices using real-time sensor data for more proactive maintenance strategies.
3. **The application of AI for Decision Support:** Developing AI techniques to enhance transparency and interpretability of machine learning models, especially in critical applications, enabling operators and decision-makers to understand AI-driven recommendations.

These studies also identified a few limitations: Data quality and availability, interpretability and explainability and operational integration. It is also worth noting that a limited number of studies applied machine learning at coal-fired power plants. However, it is also essential to note that the studies were only selected based on the keywords and the research protocol. For future research, it would be suggested to remove some of the keywords so that more studies are evaluated, and more insight is obtained from how machine learning is applied for optimal asset management.

University of South Africa, South Africa
sandis@unisa.ac.za

ABSTRACT

The digital transformation of healthcare in South Africa requires secure and reliable systems for patient identification. MediScan Solutions, a biometric fingerprint verification platform, was piloted in Johannesburg clinics and an emergency service to address fraud, data fragmentation, and misidentification. Using a qualitative case study approach, the study combined interviews (n=10), observations, and document analysis. The pilot reduced patient intake time by 35 percent, eliminated duplicate records, and blocked seven attempted cases of fraudulent access. Thematic analysis highlighted usability, trust and integration barriers as key factors shaping adoption. Findings show that biometric authentication, when designed for local conditions and compliant with data protection regulations, can strengthen efficiency, enhance fraud prevention, and align with national health priorities, including the phased implementation of the National Health Insurance.

Keywords: Biometric healthcare, fingerprint scanning, digital identity

1 INTRODUCTION

The healthcare sector is undergoing a digital revolution with increasing reliance on data-driven systems to improve care delivery, patient safety, and resource efficiency. Globally, innovations such as electronic health records, telemedicine, and biometric authentication are being deployed to address longstanding issues of access, accuracy, and operational cost [1]. In the South African context, the potential benefits of these technologies are particularly compelling, given the dual public and private health system, uneven resource distribution, and widespread inefficiencies in patient data management [1].

Public healthcare institutions continue to struggle with fragmented record keeping, paper-based systems, and inconsistent data verification processes. This leads to duplication of services, treatment delays, and administrative bottlenecks. One of the most pressing challenges is the absence of a reliable and secure national patient identification system. This gap not only undermines clinical continuity but also facilitates medical aid fraud, which has grown to billions of rand annually and places additional strain on both private and public health resources [2].

Biometric identification technologies, particularly fingerprint scanning, have emerged globally as reliable and cost-effective tools for verifying patient identity at the point of care. Studies from India, Ghana and Kenya demonstrate their ability to streamline access to health records, authenticate treatment eligibility, and reduce fraudulent claims [3], [5]. Yet adoption in South Africa remains limited and fragmented, often confined to pilot projects or isolated administrative tasks [3].

MediScan Solutions responds directly to these challenges by offering a biometric platform tailored for the South African healthcare landscape. The system enables healthcare professionals to retrieve verified patient records and medical aid details using fingerprint scanning. Built on a cloud-based architecture, MediScan ensures secure data access across facilities, supports interoperability with existing hospital information systems, and aligns with the strategic goals of the National Health Insurance (NHI) framework [1].

By integrating biometric authentication into routine care processes MediScan has the potential to reduce clinical errors, speed up patient registration and combat fraudulent billing. More broadly, it demonstrates how targeted digital innovations can support a more efficient, transparent and equitable healthcare ecosystem. This paper presents MediScan as a case study in digital health intervention and evaluates its practical implications using stakeholder feedback, pilot data and policy alignment analysis.

2 LITERATURE REVIEW

2.1 Biometric authentication in healthcare

Biometric technologies have gained increasing traction in global healthcare systems as tools to enhance patient identification accuracy, reduce administrative duplication, and combat medical fraud. Fingerprint scanning has emerged as a cost-effective and accessible method for authenticating patient identity, especially in resource-constrained settings. Misidentification remains a global concern, with over 60 percent of healthcare institutions reporting instances where duplicate records or mismatched files have compromised patient care [1].

In high-income countries, biometric platforms have been integrated with electronic health records (EHRs) to reduce incorrect treatments and support compliance with patient safety standards. For example, a 2022 clinical study in the United States found that biometric scanning reduced wrong-patient procedures by 45 percent and improved care coordination [2]. Meanwhile, in lower- and middle-income countries, fingerprint systems have shown strong uptake. Simprints, an open-source biometric nonprofit, has deployed fingerprint technology

in Bangladesh, Ghana, and Kenya, achieving over 80 percent reduction in data entry errors and a 90 percent user satisfaction rate among healthcare workers [3].

These findings underscore the potential of biometric tools to deliver high-value outcomes across diverse healthcare systems. However, challenges remain. Infrastructure limitations, system interoperability, and public trust continue to influence adoption rates, especially where digital literacy is uneven or policy frameworks are underdeveloped [4].

2.2 Digital identity, fraud prevention, and policy alignment

One of the central challenges facing South Africa's healthcare system is the absence of a unified patient identification mechanism. Patient records remain fragmented across public and private institutions, leading to duplication of services, loss of patient histories and inefficiencies in administration. In this environment, accurate and consistent verification of identity across facilities becomes difficult. The weakness in identity infrastructure not only disrupts continuity of care but also increases vulnerability to medical aid fraud, false claims and misuse of entitlements [5].

Medical fraud in South Africa is estimated to cost the sector billions of rand each year, driven by identity theft, double billing, and untraceable service provision [6]. The Health Funders Association has highlighted that the lack of biometric checks at the point of care allows unauthorised access to benefits, while legitimate claims are often delayed due to verification challenges [7]. Introducing biometric verification at the first point of contact can help address these risks by linking each consultation, prescription, or claim to a verifiable patient identity

International case studies show the potential of digital identity systems when aligned with broader health strategies. In India, the Aadhaar programme linked health entitlements to biometric verification, reducing duplicate enrolments and improving targeting of services [5]. In Rwanda and Kenya, similar systems have reduced ghost patient billing, improved control of entitlements and enhanced accountability among providers [9]. These examples demonstrate that digital identity tools can strengthen governance when they are embedded into national policy frameworks rather than used as isolated solutions.

South Africa's National Digital Health Strategy (2020–2025) and the phased implementation of the National Health Insurance recognise the importance of secure identity systems that ensure patient traceability while safeguarding privacy [6]. The regulatory context is shaped by the Protection of Personal Information Act (POPIA), which requires strict compliance for sensitive personal data, including biometrics [10]. Any health technology operating in South Africa must therefore incorporate robust encryption, consent management, and audit controls to maintain public trust and legal compliance.

MediScan has been designed to meet these requirements. Its cloud-based infrastructure allows cross-institutional data access while enforcing access controls consistent with POPIA. Fingerprint verification creates a secure front-end authentication process and a traceable audit trail for each medical transaction. This not only reduces fraudulent activity but also aligns with national objectives for equitable access, universal coverage, and improved accountability in healthcare delivery.

2.3 Implementation challenges and ethical considerations

While international evidence highlights the effectiveness of biometric identification systems in strengthening patient verification and reducing fraud, the South African context presents distinct implementation challenges. Public healthcare facilities often face infrastructure deficits, including unstable electricity supply, unreliable internet connectivity and outdated or incompatible information systems [10]. These constraints limit the seamless deployment of cloud based biometric platforms that depend on real time synchronisation and secure digital access.

Human factors also remain a critical issue. The successful introduction of any digital health technology depends on staff readiness, training and perceptions of usability. Studies have shown that healthcare workers may resist new systems when they are introduced without adequate orientation or when they are perceived as adding to workload pressures [11]. In overstretched clinical environments, this resistance can undermine adoption even when the technology itself has proven benefits.

Data security and regulatory compliance form another major concern. Under the Protection of Personal Information Act (POPIA), biometric data is classified as sensitive personal information. It is therefore subject to strict requirements regarding consent, encryption and auditability [12]. Yet few public institutions currently have the governance frameworks or technical capacity to meet these standards consistently. Weak compliance risks erode patient trust and may create legal vulnerabilities for institutions.

South Africa has also seen a pattern where promising pilot projects remain isolated, lacking integration into national digital health strategies or sustained institutional support. Many projects end when donor funding is exhausted, leaving behind fragmented systems that cannot scale or interoperate effectively with broader health reforms. Without a coordinated national framework, biometric initiatives risk remaining siloed, reducing their potential impact.

These challenges emphasise the need for any biometric solution to be designed with local realities in mind. Infrastructure support, staff engagement, and strong governance structures are essential if systems such as MediScan are to be successfully scaled and sustained in the South African healthcare environment.

2.4 Literature gaps

First, most documented studies focus on either public sector pilots or NGO-led projects, with limited exploration of mixed public–private healthcare environments. Given South Africa's dual health system, there is a need for studies that consider how biometric systems function across diverse providers where interoperability, funding, and consent models differ.

Second, little attention has been given to staff and patient experiences of biometric systems in daily clinical practice. Many evaluations focus on technical performance indicators, such as error rates or enrolment numbers, while overlooking qualitative aspects such as trust, training, workflow integration, and user acceptance. These human factors are essential for long-term adoption.

Third, although legal and ethical frameworks such as POPIA are well established, there is limited research assessing whether real-world deployments in South Africa comply with these requirements. Key questions around informed consent, data governance and secure cloud storage remain underexplored in practical terms.

Finally, the integration of biometric solutions into broader health reforms, particularly the National Health Insurance (NHI), is still largely discussed in theory. Few studies analyse the operational role that biometric identity systems could play in improving coverage, reducing fraud and enabling more coordinated care within the NHI framework.

This study addresses these gaps by presenting MediScan as a case study situated within the South African healthcare landscape. By examining design, deployment, and evaluation, it contributes practical insights into how biometric identity systems can align with national digital health objectives while responding to operational realities.

3 METHODOLOGY

This study uses a qualitative case study approach to examine the implementation of MediScan in healthcare settings in Gauteng. The design follows principles of design research, with attention to contextual relevance, system functionality, and stakeholder experiences. A case

study approach is appropriate because it allows for in-depth exploration of how a technology is used in a real-world setting where social, organisational, and technical factors interact.

3.1 Research design

The research design is interpretivist, focusing on how the system was experienced and evaluated by participants. This paradigm is suited to studies of new technologies where meaning and usability are shaped by context. The goal was not only to understand what MediScan does, but how healthcare professionals, administrators and developers perceived its usefulness, risks, and integration potential.

3.2 Data collection methods

Three main data sources were used to triangulate findings:

- **Semi-structured interviews:** Ten participants were interviewed, including healthcare professionals (n=5), system developers (n=3), and medical aid administrators (n=2). The small sample was justified by the pilot's limited scope and by the depth of qualitative data generated. Interview questions focused on usability, workflow impact, trust in the system, and regulatory concerns.
- **Document analysis**: Technical specifications, design reports, and internal pilot documentation were reviewed to understand the system architecture, interoperability features, and compliance mechanisms.
- **Observation and informal feedback**: The researcher observed two pilot sessions at clinics in Johannesburg. Attention was given to registration times, scanning errors, and staff–patient interactions. Informal feedback was also recorded during these sessions

Participants were selected purposively, as they were directly involved in the pilot. Demographic information indicated a mix of clinical and administrative staff aged between 30 and 60.

3.3 Data analysis

Interview transcripts and observation notes were analysed thematically using NVivo. Codes were developed inductively, grouped into categories, and refined through repeated reading. Emerging themes included system trust, ease of integration, fraud prevention, and ethical considerations. To improve reliability, coding was peer reviewed by a second researcher, and member checking was used to confirm accuracy with participants.

3.4 Validity and limitations

The study benefits from triangulating three sources of data and from collecting perspectives across different stakeholder groups. However, the pilot had a small sample size and short duration, which limits the generalisability of findings. The results should therefore be viewed as exploratory. Ethical considerations were addressed through informed consent, anonymisation of participants and attention to POPIA compliance in the handling of biometric data.

4 CASE STUDY

MediScan Solutions is a biometric verification platform designed to improve patient identification, streamline data access, and reduce fraud across South Africa's fragmented healthcare system. Using fingerprint scanning, MediScan allows healthcare professionals to retrieve a patient's medical history, medical aid status, and allergy or medication data in real time, thereby enhancing service efficiency and clinical decision-making.

4.1 System Features and Technical Architecture

MediScan is designed as a biometric verification platform to address patient misidentification, fraud, and fragmented data access. The system uses fingerprint scanning to link patients to verified medical and administrative records stored on a secure cloud-based platform. Key features include:

- **Real-time patient data access** to patient data at the point of care, enabling quicker registration and safer treatment decisions.
- **Secure cloud hosting**, with encryption and redundancy for data recovery.
- **Interoperability** with existing hospital information systems to ensure adaptability across both public and private facilities.
- **Audit trail functionality** hat tracks each login and record retrieval, supporting claim validation and accountability.

As shown in *Figure 1*, the registration and verification workflow captures biometric consent, encrypts patient data and uploads it to MediScan's secure cloud. Authorised healthcare staff can then retrieve this information in real time through portable fingerprint scanners.

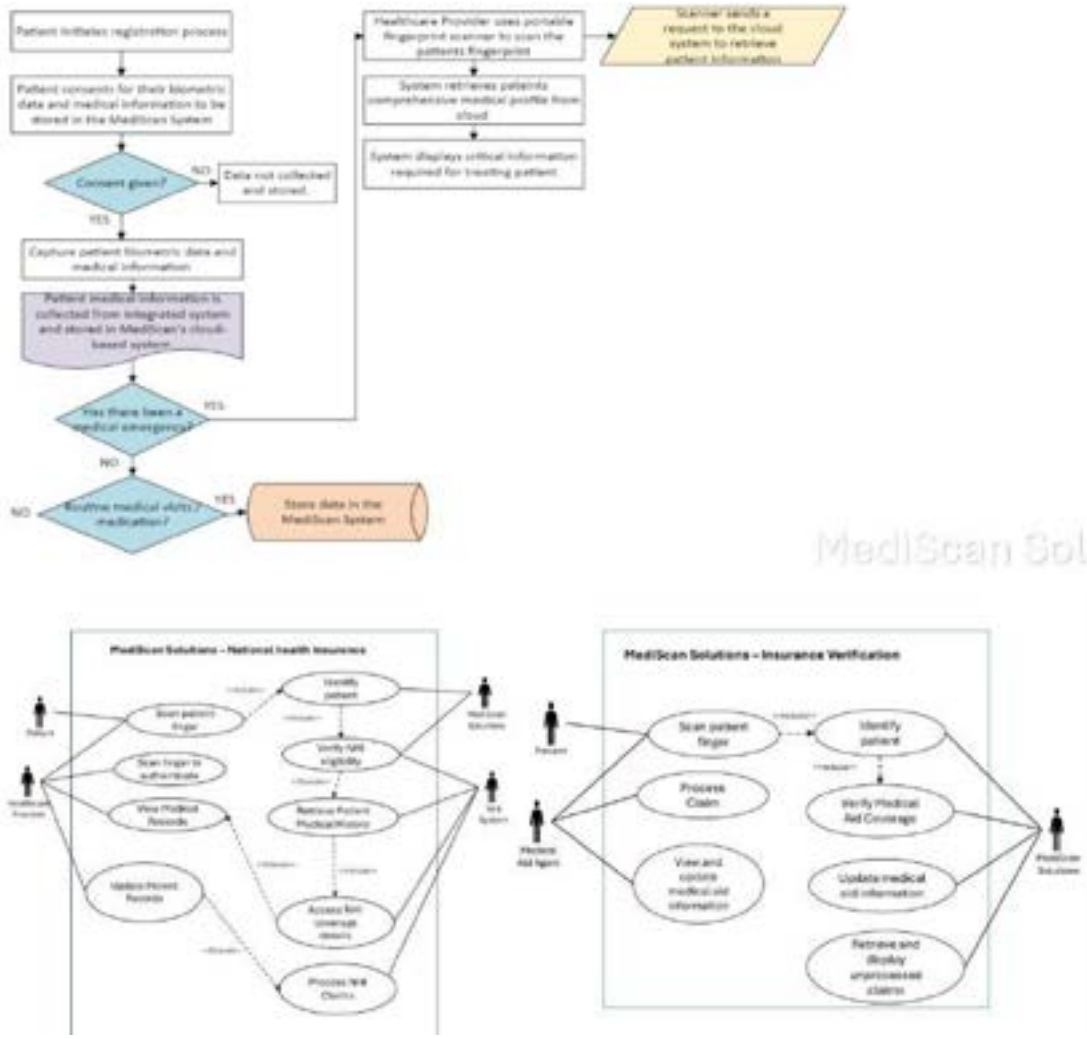

Figure 1: MediScan registration and verification workflow

4.2 Pilot Deployment and Implementation

The pilot study was conducted over six weeks in 2023 at two clinics and one emergency medical service provider in Johannesburg. These sites were chosen to reflect different use cases: routine outpatient care, administrative registration, and emergency response. The patient population included both insured and uninsured individuals, reflecting South Africa's dual public–private health system.

Training was delivered to staff in a one-day workshop at each facility, covering scanner use, troubleshooting, and consent protocols. Integration varied across sites: one clinic connected MediScan with its existing digital system, while others relied on temporary databases. Stakeholders included nurses, administrators, emergency staff, developers, and medical aid administrators, each contributing different perspectives on usability, workflow impact, and compliance requirements.

4.3 Observed Benefits and Performance Metrics

The pilot demonstrated several measurable benefits:

- **Efficiency**: Registration times decreased by about 35%, from 5–6 minutes to under 2 minutes.
- **Fraud prevention**: Seven attempted fraudulent registrations were blocked due to fingerprint mismatches.
- **Data integrity**: No duplicate patient records were generated during the pilot.
- **User acceptance**: Eighty percent of participating staff described the system as user-friendly and well aligned with existing workflows.

Beyond these metrics, clinical staff highlighted that rapid access to allergy and medication information supported safer treatment in emergencies where patients could not communicate. This suggests that the technology not only improves efficiency but also strengthens clinical safety.

4.4 Implementation Challenges

Despite the positive outcomes, challenges were identified:

- *Fingerprint quality issues*, particularly among elderly patients with worn biometric markers, required multiple scan attempts.
- *Initial hardware costs that* include fingerprint scanners and network routers were cited as a barrier for small clinics.
- *Connectivity limitations* during load-shedding were partially mitigated through local data caching and solar-powered routers.

4.5 SWOT Analysis

Strength	-Secure, auditable patient verification with proven fraud reduction. -Significant efficiency gains in patient registration. -High user satisfaction with minimal training required.
Weakness	-Infrastructure and hardware costs may limit adoption in smaller clinics. -Biometric limitations reduce universality across certain patient groups. -Dependence on stable connectivity exposes facilities to external risks such as load shedding.
Opportunity	-Alignment with the National Health Insurance (NHI) strategy creates potential for phased national rollout. -Scope to bridge data gaps between public and private providers. -Potential to extend services to rural areas, addressing inequities in access.

Threats	Public mistrust if privacy protections and ethical standards are not consistently demonstrated. -Regulatory complexity under POPIA and related compliance burdens. -Possible vendor dependency or limited interoperability with legacy systems.

5 DISCUSSION

The MediScan case study provides evidence of the practical benefits and systemic relevance of biometric verification systems in the South African healthcare context. By offering secure, real-time access to patient data, the platform directly addresses challenges of misidentification, fragmented records and medical aid fraud that have long undermined efficiency in both the public and private sectors [1], [2].

5.1 Operational benefits and competitive advantage

The pilot findings confirm that MediScan improves operational efficiency by reducing registration times, preventing duplicate records and strengthening fraud detection. These outcomes align with international evidence on biometric systems [3]. However, MediScan's competitive advantage lies in its contextual design for South African realities. Its architecture accommodates intermittent connectivity through local caching, its user interface was described as intuitive by clinical staff, and it incorporates compliance with POPIA from the outset. These features distinguish it from generic imported systems and reflect the importance of local innovation in digital healthcare.

5.2 Integration with policy frameworks

From a policy perspective, MediScan aligns with the strategic priorities of the National Digital Health Strategy (2019–2024) by contributing to secure patient identification, interoperable systems and improved fraud management [1]. More importantly, it has potential relevance for the rollout of the National Health Insurance (NHI). The NHI requires a reliable mechanism to verify patient identity across multiple facilities and providers. MediScan's ability to create an auditable, biometric-linked identity for each patient transaction suggests that it could play a role in strengthening reimbursement systems, ensuring that entitlements are linked to the correct beneficiaries, and preventing misuse of public funds.

5.3 Broader implications for system integration

The pilot also highlights broader opportunities and risks for system integration. By supporting both insured and uninsured patients, MediScan demonstrates capacity to operate across South Africa's dual health system. This makes it well placed to bridge gaps between private schemes and public institutions. At the same time, concerns remain around vendor dependency, interoperability with legacy systems, and sustainability in resource-constrained settings. Addressing these challenges will require deliberate policy support, infrastructure investment and public–private collaboration.

5.4 Linking back to research objectives

The objectives of this study were to evaluate MediScan's impact on efficiency, fraud prevention and policy alignment. The pilot results showed measurable improvements in efficiency and fraud detection, while analysis demonstrated clear alignment with national digital health priorities. However, gaps remain in fully realising integration with NHI reimbursement pathways and in demonstrating scalability to rural or under-resourced settings. These findings underline the need for phased implementation strategies, accompanied by continuous evaluation and adaptation.

6 CONCLUSION

This study examined MediScan Solutions as a case study of biometric fingerprint verification in the South African healthcare system. The pilot demonstrated clear operational benefits,

including faster patient registration, improved data accuracy, and effective prevention of fraudulent access. These outcomes confirm the potential of biometric platforms to address longstanding challenges of inefficiency, duplication, and fraud in patient management.

Beyond technical outcomes, the case illustrates the value of context-specific innovation. MediScan was designed with South African realities in mind, incorporating features such as compliance with POPIA and resilience to unstable connectivity. These attributes strengthen its competitive advantage over generic systems and support alignment with national health priorities.

At the same time, challenges remain. Infrastructure costs, biometric limitations among certain patient groups, and risks of vendor dependency highlight the importance of phased deployment and policy support. Integration with National Health Insurance pathways is promising but requires further development to ensure sustainability, interoperability and equitable access.

The study's objectives were to assess MediScan's contribution to efficiency, fraud prevention, and policy alignment. While the findings affirm progress in each area, they also indicate that broader integration and long-term scaling will depend on public–private collaboration, infrastructure investment, and ongoing monitoring.

In conclusion, biometric systems such as MediScan should not be viewed simply as technological add-ons but as strategic enablers of healthcare reform. With careful implementation, they have the potential to strengthen trust, reduce waste, and contribute to a more equitable and efficient health system in South Africa.

7 RECOMMENDATIONS

To maximise the value of biometric platforms like MediScan in improving healthcare efficiency and integrity, the following recommendations are proposed:

1. ***Phased National Rollout***: Begin deployment in high-volume urban clinics and emergency centres where efficiency and fraud prevention gains can be demonstrated most visibly. Use these sites as proof-of-concept before expanding into rural and under-resourced areas.
2. ***Integration with NHI frameworks*:** Align MediScan's architecture with the implementation of the National Health Insurance by ensuring interoperability with reimbursement systems, public provider networks, and centralised patient databases.
3. ***Public-Private Partnerships*:** Encourage collaboration between government, private medical aid administrators, and technology providers to share costs, fund infrastructure, and create sustainable governance models for biometric platforms.
4. ***Capacity and Change Management:*** Introduce structured training programmes for healthcare workers and administrators. Training should address technical use, data ethics, consent protocols, and troubleshooting to build confidence and reduce resistance to adoption.
5. ***Transparent communication with the public***: Develop clear communication strategies to address concerns about privacy, surveillance, and data misuse. Public trust will depend on visible compliance with POPIA, inclusive policy processes and transparent system governance.
6. ***Continuous Evaluation and Adaptation***: Establish ongoing monitoring mechanisms that combine system data with stakeholder feedback. Regular evaluation will help refine implementation, identify emerging challenges and ensure that biometric platforms remain responsive to user and policy needs.

ABSTRACT

A comprehensive framework for systematically assessing the factors influencing the use of artificial intelligence (AI) in mineral resource management (MRM) is currently absent. Incorporating AI in this field can revolutionize the mining and mineral processing sectors by significantly improving efficiency, productivity, and sustainability. However, the successful adoption of AI in MRM requires a comprehensive policy framework that addresses the complex interplay between technological innovation, environmental responsibility, and social governance. This paper introduces the AI-Investment Decision Matrix (AI-IDM) providing measurable pathways for translating AI capabilities into investment outcomes. The study will conduct a structured review to collect information on AI techniques related to mineral resource management and utilize an in-depth text analysis to contextualise the appropriate AI techniques that will provide a roadmap for policymakers, industry leaders, and stakeholders to harness the benefits of AI in mineral resources management while ensuring responsible and sustainable practices.

1 INTRODUCTION

The conspicuous absence of mineral resources from UN Sustainable Development Goals represents a critical oversight in global sustainability architecture, given minerals' foundational role in socioeconomic development [1]. This omission perpetuates resource curse phenomena, Dutch disease mechanisms, and suboptimal mineral economics frameworks across developing economies. Conventional Mineral Resource Management (MRM) suffers from systemic deficiencies: fragmented decision-making protocols, inadequate organizational discipline, and disconnected geological-extraction-IT integration [2]. These gaps manifest as poor delivery outcomes despite meticulous project planning, necessitating transformative approaches beyond traditional capacity-building initiatives. Decision-making complexity spans structured, semi-structured, and unstructured paradigms requiring sophisticated reasoning architectures [3]. This research proposes Intelligent Decision-Making (IDM) through Human Intelligence-Artificial Intelligence convergence, addressing investment decision complexities that obstruct effective MRM implementation [4]. Intelligent Decision Support Systems (IDSS) leverage AI-information technology-systems engineering integration, deploying Fuzzy Logic, Case-based Reasoning, and Artificial Neural Networks for distributed data challenges ([3]. These methodologies enable data-driven policy optimization aligned with Earth4all objectives and SDGs 9, 10, 12, and 16 [5]. African mineral sectors exemplify MRM failures: environmental degradation, social instability, and unsustainable development patterns stemming from institutional corruption, expertise deficits, and political interference. The Ukraine conflict and P&ID-Nigeria disputes illustrate mineral security's geopolitical implications and investment complexities. Resource curse manifestations—including rent-seeking behaviours and Dutch disease effects—demonstrate how abundance paradoxically constrains economic growth. Despite African Mining Vision frameworks, technological innovation adoption remains limited, with policymakers underutilizing analytical tools for informed development strategies.

This study advocates intelligent frameworks integrating data-driven approaches and expert knowledge systems for policy refinement. AI-enabled analysis of economic viability, investment risk profiles, sustainability metrics, and innovation indicators enhances stakeholder decision-making capabilities. Scientific assessment of these parameters promotes resource sustainability, scalability, and productive utilization while mitigating environmental risks and fostering socioeconomic stability through systematic mineral resource optimization.

The outline of the papers is as follows: Section 2 describes the theoretical works related to the research domains, describes the methodology in Section 3, and presents and discusses the results in Section 4. Section 5 outlines the possible implementation strategy, and the recommendations and path forward are in Section 6. Finally, the conclusion of the paper is in Section 7.

2 THEORETICAL LITERATURE OF THE RESEARCH THEME

Mineral resources (MR) represent finite crustal concentrations critical for industrial advancement yet exhibit temporal depletion patterns [6-7]. These assets drive construction, electronics, pharmaceuticals, and manufacturing sectors while creating geographic wealth asymmetries between resource-abundant and resource-scarce regions [8]. Paradoxically, natural resource endowments generate economic curses in developing economies through Dutch disease mechanisms, contrasting with value capture in industrialized nations [9]. Sub-Saharan Africa exemplifies mixed developmental outcomes despite substantial mineral wealth [10]. Contemporary mineral resource management (MRM) frameworks suffer from fragmented policymaking architectures, inadequate data integration protocols, and suboptimal value optimization strategies [11]. Transformative MRM requires deployment of specialized technological assets enabling comprehensive value maximization while minimizing resource

destruction through strategic economic conversion mechanisms rather than conventional value-addition approaches.

2.1 Minerals Resource Management (MRM)

Africa's mineral investment paradox manifests through 15% global expenditure allocation despite controlling 30% of worldwide reserves, constrained by state intervention, resource nationalism, and perceived investment risks leading to systematic underinvestment [4]. Critical governance deficiencies stem from inadequate decision-making frameworks driven by skills shortages and expertise gaps in mineral resource management. Mineral Resource Management integrates essential functions from extraction to market delivery, optimizing transaction efficiency while maximizing value and minimizing operational risks [12]. Core objectives encompass value maximization, opportunity identification, and value erosion prevention through innovative technological applications and methodological advancements in exploration, development, and trend analysis [13]. MRM emphasizes cohesive resource planning across value chains, incorporating functional specialization through horizontal and vertical integration models [14-15]. The African Mining Vision, adopted by the African Union in 2009, establishes foundational MRM frameworks recognizing mineral resources' finite nature while emphasizing intergenerational benefit optimization ([16-17]. AMV objectives include developing comprehensive management models enhancing commercial, small-scale, and artisanal investment levels [18]. The 2018 AMV evaluation emphasized coherent policy requirements and regulatory enforcement efficacy, addressing common MRM policy deficiencies. Knowledge-driven economic transformation necessitates addressing educational disparities, facilitating skill transfer, and building institutional capacity [17]. Local content policies transcend technical and managerial efficiencies, requiring organizational discipline, extensive training, and strategic leadership focusing on extraction planning and processing optimization [4].

This research explores MRM's potential for mitigating decision-making risks in investment portfolios, emphasizing sustainable resource economy development, enhanced governance frameworks, and policy architectures that optimize resource wealth management while circumventing resource policy curse phenomena.

2.2 Decision-Making (DM)

Decision-making processes involve evaluating one or more objectives across various industries [19]. This study will specifically focus on multi-criteria approaches in mineral resource management (MRM). Multi-criteria decision-making (MCDM) methods select the best option among similar alternatives by considering multiple influential criteria. These methods find application in areas such as equipment selection, process reagents, and technology choices [20]. MCDM is particularly effective for managing complex criteria, although it does have potential limitations.

2.3 Artificial Intelligence (AI)

Artificial Intelligence technologies enable machines to mimic human cognition through environmental perception and adaptive learning mechanisms, utilizing computational algorithms for big data analytics [20-21]. Exponential AI growth stems from enhanced computing capabilities and reduced cloud storage costs, with data functioning as the primary catalyst for algorithmic advancement. African AI deployment strategically addresses poverty alleviation, educational enhancement, healthcare optimization, and sustainability initiatives. Digital economy integration and research institute establishment by African governments democratize technology access, generating high-value employment while significantly impacting GDP through improved productivity and resource allocation efficiency. Despite persistent infrastructure constraints, data limitations, skills deficits, and ethical challenges, AI adoption accelerates continent-wide through advanced analytics and predictive modelling

applications spanning mining, wildlife conservation, precision agriculture, water management, and forest monitoring systems [23-25]. AI fundamentally transforms mineral resource management through sophisticated resource estimation, exploration optimization, financial modelling, environmental sustainability protocols, and comprehensive data analysis frameworks [26]. Geospatial analysis and mineral resource estimation represent predominant AI applications, optimizing extraction processes while minimizing societal and environmental impacts [27]. Current research addresses economic, sustainability, and social evaluation parameters for mining operations [28-29].

This manuscript proposes an innovative interdisciplinary framework integrating AI into mineral resource management, specifically targeting investment policy optimization. The framework emphasizes ecological sustainability, energy optimization, circular economy principles, and AI-influenced energy planning, ultimately guiding stakeholder decision-making toward equitable sustainability through data-driven policy formulation [30].

2.4 Mineral Resource Investment

Mineral resource investment demands comprehensive risk assessment frameworks addressing multidimensional uncertainties across geological, sociopolitical, economic, and operational dimensions [31-32]. Current prioritization models inadequately integrate internal constraints with external market dynamics, creating suboptimal capital allocation decisions for investments characterized by substantial capital requirements, extended development timelines, and elevated uncertainty profiles compared to conventional sectors [7,33]. Investment attractiveness hinges on political stability, legal frameworks, infrastructure adequacy, and economic volatility considerations. Moerenhout et al. [34] propose a tri-dimensional funding architecture addressing these capital constraints through integrated financial mechanisms. This framework combines concessional debt instruments, targeted grants, and equity mechanisms with industry-led thematic bonds and vertical integration hubs to reduce capital expenditure burdens. Standardized trade infrastructure featuring differentiated pricing mechanisms rewards responsible operators while penalizing non-compliant producers. Strategic revenue stabilization through active offtake policies, floor pricing mechanisms, and political risk guarantees enables competitive positioning against state-backed entities while ensuring supply chain resilience and capturing environmental and security externalities.

2.5 Comparing the traditional DM and IDM Framework

Traditional decision-making frameworks rely on hierarchical structures and linear processes that are grounded in rational choice theory. These frameworks rely on historical data and established protocols, providing predictability and compliance. However, they often struggle in dynamic environments due to limitations in sequential processing, decision bottlenecks, and an inability to manage large volumes of data or complex relationships among variables. As a result, organizations are increasingly turning to alternative frameworks that incorporate advanced analytics and adaptive management techniques. These new approaches enhance information processing, accommodate uncertainty, and support continuous adaptation.

The IDM transforms traditional mineral resource management by integrating human expertise with AI. IDM employs predictive analytics to foresee challenges, positioning governance and risk management as foundational. This framework tackles Africa's mineral investment paradox and transmute it into tangible investment outcomes. It also provides the transparency and risk mitigation needed for modern investors. Most significantly, the IDM framework directly addresses Africa's mineral investment paradox by translating 30% of global reserves into proportional investment attraction. Table 1 compares traditional investment decision-making frameworks with AI-driven methodologies (AI-IDM), illustrating how machine learning enables

real-time analytics, predictive risk assessment, and automated optimization, versus conventional, manual, and reactive approaches.

Table 1: Comparative Analysis: Traditional vs. AI-Driven Investment Decision-Making Frameworks

Aspect	Traditional Frameworks	AI-Driven Framework (AI-IDM)
Decision Speed	Slow, manual processes	Real-time, automated analysis
Risk Assessment	Historical data-based	Predictive analytics with ML
Data Integration	Fragmented, siloed	Comprehensive, multi-source
Adaptability	Limited, reactive	Dynamic, proactive learning
Investment Optimization	Experience-based	Algorithm-driven optimization
Sustainability Integration	Separate consideration	Embedded in all decisions
Stakeholder Engagement	Ad-hoc consultation	Systematic, data-driven
Performance Monitoring	Periodic reviews	Continuous, real-time metrics

Ultimately, this study fills the identified research gap by developing the first comprehensive framework for systematically assessing AI factors in mineral resource management. The AI-Investment Decision Matrix provides measurable pathways for translating AI capabilities into investment outcomes, addressing the absence of structured approaches that link artificial intelligence, investment policy, and mineral resource management—a critical void evidenced by minimal academic convergence (0.54%) across existing literature.

3 METHODOLOGY

This research deployed a tripartite methodological framework comprising meta-methodological analysis integrating expert opinions to identify research gaps and barriers in AI-driven mineral resource policy; SWOT analysis establishing multidisciplinary frameworks for AI-enhanced investment strategies; and systematic roadmap development delineating critical implementation milestones for maximizing AI benefits. This systematic approach synthesizes theoretical analysis with practical implementation protocols, ensuring comprehensive coverage of AI applications through structured interrogation and robust analytical frameworks.

3.1 Bibliometric analysis:

This analysis was carried out based on earlier study [35]. The systematic literature review used four premier academic databases—Wiley, Elsevier, MDPI, and IEEE—to explore the economic and financial dimensions of mineral resource management with a focus on AI. Identification of relevant journals was searched using targeted keywords: investment, artificial intelligence, and mineral resource management. A screening tool (Rayan) ranked selected articles. Whereas, VOSviewer v.1.6.20 and Biblioshiny 5.0 facilitated the visualization of relationships among key research terms (AI, investment policy, and mineral resource management) and highlighted recommended journals with the aim of identifying research gaps in the research domain.

3.2 Framework for AI-Driven Investment Policy in Mineral Resource Management: A Multidisciplinary Approach

3.2.1 Expert Validation Framework

This study employed a multi-expert validation approach comprising five specialists with over 120 years of combined experience from academia, industry practice, policy-making, and data science. The expert panel validated investment criteria through systematic categorization and ranking protocols, ensuring comprehensive coverage of mineral resource management investment dimensions.

3.2.2 AI Methodology Validation

Five AI methodologies—Ensemble Learning, Bayesian Networks, Deep Learning, Genetic Algorithms, and Reinforcement Learning—were evaluated using a robust validation framework incorporating:

- K-fold cross-validation (k = 5) for model reliability
- Monte Carlo simulations for sensitivity analysis
- Industry benchmarking for practical applicability
- Statistical significance testing at 95% confidence level

This comprehensive evaluation ensures selected AI techniques effectively support investment decision-making and risk assessment in mineral resource management.

3.3 SWOT Analysis Methodology

A five-member expert panel conducted a structured four-phase SWOT analysis. We systematically identified internal and external factors affecting AI-driven mineral resource investment through expert brainstorming and literature synthesis. Each factor was prioritized and classified as High, Medium, or Low based on its immediate impact on investment, its significance for project success, and its frequency of occurrence. The synthesized SWOT elements formed actionable strategies that focused on transforming investment weaknesses into competitive advantages enabled by AI. To ensure comprehensive coverage of important investment risk factors, we validated our findings through expert consensus.

3.4 Roadmap Development Process

Table 2 outlines the systematic 9-step methodology for developing the AI-driven investment policy framework, emphasizing economic and financial aspects while maintaining stakeholder engagement throughout the development process.

Table 2: Roadmap Development Process for AI-Driven Mineral Resource Management (MRM) Investment Policy

Step	Activity	Rationale
1	Define the objectives and scope	The aim is to develop a roadmap for AI-driven mineral resource management with emphasis on the economic and financial aspects (investment policy) with little consideration on other aspects, such as technical and social community.
2	Conduct stakeholder analysis:	Five multi-experts including academia, industry practitioner, policy-maker, and data=scientist with around 120 years of experience.
3	Assess current state of AI in MRM:	Systematic literature review was carried out with best global practices with identification of barriers and challenges of utilising AI-driven mineral resource management investment policy.
4	Identify key areas for AI adoption:	The investment risk and mitigation coupled with attracting investment were identified for adoption.
5	Develop AI-driven investment policy framework:	Create a framework for AI-driven investment policy in MRM and outline the key principles, guidelines, and regulations.
6	Establish implementation roadmap:	Identify milestones, timelines, and responsible parties and develop the roadmap.
7	Define performance metrics:	Establish metrics by identifying the key performance indicators and monitoring mechanisms
8	Engage stakeholders and foster collaboration:	Engage stakeholders and collaborators throughout the roadmap development process.
9	Review and update roadmap:	Continuous review and update to ensure relevance.

4 RESULTS

4.1 Bibliometric Analysis

This study offers a bibliometric analysis identifying optimal publication venues at the nexus of artificial intelligence (AI), investment, and mineral resource management. Utilizing a robust five-stage hierarchical filtration methodology, the study scrutinized 6,073 journals from prominent publishers—Elsevier, Wiley, Springer, and MDPI—selectively retaining 33 top-tier venues, representing a mere 0.54% retention rate (Table 3). The filtering process progressed through stages of keyword filtration (17.6% retention, n=1,070), relevance assessment (13.2% secondary retention, n=141), quality refinement (65.2% tertiary retention, n=92), culminating in final selection (35.9% quaternary retention, n=33). A multi-dimensional scoring system evaluated journals based on three criteria: AI sophistication, investment relevance, and focus on mineral resource management, employing a standardized 1-10 scale (Table 4). Through interactive network visualizations using D3.js force-directed algorithms, there are four identified research clusters: AI-centric journals, resource-focused publications, investment-oriented journals, and hybrid bridge publications.

Methodological evaluations of the research gap opportunities (Figure 1) across six dimensions indicated deep learning's saturation but limited growth, while genetic algorithms exhibited optimal potential with less competition yet substantial application scope. Machine learning and AI displayed balanced interdisciplinary engagement, whereas neural networks presented moderate performance with emerging policy integration needs. The literature review landscape analysis (Figure 2) highlighted a critical gap in decision-making process publications (n=1 since 2021) and a lack of articles addressing mineral resource management. Thus, suggesting significant opportunities for enhancing human intelligence within this domain through AI methodologies. The convergence efficiency of 0.54% emphasizes the specialized nature of this evolving field and reveals strategic positioning opportunities among publishers. Our recommendations advocate targeting Elsevier journals for impactful contributions pertinent to current policy challenges while leveraging identified gaps for foundational advancements in the field. Effective mineral resource management demands integration across seven dimensions crucial for operational success and sustainability: technical, environmental, economic, governance, social engagement, strategic planning, and risk management. This integrated framework emphasizes the imperative for synchronized multi-stakeholder engagement for effective operational paradigms within dynamic resource environments.

Lastly, a search in the only identified journal of mineral resource management revealed that mineral resource investment has 56 results, 5 related and one is in polish language. Also, the search for AI and the various subsections have only one entry. This reinforced the need for this study.

Table 3: The Journals Relevance for AI-Driven Investment Policy Research in Mineral Resources Management

S/N	Journal Number	Elsevier	Wiley	Springer	MDPI	Total
1	Total	2,900+	1,600+	1,100+	473	6,073
2	Appeared	627	57	363	23	1,070
3	Related	74	23	21	23	141
4	Refined	60	5	4	23	92
5	Chosen	15	4	4	10	33

Table 4: Scoring Methodology for Assessing the Various Keywords in Determining Top Performing Journals

S/N	Score	AI	Investment	Mineral Resource Management
1	10	Premier AI/ML journals with broad scope	Core finance/investment management journals	Core mineral/mining/extractive industry journals
2	8-9	Strong AI focus with established reputation	Strong investment and financial analysis focus	Strong natural resource management focus
3	6-7	Moderate AI content or emerging AI focus	Moderate investment/economic content	Moderate resource/energy applications
4	4-5	Limited but growing AI applications	Some investment applications	Some resource-related content
5	1-3	Minimal AI focus	Limited investment focus	Limited resource focus

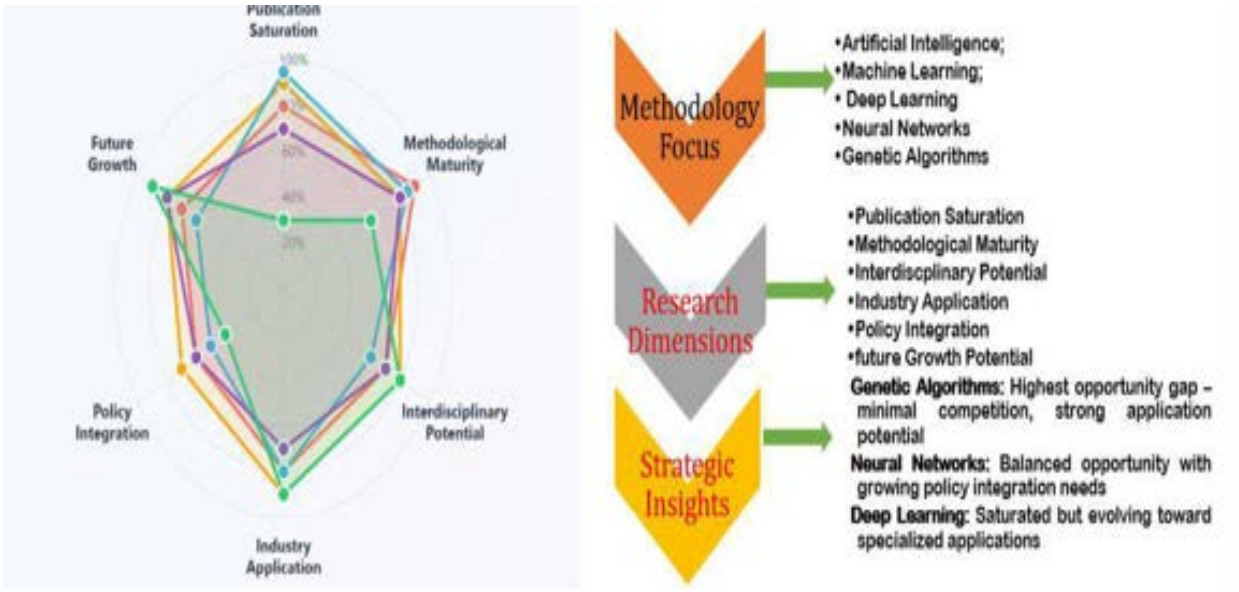

Figure 1: Research Gap Opportunity Radar Chart -Strategic Overview of AI-Investment-Mineral Resource Management Research Landscape

Research Domains	Investment Policy	Resource Extraction	Environmental Impact	Risk Assessment	Sustainability Metrics
Deep Learning Applications	Low Gap: 153 publications	Medium Gap: 48 publications	High Gap: 22 publications	Low Gap: 149 publications	Medium Gap: 72 publications
Machine Learning Integration	Low Gap: 149 publications	Low Gap: 72 publications	Medium Gap: 15 publications	Medium Gap: 123 publications	Low Gap: 89 publications
Genetic Algorithm Optimization	High Gap: 22 publications	High Gap: 9 publications	Medium Gap: 5 publications	High Gap: 18 publications	High Gap: 12 publications
Neural Network Modelling	Medium Gap: 55 publications	Medium Gap: 33 publications	Low Gap: 28 publications	Medium Gap: 45 publications	Medium Gap: 38 publications
Expert Systems Development	Minimal Gap: 225 publications	Low Gap: 123 publications	Medium Gap: 95 publications	Minimal Gap: 187 publications	Low Gap: 156 publications
Predictive Analytics	Low Gap: 89 publications	Medium Gap: 67 publications	Medium Gap: 45 publications	Low Gap: 78 publications	Low Gap: 62 publications
Real-time Decision Systems	High Gap: 12 publications	High Gap: 8 publications	High Gap: 6 publications	Medium Gap: 15 publications	High Gap: 9 publications
Hybrid AI Approaches	High Gap: 8 publications	High Gap: 5 publications	Medium Gap: 3 publications	High Gap: 12 publications	Medium Gap: 7 publications

Research Gap Legend

High Gap: Severely underexplored areas with significant potential

Medium Gap: Moderately researched with room for expansion

Low Gap: Well-researched but evolving areas

Minimal Gap: Saturated research areas

Figure 2: Research Gap Landscape Matrix - AI-Driven Investment Policy & Mineral Resource Management

4.2 Key Aspects of Mineral Resource Management Framework

Figure 3 illustrates a comprehensive Mineral Resource Management framework with seven interconnected dimensions surrounding a central hub. This holistic approach integrates multiple stakeholder perspectives to ensure sustainable and responsible mineral resource development. Appendix A1 outlines a structured framework that categorizes key components critical to investment policy in mineral resource management. Each component's score, scaled from 0 to 100, indicates its significance for investment success, foundational role in sector growth, and direct influence on policy efficacy. Analysis at the category level reveals weighted averages that highlight policy priorities. Governance & Risk Management rank as the foremost priority (92 points), emphasizing the need for robust systems before other elements can successfully function. Economic & Financial considerations (82 points) serve as primary influencers of investment decisions and capital distribution. Social & Environmental aspects (70 points) promote sustainable practices, while International Cooperation (65 points) enhances domestic policy frameworks. This hierarchical model underscores that successful mineral resource investment policies must prioritize strong governance and risk management, followed by economic optimization, with social, environmental, and international cooperation facilitating investment attraction and risk mitigation. High-Priority Investment Policy Components (75-95 points) are identified as crucial for mineral resource investment success. Leading this category, the Regulatory Framework (95 points) and Risk Assessment and Mitigation (90 points) establish governance structures critical for investment stability and risk management. Next, Financial Risk Assessment (85 points) and Economic Considerations (82 points) serve as core economic drivers affecting investment viability. Market Analysis (80), Investment Attraction Strategies (78), and Financial Incentives (75) complete this high-priority tier, focusing on market dynamics and mechanisms to attract and retain investment capital. It was established that risk assessment and mitigation are linked to investment attraction, emphasizing the economic and financial dimensions of mineral resource policy. Therefore, the strategies are to secure funding throughout the mineral value chain, from exploration to sustainable development, while implementing rigorous risk management throughout

project lifecycles. The objectives include mitigating the resource curse, optimizing resource recovery rates, and ensuring sufficient capital inflow to enhance profitability and project viability, thereby balancing investment attraction with prudent risk management for successful mineral resource development.

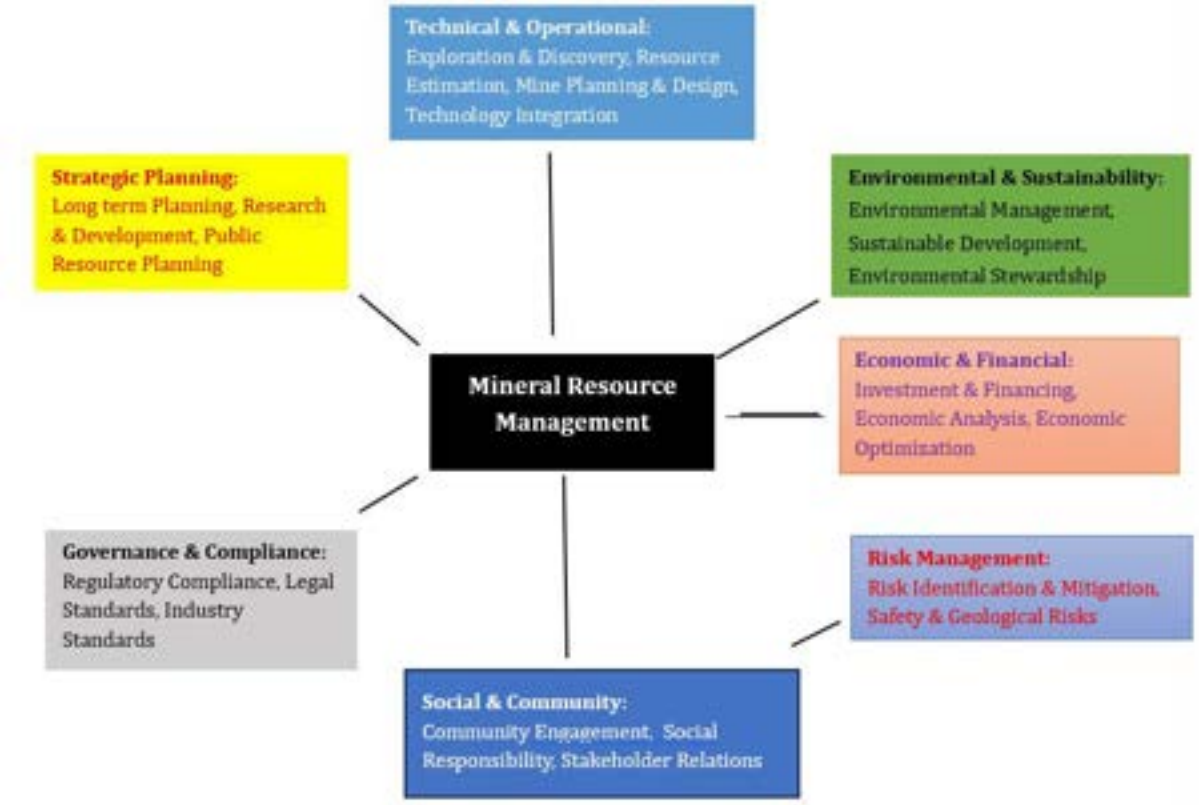

Figure 3: Categorization of the key aspects of mineral resource management

4.3 SWOT Analysis Results:

The SWOT analysis framework serves as a systematic tool to evaluate risk factors in mineral resource investment management across four strategic dimensions (Table 5). Priority levels—High, Medium, and Low—are assigned to denote the importance and immediacy of addressing each factor in comprehensive investment risk assessments. The strengths quadrant identifies essential assets such as advanced risk assessment methodologies, diversified management tools, regulatory compliance expertise, and technology integration that form a robust basis for informed investment decisions. Conversely, the weaknesses quadrant reveals vulnerabilities including substantial capital requirements, exposure to commodity price fluctuations, environmental liabilities, and geological uncertainties leading to elevated investment risks. The opportunities quadrant highlights favourable market dynamics such as the shift toward green energy, advanced technological integration opportunities, the availability of ESG-focused capital, and collaborative risk-sharing mechanisms, which can enhance investment prospects. The threats section delineates external challenges that could jeopardize project success, including geopolitical instability, climate change repercussions, regulatory ambiguities, supply chain vulnerabilities, and community opposition. To address these factors, Table 6 illustrates a strategic pivot toward AI-enhanced investment decision-making. AI techniques enable organizations to process extensive geological datasets, forecast commodity price trends, optimize portfolio allocations, and automate risk mitigation strategies. This shift transforms traditional investment methodologies into data-driven, intelligent frameworks that significantly boost project success rates and financial outcomes.

Moreover, Table 7 outlines a specialized SWOT analysis framework for evaluating digital business transformation strategies within organizations. This framework meticulously assesses the factors affecting investment attraction in mineral resource management, utilizing impact levels.

Critical, High, and Medium (Table 8) to evaluate their impact on capital funding. Key strengths include existing strategic resources and technological capabilities, while weaknesses encompass skill gaps and resistance to change. Opportunities are identified in emerging market trends and technological innovations, whereas threats stem from competitive pressures and cybersecurity vulnerabilities. Strategic integration (Table 9) synthesized SWOT elements into actionable recommendations focused on transitioning toward implementing AI-driven investment strategies, thereby enhancing portfolio performance and risk management in the evolving digital economy.

Table 5: SWOT Analysis Matrix for Mineral Investment Risk Management

STRENGTHS	WEAKNESSES
Advanced Risk Assessment Frameworks H Sophisticated geological, technical, and financial risk evaluation models provide comprehensive project analysis capabilities for informed investment decisions. **Diversified Risk Management Tools** H Insurance products, hedging instruments, and financial derivatives effectively mitigate commodity price volatility and operational uncertainties. **Regulatory Compliance Expertise** M Strong understanding of environmental, safety, and governance requirements reduces compliance-related investment risks and regulatory penalties. **Technology Integration Capabilities** M Digital monitoring systems and AI-powered analytics enhance real-time risk detection, response capabilities, and operational efficiency. **Established Stakeholder Networks** L Strong community relations and government partnerships reduce social license risks and enhance project sustainability.	**High Capital Investment Requirements** H Massive upfront investments and extended payback periods create significant financial exposure and limit operational flexibility during market downturns. **Commodity Price Volatility Exposure** H Unpredictable market fluctuations directly impact project viability, cash flows, and long-term investor confidence in mineral sector investments. **Environmental Liability Burden** H Potential for long-term environmental damage creates substantial cleanup costs, regulatory penalties, and reputational risks for investors. **Geological Resource Uncertainty** M Limited accuracy in resource estimation and grade prediction increases exploration risks and development cost overruns. **Technical Skills Shortage** M Shortage of specialized risk management expertise limits effective assessment capabilities and project execution quality.
OPPORTUNITIES	**THREATS**
Green Energy Transition Demand H Growing global demand for critical minerals in renewable energy systems and electric vehicles creates substantial new investment opportunities. **Advanced Technology Integration** H AI-driven exploration technologies and predictive analytics significantly improve project success rates and reduce geological uncertainties. **ESG-Focused Investment Capital** M Increasing focus on sustainable mining practices opens access to environmental, social, and governance-focused institutional investment funds. **Industry Risk-Sharing Mechanisms** M Development of industry-wide insurance pools and collaborative risk-sharing partnerships reduce individual project exposure and costs. **Government Support Programs** L Public sector risk mitigation schemes and investment incentives enhance project attractiveness and financial viability.	**Geopolitical Instability Risks** H Political upheaval, trade conflicts, and resource nationalism threaten investment security, market access, and operational continuity. **Climate Change Operational Impacts** H Extreme weather events and changing environmental conditions disrupt mining operations and significantly increase operational costs. **Regulatory Framework Uncertainty** H Evolving environmental regulations and complex permitting processes create project timeline delays and cost uncertainties for investors. **Global Supply Chain Vulnerabilities** M International supply chain disruptions affect critical equipment delivery, maintenance schedules, and operational continuity. **Community and Social Opposition** M Local community resistance and environmental activist campaigns can halt project development and damage investor confidence.

Table 6: Strategic Risk Management Priorities and Recommendations for Mineral resource Management

Strategic Focus Area	Key Risk Factors	Recommended Actions
Priority Risk Mitigation	High capital requirements, commodity price volatility, geopolitical instability	Implement diversified investment portfolios, establish robust hedging strategies, and develop comprehensive political risk insurance frameworks
Technology Leverage	Geological uncertainty, operational efficiency, risk assessment accuracy	Integrate AI-powered exploration technologies, implement real-time monitoring systems, and enhance predictive analytics capabilities
Market Positioning	Green transition demand, ESG investment requirements, regulatory compliance	Align projects with sustainable development goals, pursue ESG certification, and establish strong environmental management systems
Stakeholder Management	Community opposition, regulatory uncertainty, social license risks	Enhance stakeholder engagement processes, build strategic government partnerships, and implement transparent communication strategies

Table 7: SWOT Analysis Matrix for Investment Attraction in Mineral Resource Management

STRENGTHS	WEAKNESSES
Abundant Mineral Resources C Vast proven and probable mineral reserves provide strong foundation for long-term investment security and sustained production capabilities. **Established Infrastructure** C Existing transportation networks, power supply systems, and processing facilities reduce initial capital requirements and project development timelines. **Government Support Policies** H Favorable fiscal regimes, tax incentives, and investment promotion agencies actively facilitate foreign and domestic investment attraction. **Technical Expertise** C Skilled workforce and established technical capabilities provide operational competency and reduce technical risks for investors. **Strategic Geographic Location** M Proximity to major markets and established trade routes enhance export capabilities and reduce logistics costs for mineral products.	**Regulatory Complexity** C Complex permitting processes, bureaucratic delays, and inconsistent policy implementation create barriers to investment attraction and project development. **Infrastructure Deficits** C Inadequate power supply, transportation networks, and telecommunications systems increase operational costs and investment risks. **Limited Financial Markets** H Underdeveloped capital markets and limited access to long-term financing options restrict local investment participation and project funding. **Environmental Legacy Issues** H Historical environmental damage and rehabilitation liabilities create additional costs and reputational risks for new investors. **Skills Development Gaps** M Limited specialized training programs and technology transfer mechanisms constrain local capacity building and sustainable development.

OPPORTUNITIES	THREATS
Global Energy Transition C Massive demand for critical minerals in renewable energy, electric vehicles, and battery storage creates unprecedented investment opportunities. **ESG Investment Momentum** C Growing environmental, social, and governance investment focus opens access to sustainable finance and green bonds for responsible mining projects. **Technology Integration** H Digital transformation opportunities in automation, AI, and IoT enhance operational efficiency and attract technology-focused investors. **Regional Integration** H Continental trade agreements and regional value chains create opportunities for integrated mineral processing and beneficiation investments. **Public-Private Partnerships** M Collaborative frameworks between government and private sector enable shared risk investment models and infrastructure development.	**Global Economic Volatility** C Economic recessions, trade wars, and financial market instability reduce investor confidence and limit capital availability for mineral projects. **Resource Nationalism** C Increasing government intervention, nationalization risks, and changing ownership requirements deter foreign investment and create political risks. **Environmental Regulations** H Stringent environmental standards and climate policies increase compliance costs and create operational restrictions for mining investments. **Competition for Capital** H Alternative investment opportunities in technology and renewable energy sectors compete for limited institutional investment capital. **Social License Challenges** M Community opposition, land rights disputes, and social activism can delay or halt investment projects and damage investor relations.

Table 8: Investment Attraction Metrics Framework for the Mineral Investment Policy

Investment Climate Indicators	Performance Benchmarks
Regulatory Efficiency Index	Time-to-permit: <18 months
Infrastructure Quality Score	Power reliability: >95%
Investment Risk Rating	Political risk: <30% probability
ESG Compliance Level	Sustainability score: >75/100

Table 9: Investment Attraction Strategies and Implementation Priorities for Mineral resource Management

Strategic Priority	Key Success Factors	Implementation Actions
Regulatory Excellence	Streamlined permitting, policy consistency, transparent governance frameworks	Establish one-stop investment facilitation centres, implement digital permitting systems, and create investor grievance mechanisms.
Infrastructure Development	Reliable power supply, efficient transportation, modern telecommunications	Prioritize mining corridor infrastructure projects, develop public-private partnership models, and establish infrastructure investment funds.
Technology Leverage	Geological uncertainty, operational efficiency, risk assessment accuracy	Integrate AI and digital transformation enhance operational efficiency and attract technology-focused investors.
ESG Leadership	Environmental compliance, community engagement, sustainable development impact	Develop green mining certification programs, establish community development funds, and implement transparent ESG reporting standards.
Market Positioning	Critical mineral focus, value chain integration, technology adoption	Target battery mineral investments, promote local beneficiation, and establish mineral processing hubs with technology partnerships.

4.4 Roadmap Development

This strategic roadmap outlines a nine-step methodology for formulating an AI-driven investment policy in mineral resource management. Structured in three interconnected phases, it addresses the complexities of integrating artificial intelligence into investment

decision-making. The foundation phase establishes clear investment-centric objectives, leveraging insights from a multidisciplinary panel with over 120 years of collective expertise. A comprehensive stakeholder analysis and systematic literature review assess current AI applications, identifying best practices and existing challenges. The development phase focuses on integrating investment attraction and robust risk management through a framework of advanced AI techniques, emphasizing transparency and performance-driven methodologies to foster investor confidence. Implementation planning prioritizes measurable outcomes and continuous improvement to adapt to evolving technological and market landscapes. The final phase ensures sustainable deployment through tailored performance metrics that balance risk and innovation while maintaining stakeholder engagement throughout. Regular review protocols are crucial for the framework's relevance and effectiveness, enhancing investor confidence, risk management, and compliance and establishing a competitive advantage in mineral resource management through optimized AI integration.

4.5 Framework Value for Investment Decision-Making

The IDM framework transforms mineral resource investment from high-risk speculation to data-driven decisions. It addresses Africa's investment paradox of receiving only 15% of global expenditure despite controlling 30% of worldwide reserves [4]. The framework's scored investment policy structure provides quantifiable risk mitigation: regulatory compliance automation (95 points), enhanced risk assessment (90 points), and optimized financial analysis (85 points). By converting traditional weaknesses—commodity price volatility, geological uncertainty, and high capital requirements—into competitive advantages through predictive analytics and machine learning, the AI-IDM reduces decision-making time from months to weeks while establishing measurable benchmarks: <18-month permitting, <30% political risk probability, and >75/100 ESG compliance scores. The framework directly addresses the challenge of attracting investment, as traditional methods have not managed to unlock Africa's mineral potential despite the continent's abundant resources.

5 STRATEGIC IMPLEMENTATION AND RECOMMENDATIONS

Strategic implementation requires classifying governance and risk management frameworks as foundational prerequisites before advancing economic optimization initiatives (Figure 4), given their 92-point priority rating within the comprehensive evaluation matrix. Organizations should leverage genetic algorithms for portfolio maximization while addressing critical data science capability gaps through targeted workforce development programs that enhance institutional AI readiness. Key recommendations include establishing AI-powered due diligence systems, implementing blockchain-integrated transparency platforms, and developing IoT-enabled protocols that collectively boost operational efficiency and investor confidence. Investment attraction strategies must emphasize ESG-driven AI models and climate-resilient resource management approaches to align with emerging market demands and regulatory expectations. Immediate actions involve fostering strategic partnerships with technology providers. Continuous performance monitoring throughout the developed nine-step roadmap ensures sustainable competitive advantages and regulatory compliance in evolving digital mineral resource management landscapes.

6 PATH FORWARD

The path forward requires immediate focus on genetic algorithms and hybrid AI approaches for investment optimization, as these present substantial opportunities with minimal competition. Organizations must first establish robust governance frameworks before implementing economic optimization strategies. Strategic partnerships between technology providers, industry practitioners, and academic institutions are crucial for developing practical AI-driven policies. Key implementation steps include investing in data science capabilities, modernizing legacy systems, and following the developed nine-step roadmap for

systematic AI integration. Further research should focus on the underexplored opportunities in AI-finance integration. Continuous stakeholder engagement and performance monitoring will ensure sustainable competitive advantages in mineral resource management through intelligent decision-making systems that optimize investment outcomes and regulatory compliance.

7 CONCLUSIONS

This study systematically explored the integration of AI in mineral resource management through bibliometric analysis, SWOT evaluation, and roadmap development. Key factors influencing AI adoption were identified, including technological infrastructure, regulatory frameworks, and organizational readiness for digital transformation. The analysis revealed Genetic algorithms are promising, while deep learning faces saturation with limited growth. Machine learning and neural networks exhibit balanced interdisciplinary characteristics, demonstrating strong research foundations and ongoing development potential. A nine-step strategic roadmap was established, focusing on stakeholder engagement, risk management, and performance-driven outcomes to enhance investor confidence and regulatory compliance. The findings indicate a 0.54% convergence efficiency across 6,073 journals, highlighting the specialized nature of this field. The recommendations include addressing gaps in AI integration and investment while incorporating hybrid computational methods. This approach aims to establish a solid groundwork for enhancing mineral resource management through impactful AI applications and data-driven policy development.

10 Appendix A

Appendix A1: Mineral Resource Investment Policy Framework - Comprehensive Ranking

Policy Component Rank	Component Score	Category Rank	Category Score	Category	Policy Component	Description
1	95	1	92	Governance & Risk Management	Regulatory Framework	Clear guidelines and regulations that govern investment in the sector, ensuring compliance and stability
2	90	1	92	Governance & Risk Management	Risk Assessment and Mitigation	Evaluating and addressing the risks associated with mineral investments
3	85	2	82	Economic & Financial	Financial Risk Assessment	Currency stability, and infrastructure investment requirements play crucial roles in determining the attractiveness of mineral investment opportunities
4	82	2	82	Economic & Financial	Economic Considerations	Investment policies must balance attracting foreign direct investment with maximizing national economic benefits
5	80	2	82	Economic & Financial	Market Analysis	Understanding market trends and economic factors that influence investment decisions in the mineral sector
6	78	2	82	Economic & Financial	Attracting Investment	Strategies to draw both domestic and foreign investment into mineral exploration and development
7	75	2	82	Economic & Financial	Financial Incentives	Policies such as tax breaks, grants, or subsidies that encourage investment in mineral projects
8	72	3	70	Social & Environmental	Sustainable Practices	Ensuring that investments align with environmental protection and sustainable resource management goals
9	68	3	70	Social & Environmental	Community Development	Encouraging investments that benefit local communities and support socio-economic development
10	65	4	65	International Cooperation	Market Access & Cooperation	International coordination through trade agreements, standards, and regional cooperation enhances market access and resource management effectiveness

CIRCULAR ECONOMY: A REVIEW OF CRITICISMS, LIMITATIONS AND CHALLENGES

S. Singh[1*]

shalinis@dut.ac.za

ABSTRACT

The exploitation of resources under the linear economy model has compelled industry to rethink traditional practices. The ISO 59000 guidelines for a Circular Economy advocate for reusing materials through extended product lifecycles, recycling to establish closed-loop systems, reducing waste by designing efficient operations, and redesigning products through systemic thinking. These guidelines outline the requirements for responsible practices and long-term sustainability. Experts caution that achieving this vision remains theoretically, practically, and ideologically challenging. A bibliographic survey is used to assess the related challenges and limitations. Gaining deeper insights of these complexities may offer more effective strategies when implementing CE principles.

Keywords: Circular Economy, ISO 59000, Integrated Management Systems

1 INTRODUCTION: BACKGROUND AND PROBLEM STATEMENT

The exploitation of resources in the linear economy (LE) has led to the depletion of many natural resources, pollution and emission of greenhouse gases, stressed ecosystems and even extinction of certain species [1, 2 and 3]. These exploitations have become controversial particularly in view of their influence on climate change and have forced industries to rethink the way they do business. Experts propose the adoption of circular economy (CE) programmes, with its transformative, regenerative and restorative focus to mitigate these exploitations [2, 3 4, 5, 6]. Central to this approach, the "6 R principle" cover reuse, reduce, recycle, recover, redesign and remanufacture [1, 2; 6; 7 and 8]. The problem with sustainability programmes is that the formal adoption of the CE standards has caused much debate and scepticism among the scientific community because of the challenges that are associated with the transformation to CE principles. These challenges are related to organisational processes, action and intent, compliance with regulations, competitors, uniformity of practice, economic benefit, lack of universally accepted metrics, among others [4, 7, 9,11, 14, 15,16 in 1]. This study is grounded in the theoretical framework of compliance with standards. It conducts a narrative review of global literature and case studies to identify key criticisms, limitations, challenges and success factors related to CE. It associates past frameworks to contemporary standards and presents successes from sectors like the food and steel-industry, wastewater treatment, hospitality and agriculture.

The intention of this study is to enhance the fundamental understanding of the limitations, challenges and opportunities of CE for operations engineers, quality practitioners and industrial engineers, by providing a structured approach to effectively adopt CE principles.

Focus and initiatives on CE have been ongoing for many years to manage the excessive use of natural resources and to "close the loop" from use to reuse, mitigate the risks of extreme weather events and strengthen market share [2, 4 and 7]. The first attempts to achieve CE were initiated by countries like France and the United Kingdom who developed standards, XP-30-901:2018 General Approach for CE Projects and BS-8001:2017 General Framework for Application of CE Principles, respectively. The French XP-30-901:2018 Standard was certifiable by a third party, while the BS-8001:2017, regarded as vague and non-prescriptive was also certifiable [5].

It can be inferred from Table 1 that the XP-30-901:2018 Standard emphasises efficient use of energy, and smarter utilisation and extension of resources along the value-chain. While the BS-8001:2017 shares a similar focus on use of materials and resources, it is less explicit in its guidance and appears to approach CE from a Corporate Social Responsibility (CSR) perspective.

Apart from the scepticism around the veracity of these standards, both have produced positive results in CE initiatives for all types and sizes of organisations [4 and 7]. This assisted organisations to rethink the way they did business, to renew, repair and regenerate materials by informing better design, planning and optimising of production processes to remain circular [4 and 7].

As of August 2022, Google Scholar reported less than 500 scientific publications in 2015 and more than 3000 by 2021. Scopus and the Web of Science each reported less than 2000 publications, for 2021 [5] alongside debates and discussions on the merits of CE tripling in the last six years.

Recently, the International Organisation for Standardisation (ISO) presented a family of ISO 59000 Standards to assist organisations from all sectors and sizes in the adoption of a CE [3 and 10]. Not only is this suite of standards mooted to bring about standardisation and uniformity in practice, but it also focusses on developing and measuring streams on re-using materials by extending product life cycles, recycling materials to form closed loops, and

waste-reduction. This can be achieved by designing operations for efficiency and product redesign by rethinking the system [5 and 6]. This format of standards is consistent with the Sustainable Development Goals (Goal 12: Promoting sustainable production and consumption practices) [3 and 6].

Table 1: Traditional French and British Standards [5]

XP-30-901:2018 General Approach for CE Projects	BS-8001:2017 General Framework for Application of CE Principles
Eco-design – Integrate efficient processes, energy & design	**Systems Thinking** – System wide impact
Industrial Symbiosis–Collaborations to reuse of biproducts & waste	**Innovation** –Rethink Resource Mgt & Value creation
Functional or Service Economy– Use service-based models & reduce product ownership	**Stewardship**- Responsibility for activities
Responsible Consumption– Promote sustainable consumption	**Value Optimisation** –Materials at highest value
Extension of Duration of Use - Strategy to prolong end -of-life	**Transparency** –Honesty on benefit & barriers
Efficient Management of End-of-Life Product/ Material – Improved recycling & repurposing materials	

Table 2 outlines the suite of standards in the ISO 59000 series [5 and 8]. It suggests that each standard in the ISO 59000 series has a focused and strategic purpose, addressing the core aspects for the implementation of CE and administration processes needed to manage the resources sustainably. For example, ISO 59004 provides terminology, principles and frameworks to provide a platform for a common language to bring about consistency and uniformity of practice because a lack of a common language and terminology was heavily criticised as a bottleneck for CE implementation. Thereafter, it proposed frameworks to establish organisational practice with the concomitant principles to govern this practice and behaviour. ISO 59010 focusses on business strategies to improve efficiency, improve waste management, stay abreast of changing regulations and achieve market demands. ISO 59020 addresses data collection highlighting suitable circularity indicators linking measurement and assessment to the CE initiatives. The key function of ISO 59040 is to provide the necessary data sheets so that the entire supplier chain can be informed of the nuances of the product and thus take the necessary steps to accurately and transparently manage it within its context. ISO 59014 covers efficient use of resources and how they can be recovered and recycled to extend their use. ISO 59031provides case studies to guide the performance of organisations on CE practices and finally, ISO 59032 presents existing value-networks and promotes the collaboration between CE organisations to share practice [2, 3 and 5]. It is reasonable to assume that these traditional standards provided a foundation for the development of the ISO 59000 series, strategically informed by BS 8001 and operationally influenced by XP-30-901. It can also be observed that elements from the French and British Standards have been integrated in the ISO 59000 series, outlined in Table 2, particularly in areas such as business models, value-networks, performance- based approaches and secondary materials, and sustainability.

There was emphasis on the benefit to society, the economy and the environment. Early adoption of these standards provided confidence and flexibility that CE can be implemented successfully and adapted to various types of organisations, globally. For example, the principles of BS 8001 informed the development of ISO 59004 (Framework and Principles) using much of its terminology. The French XP-30-901 shaped the implementation and performance focus of ISO 59010 and ISO 59020 for life-cycle management, measurement and assessment. It also informed ISO 59004 with external and internal stakeholders' involvement and systems thinking [4]. It can be appreciated that under the current circumstances there is sufficient evidence that the climate is stressed, providing reasonable grounds for the adoption of CE to use the remaining natural resources responsibly and sustainably. The CE guidelines,

particularly the ISO 59000 series, have not matured adequately and hence its full potential is unknown. Therefore, researchers and scientists are using their ingenuity to find ways of mitigating or changing past behaviour. They are also using lessons learnt from the past, particularly how the French and British standard has helped to transform LE thinking, to advise, inform and progress current CE initiatives. Past lessons can still be applicable to the mandate of the new standards of ISO 59000 as these standards have been conceptualised from past business models and actual practical experience [11]. For example, direct benefits of ISO 59020 and circularity have been reported by a Sicilian waste-water plant [12].

Table 2: Suite of ISO 59000 series [5 and 8].

Standard	Purpose
ISO 59004	Key terminology, framework and principles on CE
ISO 59010	Guidance on business models and value networks
ISO 59020	Measurement and assessment of circularity
ISO 59040	Product circularity data sheet for certification
ISO 59014	Secondary materials-Principles, sustainability and traceability
ISO 59031	Performance based approaches
ISO 59032	Review of business model implementation

2 METHODOLOGY

This paper used a narrative literature review, and a qualitative approach of secondary data to collect information from academic peer-reviewed journal articles. A bibliographic survey was used to investigate the subject content in its historical context. This type of survey identifies and compiles appropriate literature that is synthesised in the narrative review to provide new insights on a particular topic [13]. Moreover, a bibliographic survey has the power of combining various findings and perspectives to address a research question. A predefined article selection protocol was used to select appropriate articles. These articles were extracted from multiple data bases such as, Routledge, Scilit (derives articles from PubMed, CrossRef and others), Wiley, Springer, Elsevier, European Union, and selected universities to establish points of convergence and divergence in CE. English articles during the period 2018 to 2025 were selected. The following key words were used to refine the literature search: circular economy, ISO 59000, environmental management systems, climate change and integrated management systems, were used as a basis for retrieving articles. All articles addressing CE and integrated management systems, irrespective of their methodology were included in the review. Articles that were not peer-reviewed, not addressing CE matters or those which followed video formats were excluded from the literature review. A total of twenty-five articles were retrieved. After an assessment of these articles, it was found that three articles were repeated and thus removed from the analysis due to replication and four other articles were removed because they did not meet the inclusion criteria, leaving fifteen articles for review. Each article was purposively and critically reviewed to seek new knowledge related to CE, on advancements and challenges/barriers in CE implementation, organisational guidance and new practices with CE and integrated management systems. The research question for this study was: What are current criticisms, limitations and challenges regarding the implementation and adoption of CE initiatives? To approach this research question, the current state of knowledge regarding CE from the collection of papers selected were critiqued, evaluated and appraised to establish contemporary thinking around CE and its qualities [14]. Validity was established when there was evidence of saturation of information, while reliability focussed on the repeatability of the information between articles [14].

3 RESULTS

Proponents of CE argue that by rethinking business practices within the paradigms of circularity from initial design strategies through the product lifecycle, industries can transform their approach to create, deliver and capture value, more sustainably [1, 4, 6 and 7].

3.1 Critical perspectives on CE from literature

This section addresses the discourse on CE, highlighting some of the major criticisms, limiting factors, challenges and opportunities facing the adoption of CE in contemporary society.

3.1.1 Literature-based criticisms of CE frameworks and practices

A major criticism about CE is that there is little agreement on the actual foundational elements by the scientific community [2, 18 and 19 cited in 5] and [6 and 9]. There is a sense that CE does not consider the nuances of the science of various disciplines, particularly those which include ecological economies and biodiversity management, with the biophysical limit of circularity [D'amto and Korhonen 2021, Corrvellec et al., 2021 and Giampietro 2023 cited in 5]. Another school of thought is sceptical about the ability of CE to flourish (Kofhenen et al., cited in [5] and cautions that the closed loops punted by the CE requirements are "practically and theoretically" impossible and questioned its ability to produce circular initiatives. Hass et al., (2015) cited in [5] indicates that there are grounds for concern especially in cases or industries where large amounts of energy are produced and cannot be captured for reuse. Similarly, accumulated materials for construction and infrastructure initiatives may not be able to be reused on time (within the same operation cycle) making the closed loop unattainable. Although Frishamar and Parida (2019); Lewandowski (2016); Demirel and Danisman (2019); and Prieto-Sandoval et al., (2018) cited in [1] and [15] appreciate the need to be more sustainable and to rethink present business models to "create, deliver and capture value" the methods proposed for the transition to CE are poorly understood making the circular effort very difficult. Additionally, Rincon-Moreno et al., (2021) cited in [1], states that there is an absence of a uniform model to benchmark and assess CE initiatives.

3.1.2 Academic discourse outlining the limitations on CE

A plausible contribution about constraints [Lalander and Vinneras 2022 in 5] indicated regulations as a constraint in closing the loop. For example, in the food industry, due to diseases like bovine spongiform encephalopathy recycling food waste is impossible. Kafel and Nowicki in [7] reported that limiting the use of primary raw materials is an obstacle to production. Likewise, Pamfile et al., in [15] indicated that maintaining materials at their highest point of utilisation is very difficult. Kirchherr et al., 2018 and Ryen and Babbitt 2022 in [5] mentioned that administrative processes and regulations impeded circularity and closing the loop.

3.1.3 Literature- based insights into CE implementation challenges

From the criticism and limitations, science, legislation, monitoring and measurement, uncertainty in acceptance of circular products by value-chains, administrative support, among others, makes the shift from a linear infrastructure to a circular one difficult. It will require sizable commitment across all departments of an organisation, and entire value-chain [11]. Material flow is advised to be fundamental to circular practice. However, if this to be possible, life-cycle extensions should be established prior to recycling rates, material flow and recovery to ensure that these initiatives are achievable [2]. Researchers have cautioned that poor and inconsistent measurement techniques across various levels have accounted for poor product durability, little re-use of materials and made regeneration of materials very difficult [2, 9]. Similarly, ISO (2023a) cited in [5] cautioned CE's ability to maintain the flow of resources, recover and retain materials and maintain sustainability. There is no clear guidance on these approaches, thus compromising the production processes. This was supported by Wastling et al., (2018), Corona et al., (2019), and Lacovidou et al., (2017) cited in [1] and [9] where there were so many processes within an organisation and no standardised indicators to monitor progress making measuring the CE initiatives very difficult. A formidable challenge mooted by Karuppiah et al., (2021) cited in [7] arose from the substantial administrative changes that

need to be made to prepare for CE adoption. For example, there was so much uncertainty and inconsistency in the future demands of the consumer and stakeholders of CE products, difficulty in conducting successful internal audits and management reviews, making large financial commitments risky.

Leadership and cultural buy-in was important [2]. They punted the importance of appropriate training and integration of CE sustainability and longevity into the corporate culture and among all stakeholders [2]. Similarly, Barkar and Charnley [10] supported that there are difficulties in CE implementation due to the expansive value-chains and ecosystems that need to be synchronised to practice and at the same time be compliant to national, regional and municipal protocols.

3.1.4 Opportunities to implement CE practices

As of 2024, 7.2% of the global economy is circular with 104 billion tons of materials being extracted. According to Eurostat (2023) cited in [10], the European Union (EU) is the world-leader in CE with Netherlands leading (27.5%), Belgium (22.2%), France (19.3%), Ireland (1.8%), Romania (1.4%) and Finland (0.6%). From these statistics, it is reasonable to assume that CE is obligatory and is achievable. The working group responsible for the development of the ISO 59000 suite of standards consisted of committee members from over 100 countries, private and public sector and across many institutions and industries. During this development, experts on the team interrogated and acknowledged current initiatives, various geographical and diverse cultural settings and deliberated on their contribution and interaction with CE. Thus, it can be inferred that their experiences have been adequately captured and included in the ISO 59000 series to ensure that CE initiatives are practical, realistic and achievable to guide areas where resources can be reused, repurposed, recycled or minimised to improve waste reduction and maintain production efficiency and economic viability. ISO (2023a), Heras- Saizarbitoria et al., (2023) and ISO (2023b) cited in [5] agree that there is a call to harmonise the implementation of CE in a manner that is transparent, fair, relevant, coherent, impartial and supports scientific debate and customer discourse [Velasco-Munoz et al., 2021, Kuisma and Kahiluto 2017 and Stegmann et al., 2020 in 7]. From a summation of research by Heras -Saizarbitoria et al., [5] cited by Merli et al, (2018) a structured form of developing and consolidating definitions for CE, having clear boundaries, principles and "associated" practices would be reasonable to initiate CE implementation.

The World Economic Forum, 2016 in Pamfile et al.,[15] proposed three principles to guide CE. The first principle considered conservation and improvement of "natural capital" obtained from using finite stocks and balancing the flow of renewal resources (replacing fossil materials). Secondly, optimisation and resource efficiency by always "using materials, components and products at their highest level of utility". And thirdly, promotion of the use of an effective system by identifying and designing the system to avoid impacts on soil, water, climate and health. Arana -Landin et al., [4] emphasised the role of CE in achieving competitiveness and environmental stewardship.

These narratives may have influenced the ISO 59000 series to adopt the Systems-Thinking approach, aimed at optimising processes and maximising the efficient use of natural resources and waste. Systems-Thinking, understanding the nuances of science, operations and the organisation's key performance indicators were regarded as important features [10]. Similarly, waste management (disposal and recycling), policy and legislation, stakeholder engagement, discipline specific insights, specific goals, cross functional teams and key performance indicators were criteria mooted to support Systems-Thinking to drive the CE implementation [10].

The alignment of CSR objectives was strongly encouraged [2, 4, 9, 10 and 15] and is likely to secure support from relevant departments to foster organisation-wide acceptance for CE

initiatives. Internal and external drivers were found to influence the performance requirements to achieve compliance with standard [4 and 7]. Internal drivers punted were, analyse opportunities for CE by using new technology, possibility of reducing costs and improvement in profit, environmental commitment, previous experience in training and development of circular initiatives. External drivers were, national/international regulations and assessment in public tender, effect on image of organisation and pressure from external stakeholders. However, there were challenges/barriers linked to internal factors that should be pre-empted before embarking on the adoption of CE. These are adequate financial resources to support implementation, production and waste management costs, financial uncertainty of the investment and adequate human resources, material and technology. While challenges/barriers linked to external resources were, poor clarity on regulations and uncertainty of future legislation, doubt on the effectiveness of circular products and internal constraints of members of the value-chain [4].

3.2 Reviewing the effectiveness of CE approaches supported by appropriate management systems

An assessment from literature proposes that CE cannot be implemented on its own and should be complemented by a management system. Integrated management systems, ISO 9001- Quality Managements Systems, ISO 14001- Environmental Management and ISO 45001- Occupational Health and Safety with versatility from its high-level structure, have been proposed as a "21st century model for business excellence" [1, 7, 4 and 15]. These management systems can strategically associate operational processes with the related CE principles [1] to streamline processes and meet stakeholder expectations, sustainable economic growth and consumption and production. A few examples from selected sectors highlights the success of CE initiatives.

Pamfile et al., [15] indicated that selected hotels integrated all three of these management systems and improved their sustainability performance, demonstrated a streamlined organisation and had fewer redundancies. Some hotels did not record any "measurable improvement" while others suggested that implementation of standards was shallow because it created a gap between theory and practice. For example, ISO 14001 could not support strategies for multiple streams like waste reduction, energy consumption and sustainable sourcing of materials [4 and 15]. These management systems provide a basis for improvement in operations [5]. Kristensen et al., (2021) cited in [1] demonstrated a favourable relationship that emerged when ISO 14001 and CE were integrated. Not only was there alignment between CE principles at the organisational level, but there was a standard closed loop that managed CE initiatives. Milazzo et al., (2017) cited in [1] concurred that ISO 14001 was useful in the Italian Steel Company, Fonesca et al., (2018) cited in [1] indicated that 99 Portuguese organisations were able to improve their CE imperatives from ISO 14001, while in Jabbour et al., (2020) cited in [1] moved that 86 Brazilian organisations obtained positive circularity results from ISO 9001 and ISO 14001. Conversely, CE, CSR and life-cycle assessment did not improve with ISO 14001 for 72 Chinese organisations [Pesce et al., 2018 cited in 1].

Similarly, Pamfile et al., [15], stated that the hotel industry did not get substantial improvement from integration of management systems as anticipated. A lack of awareness on CE benefits and importance, financial constraints, poor collaboration between stakeholders and poor policy, government oversight, low flow faucets for water consumption and sustainable sourcing and procurement are some of the barriers to CE that were reported. They did, report on an improvement in operational efficiency with little improvement in environmental and safety management [15]. It can be appreciated that the hotel industry is resource intensive, with its huge consumption of energy (heating, cooling, cleaning), water (cleaning, cooking laundry) and food (cooking and waste) and has a very complex network of

operational streams that require a huge financial commitment to convert the infrastructure to be circular, making CE adoption very complicated.

The olive industry, in Greece, produces large amounts of waste and by-products and faces many challenges regarding resources efficiency and waste management to transition to sustainable practices. They experienced many challenges to CE in terms of training, initial financial investment and integrating new processes with existing ones. They assessed the feasibility of integrating ISO 14001 Environmental Management to address their CE goals. They found that ISO 14001 provided a "structured framework" to implement CE (resource efficiency and waste-minimisation) and continuous improvement. They also reported numerous benefits arising from this implementation, such as improved waste management, reduced resource consumption and ensured compliance with environmental regulations [4 and 11].

Arana-Landin et al., [4] also propose the integration of a management system (French standard XP X30-901) with CE ISO 59000 initiatives to support circularity. This aided in understanding the drivers and challenges to implement circularity. They reported on an Italian Water Treatment Company, a forerunner in circularity and their experiences during CE adoption. For example, they integrated their CE with the French Standard XP X30- 901, and collaborated with external stakeholders (suppliers, auditors and public administration) as drivers for their adoption. As reported by other researchers, the initial financial investment to prepare for CE was a challenge to the treatment plant as well. On a positive note, the organisation achieved many positive outcomes. They improved the use of sustainable resources. In 2021 the waste-water plant boasted a reduction in the use of raw materials by 10%, greater than 76% of biomethane obtained from waste-water treatment and they did not purchase any potable water. ISO 14001 focus on Environmental Management has been successfully implemented as a foundation for CE adoption [1], environmental improvement and sustainability [Poltronieri et al., (2019), Nunhes et al., (2016), Krapetrovic and Casadesus (2012) and Zutshi and Sohal (2005) in 1]. Integration comes with its own disadvantages and advantages. Nunhes et al., (2016), Rebelo et al., (2014) and Asif et al., (2009) cited in [1] caution that integration requires specific human resources and financial commitment, suitable management and administrative support and a firm understanding of the integration activities. Nuhes et al., (2016), Llonch et al., (2016) and Rebelo et al., (2016) Karapetetrovic and Caseadesus (2012), Khanna et al., (2010) and Jorgensen et al., (2006) cited in [1], punt the strategic competitiveness, reduction in management, operations and insurance costs and improvement in organisational culture that can arise from integration. Moreover, this can be supported by Poltronieri et al., (2019) cited in [1] who pointed out the improvement in environmental performance, and [Zutshi and Sohal (2005); Zeng, Shi and Lou (2007) and Salome cited in 1] and [15] who indicated the better allocation, improved design, and utilisation of resources and the adoption of cleaner production technologies. Better management practices (positive support from auditors and consultants on CE and integration), improved supply-chain/value-chain collaboration (improved customer and supplier interaction), lean practices (sale of treated water to neighbours), energy efficiency practices and improvement reuse of materials (circularity of water and energy by embarking on joint projects with the value-chain) have been reported [4]. Korostelevo (2022) cited in [7] reported similar benefits from integration in their studies of 17 experts from Poland, Japan, Montenegro, Portugal and Spain.

Difficulties in securing financial investment have been noted to be a barrier to the implementation even though the benefits of CE were well known. Despite these challenges, more positive collaborative engagements between customers [6], suppliers, auditors, and public administration, made integration a positive initiative [4]. Kulczycka and Pedziwiatr 2019 cited in [7] stated that customers appreciate and support products, when they are aware of the ecological and economic benefits of CE. The usefulness of management in CE adoption has predominately showed improved overall performance in most industries. In instances

where it has not, perhaps the design and implementation of the management system could be revisited for improved training, alignment and relevance [7].

3.3 Evaluating the influence of CE practices using existing frameworks and waste/resource management initiatives to drive process optimisation

Jenet et al., [16], on behalf of the European Commission (EC), developed a framework using Eurostat data on the use of resources and waste management for the construction industry. They found that the industry would have to make significant changes in production, consumption models and behaviours. Production, consumption, waste management, secondary raw materials, competitiveness, innovation and global sustainability were key themes that emerged as indicators to monitor circularity. Sharing data was very important for product design, repair, reuse and remanufacturing, setting boundaries.

Kafel and Nowicki [7] reported the importance of new product designs and business models. Zorpas [6] reported on a working group who was selected from the European Commission (EC) to prioritise the “Rs” in circularity. They believed that the “Rs” can be supported by using smarter product designs, particularly the extension of the product, parts and components and the social aspects like behaviour and attitude. They presented new “Rs” for consideration in “pRevention”, Renting, Rebranding and Revolutionising designs and practices.

The Sicilian waste-water plant reported a reduction in processing turnaround time from three weeks to one day after applying appropriate CE tools. Among them was the ISO 020 – Guideline for measuring circularity. They were able to derive economic viability, and operational and logistical optimisation from their CE initiatives. Their focus was on material circularity indicators to monitor circular products and life-cycle assessments to measure resource efficiency [12].

There have been benefits from the adoption of CE [1 and 2] which were evident in process optimisation because it identified and eliminated inefficiencies and aligned the CE imperative with responsible use of resources. This ensured that the organisation adhered to environmental regulations, embraced sustainable practices, facilitated continuous improvement which was important in maintaining sustainability considering the dynamic nature of CE, dealt with stakeholder engagement needs and accountability, and institutional involvement and guidance to assist with Policy development, deployment and management.

Similarly, key themes from Kafel and Nowicki [7] and Kounani et al., [11] indicated that there should be a collaborative effort from stakeholders (customers, suppliers and employees) to identify environmental aspects, prioritise them and for the organisation to suitably train employees to monitor, measure and communicate, transparently to stakeholders, to sustain CE initiatives [11]. Fourteen themes emerged from Honorato et al., [2]. These were, governance structures, evaluation and prisonisation of risks, cultural change, performance monitoring and measurement, integration of policies, value-chain engagement, management and transparency and communication were common themes with certain reviews, however, leadership, definition of policies and goal detection gap analysis were new themes. Likewise, Bahnaru et al., [9] focused on measurement and standardisation and suggested 4 themes for CE adoption, namely, unified metrics, improved data reporting, sector specific frameworks and engaged stakeholders. Carlsson and Nevzorova [8] used the European Green Deal Framework to validate claims from the CE. They purported that orientation to standardised criteria, the ability to substantiate claims clearly and strict observance to guidelines formed a basis for reporting. They also indicated the importance of a clear scope of CE initiatives to maintain stakeholder understanding and the ability to confirm if renewed or recycled material reduce environmental impact.

Standardised "roadmaps" serving as criteria were mooted to be useful for CE implementation [10]. This was also highlighted by Kafel and Nowicki [7] about small and medium enterprises (SMEs) who sought standardisation of practice to facilitate CE implementation and to achieve regulatory requirements thoroughly.

Some of the key themes that emerged from this section are [1, 4, 5, 7 and 9], for success, there should be multi-shareholder approval of all activities, systemisation so that there is uniformity of processes, institutional guidance for CE implementation and improvement in working and thinking in new ways and models to ensure sustainable innovation and a positive impact on the environment.

The complexity that is required by the multifaceted nature of CE can be appreciated. Consequently, there is mention of numerous themes and there is evidence of overlap of some themes between researchers on the practical considerations required to become circular.

3.4 Creating a roadmap for progress in a CE

A common proposition among peers was the need for a collective effort to understand limitations, identify challenges/barriers and develop a formal, structured analysis and evaluation of CE framework to enable a sustainable transition.

There is major concern over the difficulties around numerous non-generative resources from an operational perspective that arose because of the numerous networks of complex processes. Consumers are more informed and seek more environmentally conscious products and services, otherwise these may not be accepted favourably. The olive industry, the waste-water treatment plant and the hotel industry found their CE integration with ISO 14001 or other standards very fruitful. Strategic planning, stakeholder engagement and external expertise supported this success. Robust environmental impact assessment also helped them to identify and prioritise key operations for environmental sustainability, monitoring and measurement and assisted in the adjustment of necessary activities for prevention and/or correction.

The restorative perspective in the design phase and lifecycle assessments encouraged the renewal of materials because it eliminated product "decommissioning" at the end-of-life and shifted to repurposing materials. Moreover, toxic chemicals were replaced to encourage re-use and systems, and production and materials were utilised to produce less waste. This created a new way of thinking to facilitate the entry of repurposed products on the market and promoted acceptance from investors and consumers.

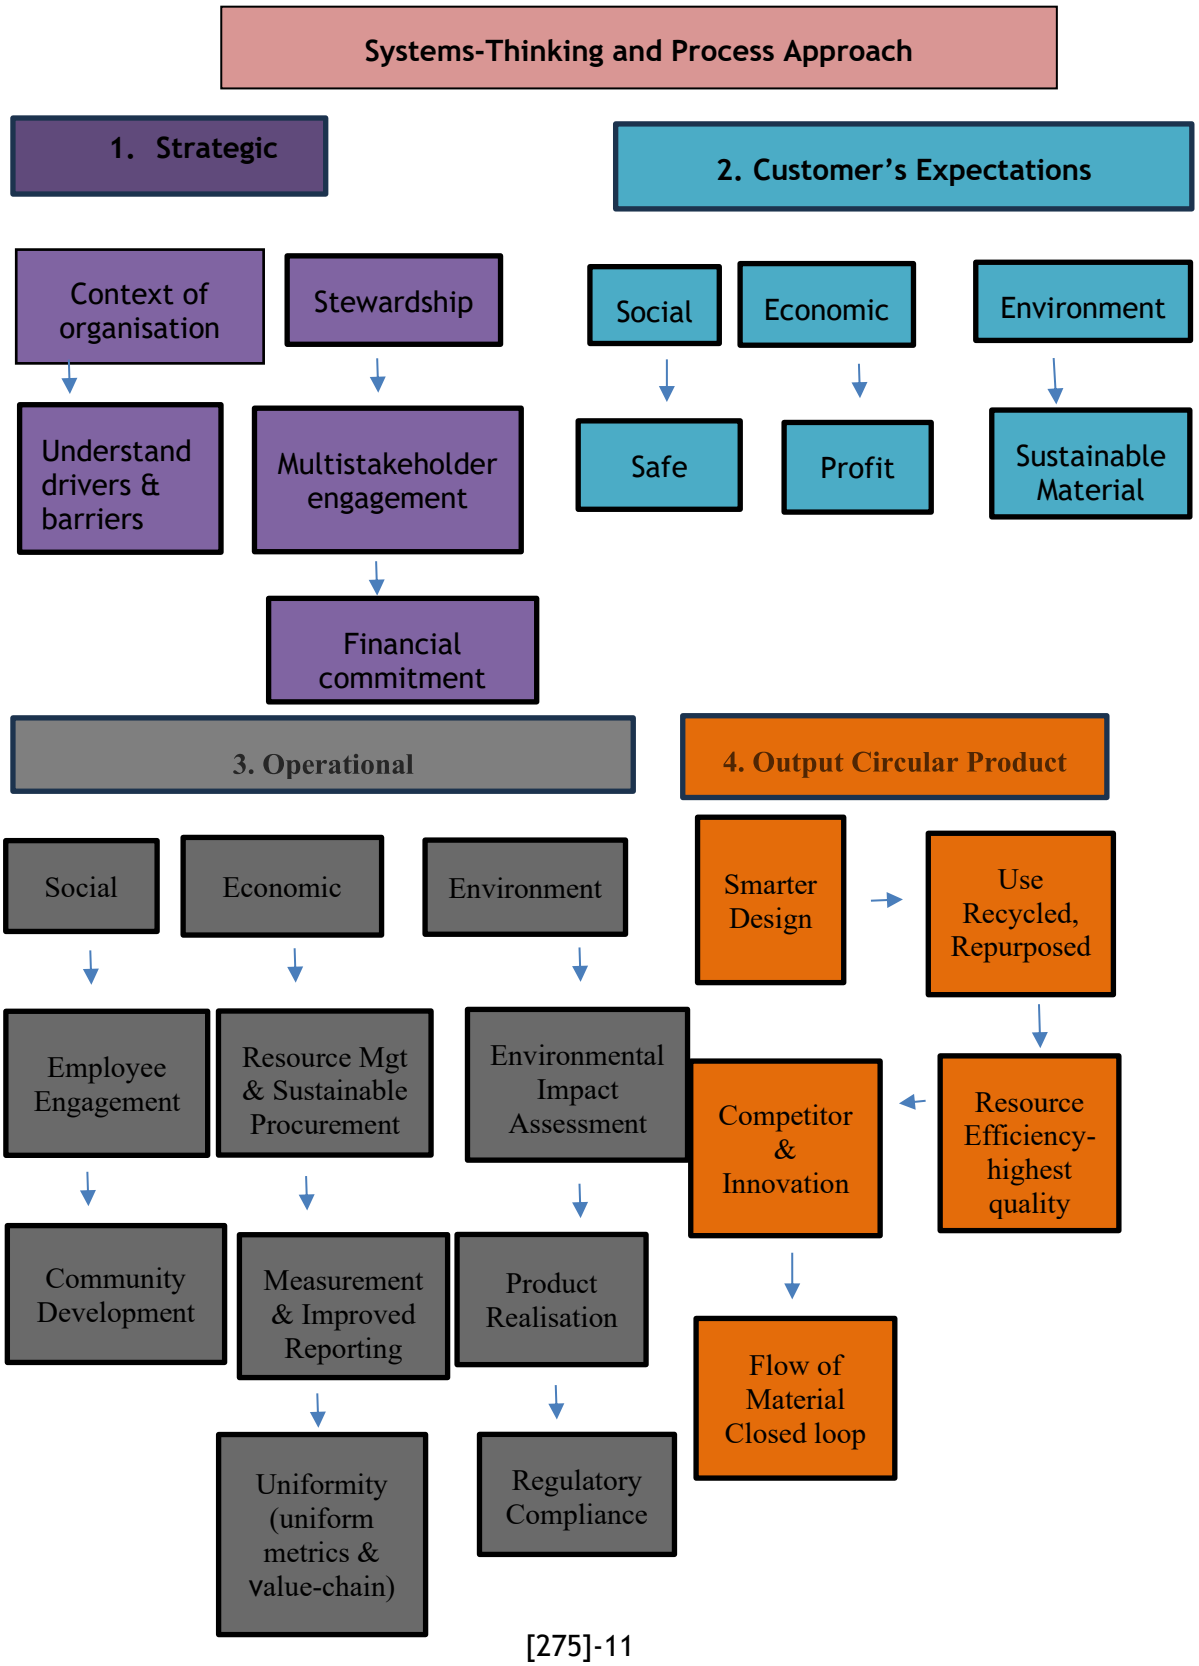
Road mapping the CE planning and implementation process was found to be beneficial to direct the transition from LE to CE in a structured fashion, particularly by outlining a realistic approach to address each step to bring about economic feasibility, environmental accountability and maintaining social interests. These maps consolidated efforts by contemplating the diversity of the stakeholders, their capabilities and responsibilities on the value-chain [10]. Road mapping is like developing a framework where it guides strategic activities in a structured way to achieve a desired goal.

Literature indicates that while CE is complex, it can be effectively implemented through a structured approach. Figure 1 presents a roadmap that integrates CE with Systems-Thinking and the Process Approach [17]. Given that ISO 9001:2015 provides tools for Systems-Thinking and the Process Approach, supports integration with ISO 14001, and enables both strategic and operational optimisation, it serves as a suitable foundation for presenting a structures pathway to circularity.

Key insights and themes drawn from the preceding narrative have been critically evaluated and incorporated into the roadmap, which begins with the strategic considerations and transitions to operational actions. This progression reflects the integration of economic, social

and environmental factors, consistently highlighted in the literature as core themes and imperatives for CE adoption. All supporting elements were assessed, consolidated and positioned with the roadmap to effectively guide CE-oriented thinking and implementation.

Figure 1: Pathway to CE implementation [Developed by researcher]



4 CONCLUSIONS

The adoption of CE practices is imperative. This paper has demonstrated that, while the transition to CE is a significant undertaking, it is achievable through a strategic and structured approach. Over the years there have been many examples of circularity in all types and sizes of organisations that can serve as benchmarks. There are also many experts globally that can be sought for assistance. Excuses surrounding the implementation of CE should make way for deliberate and decisive action. It may be plausible to start with small initiatives and then to grow to larger ones. Once the mind sets of people have changed, it will become a way for life, encourage better support and thus easier to adopt.

DEVELOPING AN APPROACH FOR SMALL BUSINESS SUSTAINABILITY: A FOCUS ON WASTE MANAGEMENT

T. Tshabalala[1*]

[1]Department of Quality and Operations Management
University of Johannesburg, South Africa
tshabalalat@uj.ac.za

ABSTRACT

Small business symbiosis is essential in ensuring the sustainability of small businesses. South Africa's small businesses produce a million tons of waste per year, a large percentage of which is either incinerated or dumped in landfills. Municipalities are challenged to find alternative waste management practices to sustain the environment. The study aims to propose a framework for small businesses' symbiosis, focusing on the reduction of waste. The method used to collect the data was questionnaires, which were analysed using the Statistical Package for Social Science. The study recommends that waste reduction and minimisation efforts need to be increased by initiating a small business ecology approach. The study found that this approach is essential in ensuring long-term partnerships amongst small businesses, which translates to small business long-term sustainability.

Keywords: Small business symbiosis, Waste reduction, Sustainable waste management.

* Corresponding Author

1 INTRODUCTION

Small and medium-sized enterprises (SMEs) are vital to economic development, job creation, and poverty alleviation in South Africa and across the African continent. SME's make a significant contributions to GDP and employment, accounting for over 50% of private sector jobs in developing economies[1]. SMEs serve as key drivers of innovation and new product development while promoting sustainable economic growth. The adaptability and responsiveness of SME's to local market needs position them as strong competitors to larger corporations[2]. In the Gauteng province, small businesses generate considerable waste, primarily consisting of plastics (59-75%), cardboard (31-61%), and food waste (21-37%) [3]. The waste management sector in South Africa holds significant potential to support the green economy through the active participation of SMEs in waste management activities. However, inefficiencies in waste management contribute to environmental degradation and economic losses[2].

Many municipalities lack the necessary infrastructure and equipment for effective waste collection, treatment, and recycling[4]. Additionally, existing recycling policies often fail to emphasise waste minimisation, a challenge further compounded by inadequate community participation and limited technical knowledge regarding recycling practices[5]. Given the pressing need for alternative strategies that promote sustainability alongside small business growth, industrial and business symbiosis—where companies collaborate to repurpose waste as a resource—emerges as an effective solution to enhance circular economy practices[6]. These symbiotic relationships enable small businesses to exchange waste, achieve cost savings, and foster long-term sustainability [7]. Nevertheless, research on small business symbiosis in South Africa remains limited, particularly concerning practical frameworks that can effectively encourage waste reduction. Immediate action is essential to address these gaps and advance sustainable practices among small enterprises.

1.1 Aim and Objectives

Research Aim: To explore waste generation, disposal practices, and collaborative potential among SMEs in Gauteng, and to use these baseline insights to propose an initial framework for small business symbiosis within the circular economy.

Objectives:

- To identify and analyse the types and composition of waste generated by SMEs.
- To assess current disposal practices and the structural barriers affecting recycling and reuse.
- To examine SMEs' willingness and barriers to engaging in symbiotic partnerships.
- To develop a preliminary Small Business Symbiosis Framework informed by the study findings.

2 LITERATURE REVIEW

2.1 Waste Disposal and Challenges

SMEs in South Africa depend heavily on municipal services for waste collection. Recycling participation remains low, with limited waste separation at source. Infrastructure gaps and inadequate policy enforcement exacerbate the problem, leading to over-reliance on landfills.

A substantial number of small businesses depend on municipal services for waste collection and disposal, with approximately 64-68% of enterprises in Gauteng utilising these essential services. However, recycling and reuse practices among these businesses remain alarmingly low [8]. Only 7-14% actively participate in recycling, and a mere 6-12% engage in reusing waste materials[9]. Many small business owners in South Africa neglect waste separation and the

acquisition of designated waste bins, mistakenly believing that it is solely the government's responsibility to provide these essential resources.

While some businesses do donate recyclable materials to informal waste reclaimers—accounting for 10-20% of their waste disposal practices—these informal initiatives often go unreported, resulting in a distorted view of the actual waste management landscape[10]. The lack of adequate waste bins and infrastructure severely hampers effective waste management systems, particularly in industrial areas like Gauteng[11].

The critical shortage of landfill space is an urgent issue, with major cities like Johannesburg and Cape Town facing acute landfill crises. Many small business owners fail to grasp the significance of responsible waste management, underscoring the need for targeted campaigns and educational programs to shift attitudes[12]. The consequences of improper waste management—such as illegal dumping and over-reliance on landfills—pose substantial environmental and public health risks. Furthermore, the undervaluation of waste further hampers recycling efforts. In response, the South African government is championing small and medium-sized enterprises (SMEs) within the waste sector to drive contributions to a sustainable green economy[13]. However, many SMEs fall short of environmental responsibility, and there is a pressing need for larger corporations to lead by example in managing environmental stewardship throughout their supply chains[13].

To achieve meaningful progress, the country must adopt a strategic and cost-effective approach to waste collection that considers socio-economic, environmental, and land-use factors. Additionally, policies such as extended producer responsibility can significantly enhance the country’s waste management and recycling initiatives. It is time to prioritise effective waste solutions for a cleaner, healthier future.

2.2 Circular economy

Global debates on sustainable waste management increasingly emphasise the circular economy (CE) as a transformative framework that challenges the traditional “take–make–dispose” linear model of production and consumption. Instead, CE promotes strategies that design out waste, extend product lifecycles, and maximise resource efficiency by keeping materials in circulation for as long as possible. Within this paradigm, waste is no longer viewed solely as an environmental burden but as a potential economic input that can generate new business opportunities and stimulate innovation [14].

One of the central operational mechanisms of the circular economy is industrial symbiosis (IS), where firms collaborate to repurpose waste streams as valuable inputs for other enterprises. Such collaborations reduce environmental footprints while simultaneously creating economic value. By aligning with circular economy principles, industrial symbiosis goes beyond recycling to foster systemic connections between businesses, enabling cost reductions, risk-sharing, and innovation. This alignment also strengthens the implementation of the waste hierarchy—prioritising prevention, reuse, and recycling before disposal—making it a more effective sustainability tool [15].

Recent scholarship underscores the role of small and medium-sized enterprises (SMEs) in advancing CE principles, given their adaptability and potential for localised innovation. However, SMEs often face barriers such as limited financial resources, lack of technical expertise, and insufficient regulatory support. In this regard, international studies, particularly those conducted in Brazil, provide useful insights. Prof. Simone Sehnem and colleagues highlight how Brazilian SMEs have begun to integrate CE practices into their operations, aligning them with the Sustainable Development Goals (SDGs) and creating opportunities for new value chains. Their work illustrates both the opportunities and the

systemic gaps that remain, emphasising the importance of institutional support, capacity building, and collaborative networks in realizing CE potential [16].

By incorporating these perspectives, this study situates its contribution within the global circular economy debate, emphasising that the development of a Small Business Symbiosis Framework (SBSF) for South Africa not only addresses waste challenges but also contributes to broader international discourses on sustainable economic transitions. This alignment underscores the relevance of the research and provides a foundation for further exploration of how SMEs in developing economies can leverage circular economy principles to achieve both environmental and economic resilience.

2.3 Potential for Symbiotic Partnerships Between Small Businesses

Symbiotic partnerships enable SMEs to share resources, reduce costs, and innovate collectively. However, challenges include a lack of trust, inconsistent by-product supply, and weak regulatory support. Symbiotic partnerships between small businesses can greatly enhance their performance and sustainability. These partnerships, characterised by mutual benefits and resource sharing, offer several significant advantages:

2.3.1 Benefits of Symbiotic Partnerships.

Risk Reduction and Increased Returns: Symbiotic relationships among micro, small, and medium enterprises (MSMEs) help minimise risks while boosting returns. This is achieved through shared resources and collaborative efforts that collectively enhance overall business performance.

Economic Gains: In developing regions, symbiotic collaborations among small and medium-sized enterprises (SMEs) aim to maximise economic benefits. These partnerships often rely on informal networks and are influenced by local regulatory environments.

Access to Resources and Markets: Collaborating with larger companies allows small businesses to access broader, more stable markets and essential resources. This relationship typically benefits both parties, as small businesses gain protection and resources, while larger partners benefit from valuable services.

Innovation and Competitive Advantage: Collaborative networks enable SMEs to share risks and combine resources, fostering the development of innovative products. Such partnerships are crucial for maintaining competitiveness in dynamic markets, often resulting in significant innovation and competitive advantages[18].

2.3.2 Challenges facing symbiosis for SME's

Cultural and Communication Barriers: Partnerships between large and small companies can encounter challenges related to cultural differences, complexity, and communication issues. Effective management and clear communication strategies are essential to overcome these obstacles.

Awareness and Regulatory Support: In developing countries, a lack of awareness and inconsistent supply of by-products can impede the formation of symbiotic partnerships. Proactive engagement and support from governmental institutions through effective policy measures are necessary to facilitate these collaborations.

Trust and Commitment: Trust is a vital component for the success of symbiotic partnerships. Small businesses must establish trusting relationships with their partners to leverage competencies and achieve competitive advantages[19].

2.3.3 Strategies for Successful Partnerships

Small and medium-sized enterprises (SMEs) need to develop their capabilities to participate effectively in business ecosystems. This involves understanding their roles within these ecosystems and acquiring the necessary skills and resources to add value. Utilising technological tools and methods can improve the efficiency and effectiveness of collaborative innovation projects, helping to manage the diversity and complexity of SME networks[20]. Additionally, small businesses should seek long-term and committed partnerships with community-based nonprofits and other organisations to address local issues and achieve sustainable growth.

2.4 Practical Framework for Small Business Symbiosis

Small business symbiosis is a powerful strategy where small businesses actively collaborate with one another and engage with larger entities to achieve significant mutual benefits. This literature review compiles recent research conducted since 2020, establishing a robust framework for small business symbiosis that highlights essential elements such as collaboration, resource sharing, and innovation.

2.4.1 Key Elements of Small Business Symbiosis

Collaborative Networks: Small businesses must leverage inter-organisational cooperation to enhance sustainability and drive innovation. Forming strategic partnerships with other businesses, participating in government initiatives, and collaborating with higher education institutions are crucial[21]. The relationship between small and large firms, akin to the dynamic between sharks and pilot fish, provides small businesses with vital protection and resources while delivering valuable services to larger firms.

Resource Sharing and Efficiency: Effective resource sharing is essential for reducing environmental impact and maximising efficiency. The exchange of by-products, materials, energy, or waste among firms not only drives down costs but also helps generate additional revenue. Frameworks for industrial symbiosis must prioritise financial considerations, risk management, and intangible benefits. These concepts play a critical role in facilitating resource sharing and networking, enabling small businesses to identify synergies and optimise their resource utilisation[22].

Innovation and Knowledge Transfer: Integrating artificial intelligence into product innovation processes is crucial for small businesses to overcome financial and technical obstacles and gain a competitive advantage. Collaborating with higher education institutions is indispensable for accessing essential research, development, and innovation resources[23].

Financial and Technological Support: The adoption of innovative modelling tools is vital for the successful planning and management of industrial symbiosis networks. These tools empower businesses to quantify their collaborative efforts and devise effective strategies for mutual growth[24].

3 METHODOLOGY

This study adopted a quantitative, cross-sectional design to explore waste practices among SMEs in Gauteng. A stratified random sample of 116 SMEs participated via questionnaire survey. The design was chosen as an exploratory step to provide baseline insights in a field where little empirical work has been done.

Data were analysed descriptively using SPSS. While this provides important contextual insights, it is acknowledged that more robust, multi-method approaches (e.g., interviews, case studies, longitudinal tracking, and triangulation across multiple data sources) are necessary for fully developing and validating a comprehensive framework. Thus, this work should be seen as a first stage in a broader research agenda. Sectoral distribution included:

Table 1: Business participants

Business type	Number of business participants	Mean
Food	22	18.97%
Plastic	17	14.66%
Textile	19	16.38%
Metal	20	17.24%
Wood	18	15.52%
Electronics	14	12.07%
Glass	6	5.17%
TOTAL	116	100%

4 RESULTS AND DISCUSSION

The results and discussion section focuses on the composition of waste material, waste disposal practices, structural barriers to green recycling, usable waste produced, barriers and drivers to SME's symbiosis.

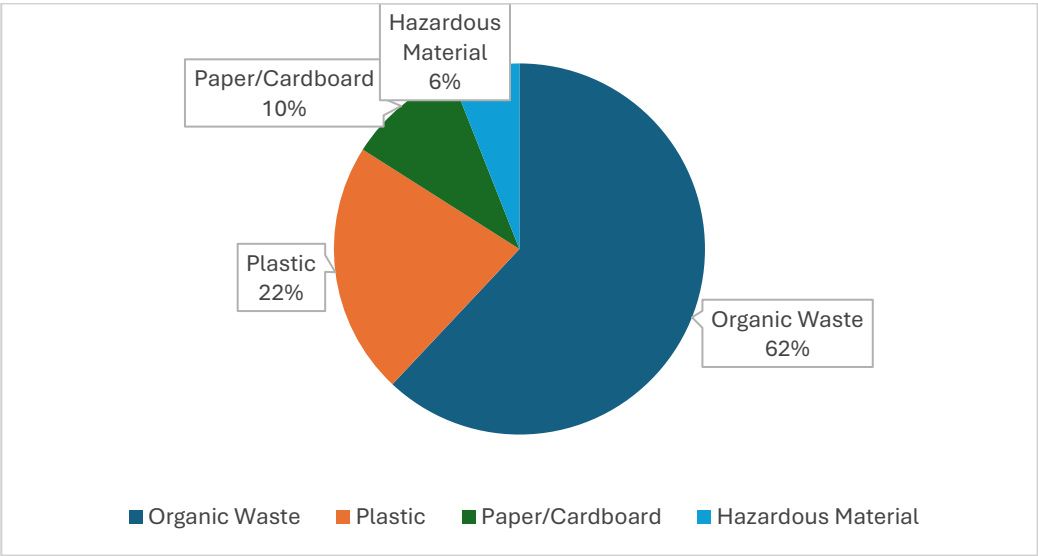

Figure 1: Composition of Waste material

Organic Waste (62%)

Organic waste represents the most significant component of the total waste stream (figure 1), and if unmanaged, organic waste can lead to the increased production of methane emissions in landfill settings, contributing to greenhouse gas emissions. Plastics form the second-largest fraction with 22%, this figure is concerning because It underscores the urgent need for plastic reduction initiatives, consumer awareness campaigns, and the development of circular economy models that promote plastic reuse and recycling. Although paper and cardboard comprise only 10% of the waste stream, they are among the easiest materials to recycle. Their presence indicates an opportunity for enhanced source segregation practices, recycling systems, and collection logistics to ensure recovery before landfill disposal. While constituting the smallest percentage, hazardous waste demands special attention due to its potential to cause environmental contamination, human health risks, and regulatory violations. Proper classification, storage, and treatment protocols are essential to manage this waste stream safely.

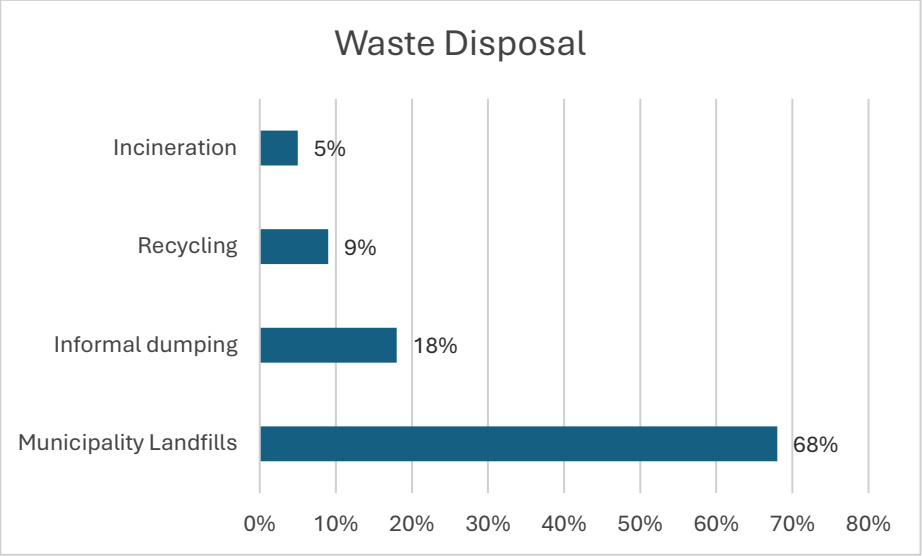

Figure 2: Waste disposal practices

The analysis of waste disposal practices (Figure 2) reveals a critical environmental and economic challenge: 68% of small business waste ends in landfills, while only 5% is recycled. The dominance of landfills and incineration (collectively 86%) underscores the urgency for interventions that redirect waste streams into circular systems.

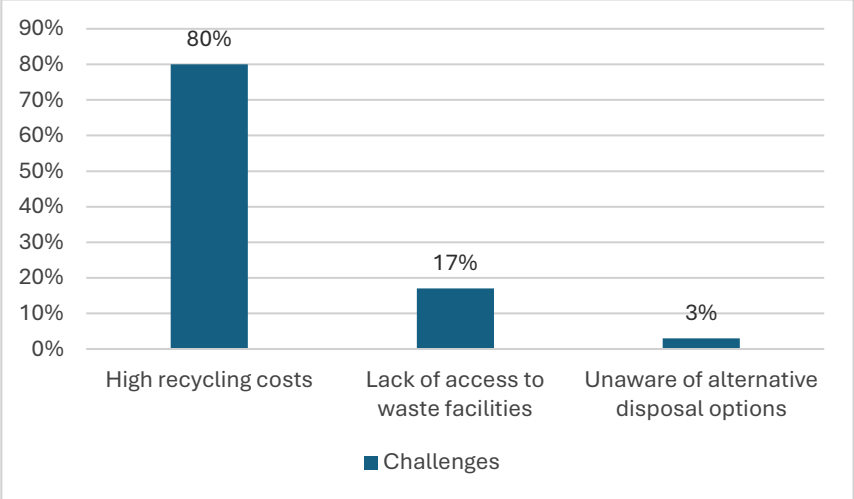

Figure 3: Structural barriers to green recycling

Figure 3 highlights the structural barriers enabling this linear system: 80% of businesses cite *high recycling costs*, while 17% lack access to waste segregation facilities. 3% of operators remain unaware of alternative disposal options—a knowledge gap that stymies circular economy adoption. This triad of barriers (*economic*, *logistical*, and *informational*) necessitates the Small Business Symbiosis Framework *Implementation phase*, where municipal incentives lower cost barriers, while digital platforms democratise access to recycling infrastructure.

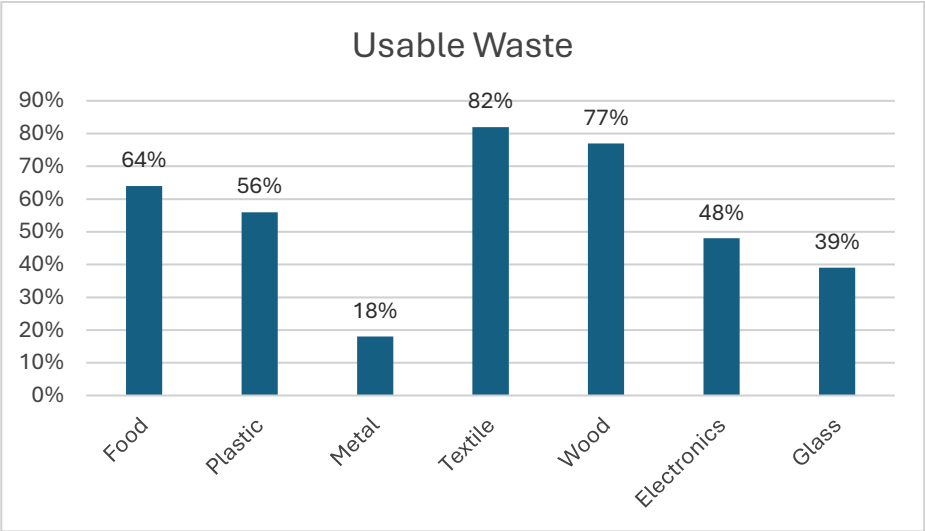

Figure 4: Usable waste produced

Textile waste has the highest usability rate (82%), indicating strong potential for reuse through upcycling, resale, or reprocessing into new materials. Wood waste (77%) also shows high reusability, often applicable in construction, energy production (biomass), or furniture repurposing.

These materials should be targeted for circular economy initiatives and material exchange partnerships among small businesses. Food waste (64%) is largely compostable or usable in organic waste-to-energy systems, reinforcing the potential for local composting networks. Plastic at 56% usability implies moderate recycling potential, though this depends on plastic types and local recycling infrastructure.

Electronic waste (e-waste) usability sits at 48%. While some components are recyclable, e-waste requires specialised handling and is often under-recycled due to complexity and cost. Glass usability is relatively low (39%) likely due to contamination, collection issues, or lack of sorting at source. Surprisingly, metal waste reflects the lowest usability at 18%, despite typically being highly recyclable.

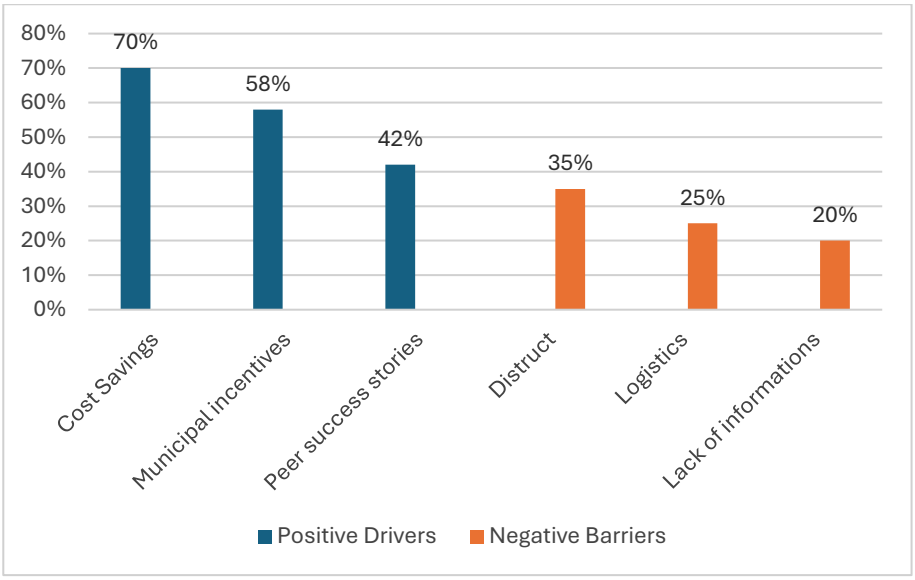

Figure 5: Positive drivers and Negative barriers

However, Figure 5 exposes a behavioural paradox: while 70% of businesses express willingness to collaborate for cost savings, 35% distrust competitors as partners. This misalignment between economic motivation and relational caution echoes global studies on industrial symbiosis [22]. Trust deficits—often rooted in intellectual property concerns or transactional risks—threaten to undermine resource-sharing initiatives.

5 PROPOSES SMALL BUSINESS SYMBIOSIS FRAMEWORK (SBSF)

The study's findings, supported by the literature review and aligned with the study findings, point to the need for a structured approach to embed circular economy principles within the SME sector. Rather than isolated interventions, the recommendations are presented as components of a proposed Small Business Symbiosis Framework (SBSF). This framework integrates waste management practices, collaborative mechanisms, and enabling policy measures into a coherent system that SMEs and municipalities can adopt. By addressing waste separation, partnership facilitation, capacity building, and incentive structures, the SBSF provides a roadmap for transforming current practices into a sustainable, symbiotic model that both reduces environmental impact and enhances SME competitiveness.

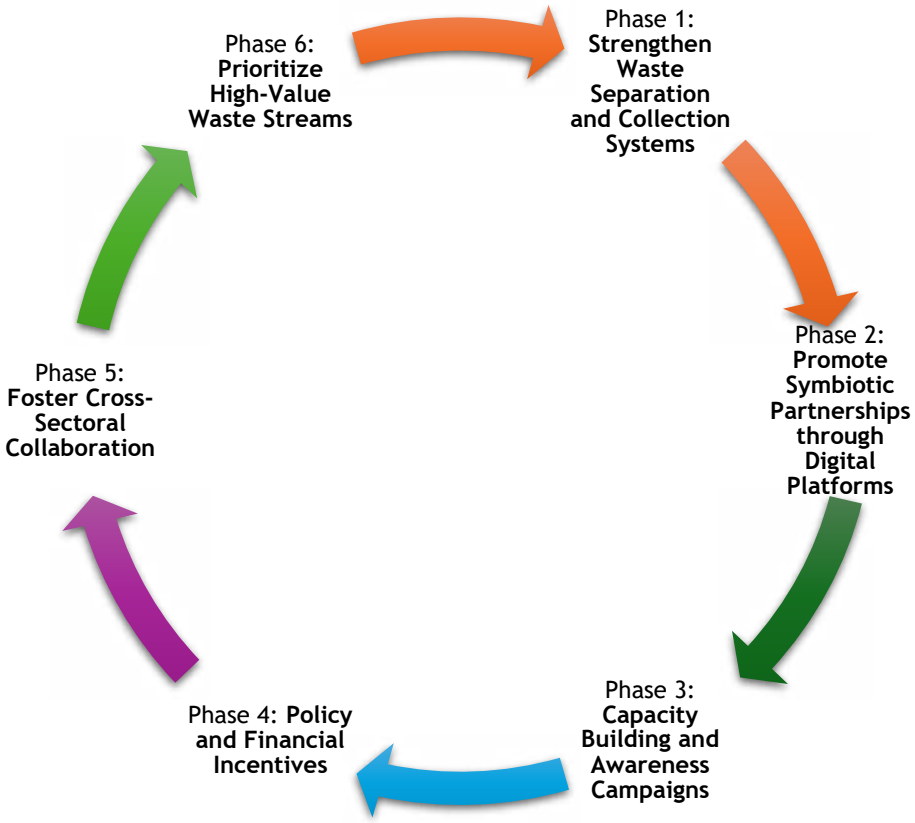

Figure 6: Small Business Symbiosis Framework(SBSF)

Phase 1, Strengthen Waste Separation and Collection Systems: SMEs should be supported with access to affordable waste segregation facilities and clear guidelines to improve recycling rates. Municipalities can provide designated bins and collection schedules aligned with circular economy principles [14].

Phase 2, Promote Symbiotic Partnerships through Digital Platforms: Building on the willingness of 70% of SMEs to collaborate, municipalities and business associations should create digital platforms for waste exchange and resource matching, reducing transaction costs and mistrust among competitors [15].

Phase 3, Capacity Building and Awareness Campaigns: Training and awareness programs are essential to address knowledge gaps and to highlight the economic and environmental benefits of circular practices. Case studies from Brazil [16] demonstrate the importance of education in embedding CE practices among SMEs.

Phase 4, Policy and Financial Incentives: Government should provide tax breaks, subsidies, or reduced landfill fees for SMEs engaging in symbiotic practices, addressing cost-related barriers identified in the results. Such incentives can stimulate adoption of the Small Business Symbiosis Framework (SBSF).

Phase 5, Foster Cross-Sectoral Collaboration: SMEs should be encouraged to collaborate with larger firms, non-profits, and universities to access resources, technical knowledge, and innovation support, reinforcing the circular economy ecosystem.

Phase 6, Prioritise High-Value Waste Streams: Results show textiles, wood, and food waste have strong potential for reuse. These should be prioritised for pilot projects in local circular economy initiatives, ensuring maximum resource recovery.

6 CONCLUSION

This study has provided valuable baseline evidence on SME waste management practices in Gauteng and has proposed a preliminary Small Business Symbiosis Framework (SBSF). By identifying the types of waste generated, current disposal practices, and barriers to symbiotic collaboration, the research contributes to both local policy debates and global circular economy discourse. The integration of insights from international literature, particularly circular economy applications in Brazil, further grounds the relevance of the study. The findings underscore the urgency of addressing landfill dependency, high recycling costs, and knowledge gaps, while also highlighting SMEs' willingness to collaborate under the right conditions. Although the SBSF remains exploratory, it provides a foundation for future refinement and testing.

Future research should employ mixed methods, including qualitative interviews and longitudinal studies, to test the SBSF in practice. Comparative studies across regions and integration of digital technologies in waste tracking and partnerships

ABSTRACT

The Diamond Mining (DM) sector in Africa relies on high-volume data for operational-decisions. However, the absence of specialised Quality-Assurance/Control Frameworks (QAC-F) hinders reliability and advanced analytics. This Systematic Review (SR) investigates QAC and data-governance strategies used in DM within the SADC region (2020–2025), emphasizing their integration with Machine-Learning (ML) and applicability among diamond concessionaires. We examined peer-reviewed articles, industry reports, and frameworks from the past decade to evaluate approaches addressing data validation, real-time analytics, and advanced automation. The findings emphasize a significant lack of specialized QAC-F in mining, with limited integration of ML, which hampers effective operational decision-making. By highlighting gaps in current practices, this review underscores the necessity for a tailored QAC-F that addresses data-integrity, fosters predictive analytics, and strengthens competitive advantage in DM industry. Implementation of these findings could significantly enhance operational efficiency and sustainability across similar contexts.

Keywords: Diamond mining, Quality Control, Data-driven decision-making, ML, Data governance.

1 INTRODUCTION

1.1 Background

The diamond mining industry (DMI) has been an important driver of economic growth in many sub-Saharan African countries, especially in the Southern African Development Community (SADC) countries, such as Angola, Botswana, Namibia, Zambia, Zimbabwe, as well as South Africa [1],[4].

Despite their great economic relevance, many mining industries in this region face several challenges in adopting and applying emerging technologies to customize and optimize processes, as well as manage the large volumes of data produced. Among the various challenges, the following stand out: financial limitations, skills shortages, organizational resistance and resistance to digital transformation, among others [5],[8].

Other challenges include cybersecurity risks, outdated infrastructure, limited scalability, as well as sociocultural resistance, which are also highlighted by the authors [9],[11]. An additional concern associated with digital transformation is the complexity and volume of data generated daily across mining operations.

This data varies in structure, ranging from structured and semi-structured to unstructured, and originates from multiple departments, including geology, drilling, and equipment monitoring [12]. Notably, significant data streams come from Internet of Things (IoT) devices and advanced monitoring systems [13],[14].

Several research studies have been developed to mitigate these challenges. Ruiyu *et al*. [15] highlight the relevance of implementing efficient and effective solutions based on robust big data integration strategies to unify heterogeneous data sources. In turn, Escobar et al. [16] highlight the importance of adopting AI, big data, and industrial internet of things (IIoT) technologies to optimize processes and improve decision-making.

Considering that, data is crucial for industrial decision-making and ensuring quality control, the gap in effectively integrating unstructured data into quality assurance systems can significantly undermine the operational efficiency of the entire diamond mining value chain, as highlighted by Masialeti *et al*. [1].

1.2 Relevance of Quality Assurance and Control

From an industrial point of view, Quality Assurance and Control (QAC) refers to the process by which production is ensured based on predefined requirements [9]. These techniques have been widely used in the mining industry, not only to ensure analytical accuracy but also enable real-time process control [10],[11].

Furthermore, it can also be applied to trace data throughout the production chain, based on digital management systems and emerging technologies, such as blockchain and smart contracts, which increases transparency and trust in the diamond life cycle [11],[12].

However, QAC implementation faces notable challenges, including the need for continuous adaptation to evolving standards, high integration costs, and organizational adjustments such as staff training [12],[13].

Despite these challenges, continuous improvement supported by regular audits and periodic reviews of methodologies is essential to maintain the effectiveness and sustainability of QAC systems adapted to specific mining operations, as mentioned [14].

Additionally, although large amounts of data are collected at various stages of production, only a fraction is estimated to be less than 10% and is effectively used for decision-making and optimization [15],[16].

Thus, this underutilization limits real-time deviation detection and makes quality control difficult, especially in DMI. Subsequently, fragmented data systems across departments, such as geology, drilling, and logistics, can create information silos that hinder operational integration and impede data-driven decision-making (DDDM), as referred by Zhana *et al*. [17].

1.3 The Emerging Role of Machine Learning

Machine learning (ML) is a subfield of Artificial Intelligence (AI) that focuses on the development of algorithms and statistical models that allow computers to perform tasks without explicit programming instructions [18],[25]. Due to their particularities, ML techniques are increasingly recognized for their transformative potential in the mining industry, particularly in predictive maintenance, ore classification, and data quality control [15].

In the context of predictive maintenance, ML models are also applied to analyse sensor data to anticipate equipment failures. However, these applications are not only crucial to reducing equipment downtime but can also provide significant gains in cost efficiency and operational reliability [26]-[28].

Similarly, Deep Learning (DL), a subset of ML, uses large data sets to increase the accuracy of extraction and processing, improving product consistency and reducing human error. This method has also been widely used for image analysis, as well as to support automated quality inspection, ensuring uniform standards across all mining outputs [18]-[20].

In addition, these approaches are also used to aid in real-time decision-making, as well as to continuously analyse and evaluate real-time data streams. When combined with IoT and edge computing, ML can enhance operational agility, as well as enable rapid responses factors that are critical for effective decision-making in dynamic mining environments [21],[22].

From the mining industry's perspective, operational inefficiencies persist due to the lack of integrated data pipelines, as noted by Escobar et al. [16]. Subsequently, it is notable that disarticulation can limit reactive operations, as well as the effectiveness of data governance platforms, especially when data is incomplete, outdated, or inaccessible [22],[32].

1.4 Objectives

This study, based on a systematic review, aims to identify existing QAC and data governance strategies relevant to diamond mining, with a focus on their adaptability and integration with ML. To achieve this, we review peer-reviewed articles that focus on data validation, real-time analytics, and advanced automation.

The specific objectives of this study are:

a) To examine how ML techniques are applied to data quality control by mapping their integration into QAC processes within the DMI sector;

b) Assess the effectiveness, advantages, and limitations of ML-based approaches compared to traditional QAC methods;

c) To identify the main challenges and enabling factors affecting the successful implementation of ML technologies in the diamond mining industry across SADC region countries.

1.5 Research question

In line with the objectives defined above, the research seeks to answer the following Research Questions (RQs):

- *1st RQ: How can machine learning be applied to improve quality assurance and control in the diamond mining industry within SADC countries?*
- *2nd RQ: What are the key challenges and enabling factors influencing the successful implementation of ML-based QAC strategies in this context?*

1.6 Paper structure

This article is organized into the following chapters: Section 1 presents the research history, problem statement, definition of objectives, and research questions. In turn, Section 2 seeks to describe the applied research methodology and the Section 3 presents a discussion of emerging trends and limitations. Finally, Section 4 presents the conclusions, recommendations, and directions for future research on the proposed theme.

2 METHODOLOGIES

Research methodology refers to the process which describes the techniques and procedures used to identify and analyse information, as well as data, of a specific research topic [23]. To this end, the present work was based on a SLR, and the methodological framework guided by the PRISMA 2020 guidelines, as recommended by Qiao *et al*. [34].

The analytical approach is exploratory, with elements of mixed methods integration to enhance contextual interpretation. The SLR conducted aimed to map the current state of research, identify gaps, as well as evaluate trends in the application of ML techniques for QAC processes in DMI in the SADC region.

2.1 Search Strategy

The search strategy used a Boolean approach. Boolean search is a technique that enables the creation of more specific search queries in databases through the combination of keywords and logical operators [24]. Thus, our searches were conducted in the Scopus database [25] and employed combinations of the following targeted keywords:

- "*Quality Assurance" AND "Machine Learning" AND "Diamond Mining"*
- *"Quality Control" AND "Machine Learning" AND "Mining Industry"*
- *"Predictive Analytics" AND "Fish Production" AND "Data-Driven Decision Making"*
- *"Intelligent Systems" AND "Mining Operations" AND "Quality Control"*
- *"Data Governance" AND "Diamond Mining" AND "Artificial Intelligence".*

2.2 Inclusion and Exclusion Criteria

A SLR process requires a definition of a search strategy, which aims to establish criteria for the inclusion and exclusion of articles, as well as a careful analysis of the quality of the selected literature, as suggested by Suyo-Vega et al. [24].

Thus, the present review and inclusion criteria included peer-reviewed studies published between 2020 and 2025, written in English, and focused on quality assurance, quality control, machine learning, or data governance in the mining sector, particularly in DMI.

The criteria for selecting materials for this SLR encompassed peer-reviewed articles, industry reports, and frameworks published from 2020 to 2025, written in English, and concentrated on QA/QC, ML, data governance, or unstructured data integration within the DMI.

The exclusion criteria applied in this study were as follows: *(i)* publications not appearing in peer-reviewed journals or conference proceedings, *(ii)* works not written in English, *(iii)* studies published outside the 2020–2025 period, and *(iv)* research with subject areas unrelated to the scope of this investigation.

Furthermore, sources were excluded if they were opinion-based, published in non-English outlets, or derived from unverified repositories. In addition, the quality of the included studies was assessed using parameters such as journal impact factor, indexing status, citation counts, organisational credibility, author qualifications, the robustness of supporting evidence, verified application in industry or research, and the degree of adaptability to the Diamond Mining Industry (DMI) framework.

Priority was given to empirical research and technological implementations. Therefore, studies from unrelated fields, non-peer-reviewed sources, preprints, and texts in languages other than English were excluded.

2.3 Screening, and Selection Process

The PRISMA protocol was applied, as illustrated in figure 1, with an initial search and filtering process of 4 phases, where a total of 20,191 were initially identified. In addition, connected papers were also used to explore the co-citation landscape of influential works [26], as depicted in figure 2.

Stages included exclusions based on publication date (**n=5,928**), domain relevance (**n=10,743**), document type (**n=2,016**) and no Inglish language (**n=1,387**). Finally, **117** articles were identified as relevant, which were the basis of the literature review.

Considering the specificities of the search defined at the Scopus level, **12** other articles not linked to scientific research methodologies were extracted from Google Scholar [23]. To better manage the extracted materials, as well as customize the bibliography, Mendeley software was adopted [25].

Figure 1: SLR PRISMA flow diagram, adapted from [66].

Figure 2:Topic Visualization of Co-Citations adapted from [72]

2.4 Temporal Trends in Scientific Output

From 2020 to 2024, there was a notable rise in scientific publications related to QAC and ML in the mining sector. Annual outputs increased from 12 publications in 2020 to 34 in 2024, with intermediate counts of 17 (2021), 16 (2022), and 27 (2023).

By May 2025, 11 studies had been indexed, a figure likely influenced by delays in database updates rather than a decline in research activity. As illustrated in figure 3, this trend reflects growing global momentum toward data-driven quality frameworks and the increasing integration of AI and ML in mining operations.

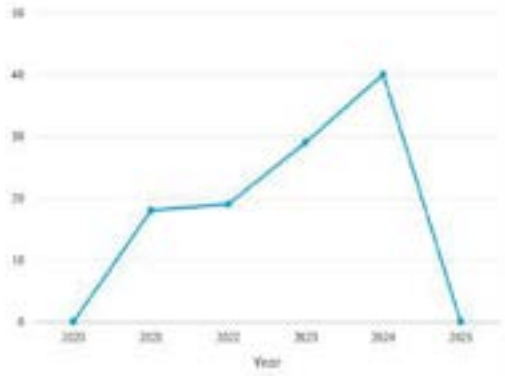

Figure 3: Figure 3. Annual distribution of SLR-reviewed literature from Scopus data.

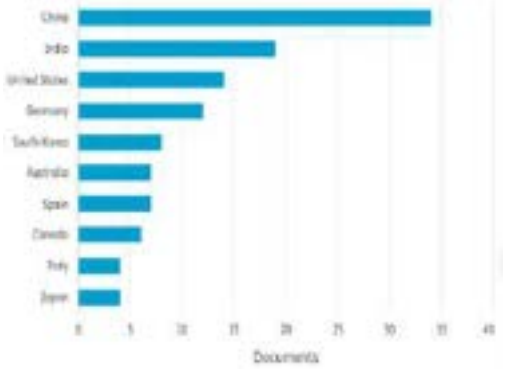

Figure 4: Geographic distribution of publications from from Scopus data.

2.5 Institutional and Regional Contributions

Geographically, most contributions originated from China (**n=27**), India (**n=18**), Germany (**n=14**), and the United States (**n=11**), with additional input from Australia, South Korea, Spain, Canada, Italy, and Greece, as depicted in figure 4.

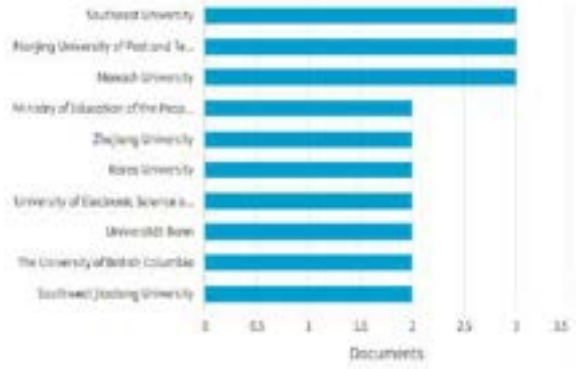

Figure 5: Publications per institution from Scopus data

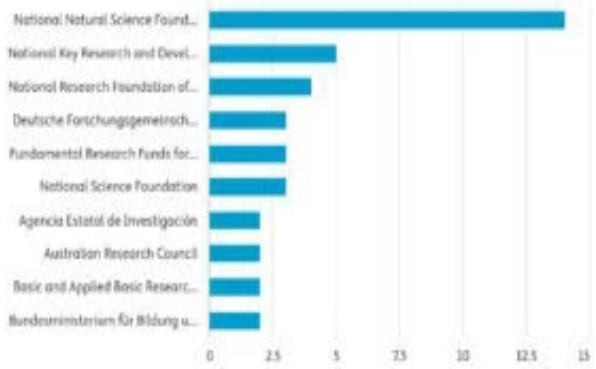

Figure 6: Publications by funding agency from Scopus data

From the point of view of contributions from African institutions, the weak production of research related to the topic is notable, as shown in figure 5. This gap is notable, especially in the countries of the SADC region.

From the point of view of institutions, the main institutions, such as Nanjing University of Posts and Telecommunications, the Ministry of Education of China, Zhejiang University, Korea University, the University of Bonn, as well as the University of British Columbia, stand out in the scientific production inherent to QAC and ML in mining, as demonstrated in figure 6.

2.6 Digital Transformation of the DMI in the SADC Region

The DMI has historically been a significant catalyst for economic growth in several sub-Saharan African countries, especially within the SADC region [1],[2]. Currently, these nations are experiencing a swift and intricate phase of digitisation in the diamond mining industry, along with the overarching changes linked to Industry 4.0 [8].

The timeframe 2020–2025 was intentionally chosen to encompass the post-COVID-19 surge in technological advancements, specifically in quality assurance and control frameworks (QAC-F) and ML applications [3].

The literature research findings, illustrated in figure 4, demonstrate that the utilisation of QAC-F and ML-based solutions in Africa's DMI is both restricted and peripheral. This discovery emphasises the nascent stage of adoption in the region and stresses the urgent necessity for heightened involvement from both the scientific community and industry partners to facilitate technology integration.

3 RESULTS

3.1 Challenges in Mining Information Systems

Based on the results obtained, it can be concluded that the digital transformation of the mining sector has been driven, above all, by the adoption of several technologies, among which IoT, big data analysis, and ML stand out, as illustrated in Table 1.

Table 1: Key challenges and limitations in mining information systems

Challenge/Citations	Description
Fragmentation and Limited Functionality. [39],[5]	Data silos and the limited functionality of traditional tools hinder integration and analysis.
Visualization and Real-Time Fusion.[40],[41]	The high velocity and volume of IoT data overwhelm traditional tools, delaying decisions. The fusion of data visualization and data analytics in the process of digitalization.
Data-Management/ Constraints.[42],[43]	Large-scale, distributed IoT data overwhelms systems, causing redundancy and inefficiency.
Security Risks.[27],[28]	Vulnerabilities in IoT devices and systems pose risks of breaches and attacks.
Data Fusion Barriers.[29],[15]	Heterogeneous sources and formats complicate fusion processes. The fusion of data visualization and data analytics in the process of DMI
Complexity of Data [30],[7]	Integration of routine and IoT data adds complexity due to differing structures.

Diamond dealers produce large and varied qualities of data, structured as well as semi-structured, originating from different departments, namely geophysics, manufacturing, and production, among others, summarized in table 2.

However, effective integration of these datasets can be hampered by interoperability issues, data heterogeneity, and communication limitations. To this end, there must be standardized communication models based on AI, as well as the adoption of cutting-edge computing infrastructures, capable of responding to the challenges inherent to the DMI [37],[27].

As measured in table 3, current and emerging technologies are driving digital transformation in the mining sector.

Table 2: Comparative analysis of mining data types and corresponding solutions

Data type/ Citation	Solutions
Geological Data [15],[32]	Heterogeneity, integration difficulties. Standardized data platforms, AI-driven analytics
Environmental Data [33]	Real-time monitoring, sensor limitations. Wireless sensor networks, edge computing
Equipment-Related Data [31]	Predictive maintenance, interoperability. IIoT architecture, ML models
Production Data [34]	Data velocity, scalability. Stream processing frameworks, distributed systems
Hazard-Related Data [35],[36]	Risk detection, early warning systems. AI models, real-time monitoring systems

Table 3: Overview of current and emerging technologies in the mining industry

Technology/References	Application /Adoption
IoT [38],[39]	-Enables real-time data acquisition and monitoring; improves machine tracking and environmental awareness. Widely adopted
Big Data Analytics [39],[40]	-Analyses large datasets to enhance decision-making, reduce costs, and improve safety. Moderately adopted
Computational Intelligence (CI) [41],[42]	-Uses neural networks and fuzzy logic to model complex systems and optimize mining operations. -Emerging use
Digital Twins [43],[31]	-Creates digital replicas for process simulation, predictive maintenance, and operational optimization. Growing adoption
AI [38],[20]	-Supports automation and predictive analytics, potential for advanced process optimization. Exploratory stage
Blockchain [42],[46]	-Improves supply chain transparency and data security in mining transactions.
I4.0 Technologies [48],[49]	-Integrates cyber-physical systems for real-time control, visibility, and smart manufacturing. Early stage
Extended Reality (XR) [38]	-Used in immersive training and safety simulations for hazard preparedness. Experimental/Pilot programs

3.2 Discussion

Although few studies focus specifically on DMI, several provide adaptable methodologies for integrating ML with quality QAC. As summarized in table 2, six main thematic areas emerged: *(I)* triage and classification, *(II)* automation, *(III)* digital twins and simulation, *(IV)* data fusion, *(V)* decision support systems, and *(VI)* persistent barriers including data scarcity and shortage of skilled professionals, especially in the SADC region

However, these themes highlight the promise of ML in DMI and highlight the need for localized and context-specific research and implementation strategies.

Based on the extracted data, it can be seen that the ML techniques that have been frequently applied were Artificial Neural Networks (**n=23**), followed by DL models such as CNNs and LSTMs (**n=15**), Support Vector Machines (**n=13**), Random Forests (**n=11**), and Gradient Boosting algorithms such as XGBoost (**n=9**).

However, only 19 studies addressed QAC processes directly, and only 12 specifically targeted DMI. These data reveal a significant gap in the specific literature in this domain, as measured in table 4.

Table 4: Overview of current and emerging technologies in mining

Author(s)	Approach	Relevance to DMI
[51],[57]	A systematic review of 109 ML studies	Identifies gaps; lacks diamond-specific focus
	AI/ML in sorting and classification	General mining focus; adaptable to diamond mining
	ML for complex mineralogical data	Relevant to QAC; adaptable to diamond operations
	Barriers to ML adoption	Highlights challenges for diamond integration
	DL for mineral grain segmentation	Applicable to diamond sorting
	DL for more image classification	Enhances sorting; not diamond-specific
[58],[57]	Supervised Learning	Transferable to diamond sorting
	Unsupervised Learning	Applicable to diamond processing
[31],[59]	Digital twins for real-time control	Promotes real-time QAC in mining
	Real-time sorting using sensors	Enables QAC in diamond-bearing ore

5. CONCLUSION AND RECOMMENDATIONS

This section discusses the future concerns of data management in an integrated mining information system, the application of ML and quality assurance, and control for the diamond mining industry.

Although ML has the capacity to elevate operational efficiency, its practical application within the regional mining sector remains restricted and limited, due to limited, contextual and systemic challenges.

The study highlights enduring obstacles to ML integration, such as organizational reluctance to embrace technological change, a deficit of qualified personnel, and the prevalence of disconnected data environments.

However, the SRL identified several enabling conditions, such as access to region-specific datasets and the adoption of digital transformation. These highlights the essential role of comprehensive Data Governance Strategies and targeted capacity-building initiatives in ensuring the effective and sustainable integration of ML technologies within the mining sector, across SADC countries.

5.1 Future work

ML holds a substantial promise for advancing QAC, however, its application in DMI, especially in SADC countries, remains underdeveloped. The SRL also suggests that the main barriers include fragmented data systems, lack of standardized protocols, limited regional technical capacity, resistance to adopting new technologies, as well as limited skilled personnel.

However, despite the large infestations, the African continent, especially the SADC countries, is lagging in the application of emerging technologies, especially ML practices for data quality control.

To this end, there must be actions that can promote the adoption of ML at the stakeholder level, aiming to reinforce better data governance. Another aspect, no less relevant, concerns investments in digital infrastructures. For future research, it is suggested that priority should be given to research on the impact of Data Silos on the diamond industry and its operational and economic implications. As well as understanding how ML models and digital tweens can mitigate this issue.

5.2 Insights

ML offers significant potential in data mining from a data quality perspective, its implementation still faces several barriers, subsequently affecting data quality. This limited data availability can not only affect the detection of rare events but can also reduce the interpretability of complex models such as DL, which can undermine confidence in critical decision-making [21].

Another challenge concerns integration with connected systems, which also presents challenges due to interoperability and real-time access requirements [62].

Aiming to mitigate these challenges, several strategies have been proposed, among which the development of open access data, investment in advanced online sensors, as well as the adoption of Multimodal Machine Learning (MML) for greater robustness stand out [61]. Studies suggest that research remains fragmented, with limited studies on data infrastructure in the SADC region [52],[64].

5.3 Key challenges in implementing a tailored QAC-F

The effective execution of a customised QAC-F in operational diamond mining is hindered by multiple factors: the absence of frameworks specifically tailored to the sector's unique complexities, insufficient integration of machine learning for predictive and anomaly detection functions, and the widespread occurrence of inconsistent or incomplete multi-source data.

The issues are exacerbated by insufficient digital infrastructure in remote areas, human-related obstacles such as skill deficiencies, reluctance to adapt, and inadequate stakeholder alignment.

Additional challenges encompass the difficulties in complying with national, and international regulatory standards, the intricacies of connecting with legacy systems such as Enterprise Resource Planning (ERP), and manual reporting, as well as the significant expenses related to implementation and continuous maintenance.

5.4 Conclusion

The DMI in Africa relies on high-volume data for operational decisions. However, based on the studies, it is notable that there is a lack of specialized Quality Assurance and Control structures, which hinders reliability and advanced analysis.

The systematic review identified the various existing QAC and data governance strategies relevant to diamond mining, with a focus on their adaptability and integration with ML in the SADC region countries.

The results examine peer-reviewed articles, industry reports, and frameworks from the past five years, where you can evaluate approaches that address data validation, real-time analytics, and advanced automation. The findings reveal a dearth of specialized QAC guidelines for mining, with many solutions failings to incorporate ML-driven processes.

By highlighting gaps in current practices, this review underscores the need for a tailored QAC framework that addresses data integrity, promotes predictive analytics, and strengthens competitive advantage in the diamond mining industry in SADC countries. Findings reveal a dearth of specialized QAC guidelines for mining, with many solutions failings to incorporate ML-driven processes.

AN ANALYSIS OF THE EFFECTS OF ERGONOMIC IN WORKSTATION DESIGN BASED ON INDUSTRY 4.0 CONCEPT: A CASE STUDY IN THE AUTOMOTIVE INDUSTRY

K.R. Ramdass[1*] and H.S. Phuluwa[2]

[1,2]Department of Industrial and Engineering Management
University of South Africa, South Africa
[1]ramdakr@unisa.ac.za, [2]ephuluhs@unisa.ac.za

ABSTRACT

The integration of Industry 4.0 technologies in automotive manufacturing has brought renewed focus on ergonomics, emphasising the need for workstation designs that enhance worker well-being and productivity. This study compares ergonomic assessment scores between traditional workstations and those reimagined through Industry 4.0 principles, evaluating key factors such as comfort, posture support, reachability, and user satisfaction. Results indicate that modern ergonomic designs significantly reduce physical strain and improve job satisfaction, leading to safer and more efficient work environments. Given the global prevalence of musculoskeletal disorders and the associated economic burden, this research highlights the critical role of advanced ergonomic solutions in adapting to technological advancements and evolving workplace structures. The findings advocate for adopting Industry 4.0 practices to optimise workstation conditions, prioritising employee health and operational efficiency.

Keywords: industrial engineering; process optimisation; ergonomics

* Corresponding Author

1 INTRODUCTION AND BACKGROUND

Ergonomic impact is a key issue in manufacturing, especially on assembly lines with sequentially moving workstations. In the automotive industry, operators handle various parts and perform repetitive tasks while standing for long periods, leading to discomfort and musculoskeletal disorders (MSDs) affecting the shoulders, arms, wrists, neck, and lower back [1]. This also increases the risk of errors due to reliance on human labour and documentation. Manufacturers must balance reducing cycle times with ensuring operator safety. Optimising workstation design to prevent MSDs and conducting ergonomic evaluations are essential for addressing discomfort and improving working conditions. Ergonomics, or human factors, focuses on designing systems that enhance performance and well-being by studying human interactions with system components.

Industry 4.0 significantly transforms from the industrial revolutions by integrating people, machines, and information technologies into smart, digital operations. This shift, digital or smart manufacturing, is becoming increasingly important in global production environments. This study explores how Industry 4.0 technologies can tackle ergonomic challenges in the automotive industry. This study aims to analyse ergonomics in assembly lines from the factory design phase, exploring how integrating ergonomic principles can reduce musculoskeletal disorders (MSDs) caused by poorly designed workstations. While technological advancements are crucial, prioritising worker well-being remains essential. Incorporating human factors into workstation design requires a unified approach that combines existing methods to create ergonomically optimised workplaces.

The challenge faced is designing workstations without initially considering ergonomics, leading to the need for retroactive adjustments. Typically, infrastructure and workstations are built first, with ergonomic concerns addressed later; an approach could reduce issues by about 70% if ergonomics were integrated [2]. Industry 4.0 technologies are increasingly adopted to enhance production environments and drive innovation through digital technology, process redesign, and real-time monitoring. The focus is on how Industry 4.0 can transform manufacturing through these advanced technologies.

Over time, ergonomics has evolved to focus on identifying, analysing, and eliminating workplace risk factors. Modern ergonomics leverages advancements in science and technology to prevent musculoskeletal disorders (MSDs), a global concern due to their substantial impact on employee health and associated costs. Companies aim to reduce MSDs to mitigate physical and economic consequences for individuals and organisations. With rapid advancements in technology and organisational structures, there is a growing need for thorough investigations into workstation design to address these challenges effectively.

2 LITERATURE REVIEW

The vehicle assembly line is a complex system with many components and workstations. Organisations must manage various risks in a competitive and intricate market while maintaining high performance through flexible strategies and ongoing improvement. Automotive manufacturing is energy-intensive, requiring significant raw materials and water. To stay competitive, OEMs must enhance product quality through continuous process improvements, focusing on reducing carbon emissions and increasing sustainability [3].

2.1. Ergonomics

Ergonomics aims to create comfortable and efficient work environments [4]. With the rise of Industry 4.0, including technologies like simulation, virtual reality, and augmented reality, manufacturers can use virtual environments to enhance ergonomics. Integrating these tools helps identify hazards, analyse sources of discomfort, and improve workplace efficiency [5]. Implementing ergonomics adds significant value by boosting employee engagement and

satisfaction. Organisations understand that a healthy work environment supports well-being and fosters a culture of innovation and creativity [6]. Raj Kumar employed the Taguchi experimental approach to assess the workstation design. This method allows for selecting processes or products that operate more reliably in real-world settings, reducing the experimentation needed to develop effective and dependable workstation designs. The Taguchi technique is widely used across industrial sectors to optimise design and development [7].

2.2. Industry 4.0

The adoption of Industry 4.0 technologies requires employees to acquire new skills. This digital transformation integrates advanced techniques like AI, IoT, Big Data, and Blockchain, offering significant opportunities for innovation and efficiency across industries [8]. Industry 4.0, driven by advanced technologies, promises production efficiency and sustainability improvements but lacks comprehensive guidance on its impact. Growing research focuses on how these technologies can enhance sustainability through supply chains, products, and processes [9]. Industry 4.0 is reshaping production, supply chains, and organisational aspects, enhancing resource efficiency, community ties, customer involvement, and employee conditions. It enables mass customisation and responsive manufacturing while requiring strategic adjustments [10]. In the laser welding industry, smart factories use IoT and advanced data collection to boost performance and sustainability by reducing waste, increasing productivity, and cutting costs. Successful implementation of Industry 4.0 involves understanding its principles and addressing integration challenges [11]. Industry 4.0 shifts from traditional production to digital methods, connecting the digital and physical worlds. It benefits manufacturing with real-time connectivity, combining customisation flexibility with mass production efficiency, and addressing competitive challenges.

2.3. Digital twin

The concept of digital twins is broad and needs more clarity and alignment with business standards. The wide range of activities could be detailed in the scope and applications. However, the study will use qualitative metrics to measure the broad impact of digital twins on the industry. Research has analysed core technologies related to digital twins, such as data technologies, high-fidelity modelling, and model-based simulation. It has categorised their applications by lifecycle stages, offering observations and future research directions [11].

Digital twins, or "device shadows," have become a key technology trend, bridging digital models with real-world data for near-real-time representations. This technology supports real-time monitoring and has applications beyond manufacturing, including training, marketing, transportation, energy, healthcare, and sports [11]. In manufacturing, CAD models ensure vehicle integrity before release, but post-release faults can lead to high repair costs and downtime. Simulation replicates real-world processes, aiding design and verification, and offers benefits in manufacturing. However, achieving a complete digital twin representation requires more than sensor data [12]. In summary, manufacturing industries aim to improve product quality, reduce costs, and increase efficiency through extensive research and investment. Simulating these processes in real-time environments can greatly support these goals.

2.4. Facility planning

Facility planning involves designing and organising spaces to meet operational needs, including space utilisation, workflow optimisation, equipment placement, and compliance with safety and regulatory standards. The goal is to create an environment that enhances productivity, efficiency, and safety while considering future growth and flexibility. Integrating design, technology, and operational needs into a cohesive plan that aligns with organisational goals

and budget requires collaboration. Research on integrating lean manufacturing into facility layout emphasises that effective design is crucial for optimising workflow and material movement. Proper facility design improves manufacturing processes and working conditions and supports new business models [13]. Effective facility management increasingly relies on the latest technologies like Building Information Modelling (BIM) for data integration. Key aspects include optimising production, minimising material handling, improving workflow, and ensuring safety, scalability, and sustainability. Facility planning must balance operational needs with cost-effectiveness and adaptability for future challenges.

2.5. Literature Gap

Authors have studied ergonomics as a standalone topic and through digital software for evaluating workstation issues. However, there is a gap in exploring how Industry 4.0 technologies can address broader problems beyond just assessing musculoskeletal risks. The concept of digital twins is evolving, with a need for more research on modelling frameworks and applications across sectors. This research could reveal the benefits of integrated digital twins, encourage investment, and drive adoption. Current literature often focuses on redesigning existing objects rather than creating new designs, presenting opportunities for using virtual models in innovative design and asset management. The literature review is descriptive and reviews key fundamentals in the effects of ergonomics in workstation design based on the Industry 4.0 concept.

3 RESEARCH METHODOLOGY

To develop a robust research technique, define the study's nature: exploratory (qualitative), confirmatory (quantitative), or mixed methods. This qualitative study uses numbers and statistics, with a case study approach and some investigative elements. The research methodology follows the "Research Onion" model by Saunders, Lewis, and Thornhill, which structures the research process from philosophical underpinnings to data collection. This model helps to organise the research strategy effectively. The study used a qualitative approach to understand the challenges in manufacturing activities fully. The data was collected through a systematic literature review, secondary data collection, and semi-structured interviews with manufacturing experts and operators.

Positivism was the philosophical approach, given that existing literature addresses some but not all study objectives. The research explores the impact of Industry 4.0 on facility planning and ergonomics, aiming to contribute new insights. A deductive approach within a qualitative context was used, relying on secondary data to conclude. The study employs a mono-method qualitative approach, combining theoretical and practical perspectives through literature reviews and empirical research.

A longitudinal time horizon reviews historical literature and technological advancements to assess changes. Historical data on Industry 4.0's evolution was collected to ensure long-term feasibility and sustainability. The study uses the Saunders Research Onion model to guide the literature review, data collection, and analysis. It features a case study design, an epistemological philosophy, and a qualitative mono-method approach, addressing how ergonomics can be integrated during initial workstation design and improved with Industry 4.0 technologies.

4 RESULTS AND DISCUSSION

With its complex and labour-intensive processes, the automotive manufacturing industry relies on ergonomics to enhance worker safety, productivity, and efficiency. Effective ergonomics design improves worker well-being by addressing health and performance challenges. Current ergonomic practices often lack comprehensive problem definitions and objective validation. Traditionally, fixed and task-specific workstations were inflexible, leading to inefficiencies as

production needs changed. Although lean manufacturing aimed to reduce waste, its ergonomic design was less advanced and adaptable. Improving ergonomics can boost productivity by addressing physical issues like musculoskeletal disorders and mental health issues from high workloads. Creating an ergonomic environment is essential for better worker well-being and efficiency.

4.1. Working environment challenges

As technology advances, work environments shift from traditional manufacturing settings to complex "smart factories" with advanced technologies that boost speed and quality. In these high-tech environments, employees face new challenges adapting to computerised and automated systems, which will increasingly involve human-robot collaboration. Despite technological advancements, manufacturing tasks remain physically demanding, involving heavy lifting, repetitive motions, and awkward postures, contributing to ergonomic hazards like musculoskeletal disorders (MSDs). These issues can lead to injuries such as strains, sprains, and carpal tunnel syndrome. Addressing these hazards requires ergonomic workstation design and training programs focusing on proper lifting techniques and posture. Key design considerations include reach distances, equipment height adjustments, and tool accessibility to reduce strain and improve workflow.

The rise of automation and robotics adds new ergonomic challenges. While automation reduces some physical demands, designing effective human-robot interfaces and collaborative environments is essential to prevent excessive physical strain on workers. Proper ergonomic assessment is crucial for safe interaction between workers and robots. The accompanying graph compares ergonomic challenges across automotive, electronics, textiles, and machinery industries, highlighting differences in challenge percentages.

	Globalization	workstation design	Complex tech changes	Increased customer demand
Other industry	75%	81%	95%	65%
Automotive industry	80%	79%	85%	79%

Figure 1 Comparison of challenges faced by manufacturers.

4.2. Ergonomics and human factors

Recognising human factors in production innovation is crucial. Human factors mitigate adverse effects and enhance profitability and strategic advantages. Integrating human factors boosts productivity, aids technology adoption, improves product quality, and increases system reliability. Research shows that the benefits of applying human factors far exceed the financial savings from reduced compensation costs.

4.2.1 Human challenge

The manufacturing industry involves complex, labour-intensive processes where ergonomics is crucial in optimising environments and products for human well-being. This review explores ergonomic challenges in the automotive sector, emphasising factors affecting worker health, safety, and performance.

Key Challenges:

- Poorly designed workstations can worsen ergonomic issues, affecting comfort and productivity. Factors like work surface height, tool positioning, and seating suitability are crucial.
- Repetitive tasks without breaks can lead to muscle and joint strain, causing discomfort. Job rotation and task redesign can help reduce these risks.
- Manual handling of heavy or awkward loads strains muscles and joints. Proper lifting training and aids like hoists are essential to minimise injury risks.
- Adopting Industry 4.0 technologies, including automation, IoT, and AI, requires significant investment and upskilling to integrate and maintain these systems effectively.
- Manufacturing faces increasing pressure to adopt sustainable practices, such as reducing carbon footprints and waste, while complying with environmental regulations.

In conclusion, manufacturing industries face complex challenges that require comprehensive strategies. Addressing technological advancements, environmental sustainability, workforce management, and ergonomics requires careful planning, investment, and innovation. Effectively navigating these challenges ensures operational efficiency, competitiveness, and sustainable growth while enhancing workplace well-being. Emphasising adaptation, continuous improvement, and regulatory compliance will help industries build a resilient and prosperous future.

4.2.2 Technology challenge

Companies face ongoing technological transformations in both industrial and service sectors, necessitating the assessment of technology compatibility, maturity, and potential safety issues. Insufficient information from manufacturing systems can create new challenges for operators. Digitalisation and assistive technologies, like exoskeletons, can boost efficiency by reducing non-productive activities. However, integrating advanced technologies and automation presents ergonomic challenges in automotive manufacturing. While robotics can handle physically demanding tasks, designing human-robot interfaces and collaborative environments requires adherence to ergonomic principles to ensure safe and effective interaction. This includes adapting ergonomic standards to new technologies and planning workstations to avoid strain or safety hazards for human operators working alongside robots.

Key Challenges:

- Automation and robotics enhance productivity but can introduce ergonomic issues, such as repetitive motion injuries.
- Maintaining and supporting new technology poses challenges, particularly for complex systems or equipment, as downtime due to maintenance can disrupt production and affect profitability.
- Environmental and ethical considerations in technology production and disposal are crucial, including managing electronic waste and minimising energy consumption.

- Advanced manufacturing techniques like 3D printing require new ergonomic designs for workstations and tools to reduce fatigue and injury risks.
- Integrating new technologies with existing systems can be complex and time-consuming, often involving compatibility issues with legacy systems.
- The initial investment for new technologies, including equipment, software, and training, can be significant and challenging for small and medium-sized manufacturers.

In conclusion, the manufacturing industry is at a key moment where technological advancements and ergonomic practices intersect. While automation, robotics, and other innovations can boost efficiency, they must be integrated with ergonomic principles to minimise strain and injury. Adhering to regulations, investing in continuous improvement, and prioritising worker training are crucial. By aligning technology with good ergonomic practices, the industry can enhance safety, productivity, and overall workforce well-being.

4.3. Industry 4.0 Evolution

The Industrial Revolution transformed economies from agrarian to manufacturing-based systems. Machines replaced human labour, boosting productivity and efficiency, which lowered production costs and increased the variety and volume of goods. This economic shift led to higher incomes and prompted migration from rural areas to cities in search of opportunities in the growing industrial sector. Traditional OEMs are upgrading existing facilities and building new smart factories, while modern EV companies like Tesla operate entirely smart facilities from the start, avoiding the transition costs.

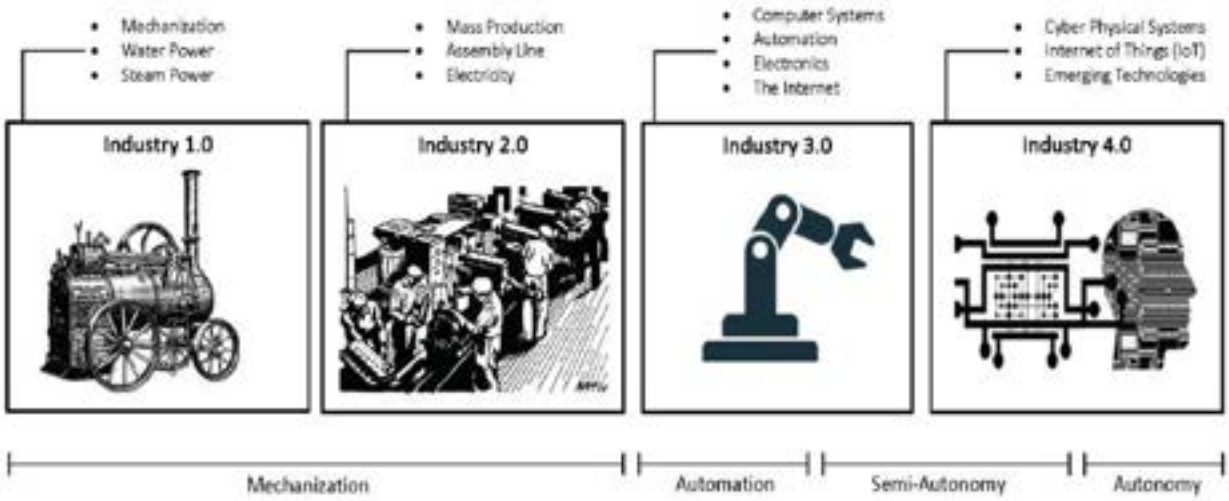

Figure 2: Diagram depicting the four industrial revolutions and degrees of system sovereignty [Picture was taken from [14]

In a brilliant factory, benefits include complete vertical integration to minimise supply chain issues, automation of complex sub-assembly lines, enhanced efficiency and production volume, mass customisation capabilities, reduced downtime and defects, improved product quality, and greater sustainability. These innovations streamline production, boost efficiency, and ensure high product quality through automation and real-time monitoring. Predictive maintenance reduces downtime, and flexible manufacturing systems adapt quickly to market demands and customisation. Adopting Industry 4.0 enhances operational efficiency, competitiveness, and sustainability by optimising resource use and minimising environmental impact.

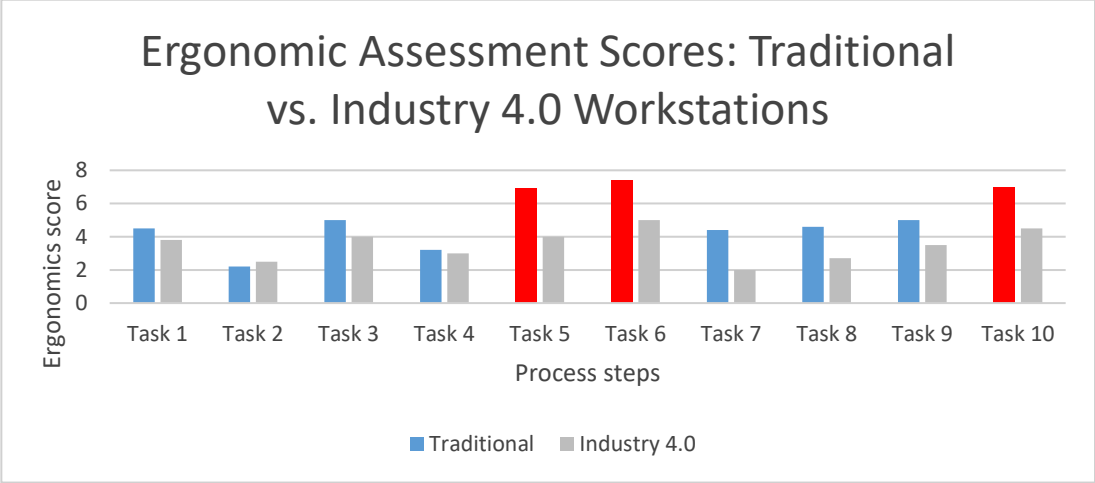

Figure 3: Ergonomic Assessment Scores: Traditional vs. Industry 4.0 Workstations

Industry 4.0 revolutionises manufacturing in the automotive sector by enhancing efficiency, quality, flexibility, and sustainability. These advancements streamline production, enabling manufacturers to innovate quickly and adapt to changing market demands.

4.4. Consequences of planning a factory without ergonomics in mind

Assessing a facility focuses on optimising layout for improved workflow efficiency. Facility Layout Planning involves strategically placing production components to enhance operations and material movement. Modern facility management requires new technologies for integration and information management. Building Information Modelling (BIM) offers a unified data platform that improves beyond traditional methods. Facility management aims to boost employee well-being, cost-effectiveness, and organisational reputation. According to [15], it integrates people, place, and process to enhance quality of life and productivity, extending beyond maintenance to strategic management.

Planning a factory without considering ergonomics can lead to several significant consequences, namely:

- Repetitive strain injuries, such as carpal tunnel syndrome and back pain, are often caused by poor ergonomics, including awkward postures and improper lifting.
- Ineffective layouts and uncomfortable workstations can lower productivity, as discomfort and fatigue lead to longer breaks and more mistakes.
- Health issues from poor ergonomics may increase sick days and impact overall attendance, reducing productivity.
- Poor ergonomics can lower employee morale if workers feel their employer neglects their health.
- Neglecting ergonomic design can result in missed opportunities to enhance workflows and operational efficiency.
- Investing in ergonomic design can save long-term costs by reducing injuries, absenteeism, and turnover, improving productivity, and lowering operational costs.

4.5. Benefits of facility planning with consideration of ergonomics

Integrating ergonomics into factory planning is crucial for worker health, productivity, cost-efficiency, and regulatory compliance.

- Ergonomic design improves productivity by streamlining workflows, reducing fatigue, and enhancing efficiency, increasing throughput and quality.
- It saves cost by preventing injuries, reducing workers' compensation, medical expenses, and turnover, and minimising downtime.
- Prioritising ergonomics boosts employee satisfaction and morale, increasing engagement and loyalty.
- Ergonomic planning supports future adaptability, allowing facilities to adjust to technological, process, and workforce changes.
- It helps prevent musculoskeletal disorders by addressing repetitive motions, awkward postures, and excessive force, creating a safer work environment.

In summary, ergonomic planning creates safer, more efficient workplaces, enhances employee well-being, reduces costs, and supports long-term success.

4.6. The use of a Digital Twin looking into the Factory of the Future

A Digital Twin Prototype (DTP) is a detailed virtual model containing essential data like the Bill of Materials (BOM), design files, and CAD models. It undergoes various tests to identify potential issues before physical production. The accuracy of the physical counterpart depends on the DTP simulation quality. Digital twins provide numerous benefits, including faster time to market, improved operational efficiency, lower maintenance costs, and better user engagement. They allow for effective factory layout planning, visualising component placement, line conditions, and operator work areas. This facilitates ergonomic analysis by identifying and optimising potential issues. By examining the digital twin, we can assess the operator's tasks and workstations, considering height and reachability. Simulations help determine if processes are feasible and ergonomically suitable at each station. In summary, digital twins enhance factory planning by addressing ergonomic factors, leading to a safer and more efficient work environment. The digital twin model lets us visualise the operator's tasks and workstation conditions, enabling precise ergonomic assessments and process optimisation before physical implementation.

Figure 4, virtual assembly line showing the complete line. The image below depicts a real-time production line, highlighting the operator's workflow.

Figure 1: Virtual assembly line, closeup

Although eliminating risk in some processes can be challenging, AI offers solutions, especially for underbody stations where traditional pits are no longer used. Manufacturers can reduce downtime and maintenance costs through real-time equipment monitoring and predictive maintenance by leveraging digital twins. Virtual simulations facilitate the evaluation of new features and technologies, reducing the need for costly physical testing. This approach also supports continuous upgrades and refinements of car models based on performance feedback and real-world data.

4.6.1. Benefits of Digital Twin Prototyping

- It enables the simulation of physical assets and workspaces, allowing for planning and performance improvements without physical prototypes by defining aspects like material types and functionality in advance.
- Digital twins can identify discrepancies and predict potential failures, supporting preventive maintenance and reducing downtime and maintenance costs, thus lowering overall ownership costs.
- They help companies focus on strategic performance and process efficiency, potentially driving significant business value and transforming operations.
- Digital twins are increasingly adopted in the automotive and heavy industries for product development, asset performance optimisation, and process efficiency, and are also expanding into healthcare, construction, and smart cities.
- These models capture vehicle data, aiding in performance analysis and providing personalised services for customers.

The evolution of digital twins reflects growing adoption, diverse applications, and technological advancements across various industries, with adoption rates and applications varying by source and sector.

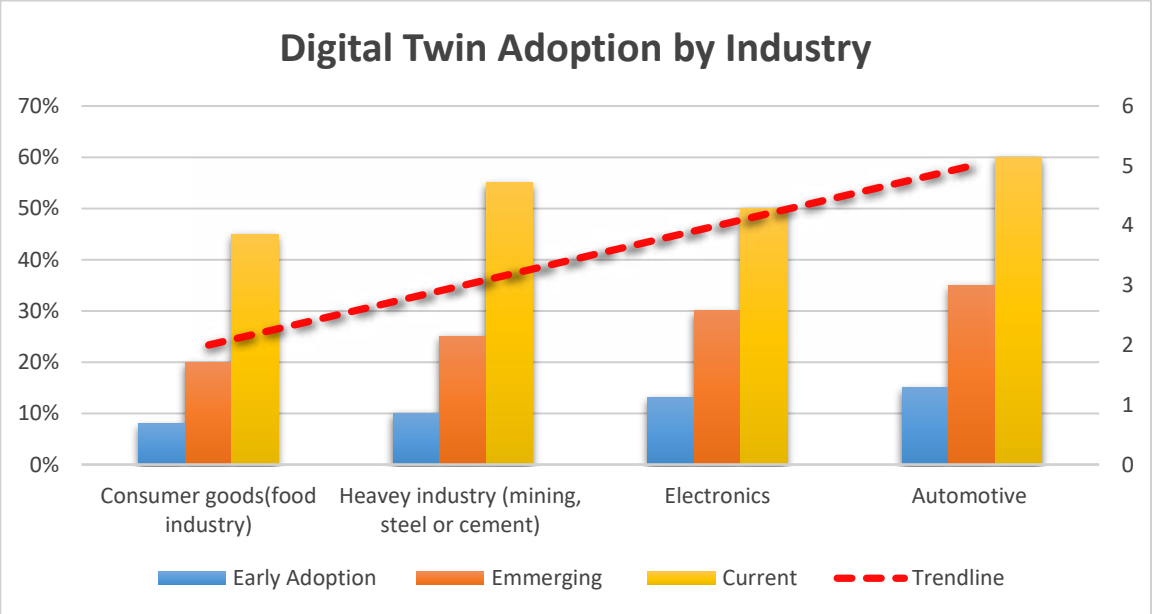

Figure 5: Digital Twin Adoption by Industry from 2010 to 2024

Industries face various challenges, but emerging technologies like digital twins offer innovative solutions. Although the concept has been around for decades, its significant impact is becoming clearer as more industries adopt it. The digital market is poised for growth due to digital twins' potential to reduce costs, boost productivity, improve maintenance, and enhance

safety. Unlike traditional methods, digital twin-based research examines interventions in complex organisations by integrating virtual and physical environments, providing new insights and advancements for the manufacturing sector.

5 CONCLUSION AND RECOMMENDATION

The research focused on ergonomics in assembly line design, emphasising integrating ergonomic principles into factory planning. The literature review revealed the importance of workstation design for operator well-being and highlighted the trend of involving employees in ergonomic assessments.

Organisations should adopt digital twin technology to reduce MSDs and lower testing costs through virtual simulations. Digital twins enable accurate performance predictions, cost savings, and improved productivity, but require investment in skilled personnel. Blockchain can enhance digital twins by securing intellectual property and ensuring smooth data access. Manufacturers should create physics-based digital equipment models, linking them to real-time data for continuous updates.

Investing in industrial exoskeletons can reduce occupational fatigue and MSDs by enhancing workers' strength and stamina and improving lifting and repetitive operations performance. Exoskeletons can reduce strain for workers assembling large machines or moving parts. Passive industrial exoskeletons, which require no electricity, use springs and materials to distribute weight and relieve pressure on body parts like the back or shoulders. Powered industrial exoskeletons, equipped with motors and actuators, enhance lifting capabilities and support specific body parts, such as the back or hands, to handle heavier loads.

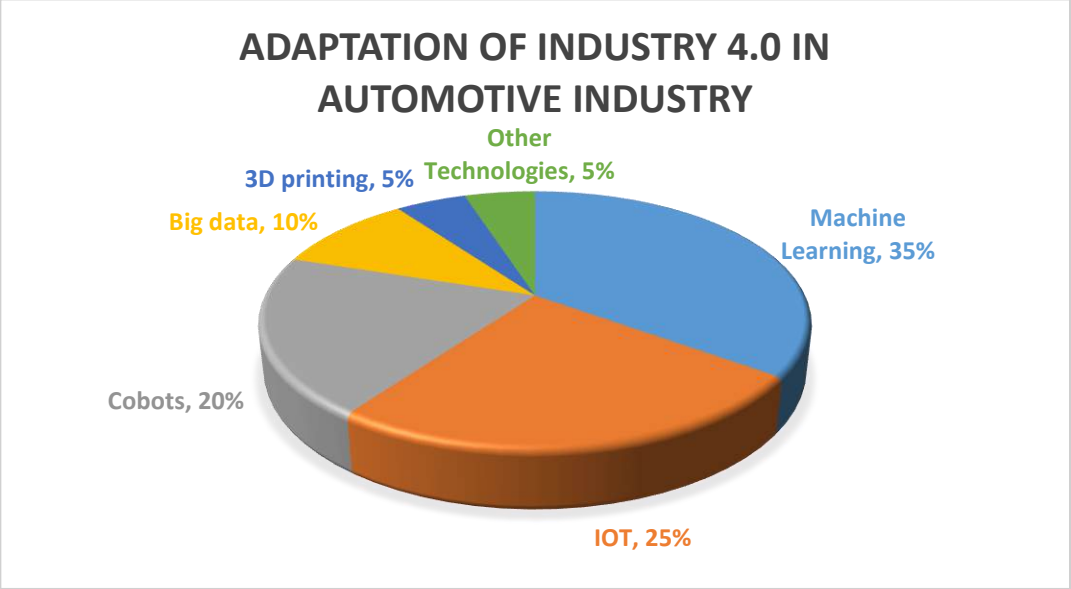

Figure 6: Adaptation of Industry 4.0 in the automotive industry

Governance, safety, and compliance for industrial exoskeletons are covered by ISO 13485. In 2020, powered industrial exoskeletons held a 64.8% market share, expected to increase to 69.9% by 2025, indicating rising popularity. Exoskeletons are particularly beneficial for workers performing overhead tasks. In the automotive industry, upper exoskeletons reduce strain by distributing weight along the arm, easing the physical burden on workers.

Figure 7: Exoskeleton for upper body support (Ekso Bionics)

"Chairless chair" exoskeletons are hydraulic devices for the lower body that adjust to support the user's weight and posture, reducing back strain and maintaining ergonomic positions. Additionally, wearable aids for the hands or thumbs help with forceful tasks, enhancing comfort and minimising strain.

Figure 8: Exoskeleton for lower body support

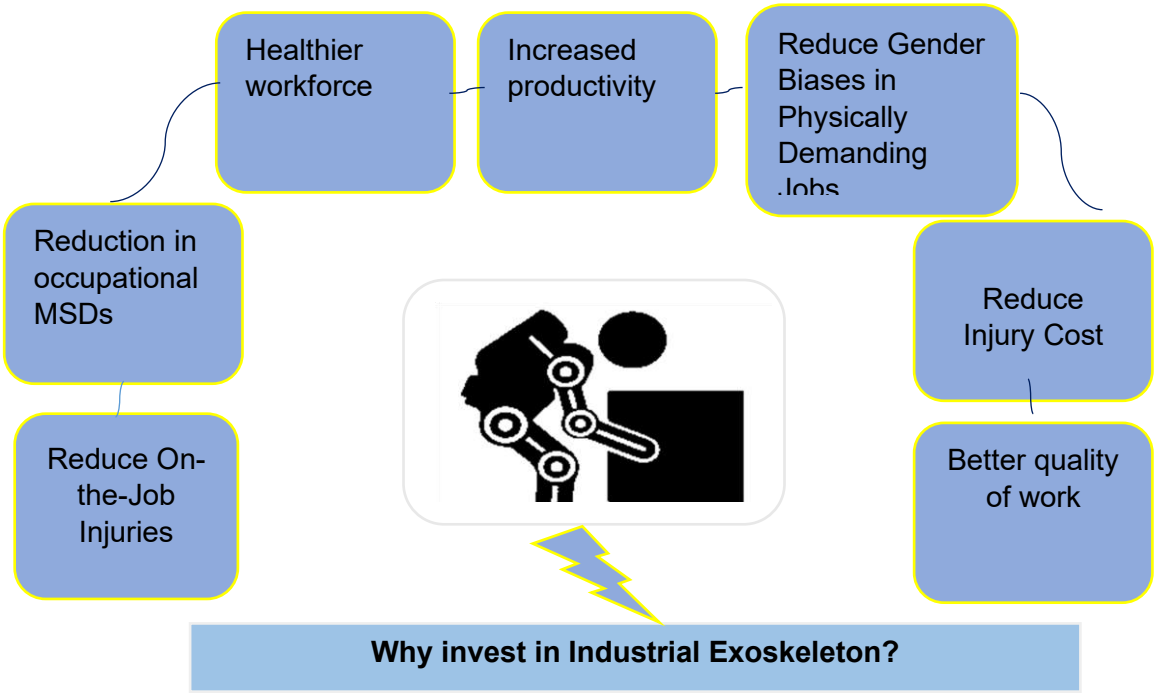

Figure 9: Benefits of exoskeleton

Exoskeletons, while beneficial, have some concerns. Regular maintenance, like cleaning and lubrication, can extend their lifespan, usually 3 to 5 years, or up to 7 years for heavy-duty models. Challenges include high costs, ensuring comfort over time, regular maintenance needs, transportation difficulties, and limited access to tight spaces. Countries like Japan increasingly use exoskeletons to reduce absenteeism and physical strain, especially for high-risk tasks. The type of exoskeleton should match the specific process risks. For new facility layouts, involving all relevant stakeholders, including ergonomics experts and process designers, is essential for effective planning and ergonomic design.

The research agenda for the future can be summarised as follows:

The literature often covers different assembly aspects, but a systemic investigation could yield new insights. Potential topics include:

- Lean Manufacturing and Technological Advancements: Explore how digitalisation integrates lean principles with technological progress. Consider the balance between automation and human involvement in systems.
- Supply Chain Impact and Blockchain: Investigate how digitalising the supply chain can enhance ergonomics in part delivery. Examine how blockchain technology can improve supply chain efficiency and ergonomics.
- Transition from Industry 4.0 to 5.0: Analyse how shifting to Industry 5.0 changes manufacturing processes, focusing on combining technology and human skills to achieve customised mass production.

Industry 4.0 advances technology but won't eliminate human roles in production. While boosting productivity, it may introduce new risks. The impact of Industry 4.0 Technologies (I4.0T) varies by industry, and assessing their sustainability is complex. A multi-context analysis is recommended to evaluate I4.0T's performance. Digital twins will become key industry tools, using real-time data and simulations to predict performance and identify issues. Industry 4.0 accelerates global production changes through interconnected supply chains and rapid

information flow. This interconnectedness means minor adjustments can have significant impacts. Fast adaptation to Industry 4.0 is crucial for global market success. The study shows Industry 4.0's potential to cut injury-related costs and emphasises agility and flexibility. Integrating ergonomics with virtual assembly lines could reduce musculoskeletal disorders (MSDs) on assembly lines.

LEARNING FROM THE ELECTRICITY CRISIS TO AVERT A WATER CRISIS IN SOUTH AFRICA

N. Gangadayal[1*] and B. Emwanu[2]

[1.2]School of Mechanical Industrial and Aeronautical Engineering,
University of the Witwatersrand, South Africa
[1]nashilgangadayal@gmail.com, [2]Bruno.Emwanu@wits.ac.za

ABSTRACT

This study posits that the experience gained in dealing with South Africa's electricity crisis provides crucial lessons for enhancing the management of the country's water resources to avert a crisis. Commonalities in the two resources provide transferable lessons from a wide range of perspectives including governance, supply-chain, operations, funding, and skills, among others. Secondary data are used to obtain insight on key issues, measures tried, and outcomes achieved or actions unsuccessful. Notable challenges comprised an aging infrastructure, limited supply sources and wastage, among others. A causal loop diagram is used to analyse the data. To efficiently manage water resources, a framework identifying critical areas from the study is developed giving recommended actions from an Industrial Engineering perspective to manage potential issues in each area. From the critical list, three most important ones are identified for prioritisation being Infrastructure maintenance and efficiency, managing politics and enabling policy and good governance.

Keywords: Electricity, Water Resource Management, Infrastructure, Politics

1 INTRODUCTION

This paper investigates similar factors between the South African electricity crisis known as 'loadshedding' and a pending water crisis in the country. After recovering from decades-long events leading to a major electricity crisis in 2023, South Africa's energy provider, Eskom, has become a stable entity in electricity generation and transmission. This paper explores the notion that lessons from the electricity crisis can be applied to the water sector, which has been predicted to collapse by the year 2030 [1-2] – leading to a shortage of potable water and another South African crisis.

1.1 Electricity

Loadshedding is understood as a mitigation process which Eskom implements to relieve the electricity grid of 1000MW at each stage [3]. For example, a stage 6 implementation is where 6000MW from the grid is shed every day, sometimes done through multiple periods in a day. To quantify the loadshedding crisis, the number of blackout hours experienced nationwide, from the year 2014 to 2022 totalled 53 days (1 day = 24 hours) [4]. However, the worst of the crisis came in 2023 where the equivalent, 54 days of loadshedding was experienced in a single year - ending in week 33 [5].

Over the years several factors have been suggested as contributing to the continued loadshedding, the most well-known being the lack of maintenance leading to aging infrastructure. To mitigate this, Eskom implemented Open Cycle Gas Turbines (OCGT) - a temporary solution spanning over a decade [6].The cost of running the OCGTs propelled Eskom further into debt especially with the rise of diesel prices. During this period, reports were made by popular press about investigations into irregular practices regarding procurement processes for the diesel and raising concerns over other processes within the utility. The exploitation of procurement processes for personal gain has been a rampant problem in South Africa and is a form of corruption [7]. It is noteworthy to consider corruption as a major contributing factor to the collapse of infrastructure within the country.

1.2 Water

The Department of Water and Sanitation (DWS) is the head authority in the country responsible for securing the country's water supply for drinking and commercial use; water boards report to the DWS. In this paper, lessons from the electricity crisis are extracted and translated into workable strategies for water management. The water crisis stems from projections by analysts, suggesting that at the current rate South Africa will experience a deficit in the water supply of 17% by the year 2030 [1-2].

Water scarcity can be considered from two aspects, namely the physical and economic aspects [8]. From a physical aspect, South Africa has extracted nearly 75% of its physical surface freshwater and has a higher than global average water consumption in the country [9]. South Africans consume 218 litres per capita per day compared to 173 litres per capita per day globally [9]. On the other hand, the economic scarcity of water in South Africa relates to the failing and aging infrastructure making it difficult to extract and distribute the resource efficiently [8].

A water crisis already afflicted Cape Town, known as day zero, whereby droughts led to the evaporation of most of the water in the reservoirs. The citizens rationed water successfully using a plan created by the local governing body and eventually mitigated the crisis, preventing loss of life and possible societal collapse [10]. In Johannesburg (JHB), the infrastructure failure is extensive, 47% of total water coming from the dams is lost in the JHB reticulation system [11]. According to Hingmire [12] Water loss in large systems can range from 25% to 75% in developing countries. To accurately calculate an acceptable water loss, Obunga and Rwanga [13] suggest using an Infrastructure Leakage Index (ILI) formula which

measures the performance of real-world losses to expected/acceptable losses. SA fits within the developing country range, however, the combination of higher-than-average use and natural water scarcity should be a caution to the continuation of such high rates of water loss. This type of loss is commonly referred to as Non-Revenue Water (NRW) and occurs through leakages and/or illegal connections [10]. Given SA's current water climate, the city of Johannesburg's NRW loss should be considered as unacceptably high, producing an unnecessary strain on the water supply.

2 LITERATURE REVIEW

The energy sector in South Africa is monopolized by the state-owned utility Eskom and since apartheid times has been responsible for electricity generation, transmission and distribution [14] Historically, Eskom operated within a government subsidised model which allowed for low-cost production of electricity, making it affordable rather than profit driven. Tariffs were low until an increase in demand signalled that it would outpace the current supply [15].

In 1998, the Department of Minerals and Energy (DOE) wrote the White Paper Energy Policy act to institute grand changes within the electricity sector [15]. These changes would initiate the unbundling of Eskom to open the generation of electricity to private sectors. The infrastructure for transmission and distribution is already built and therefore naturally monopolised by Eskom. The main directive in the White Paper was that the DOE and Eskom should proactively source private electricity generation. However, since Eskom received subsidies, they could provide cheap power from equally cheap coal, making it financially unfeasible for the private sector to compete [14-15]

Eskom were unable to gather any Independent Power Provider (IPP), so to reverse this, in 2001 the DOE passed a ban which forbade Eskom from constructing additional power capacity. However, in 2004 Eskom's CEO issued further warnings that supply was exceeding demand and the DOE was forced to overturn the ban. This led to the commissioning of the Kusile and Medupi power plants in 2005. The decision created more debt for Eskom, requiring more government subsidies [15]. Medupi was set to be finished by the year 2021, however once activated, the Unit 4 power generator exploded. It is expected to be repaired and commence operation by the end of 2025. These decisions and their delays have cost nearly R145 billion (rand), for a return of 4.8GW capacity. A portion of which was made available in 2015, when the first unit become operational [16].

The structure of Eskom within government is important to understand so that a chain of command can be established. The Department of Public Enterprises (DPE) serves as the sole shareholder. The DOE designs policies controlling energy, while the National Treasury (NT) guarantees finances. The National Energy Regulator of South Africa (NERSA) aims to regulate Eskom's costing structure and prevent monopolisation. Other important groups affected by Eskom are SALGA, AMEU and COSATU [14]. Ting and Byrne [14] has provided an illustration between the role of governance over Eskom in the diagram below - the solid line represents a more strict and formal relationship between Eskom and the DPE.

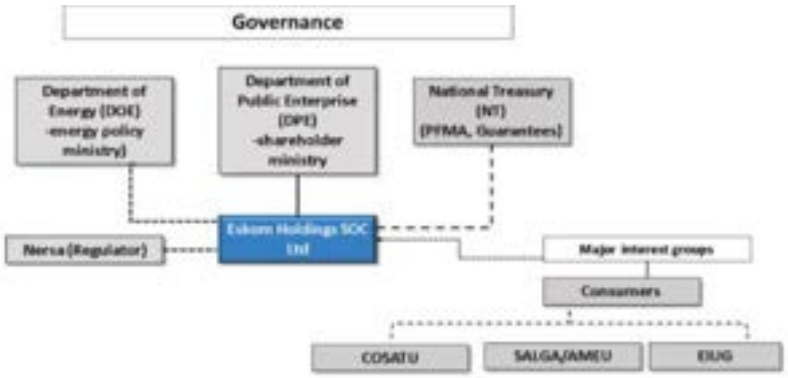

Figure 1: Governance Structure [14]

2.1 Multi-Year Price Determination

Commissioning Kusile and Medupi raised financial concerns. Responsibility of managing Eskom was spread through multiple agencies: DPE, DOE, NT and NERSA. This spread created room for inefficiency. The DOE created a new pricing framework which incrementally increased electricity tariffs. [14] This shift in 2006 abandoned reliance on the affordable electricity subsidy, moving to a cost reflective strategy. This framework, named the Multi-Year-Price-Determination (MYPD) strategy, aimed to lessen the short-term shock of a huge tariff increase while committing to long-term social and economic targets [17]. The raw data used to plot the graph in Figure 2 has been sourced from [17].

The MYPD determines price increases every 3 to 5 years. The graph below shows a massive increase between 2006 and 2018, spanning three consecutive cycles. An increase from 20 c/kWh to 100 c/kWh, represents a near 500% increase through these years [18].

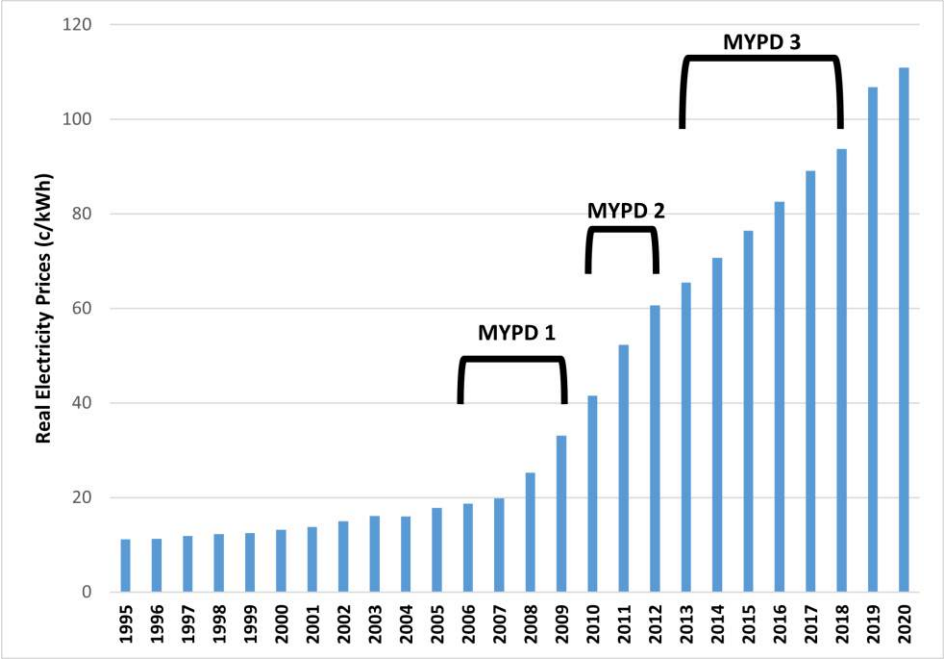

Figure 2: Multi-Year-Price-Determination (MYPD)

2.2 Eskom

2.2.1 Downfall

The beginning of the crisis started modestly in 2007, resulting in policy changes and more planned infrastructure initiatives. Delays in the Kusile and Medupi stations led to capacity shortages resulting in further loadshedding. These delays were perpetuated by corruption scandals, political interference and an undermining of Eskom's management and health. Significant periods of loadshedding lasted during 2014/2015, 2018/2019, and the worst period in 2022/2023 while constant inefficiencies resulted in wasteful operations [19-20].

2.2.2 Impact on Economy and Society

Loadshedding had a significant impact on all businesses, especially in the manufacturing and mining sector. It negatively influenced business operations and investment prospectives in the country. Productivity fell and the input cost increased particularly for companies that were generating electricity on their own using diesel-powered generators [21]. For example, big grocery stores needed to generate their own electricity to keep their refrigerators on since they were struck by record-high levels of food wastage [21]. This led to increased operational costs, causing a ripple effect that increased food prices and required a reduction in staff. On the other hand, smaller businesses had to shut down or risk going into serious debt to stay operational.

2.2.3 Recent Developments

The 16thAugust 2024 marked a change in policy where President Cyril Ramaphosa granted permission to commence the Electricity Regulation Amendment Act. The amendment changed Eskom's monopoly by adding a competitive aspect to the electricity landscape and encouraging more IPPs to participate in a potential energy trade market via a Transmission System Operator (TSO), introducing updates to regulatory criteria of tariffs by NERSA [22]. These efforts hope to boost overall generation capacity. The National Development Plan (NDP) in conjunction with the Just Energy Transition Investment Plan (JET IP) set out in 2023, contains plans to shift from an overreliance on coal to more renewable energy while protecting jobs in the mining and coal sector [22].

2.3 Root Causes and Consequence

2.3.1 Governance Failures

Several reasons have been cited for Eskom's crisis, mainly governance failures which consist of a failure in strategic planning, political interference, poor management decisions, and widespread corruption labelled as 'state capture' [23]. An example of poor strategy is illustrated in the failure to acquire IPPs despite warnings set out in the 1998 White Paper. Acquiring new IPPs was not a priority which led to the eventual supply-demand deficit that caused Eskom to initiate loadshedding nationwide. Additionally, political inference and Eskom's hesitation to give up their monopoly worsened the crisis [24]. 'State capture' weakened Eskom financially, reducing money for essential operations and causing skilled workers to leave [25]. An aging infrastructure suffered from severe underinvestment in maintenance. This led to frequent breakdowns in generating units while having limited resources to fix it [25]. These inefficiencies contributed to Eskom's shortfall in meeting the country's energy demand.

2.3.2 State Capture and Impact on Eskom

State capture severely damaged Eskom's financial and management capabilities. Investigations initiated by the Zondo Commission led to the exposure of political interferences and procurement process inflations [26]. Eskom suffered extensive financial losses because of this, leading to decay in their operational efficiency. The results of the investigation

highlighted how politics compromised Eskom's own governance, along with other State-Owned Enterprises (SOEs) in South Africa. It revealed the need for structural reforms to reinstate core values such as integrity within Eskom [26].

2.3.3 Financial Mismanagement

Corruption and mismanagement plunged Eskom further into debt. Expensive short-term contingencies such as the OCGTs, which involves burning expensive diesel, were primarily used instead of focusing on new generating units using cheaper coal. Eskom has made multiple tariffs increase proposals that were unsustainable and rejected by NERSA, thereby Eskom's funds for expansions (Medupi and Kusile) were legally confined [15].

A huge systemic issue facing South Africa, and particularly Eskom, has been municipality non-payment. An interim report from Eskom in September 2023 has identified that the amounts overdue to them by municipalities across the nation total around R70 billion – a sharp increase from R59 billion in March 2023. Additionally, 20 of the highest defaulting municipalities make up 76.7% of the total debt [27]. Furthermore, during the 2016/2017 period, the total debt owed by municipalities amounted to R225.8 billion; 43% of this value (R96.8 billion) was owed to Eskom and the countries' Water Boards (e.g Rand Water, Umgeni Water) [28].

2.4 Responses and Lessons Learned

Lamidi and Juta [29] outlined policy implementations used in addressing the electricity crisis, some can be described herein. South Africa's crisis prompted key policy responses in efforts to rebalance the national grid. The emergency measure was to introduce loadshedding in 2007 as a short-term solution, while long-term solutions were the Kusile and Medupi power plants. An Integrated Resource Plan (IRP) and Renewable Energy Independent Power Producer Procurement Programme (REIPPPP) were established to diversify the energy mix and promote renewables. The process has faced multiple regulatory delays and infrastructure setbacks [29].

Some regulations were amended to increase IPP involvement. New regulations allowed IPPs to generate 100MW or electricity without a license and municipalities were now permitted to purchase electricity from IPPs. The National Energy Crisis Committee (NECOM) was established to fix Eskom in the long-term, as part of 'Operation Vulindlela', adding new generation capacity according to the Energy Action Plan (EAP) [29].

Eskom's debt kept rising and to be stable it needed financial bailout from the government, amounting to R254 billion over three years [29].These funds aimed to improve infrastructure and reduce load-shedding which came with an unbundling of Eskom into generating, transmission and distribution entities, twenty-six years after being urged to unbundle in the 1998 White Paper. Despite these efforts, progress was hindered by political interference, regulatory hurdles, and infrastructure challenges [29].

2.5 Water Resource Management in South Africa

As stated earlier, South Africa (SA) looms on the edge of a water crisis. This is influenced by internal and external factors including increased demand, deteriorating infrastructure, poor management and climate changes. This section considers key components leading to the water crisis.

2.5.1 Water Availability

South Africa can be classified as a country that is semi-arid and water scarce. It receives an average annual rainfall below 500mm compared to the global average of 850mm [30]. To exacerbate the situation, South Africans usage of water is higher than world average, being 218 litres per capita per day compared to the global average of 173 litres per capita per day[9]. This is concerning given that the country not only has below average rainfall but the additional concern that 75% of its freshwater sources have already been utilised [9].

Moreover, while seasonal rainfall contributes to water availability and is essential to prevent droughts, there has been a change in consistency of rainfall with studies noting a drop in average precipitation leading to extended drought periods [31]. For example, continued droughts created severe conditions in the Western Cape during the 2015-2018 period, which led to the infamous "Day Zero" in Cape Town [31].

2.5.2 Growing Demand

Gauteng alone experienced a population growth of 25% in 2023 [10] This increases household water demand without even considering the demand from agricultural and industrial sectors. The agriculture sector alone constitutes 60% of the water demand in SA, while a growth in farming activity is expected by 2030 [32].

2.5.3 Aging Infrastructure

The state of water infrastructure can be compared with the decaying state in the electricity sector. Collectively, SA has an average NRW loss of 40% in all water systems throughout the country [33] which is high compared to the global average of 30% [34]. To put this in perspective, while the difference of 10% between the two may seem small, the water loss value is measured in cubic billions.

2.5.4 Future Directions

Addressing water scarcity effectively requires strategic solutions to integrate advanced technologies. This may include smart water meters capable of real-time infrastructure monitoring. Smart meters make it possible to leverage data analytics and optimise distribution networks by detecting and mitigating inefficiencies such as leaks and illegal connections which constitute NRW losses [35]. Other strategies may include scaling the use of energy intensive desalination facilities, directing more funding towards water recycling and promoting more effective water conservation practices [36].

2.6 Industrial Engineering Techniques

From literature reviewed, there is limited utilisation of Industrial Engineering techniques in water management. Some techniques that can be applied to water resource management include [37]:

1. Reliability-Centred Maintenance (RCM), 2. Condition-Based Maintenance (CBM), 3. Total Productive Maintenance (TPM), 4. Failure Mode and Effect Analysis (FMEA), 5. Queueing Theory, 6. Optimization Models (Linear Programming and MILP), 7. Predictive Maintenance with IoT & AI, 8. Real-Time Demand Forecasting & Control, 9. Water Loss Management (Non-Revenue Water), 10. Hydraulic Modelling, 11. Six Sigma for Process Optimization, 12. Kaizen (Continuous Improvement), 13. Kaizen (Continuous Improvement), 14. Smart Water Networks (SWN), 15. Energy Audits and Efficiency Improvements. This paper's main suggestion is to use RCM for the infrastructure and development of Smart Water Networks (SWN).

3 RESEARCH METHOD

3.1 Design

This paper approaches the study from a philosophy of critical realism, recognising that while public information is available from various sources, the underlying reasons for behaviour observed is not obvious. The two utilities under study are not open to sharing core information with outside researchers and therefore public information has been used. The study utilises mainly qualitative information which is analysed to derive conclusions. An exploration of narratives around the electricity crisis, constitute proxy case studies for purposes of this study, and are collected from reliable sources. They are then investigated for lessons learned, to determine how sustainable water resource strategies can be established – by transferring

lessons from the electricity crisis to the looming water crisis. Focus is placed on systemic issues contributing towards the electricity crisis. The aim is to illuminate vulnerabilities in how resources are managed so as to mitigate or prevent a future water crisis.

3.1.1 Data Collection

Secondary data is extensively used. This includes official government documentation relating to infrastructure, governance & policy, and systemic failures. Areas emphasised are indicated in table 1:

Table 1: Data collection summary

Source	Examples
Document Analysis	Government & non-Gov reports, Policy Documents (IRP, NDP2030) – both water and electricity sectors
Academic Literature	Historic and current analysis of South Africa's crises – specifically systemic failures, root causes and lessons learned
Non-Academic Literature	News reports, trends and current events from reliable local news outlets

3.1.2 Case Study

The publicly available narrative on the electricity crisis provides this paper the opportunity to create a proxy case study within the literature, from which lessons can be extracted and transformed into strategies to efficiently manage the water sector.

3.1.3 Qualitative Methodology

Table 2: Investigative steps

	Method	Description	Purpose
1.	Ishikawa Diagram	Graphically represent root causes	Identify and categorise all root causes
2.	Document Analysis	Obtain policy document, government reports, academic papers, media articles in both sectors	Thematic Analysis – identify key themes, challenges, governance failures in electricity to draw parallels for water management
3.	Systems Thinking Framework	Modelling the interconnectedness between the two sectors	Causal Loop Diagram (CLD) - Encapsulate how various factors (policy, infrastructure, governance) interact and influence each other
4.	Water Resource Management Framework	Framework for decision making focusing on ways Industrial Engineering techniques aids efficient decision making	Provide strategies and insights using lessons learned from the electricity crisis

3.1.4 Validity and Reliability

The data obtained during research can be validated by considering the sources of the literature and documents with peer reviewed and official government papers considered more valid. Official Government websites were mainly used for documentation.

3.1.5 Ethical Considerations

Only secondary research was undertaken using publicly available data and some journals; hence no risks were involved, and ethical considerations were adhered to.

4 DATA PROCESSING AND RESULTS

4.1 Root Causes and Effects

An Ishikawa (Cause and Effect) diagram is used to present categories of causes which led to the electricity crisis. Each category is known as a root ***cause*** and within it are subcategories that contribute to the ***effect*** at the 'head' of the diagram – labelled "Electricity crisis". These causes were extrapolated after a thematic, pattern analysis of the literature.

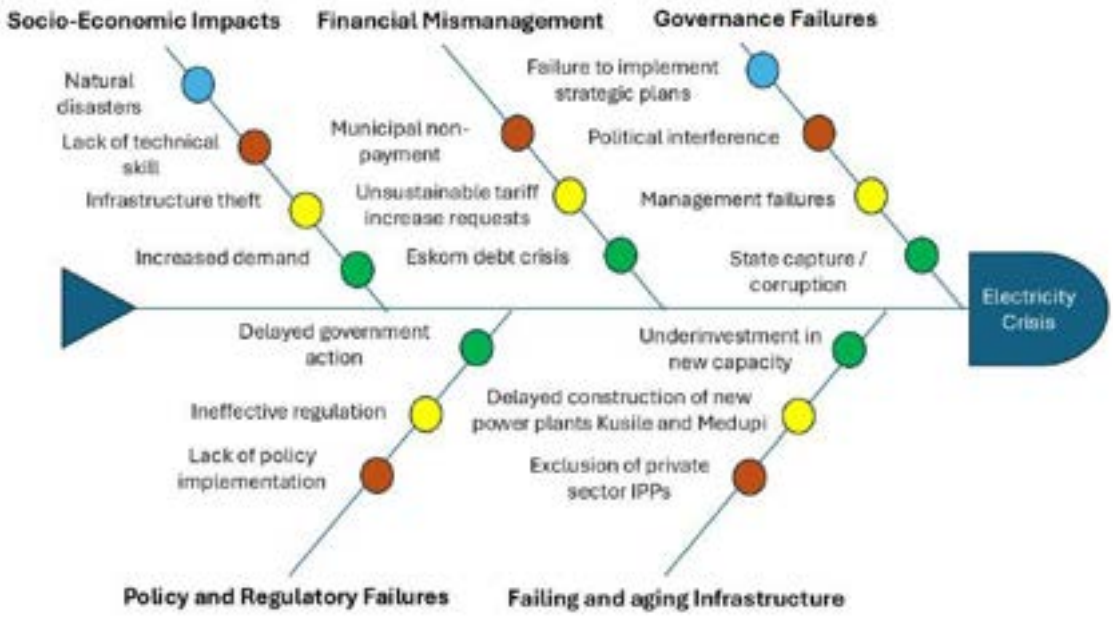

Figure 3: Root Causes contributing to the Electricity crisis

4.2 Lessons Learned from the Electricity Crisis

Table 3: Summary of lessons learned

PRIORITY	LESSONS LEARNED	EXPLANATION
1.	Infrastructure Maintenance	A healthy infrastructure network is essential to meet electricity demand. Regular maintenance should be prioritised which would prevent units failing leading to blackouts.
2.	Politics	The determining factor as to which strategies are implemented. It is the control of resource allocation and is severely threatened by state capture and corruption. The financial and operational health of utilities is heavily dependent on politics surrounding decision making.
3.	Diversification of Energy Sources	Overreliance on coal limits other options when coal-fired stations are not managed properly. Supply suffers and demand cannot be met; diversifying via IPPs may assist the national grid and alleviate crises.
4.	Demand Management	A demand management strategy known as 'loadshedding' was an act of mitigating the impact of the crisis so all citizens may have electricity; even if access was limited.
5.	Regulatory Oversight	Strict frameworks and oversight are needed along with heavy penalties for non-compliance. This creates accountability and

PRIORITY	LESSONS LEARNED	EXPLANATION
		reinforces service delivery from utilities, along with compliance from policy makers.
6.	Research and Development	Upgrading technology used in current infrastructure may make systems operate more efficiently. Additionally, investing into research can potentially unlock new ways to harness power and meet demand efficiently and using renewable energy.

4.3 Modelling the South African Water Landscape

Using the lessons learned, a number of independent variables can be created to model influential factors on the water infrastructure in SA. These independent variables are also affected by their own sub-independent variables. A systems thinking tool known as a Causal Loop Diagram (CLD) is used to depict the interconnectedness of these independent variables and allows a model of the chain of influence within the SA environment.

Following the arrows will help to interpret the diagram. The plus and minus signs each represent the first variable adding or subtracting to the consecutive variable at the end of the arrowhead. Some arrows have two dashed lines through them; this indicates a natural delay in the time it takes for the effect to occur. For example, the variable 'Policy and Governance Framework' is directly preceding to the variable 'Systemic Failures in the Electricity Crisis' in such a way that it has a direct, reductive effect on 'Systemic Failures in the Electricity Crisis'. Which is why the consecutive variable is connected via a negative sign. A positive sign indicates the opposite, an enhancing effect.

The ***dependent variable*** in this diagram is the ***'Water Resource Management Efficiency'***, which is depicted as interconnected and dependent on the rest of the variables.

These variables have been assigned letters so that the loops can be presented neatly in Table 4 below.

A = Water Resource Management efficiency

B = Lessons Learned from Electricity crisis

C = Systemic Failures in the Electricity Crisis

D = Politics

E = Policy and Governance Framework

F = Public Engagement and Trust

G = Stakeholder Collaboration

H = Innovation and Technology

I = Economic and Environmental Conditions

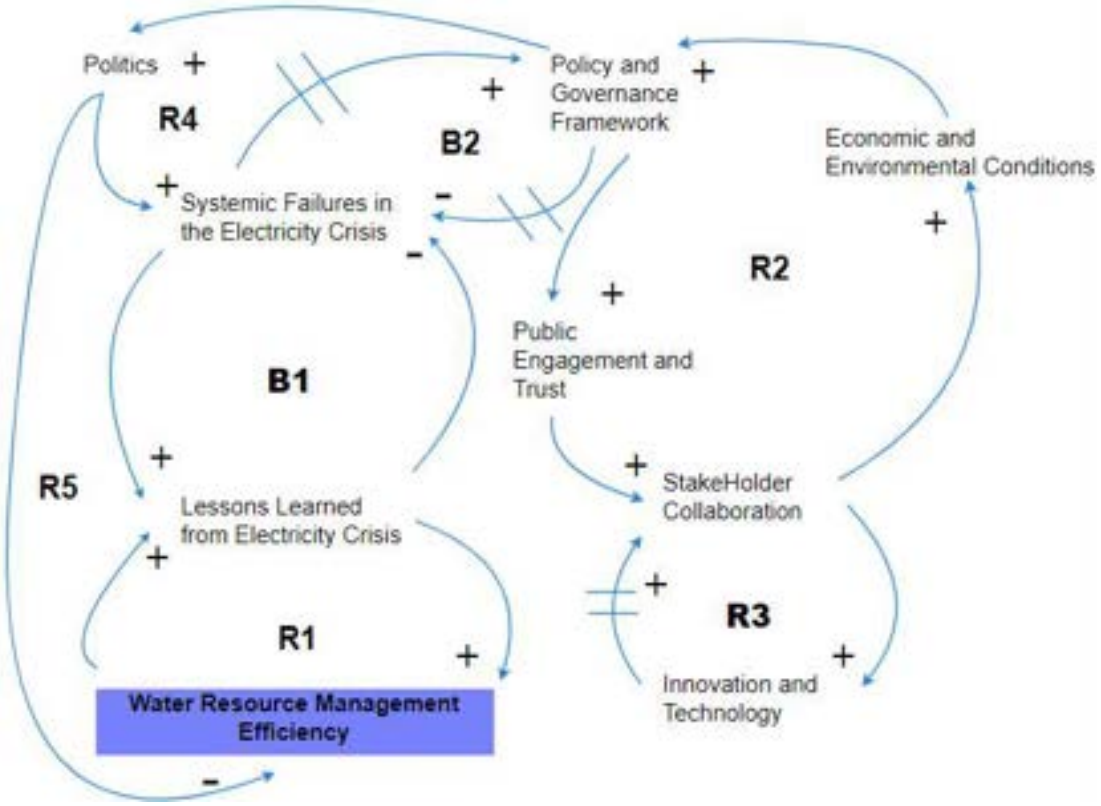

Figure 4: Model of South African Water Landscape in context of lessons learned

Table 4: CLD Loops

Loop #	Loop Name	Type	Nature	Sequence
1	R1	Reinforcing	Unstable	A > B > A
2	R2	Reinforcing	Unstable	E > F > G > I > E
3	R3	Reinforcing	Unstable	G > H > G
4	R4	Reinforcing	Unstable	C > E > D > C
5	R5	Reinforcing	Unstable	D > A > B > C > E > D
6	B1	Balancing	Stabilising	B > C > B
7	B2	Balancing	Stabilising	C > E > C

4.4 Efficient Water Management Framework

Table 5: Framework for Water Resource Management Efficiency

Key Focus Area	Actionable Strategy	Industrial Engineering Approach	Implementation Details
1. Infrastructure Maintenance and Efficiency	Regular Maintenance and Upgrades	**Reliability-Centred Maintenance (RCM):** Identify effective maintenance strategies by prioritising and predicting failures in water system assets such as pipelines, pumps and treatment facilities	**Predictive maintenance using IoT and AI:** Using IoT, an advanced water network can be created with integrated sensors, controlled by a central system of machine learning (ML) algorithms. The aim would be to create a system capable of anticipating breakdowns and enhancing maintenance planning. This would include forecasting of system irregularities and issues in components. The system

Key Focus Area	Actionable Strategy	Industrial Engineering Approach	Implementation Details
		Smart Water Network (SWN)	should culminate into an interconnected, **Smart Water Network (SWN)**
1a) Optimizing Capacity Utilization	Improve Capacity Utilization of Water Systems	**Queuing Theory:** Modelling the water distribution network could aid in streamlining water flow during high demand times. Creating a simulation for demand management. **Optimization Models:** Mixed integer linear programming may allow water efficiency to be enhanced within the network by reducing wastage and maximising capacity.	**Real-Time Demand Forecasting & Control:** This involves adjusting water distribution according to demand changes. Using ML to predict short term variations in water consumption and facilitating flow rate management. **Water Loss Management:** NRW loss is a huge problem relating to dilapidating infrastructure. Creating an optimised system with technology such as sensors, smart meters and pressure monitors, can allow the detection of leaks in the system. Also, pinpointing the location of the leaks would enhance maintenance and allow the system to work more optimally after the problem is fixed.
2. Policy and Governance Framework	Strengthening Policy Design, Implementation, and Accountability	**Governance Process Mapping:** Making use of Business Process Reengineering (BPR) to visually map government procedures. The aim is conformance to quality in water management. **Institutional Change Management:** Government systems undergoing transformation need stringent guidelines to efficiently affect positive change. Established methodologies like 'Kotter's 8 step model' may aid in facilitating a seamless transition. **Participatory Decision Making:**	**Governance Structure Simulation** By simulating governance structures an answer can be found on the efficiency of their outputs and decision making, given the complexities of water systems. **Performance Metrics & Feedback Loops:** A feedback system would facilitate an assessment to measure the impact that policies and government structures have on water management. Key Performance Indicators (KPIs) would aid in monitoring the performance of current policies and promote accountability where there is a lack of quality in decision making. **Information Systems for Communication:** Centralised Decision Support Systems (DSS) can deliver key information quickly across all

Key Focus Area	Actionable Strategy	Industrial Engineering Approach	Implementation Details
		Using a 'Systemic Design' mentality to proactively involve stakeholders in policymaking. This ensures an inclusive approach which encourages participatory decision making - in hopes of faster and more positively impactful decisions.	levels of government. Assisting in the management or planning of water and infrastructure. **Capacity Building Programs:** Initiating skill gap analyses and training needs evaluations to benchmark currents standards and skills. Once deficient areas are identified, the correct training of staff can be administered. This will enhance government capabilities and facilitate agility in management.
3. Politics	Strengthening Political Stability and Policy Alignment	**Political Risk Assessment:** To measure possible instability, conduct a Failure Mode and Effect Analysis (FMEA) **Process Optimization:** Implement Lean Management to reduce inefficiency and delays in executing policies.	**Political Forecasting:** Monte Carlo simulations model political uncertainties by simulating randomized scenarios that can forecast policy outcomes – based on past statistics and probabilities. It can aid in anticipating politically driven delays or budget constraints. This helps strategic planning in water management to mitigate these risks. **Policy Alignment Platforms:** A platform which brings together decision makers, aligning their policies on water governance and preventing political interference

5 DISCUSSION

5.1 Root Causes

The origins of the electricity crisis can be traced back to the 1998 White Paper Act – where an accurate supply-demand gap by 2007 was predicted. Eskom warned government of this but were ignored and no IPPs were procured. The delay in government response led to severe underinvestment into new infrastructure, which resulted in loadshedding. A combination of financial mismanagement and sudden investment into Medupi and Kusile, propelled Eskom into further debt – deepening the crisis. Similarly, in the water sector, poor infrastructure contributes to supply shortages. On average, 40% of water in the country's network is lost to non-revenue water (NRW) – this highlights the urgent need for dedicated maintenance and efficiency improvements to prevent further wastage.

5.2 Lessons Learned

It is the highest priority to fix infrastructure in both the electricity and water industries. Aging infrastructure requires predictive maintenance and timely upgrades to operate sustainably. Eskom's reliance on coal is symmetrical to South Africa's reliance on surface water sources, which are threatened by population growth, drought and climate change. Improving resilience

in SA means that alternative sources for both resources should be explored. Possibilities for alternative water sources include desalination, wastewater recycling and efficient groundwater management. However, strong regulatory enforcement will play a crucial role in preventing mismanagement. Moving forward, a combination of proactive governance around infrastructure, policy enforcement and sustainable resource management would aid in mitigating the future water crisis.

5.3 Variables and Modelling

Lessons from the electricity crisis were applied in the CLD to model 'Water Resource Management Efficiency' and identifying common variables between both sectors. Key influences include politics, corruption, project delays and systemic failures. It is possible that different research perspectives can assign a varying level of importance to these factors, but the CLD is meant to illustrate the authors perspective of the interconnectedness of sub-variables. It depicts reinforcing loops to illustrate instability with governance and their investment into infrastructure. The CLD model contains several unstable feedback loops which aligns with the reality of South Africa's crises.

5.4 Water Management Framework

The framework integrates Industrial Engineering techniques in an effort to enhance water resource management. It draws upon the insights learned in the electricity crisis and outlines actionable strategies. A major drawback is that that the framework does not account for government funding, it assumes that resources can be allocated if necessary. Politics plays a significant role in releasing funds to turn strategies into a reality. The framework highlights immediate areas which need to be addressed and can be seen below.

Immediate focus areas (in order of priority):

1. **Infrastructure Maintenance and Efficiency** - Ensure that technical solutions and action strategies are viable by investing in technology/modernization.
2. **Politics** - Ensure that political commitment aligns and supports the proposed strategies.
3. **Policy and Governance Framework** – Strengthen the enforcement of regulations to ensure policies are implemented effectively.

6 CONCLUSION

Working infrastructure is foundational to any technical solution. It is important to ensure that politics and corruption do not interfere with reform efforts, since political influence affects allocation of funding and how it is used. A lack of proper regulation would negate the positive policies and strategies meant to enhance infrastructure. Therefore, enforcing strict regulations is necessary to prevent a future water crisis. Fixing and upgrading the infrastructure is key to creating long-term water security.

A crucial lesson learned from the electricity crisis is the need for productive and timeous stakeholder engagement when it comes to managing water resources. The feasibility of long-term solutions depends on stakeholder involvement and may - at the least - include government and private partnerships, community engagement and general cohesion between government, businesses and society. Experience in handling the electricity crisis highlights the need for careful regulation of water consumption and supply. Contingency plans should be prepared to manage scarce periods and ensure that everyone has access to enough water.

ABSTRACT

Artificial Intelligence (AI) is a field within computer science that leverages algorithms, data processing, and computational capabilities to mimic human reasoning and facilitate decision-making. The Global South faces numerous challenges, including limited access to healthcare, education, and economic opportunities. AI presents a unique opportunity to address these issues and promote common development. This paper explores the potential of AI in fostering sustainable development in the Global South, with particular focus on the BRICS mechanism. It examines the role of AI in enhancing economic growth, improving healthcare delivery, and expanding educational access. Additionally, it discusses the ethical considerations and potential risks associated with AI deployment in these regions. The need for collaborative efforts among governments, private sector, and international organizations to harness AI's full potential for the common development of the Global South is highlighted. By leveraging AI technologies, the Global South can overcome critical developmental challenges and achieve sustainable growth.

Keywords: Artificial Intelligence, Global South, Educational tools, Machine learning, BRICS mechanism

1 INTRODUCTION

The world has been divided along the North-South dichotomy, though not on strict geographical boundaries, but largely based on historical, economic, and political factors. The Global South refers to countries that are generally classified as developing, least developed nations, or underdeveloped. Many of the countries in the Global South are in the Southern Hemisphere, largely in Africa, Latin America, the Caribbean, and parts of Asia and Oceania. On the other hand, the Global North consists of highly developed nations, including North America, Europe, Japan, South Korea, Australia, and New Zealand. These countries tend to have stronger economies, advanced technology, and higher living standards. Countries in the Global South are often characterized by lower economic development, poverty, income inequality, political instability, weaker democratic institutions, infrastructural deficits, limited industrialization, inadequate healthcare, inadequate educational opportunities, and other challenges. Unlike the Global North, which is characterized by strong democratic institutions, industrialization, advanced infrastructure, cutting-edge technology, etc., the Global South is marked by political instability and governance challenges, struggles with trade imbalances and economic dependency, and has widened economic disparities. Many countries in the Global South still struggle with poverty, inadequate healthcare, and limited educational opportunities, and depend on income from subsistence agriculture and raw material exports for income [1]. The term Global South functions as more than a metaphor for underdevelopment.

The Global South is home to over 6 billion people and makes significant contributions to the global economy. In 2023, the Global South accounted for about 42 % of the world's Gross Domestic Product (GDP), 44 % of merchandise exports, and 65 % of foreign direct investment (FDI) inflows. BRICS countries, a prominent group within the Global South, contribute about 25 % to the global GDP (Figure 1) [2]. For the countries in the Global South to bridge development gaps, enhance economic growth, and improve living standards, there is a need for emphasis on the rapidly changing economic landscape. To do this, countries must invest in strengthening economic growth, advancing technological innovation, investing in education and human capital development, improving governance and policy, and implementing sustainable development and climate action [3]. The emerging trends show that some Global South nations, like China, India, and Brazil, are rapidly industrializing and gaining global influence. Also, countries in the Global South are increasingly collaborating and forming groups such as BRICS, South-South cooperation, on trade, technology, and achieve sustainable development. These efforts, if sustained, will deliver the Global South from underdevelopment and backwardness.

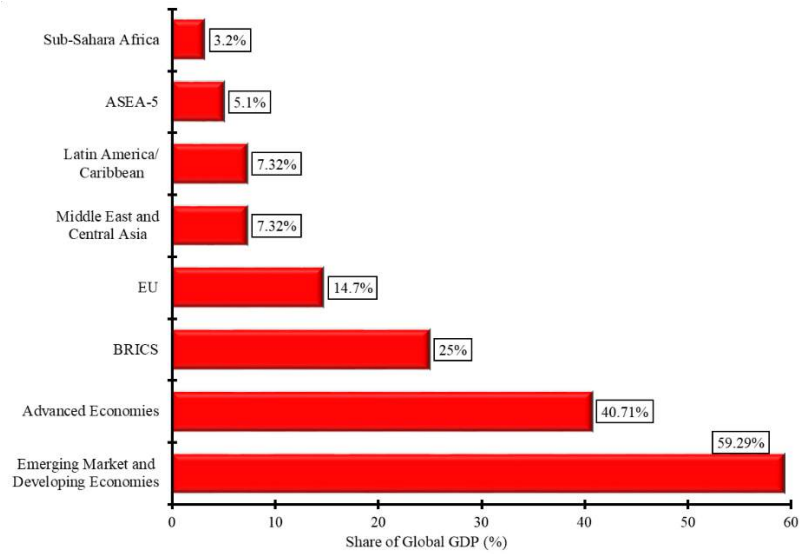

Figure 1: Share of global regions in the GDP in 2023. Data culled from [2]

The United Nations Sustainable Development Goals (SDGs) provide a universal blueprint for addressing global challenges such as poverty, inequality, and access to essential services. Artificial Intelligence (AI) offers transformative potential to accelerate progress toward these goals, particularly in the Global South where developmental gaps remain pronounced. Investments in technological innovations such as AI has been identified as one of the strategies to pursue economic growth, improve public services, pursue financial inclusion, and ensure sustainable development. AI can enhance productivity in agriculture, improve social services, upscale manufacturing, and create new job opportunities. A recent study by Subramaniam et al. [4] with countries and different levels of institutional quality found that AI is a good predictor of financial inclusion. AI can also support climate resilience, renewable energy, and smart infrastructure, helping countries tackle environmental challenges, while AI-powered fintech solutions can expand access to banking and credit, benefiting underserved populations. Recent studies by Kong et al. [5], Soares Seto [6], and Das [7] described how the Global South can leverage AI and other digital innovations to improve the lives of citizens. The authors justify the need for rapid investment in AI to improve social services, create employment, improve security and surveillance, and boost economic growth. Another study by Borines et al. [8] highlighted the importance and challenges of AI adoption and integration in sectors such as healthcare, education, agriculture, and manufacturing. They reported the application of AI in enhancing crop yield predictions, automating medical diagnostics, and improving educational accessibility in developing economies. While acknowledging the role of AI in boosting productivity and sustainable economic growth, the disparities between advanced economies and developing nations, including the Global South cannot be overemphasized. The disparities are attributed to infrastructural deficits, a lack of skilled workforce, and limited policy frameworks. Countries in the Global South also face challenges in data privacy, AI bias, and equitable access to AI-driven solutions. These can be addressed through inclusive AI governance to address ethical concerns and regulatory gaps [9, 10]. To accelerate AI adoption in the Global South, governments are encouraged to invest in AI education, digital infrastructure, and ethical AI frameworks to maximize benefits. There is a need for international cooperation and public-private partnerships to ensure countries enjoy the benefits of technological innovations [11].

Despite these studies and their outcomes, the relevant question to ask, which forms the motivation for the current study, is whether the subject matter of AI adoption and integration in the global South has been sufficiently addressed. The study uses qualitative and conceptual

analysis to explore the role of AI in fostering inclusive economic growth, technological advancement, and sustainable development across Global South nations, addressing regional disparities and enabling digital transformation, with special focus on the BRICS countries. The objective of the study is to investigate current AI initiatives that can aid development in the Global South, analyzing challenges and opportunities. This effort identifies the trajectory of AI development, opportunities, and challenges in the Global South, while suggesting future research directions in the research domain. The current study focuses on the opportunities such as economic development, social impact, and technological empowerment while identifying solutions to the challenges of infrastructural deficits, digital divide, policy and regulation gaps, and ethical concerns of AI in the Global South. The outcome of this study will draw more attention to the need for the integration of AI into the development of countries in the Global South.

2 TRAJECTORY OF AI DEVELOPMENT IN THE GLOBAL SOUTH

AI is at the forefront of recent global technological innovation and is noted for its ability to simulate human intelligence through algorithms and computing power. Globally, AI technologies hold enormous potential to address various challenges and opportunities across different sectors, thereby contributing to sustainable socioeconomic development. It is not surprising, therefore, that the global penetration of AI has increased tremendously from the USD 638.23 billion recorded in 2024 to USD 757.58 billion in 2025 and has been projected to reach USD 3,680.47 billion by 2034 (Figure 2). North America is expected to contribute about 36.92 % of the expected growth (Figure 2 inset) [12]. While there has been an increased penetration of digital technologies the Global South, the development of AI in the Global South has evolved through distinct phases, shaped by technological advancements, economic conditions, and policy frameworks. The trajectory of AI in the Global South can be divided into four distinct phases, spanning early 2010s till date, as shown in Figure 3.

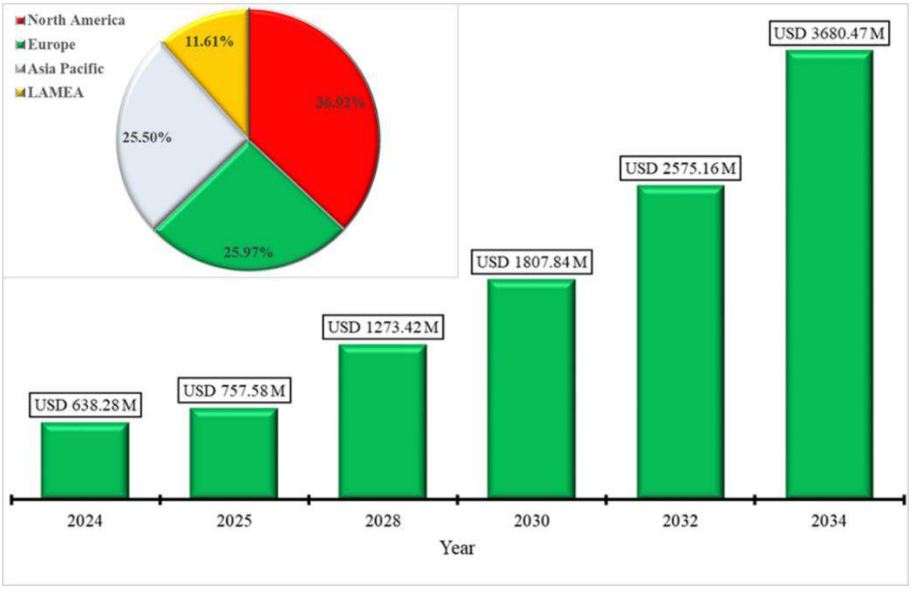

Figure 2: AI market size; (inset) regional market share. Data extracted from [12]

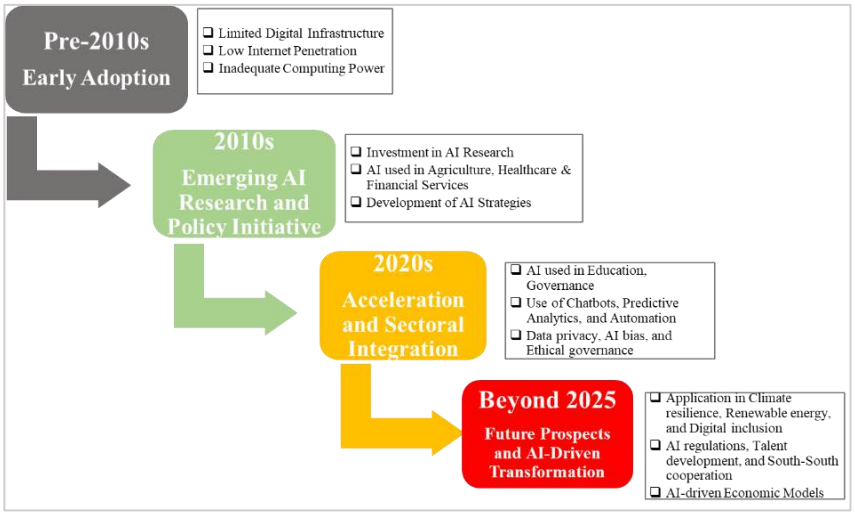

Figure 3: Trajectory of AI development in the Global South

For a considerable time, the Global South relied heavily on AI technologies and platforms developed by major technological powers and advanced economies such as the United States and China. During this period, many countries in the region were largely passive adopters of AI, rather than actively participating in shaping its development [11]. The first phase of AI development in the Global South was before the 2010s, which is marked by early adoption and limited infrastructure. This period was marked by slow AI adoption as a result of limited digital infrastructure, low internet penetration, and inadequate computing power. Most AI applications used during this period were imported from developed nations, with minimal local innovation. However, most governments in the global South focused on basic information and communication technology (ICT) development, laying the groundwork for future AI integration and utilization [13].

The second phase was the period of the 2010s, which was characterized by emerging AI research and policy initiatives for manpower development to lay a solid foundation for AI in the region. During this phase, countries began investing in AI research, with universities, research institutes, and startups exploring machine learning (ML) applications, reflected in the growth of scientific studies published on the topic [14]. This led to the introduction of AI to agriculture, healthcare, and financial services, improving efficiency and accessibility. However, the development of national AI strategies, policies, and regulatory frameworks remained weak. There is acceleration and sectoral integration of AI during which AI was extended into education, governance, and smart infrastructure [12]. This is driven by increased funding, manpower development, research, and international collaborations. The third phase also witnessed the use of AI-powered chatbots, predictive analytics, and automation in public services. With the increased popularity, adoption, and integration of AI into social and public services, there were legitimate concerns over data privacy, AI bias, ethical governance, and the need for responsible AI development across the regions. AI is expected to play a key role in climate resilience, renewable energy, and digital inclusion. Governments are escalating work on AI regulations, talent development, and South-South cooperation to strengthen AI ecosystems. There are prospects for AI-driven transformation and economic models to reduce dependency on traditional industries, fostering sustainable growth [8, 15].

3 OPPORTUNITIES OF AI IN THE GLOBAL SOUTH

3.1 Economic Development

AI presents significant economic development opportunities for the Global South, helping nations overcome traditional barriers and inclusively accelerate economic growth. AI-powered automation enhances efficiency in manufacturing, agriculture, and services, reducing costs, boosting productivity, and increasing industrialization. The adoption of AI-driven smart supply chain optimization improves logistics, reducing waste and enhancing trade competitiveness. The integration of AI solutions into the financial sector accelerates financial inclusion, provides access to banking, credit, and investment opportunities for underserved populations. The use of ML models in the economic system helps predict market trends, enabling better financial decision-making, and a wide array of activities can become more efficient. AI is enabling small businesses to optimize operations, connect to global markets, and innovate new products or services, thereby helping the development of small and medium-scale enterprises (SMEs) and startups. AI-powered digital platforms enable entrepreneurs to reach global markets and enhance entrepreneurship and innovation [8, 16]. These perspectives are much aligned with the Sustainable Development Goals by United Nations, as the number 8 – Decent Work and Economic Growth and the number 9 – Industry, innovation, and infrastructure.

3.2 Social Impact

AI presents significant social impact opportunities for the Global South, helping nations address inequalities, improve education, healthcare, public services, and foster inclusive development. AI-powered adaptive learning platforms personalize education, enhance learning, and expand access to education for students in underserved regions, while AI-driven language translation tools help bridge communication gaps in multilingual communities. In the healthcare sector, integration of AI improves medical diagnostics, enabling early disease detection and better treatment outcomes, while AI-powered telemedicine solutions provide healthcare access to remote and rural populations with limited infrastructure. AI-driven data analytics help strengthen governance and public services, promote social inclusion and equity, and address poverty alleviation, disaster response, resource distribution, and other social issues to make informed policy decisions. AI-powered chatbots and automation, assistive technologies, and predictive analytics help to streamline public service delivery, reduce bureaucratic inefficiencies, support individuals with disabilities, improve accessibility, and address social welfare programs. AI supports climate resilience and sustainability, enhances disaster prediction and response, helping communities prepare for climate-related risks, while AI-powered smart agriculture solutions improve food security and resource efficiency [13, 16]. These advancements could be aligned with the Sustainable Development Goals by United Nations concerning the number 1 – No poverty, the number 2 – Zero hunger, the number 3 – Good Health and Well-being and the number 4 – Quality Education.

3.3 Technological Empowerment

AI-driven technological empowerment presents transformative opportunities for the Global South, enabling to stablish cities and communities where above the minimum infrastructure there is also a clean and sustainable environment. The integration of AI helps to expand digital infrastructure, strengthen local innovation and collaborative research, enhance workforce development, improve public services and governance, and help to project geographical systems that embrace sustainable development. AI-driven smart grids and internet expansion projects optimize energy distribution, enhance connectivity, improve access to electricity, and bridge the digital divide. AI fosters homegrown tech startups, enhances e-governance, connects talent with opportunities, reduces unemployment, and equips workers with digital skills for emerging industries. AI-powered research platform accelerates scientific discoveries

in healthcare, agriculture, and climate resilience, while AI-driven predictive analytics help governments make data-informed decisions for infrastructure planning, streamline administrative processes, and improve service delivery [5, 13, 16]. These type of improvement could help BRICS to promote the Sustainable Development Goals by United Nations, especially focusing on that of the number 7 – Affordable and Clean Energy, 11 – Sustainable Cities and Communities and 16 – Peace, Justice and Strong Institutions.

4 CHALLENGES OF AI IN THE GLOBAL SOUTH

4.1 Infrastructural Deficits

Lack of high-speed internet, reliable electricity, advanced computing facilities, data storage capabilities, and poor cloud computing access, which might restrict AI deployment and deters AI scalability in the Global South. Inadequate infrastructure hinders the training and retention of AI-skilled professionals, limits research activities, and slows innovation and AI adoption. Governments and private sectors should invest in clean and affordable electricity generation, broadband expansion, cloud computing, and AI-ready data centers. Public-private partnerships can accelerate smart city initiatives to improve connectivity [7].

4.2 Digital Divide

Limited internet access, infrastructural deficiencies, high cost of AI implementation, inadequate AI research funding, lack of AI talent and education, inadequate public awareness, scepticism about AI's role in job displacement, etc., exacerbates inequalities, make AI adoption difficult, and hinders AI scalability. Expanding digital infrastructure, strengthening AI education and workforce development, encouraging local AI innovation, and building public awareness and trust reduces digital divide, improve inclusivity, and enhance trust and security [7].

4.3 Policy and Regulation Gaps

Policy and regulation gaps pose significant challenges to AI adoption in the Global South, affecting governance, ethical AI use, and equitable access. Lack of comprehensive AI policies, limited institutional capacity, ethical and social concerns, and especially biased perspectives on AI, pose significant policy and regulation gaps [17]. The development of AI-specific regulations, strengthening of institutional capacity, support for local AI innovation and collaboration, development of transparent AI governance, and enhancing public awareness and ethical AI use will ameliorate the challenges of policy and regulations gaps. In addition, governments should establish clear AI policies focusing on ethical AI use, data privacy, and security.

4.4 Ethical and Social Concerns

Challenges such as discrimination, job displacement and economic inequality, data privacy and security risks, and limited AI governance and regulation continue to militate against the adoption of AI in the Global South. The problem of digital divide and accessibility and lack of internet connectivity and AI literacy, are manifesting in the form of unequal access to AI-driven education, healthcare, and financial services continues to widen social gaps. Rural communities often lack internet connectivity and AI literacy, limiting participation. The government should develop ethical AI frameworks, promote inclusive AI policies, strengthen data privacy regulations, and expand AI access and digital literacy to resolve the ethical and social concerns. Countries in the Global South region should encourage South-South AI collaboration, share AI research and best practices, and encourage regional AI alliances to foster innovation and develop localized AI solutions for social challenges.

5 AI DEVELOPMENT WITHIN THE BRICS MECHANISM

The BRICS nations are actively advancing AI to enhance economic growth, technological innovation, and global competitiveness. However, their AI development trajectories vary, with some nation leading while others need strategic interventions to catch up. Individual countries have invested in and developed their AI infrastructure and expanded the utilization avenues. China can be described as the AI powerhouse with massive investment in research, infrastructure, and talent development, and has applied AI initiatives in facial recognition, autonomous systems, and AI-driven governance. India is an emerging AI hub, with rapid applications in healthcare, finance, and agriculture, supported by a thriving tech ecosystem. The focus of Russia's AI development is the military, cybersecurity, and industrial automation, while Brazil is leveraging economic inclusion to integrate AI into agriculture, healthcare, and financial services. In South Africa, the focus of AI is education, governance, and financial inclusion to bridge the socio-economic gaps. The BRICS countries are working individually and along the South-South cooperation to address the challenges facing their AI development ecosystem [18]. Figure 4 summarizes the AI development and challenges in individual BRICS countries.

Figure 4: Summary of AI development in BRICS countries

Collectively, BRICS nations must strengthen AI collaboration, expand AI research partnerships, share expertise and resources, and execute joint AI projects in healthcare, climate resilience, and cybersecurity to accelerate development. Countries lagging, i.e., Brazil and South Africa, need stronger AI infrastructure, including data centers, cloud computing, and high-speed internet. Rapid investment in AI-ready data centers and computing power should be prioritized. To enhance AI talent development, AI education and workforce training must be scaled up across BRICS, especially in Russia, Brazil, and South Africa. AI-focused university programs and vocational training can bridge skill gaps and limit the digital divide. BRICS nations must invest in the development of AI governance and ethical frameworks to safeguard against abuse and ensure responsible AI use. Ethical AI policies and regulations should address bias, data privacy, and security concerns. To encourage AI-driven economic growth and upgrade the quality of life of the citizens, AI should be leveraged for trade, industrial

automation, and financial inclusion, while AI-powered startups and innovation hubs should be funded and encouraged to drive economic transformation [19].

6 CONCLUSION AND FUTURE RESEARCH DIRECTIONS

The role of AI in fostering sustainable development cannot be overemphasized. While the developed economies and the Global North have integrated AI technologies to improve their livelihood, upscale their citizens, and move their countries towards sustainable development, there is a need to adopt such to the Global South to bridge the digital gap. The current study interrogates the adoption of AI to fast-track common development of the Global South. Bearing in mind the history and trajectory of AI in the Global South, the integration of AI in the Global South presents a transformative opportunity for fostering inclusive economic growth, technological innovation, and sustainable development. While AI has shown potential in agriculture, healthcare, governance, and education, the region faces challenges such as infrastructural deficits, digital divides, policy gaps, and ethical concerns. This study concludes that AI is a potent catalyst for sustainable development, and AI-driven solutions can accelerate industrialization, improve financial inclusion, and enhance public services, reducing socio-economic disparities. By addressing infrastructure and digital divides, tackling regulatory and ethical issues, developing sustainable and inclusive AI models, and strengthening South-South innovations and collaborations, countries in the Global South can reshape development pathways for the Global South, ensuring technological equity, economic progress, and sustainable futures [20, 21].

Going forward, the outcome of this study on adoption of AI for common development of the Global South requires targeted research to maximize its benefits while addressing infrastructural, ethical, policy concerns, and other challenges. Future research should target the application of AI for sustainable development, including the development of home-grown AI-powered smart agriculture solutions to enhance food security, circular economy, and resource efficiency. A multidisciplinary research should be commissioned to assess AI's role in boosting industrialization and financial inclusion, study AI-driven entrepreneurship models to support small businesses and startups, and examine AI-powered trade and supply chain optimization for regional economic growth. For deeper insights, other research domains such as AI and economic transformation, AI for social equity and inclusion, AI Infrastructure and digital transformation, and AI governance and ethical frameworks can be sufficiently explored.

ABSTRACT

Artificial Intelligence (AI) has the potential to drive significant socio-economic development in Africa, leveraging the continent's unique challenges and opportunities. By examining the successes and lessons learned from China's AI advancements, this paper aims to explore how African nations can effectively adopt and implement AI technologies for their common development. The study highlights key areas where AI can make a substantial impact, such as technology development, telecommunications, infrastructure, healthcare, education, agriculture, and governance. Additionally, it discusses the importance of building robust digital infrastructure and capacity, fostering AI literacy, and ensuring ethical and inclusive AI practices. By drawing on China's experience, African countries can develop tailored strategies to harness AI's transformative power, promoting sustainable growth and improving the quality of life for their populations. This paper underscores the need for collaboration between governments, the private sector, and international organizations to create an enabling environment for AI innovation in Africa.

Keywords: Artificial Intelligence, AI literacy, Digital Infrastructure, Africa, Development.

1 INTRODUCTION

Artificial Intelligence (AI) is at the forefront of recent global technological innovation and is noted for its ability to simulate human intelligence through algorithms and computing power. From healthcare, education, agriculture, security, governance, disaster risk management, and industrial development to other sectors, AI has become a great asset in ensuring significant advancements, changing the course of life in the most dramatic way. Globally, AI technologies hold enormous potential to address various challenges and opportunities across different sectors, thereby contributing to sustainable socioeconomic development. It is not surprising, therefore, that the global penetration of AI has increased tremendously from the USD 638.23 billion recorded in 2024 to USD 757.58 billion in 2025 and has been projected to reach USD 3,680.47 billion by 2034 (Figure 1a). North America is expected to contribute about 36.92 % of the expected growth (Figure 1b). The United States is expected to maintain its dominant position during the forecast, with a total market value of USD 851.46 billion by 2034 [1]. Africa's AI market size, which was USD 4.51 billion in 2025, has been projected to become USD 18.27 billion by 2031, provided there are concerted efforts to address some of the challenges confronting the sector [2]. Figure 1 shows the AI market size for the world, the United States, and Africa between 2024 and 2034 and the regional market share in 2024.

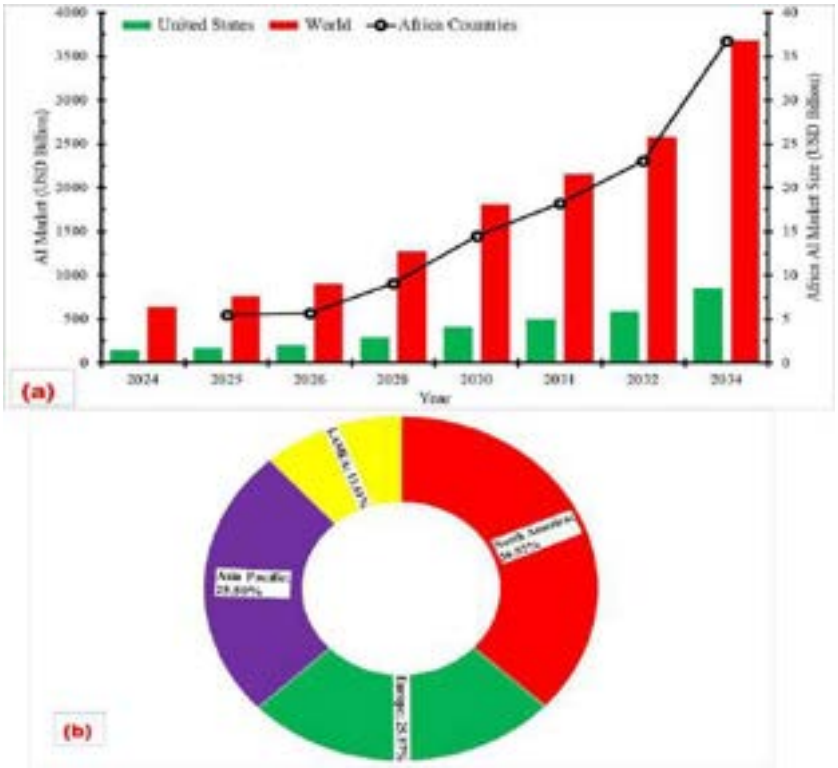

Figure 1: AI market size and regional market share. Data sourced from [1, 2]

The rising penetration and popularity of AI technologies are attributed to its increased deployment in life-saving measures such as medical services, self-driving cars, etc., across the globe. There have been consistent and heavy investments by organizations, industries, and governments in research and development and infrastructural upgrades, which are continuously fueling technological advancements, particularly in AI technologies. The development of novel deep learning, machine learning algorithms, natural language processing, machine vision, automated reasoning, and integrated cloud platforms has also contributed to the phenomenal growth of AI. Similarly, end-use industries, financial analysts, crime detectors, and others have integrated AI into their business processes to streamline

their operations, meet increasing customer needs, and gain more competitive advantage. In many jurisdictions, the government has formulated and implemented policies that favour the deployment of AI technologies in governance and other vital areas [3]. The increased investments by Google, Microsoft, IBM, Amazon, Apple, and other global tech giants in AI technologies are expected to positively impact the market growth and penetration of AI. The burgeoning demand for AI technologies among the youthful population and the emerging relevance of AI in various end-use verticals such as banking and finance, logistics, retail, automotive, security, etc., is expected to significantly drive the growth of the AI market in the immediate future.

Despite the increased penetration of AI at the planetary level, Africa has not been able to adequately harness the potential and opportunities in AI technologies despite the enormous skills and natural resources available in the continent. Similarly, the African region has not been able to harness the global reach of the AI supply chain like the giant Tech companies of the Global North and China. Though Africa's AI journey started in the mid-2010s, the expected benefits have not manifested due to poverty, deficit manpower, infrastructural deficiencies, lack of policy and operational frameworks, and other barriers. For example, as of 2022, only 2.7 % of Africans have access to 5G internet, a major requirement for AI deployment, compared to 45 % access to 5G in China. Also, Africa has only 140 data centers, while China had 449 data centers in 2022 [4]. These narratives show the level of growth of AI in Africa compared with China. Though the AI's potential in Africa is immense, the continent needs to draw lessons from China's phenomenal internet access and 5G growth by encouraging local and international participation and investments to develop its AI infrastructure.

Recently, Arakpogun et al. [5], Ade-Ibijola and Okonkwo [6], and Gwagwa et al. [7] dwelled on the benefits, opportunities, emerging challenges, and policy dimensions of effective design, development, adoption, and use of AI technologies in Africa. They were unanimous that AI holds enormous potential to aid economic growth, enhance productivity, improve medical services, education, transportation, agricultural and food security, and contribute to sustainable development of African countries. They, however, recommended the establishment of robust governance structures and infrastructures, capacity development, and collaboration with international communities in bridging the technological gaps. the comprehensive study of the development, utilization, and application of AI in various sectors of Africa's economy such as healthcare [8], agriculture [9], governance [10], transportation [11], supply chain [12], and sustainable development [13] revealed the for R&D, increased funding, and partnership with developed countries to upscale technological and infrastructural development in the sector. In a recent policy brief, Azaroual [14] suggested an inclusive and holistic approach by African countries to close the gap with other regions of the world in AI utilization. He recommended increased investment in digital infrastructure, specialized training, R&D, and collaboration among African countries and developed economies to overcome challenges and develop their AI to be able to contribute to sustainable development.

One of such collaboration is with China, whose remarkable journey in AI development serves as an inspiring model for African countries. Over the past two decades, China has leveraged AI to strengthen its industries, improve public services, and position itself as a global leader in technological innovation. This progress was achieved through strategic investments, robust policies, and a focus on talent development. Africa, with its youthful population, growing digital infrastructure, and diverse needs, stands at a critical juncture to emulate and adapt China's experience to its context. Understanding the parallels and distinctions between the two regions provides valuable insights into charting an AI-driven path for Africa's future. This is the motivation for this study. The study aims to interrogate how Africa can build on the amazing experience of China to build its AI capacity. The objective of the study is to analyze China's experience in AI development, identify opportunities for AI development in Africa,

and recommend actionable strategies for African nations to upscale and integrate AI in ways that align with their developmental goals and capacities. This study adopts a qualitative, comparative, and exploratory methodology, drawing primarily on information available on academic literature, policy documents, case studies, and other secondary sources. It utilizes thematic evaluation of key sectors and comparative analysis of China's AI development experience to identify applicable strategies for African nations. Sections such as China's AI developmental trajectory, potential benefits, opportunities, challenges, prospects, policy recommendations, and future research directions of AI in Africa, with particular focus on China's experience in AI development, are highlighted in this study. This study is essential for guiding Africa's strategic adoption of AI by learning from China's successful integration of AI into its development agenda. The findings of this study offer practical insights for policymakers, emphasizing inclusive, ethical, and locally adapted approaches to harness AI for sustainable growth. Also, the information provided will enrich existing literature with updated knowledge on the subject matter and contribute to efforts at improving AI development and penetration in Africa for sustainable socioeconomic development.

2 AI DEVELOPMENTAL TRAJECTORY IN CHINA

Although the recognition of AI as an academic field began in the early 1950s, academic research on AI in China did not start until the late 1950s. Since then, AI in China has undergone decades of theoretical development, technological advancements, and applications, marked by both global recognitions in accolades and criticism. China has demonstrated significant strengths in the development of its AI technologies by aggressive investment in cutting-edge R&D, economic, and infrastructural upgrades, which has positioned it as a major AI powerhouse. AI development in China can be categorized into three main stages (Table 1). According to Zhou [15], the period between the 1950s and 1970s was marked by skepticism and criticism of AI in China, except for the efforts of a few individuals such as Xuesen Qian and Norbert Wiener, who, through their books, expressed their belief in AI. The formation of the Chinese Association of Automation (CAA) in 1961 and the selection of Xuesen Qian as the pioneer chairman of the administrative committee signaled a turning point and the beginning of AI China. By the mid-1970s, the government had recognized modernization of science and technology as a cornerstone of its economic reform. The formation of associations, conferences, journals, and manpower development in the field of AI and other advanced technologies has enhanced the development of AI. At the first annual conference in 1978, outcomes of AI research in topics such as theorem proving, natural Chinese language comprehension, biological control, pattern recognition, robots, etc., were presented.

Table 1: Stages in AI development in China

Stages	Duration	Notable development
The Silent Stage	1950s - 1970s	• China's skepticism about AI • AI was commonly perceived as a form of "pseudoscience" and "revisionism". • No research in the field • Formation of CAA in Beijing in June 1961, dedicated to AI development
Early Foundations	1970s - 2000s	• Xiaoping Deng's economic reform prioritized the development of science and technology, including AI • Establishment of associations (CAAI, CCF) and academic journals to advance academic collaboration in the AI research domain • Government established AI research initiatives and manpower development in advanced technologies. • AI research dedicated to theorem proving, pattern recognition, robots, etc.
Rapid Growth	2006 - present	• Formulation of policies and massive investment in AI developments • Launching of NGAIDP • Policy support and financial investment

	• Surge in AI startups and corporations • Opportunities for competition and collaborations • Significant strides in AI research and talent • Concerns about data privacy and security

CAA = Chinese Association of Automation; CAAI = Chinese Association for Artificial Intelligence; CCF = China Computer Federation; NGAIDP = New Generation Artificial Intelligence Development Plan

Since 2006, China has implemented policies and provided funding to accelerate AI development. In 2017, China took another giant leap by launching the New Generation Artificial Intelligence Development Plan (NGAIDP) to make China a global AI leader by 2030. This period has witnessed an increase in R&D, talent development, competition, international collaborations, and massive development of AI infrastructure. There have also been increased concerns about privacy and security. China has made giant strides in AI development, including massive scientific research output, enhanced innovative capacity building among enterprises, strong collaborative links between industry and academia, enhanced AI industrial sector, and rapid deployment of novel AI technologies [15]. This has been demonstrated in the market share of China's AI, which grew from about USD 15.7 million in 2023 to USD 32.9 million in 2025 and is expected to rise to USD 68.6 million by 2027 and USD 206.6 million by 2030 (Figure 2) [16]. Consequently, the global AI index in 2023 ranked China in the second position globally after the United States (Figure 3) [17].

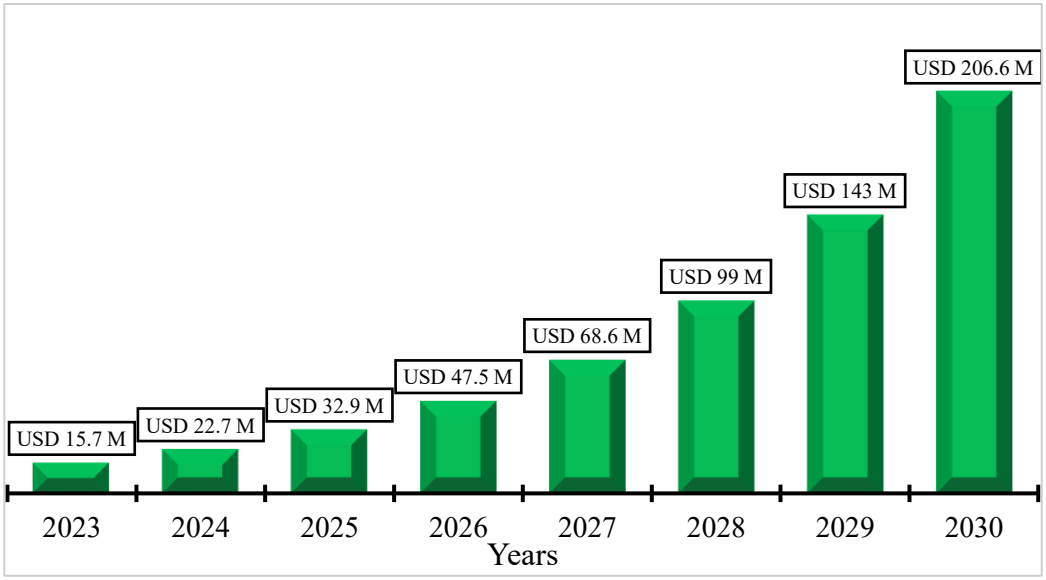

Figure 2: China's AI market share (USD million). Data sourced from [16]

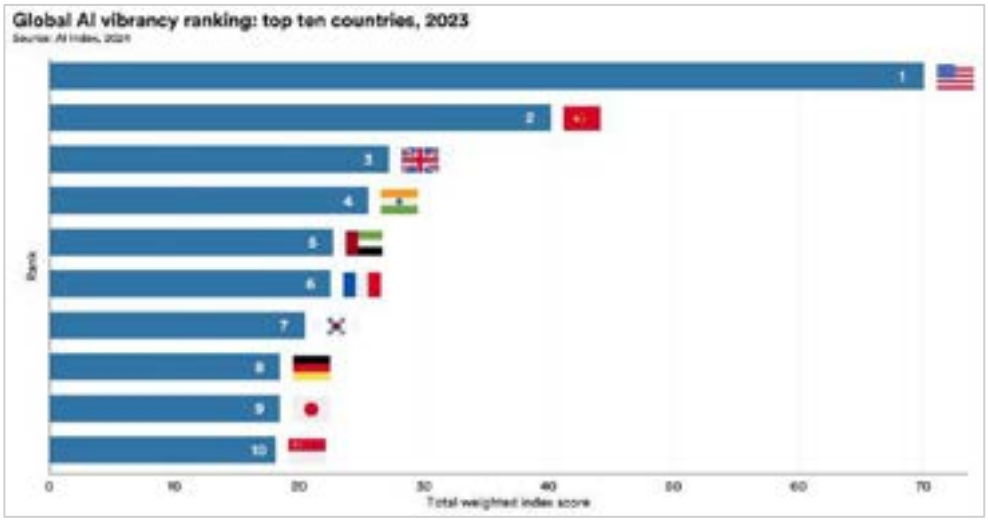

Figure 3: Top 10 countries in AI ranking in 2023

Due to innovations, collaborations, R&D, and AI have been rapidly adopted in education, healthcare, security, finance, and retail, leading to China exporting the technology to other countries. However, there have been myriad complex challenges and criticisms that cut across technological, ethical, societal, policy, and other AI spheres. The twin issues of ethical and privacy implications of AI remain the major challenges and worries, which have been heightened by the large-scale data collection practices, potential for misuse, and fears of privacy breaches by governments and private entities. China's reliance on foreign technology and advanced security exacerbates its strategic vulnerability in the global technology competition and international trade tensions. There are concerns among some China population about the ability of AI to handle complex, real-world scenarios without compromising safety and effectiveness, the fear of job displacement and workforce shifts, and the integration of AI into education and social life have continued to pose serious threats to China's AI developmental strides [18]. Figure 4 shows the major highlights of China's AI situation while Table 2 compiles the factors responsible for China's global leadership position.

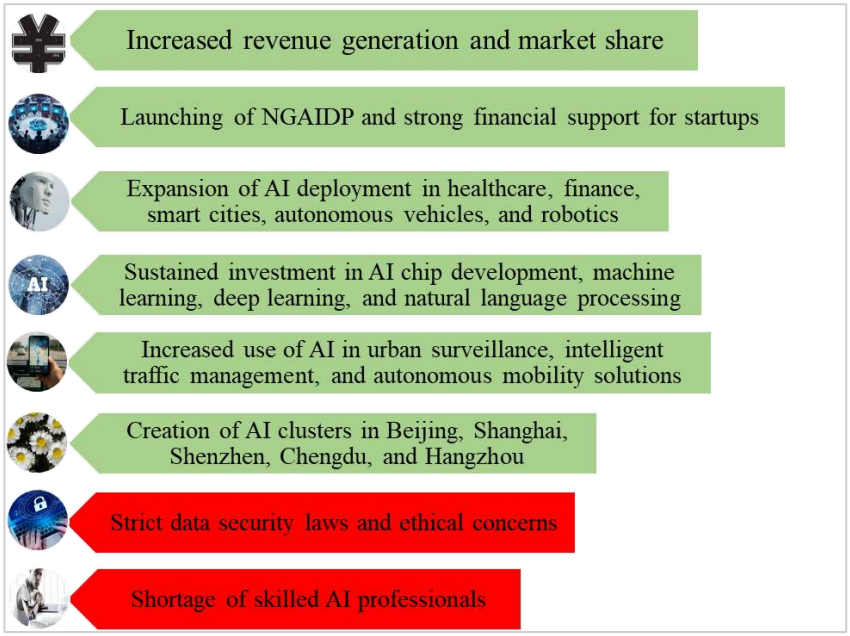

Figure 4: Highlights of China's AI development. Compiled from [19]

Table 2: Major drivers and implications of China's AI development

Major drivers	Implications
Strong government support and strategic policies	• Provision of grants, tax holidays, subsidies, and other incentives for AI startups and research institutions • Bank of China to provide 1 trillion Yuan (about USD 136 billion) for the AI sector over the next 5 years
Rapid digital transformation and industrial adoption	• Implementation of AI-powered automation and robotics • Establishment of 30,000 basic-level smart factories, 1,200 advanced-level, and 230 excellence-level smart factories
Advancements in AI Research and Innovation	• Growth in AI chip development, semiconductor manufacturing • Heavy investment in AI development by companies such as Baidu, Alibaba, Tencent, Huawei, etc.
Expansion of AI in Smart Cities and Autonomous Technologies	• Investment in AI-powered urban surveillance systems, traffic control and management, and security architecture • Testing and deployment of autonomous vehicles by companies such as WeRide, Baidu, Ponyai • Delivery of about 2.7 million parcels of drones in 2024

3 STATUS AND PROSPECTS OF AI IN AFRICA

AI is increasingly recognized as a transformative force in global innovation and socio-economic advancement. Across Africa, there is a growing interest in harnessing AI to address developmental gaps and accelerate progress in key sectors such as healthcare, agriculture, education, and governance. Despite persistent infrastructural and economic constraints, the continent holds significant potential to bypass conventional development trajectories through strategic and context-sensitive AI integration. This section critically examines the evolving AI landscape in Africa, drawing comparative insights from China's experience to identify applicable models and collaborative opportunities. It also explores the continent's prospects for AI-driven growth while highlighting the structural and ethical challenges that must be navigated to foster inclusive and sustainable technological development.

3.1 Potential African Benefits from China's AI Experience

Drawing from China's developmental trajectory and experience in AI, Africa can benefit significantly in the key areas and fast-track sustainable development in the key areas. The following are some of the key areas of potential advantage.

3.1.1 *Digital Infrastructure Development*

China's success in AI has been underpinned by robust digital infrastructure, including high-speed internet, data centers, and cloud computing facilities. Africa can benefit by prioritizing similar investments to bridge the digital divide and enable widespread AI adoption. This infrastructure will support AI applications in critical sectors like agriculture, healthcare, and education.

3.1.2 Economic Growth and Innovation

AI can drive innovation in sectors like agriculture, healthcare, and education, fostering sustainable development and creating new economic opportunities. Leveraging China's experience, Africa can deploy AI-powered tools to optimize farming practices, predict weather patterns, and enhance crop yields, improve diagnostics, monitor epidemics, streamline healthcare delivery, personalize learning experiences, and bridge educational gaps. China's focus on AI-driven industrial automation and e-commerce has boosted its economy, and Africa can replicate these strategies to create new economic opportunities [20].

3.1.3 Public-Private Partnerships

China's AI advancements have been fueled by collaboration between the government and private enterprises. Africa can adopt this model to accelerate AI research, development, and deployment. Collaborations with proven tech companies can bring expertise and resources to the continent, fostering innovation and sustainable growth.

3.1.4 AI Talent Development

China has invested heavily in education and training programs to build a skilled workforce for AI. Africa can benefit by establishing AI-focused universities, research centers, and vocational training programs. This will equip the continent's youth with the skills needed to harness AI's potential and drive technological progress.

3.1.5 Localized Solutions

Africa can develop AI applications with the capability to tackle its peculiar challenges, such as improving food security, combating diseases, and enhancing access to education. For example, Africa, leaning on China’s experience, can deploy AI in areas such as data analysis to recommend optimal farming practices, energy management to support renewable energy initiatives, and the deployment of AI-powered chatbots to provide healthcare advice in local languages.

3.1.6 Global Competitiveness

By leveraging AI like China, Africa can position itself as a key player in the global tech ecosystem. Strategic investments in AI can attract international partnerships and investments, boosting the continent's competitiveness in the global market.

3.1.7 Ethical and Inclusive AI

China's experience highlights the importance of ethical AI practices. Africa can benefit by developing frameworks that ensure AI systems respect cultural diversity, promote inclusivity, and protect data privacy. This will build trust in AI technologies and encourage their adoption.

3.1.8 Regional Collaboration

China has demonstrated the value of regional collaboration in AI development. African nations can work together to share resources, expertise, and best practices, fostering a unified approach to AI adoption and governance.

3.2 Opportunities for AI Development in Africa

3.2.1 Economic Growth and Development

By enabling seamless financial and online payments, predicting credit and insurance to previously unbanked populations, and helping small business grows, AI can revolutionize access to financial services and other Fintech innovations. With rising urbanization in Africa, AI can be deployed in building and managing smart cities in areas such as traffic management improvement, power distribution and energy efficiency, and supporting infrastructure maintenance with predictive analytics.

3.2.2 Healthcare Innovations

AI-powered technologies such as telemedicine, chatbots, and predictive analytics offer solutions and improve Africa's overburdened healthcare systems. The deployment of these technologies provides remote diagnostics in underserved rural areas, helps in predicting and monitoring outbreaks of disease, and assists in the optimization of allocation and streamlining of hospital management.

3.2.3 Educational Advancements

AI-driven tools can transform education in Africa by personalizing learning for students through adaptive platforms, bridging language and accessibility gaps, and offering online courses and AI-skills training programs, thereby equipping Africans for future jobs.

3.2.4 Agriculture and Food Security

AI presents opportunities for economic growth and development across Africa by enhancing agricultural productivity by predicting weather patterns and extreme climate conditions. By optimizing crop planting schedules, identifying pests and diseases, and minimizing losses, AI can contribute to farm yields, boost food production, strengthen food security, and contribute to agricultural development, which is the backbone of African economies.

3.2.5 Governance and Public Services

The deployment of AI in Africa can help improve public service delivery by streamlining government operations, reducing bureaucracy, automating routine tasks, and ensuring transparency in public transactions. AI can promote inclusivity in governance through improved accessibility for people with disabilities and other underrepresented groups, bridging the digital divide in underserved areas, and translation of government policies and services into multiple local languages.

3.2.6 Art and Cultural Preservation

There are opportunities for AI to document, promote, and preserve Africa's rich cultural heritage through translation of language translation tools, generate art and music, and digitize historical archives for global access and preservation. AI can serve as a catalyst for innovation in various industries, including manufacturing, e-commerce, and startups, by lowering costs, offering personalized shopping experiences, and boosting entrepreneurial and industrial growth.

3.3 Challenges of AI Development in Africa

3.3.1 Building Digital Infrastructure

Building digital infrastructure for AI in Africa faces several challenges, including unreliable power supply, limited internet connectivity, and inadequate data storage facilities. Many rural areas lack broadband access, creating a digital divide that hinders equitable AI adoption. Additionally, the high cost of infrastructure development and maintenance, coupled with a shortage of skilled professionals, further complicates progress. Addressing these issues requires strategic investments, robust policies, and collaboration between governments, private sectors, and international organizations to ensure inclusive and sustainable digital transformation.

3.3.2 Fostering AI Literacy and Skills

Fostering AI literacy and skills in Africa faces several challenges, including limited access to quality education and training programs, especially in rural areas. The high cost of AI-related resources and tools further restricts learning opportunities. Additionally, there is a shortage of skilled educators and mentors to guide learners in AI fields. Language barriers and a lack of localized content also hinder effective learning. Addressing these challenges requires investments in affordable education, partnerships with global tech organizations, and the development of inclusive, culturally relevant AI training programs.

3.3.3 Ethical and Inclusive AI

Developing ethical and inclusive AI in Africa faces challenges such as addressing algorithmic biases that may perpetuate inequalities and ensuring AI systems respect cultural diversity and

societal values. Limited regulatory frameworks and data privacy protections further complicate efforts to create responsible AI. Additionally, the lack of representation in AI development and governance risks marginalizing African perspectives. Overcoming these challenges requires fostering collaboration, establishing ethical guidelines tailored to Africa's unique context, and prioritizing inclusivity in AI adoption and deployment.

3.3.4 AI for Sustainable Development

AI for sustainable development in Africa faces challenges such as inadequate infrastructure, unreliable energy supply, and limited access to high-speed internet. These issues hinder the deployment of AI solutions for critical areas like agriculture, healthcare, and education. Additionally, the lack of localized data and skilled professionals restricts the effectiveness of AI-driven initiatives. Addressing these challenges requires strategic investments, regional collaboration, and policies that prioritize inclusivity and long-term sustainability.

3.3.5 Collaboration and Innovation

Collaboration and innovation for AI in Africa face challenges such as limited cross-border partnerships, insufficient funding for research and development, and a lack of standardized frameworks for collaboration. Additionally, disparities in technological infrastructure and expertise across countries hinder seamless cooperation. Addressing these challenges requires fostering regional alliances, increasing investment in AI innovation, and creating platforms for knowledge sharing and joint projects to drive sustainable progress.

4 PROSPECTS, POLICY RECOMMENDATIONS, AND FUTURE RESEARCH DIRECTIONS

The prospects for AI in Africa, drawing inspiration from China's experience, are promising. Africa can leverage AI to address critical challenges in agriculture, healthcare, and education, fostering sustainable development. By investing in digital infrastructure and AI talent development, the continent can unlock innovation and economic growth. Public-private partnerships and regional collaboration can accelerate AI adoption, while ethical frameworks tailored to Africa's socio-cultural context ensure inclusivity. With strategic planning and lessons from China's AI advancements, Africa has the potential to become a global player in AI-driven transformation.

For Africa to benefit from China’s experience and capabilities in AI development, appropriate policies which including strategic investments in digital infrastructure to support AI development and adoption, should be prioritized. Governments should establish national AI strategies that align with local socio-economic goals, similar to China's approach. Encouraging public-private partnerships can accelerate innovation and ensure sustainable growth. Additionally, fostering AI literacy and skills development through education programs is crucial for building a skilled workforce. Regulatory frameworks should emphasize ethical AI practices, data privacy, and inclusivity to address Africa's unique challenges and opportunities. Collaboration among African nations can further strengthen AI governance and drive regional progress.

Going forward, future research in Africa’s AI development, inspired by China's experience, could focus on developing localized AI solutions targeted to its peculiar challenges, such as food security, economic development, manufacturing, public security, social services, and human capital development. Emphasis should be placed on creating robust digital infrastructure, fostering public-private partnerships, and investing in AI talent development. Additionally, research could explore ethical AI frameworks that align with Africa's socio-cultural context, ensuring inclusivity and fairness. Collaboration among African nations and with global AI leaders can further accelerate innovation and drive sustainable development.

5 CONCLUSION

AI offers transformative potential for Africa, drawing lessons from China's experience in the global space in leveraging AI for development. By investing in digital infrastructure, fostering public-private partnerships, and prioritizing AI literacy, Africa can address its unique challenges and unlock innovation across sectors like agriculture, healthcare, and education. Ethical frameworks tailored to Africa's socio-cultural context will ensure inclusivity and fairness in AI adoption. With strategic planning and regional collaboration, Africa has the opportunity to harness AI as a catalyst for sustainable development and global competitiveness.

With strategic planning and regional collaboration, Africa has the opportunity to harness AI as a catalyst for sustainable development and global competitiveness. The practical implications of this study are far-reaching, and they include the provision of a workable blueprint for policymakers to craft responsive AI strategies, encouragement of investment in scalable digital infrastructure, and emphasizing the importance of building human capital through targeted education and training. By drawing on China’s experience, African nations can avoid common pitfalls and accelerate the responsible deployment of AI technologies. Moreover, the study offers guidance for establishing regulatory frameworks that promote innovation while safeguarding against abuse and ensuring that AI serves the public good. As Africa steps into the digital age, these insights can empower governments, businesses, and civil society to co-create an AI ecosystem that is inclusive, resilient, and uniquely African.

A QUALITY DEVELOPMENT MODEL FOR SOUTH AFRICAN SMALL MANUFACTURERS USING A CAPABILITY MATURITY PERSPECTIVE

C. Miller[1*] and J.E.W. Holm[2]

[1,2]School for Electrical, Electronic, and Computer Engineering
North-West University, South Africa
[1]claudem96@gmail.com, [2]johann.holm@nwu.ac.za

ABSTRACT

Implementing a quality management system often requires major alterations to an organisation's methods, processes, and cultures. Consequently, small manufacturing organisations often operate without a structured quality management system. This research project focuses on quality management to provide a solution to the quality management gap in the management methodology of small manufacturers. Using Design Science Research, a manufacturing-oriented framework for total quality management was utilised in an industry survey to define a cross-sectional view of quality management among South African small manufacturers. This research project explored the Capability Maturity Model as a solution to make quality management more accessible and of systemic value to manufacturing SMEs. The validation relied on a cross-comparative literature analysis between the Capability Maturity Model and ISO 9001, as a globally recognised standard for quality management capability and one of the most prominent quality management paradigms among South African organisations.

Keywords: Quality, Capability Maturity, Manufacturing

* Corresponding Author

1 INTRODUCTION

Adopting a Quality Management System (QMS) more than often brings about profound organisational changes, requiring significant effort and resources [1]. As a result, many small manufacturing organisations select to operate without a structured quality management system. The reason is that motivation is limited mainly by the absence of a realistic roadmap towards comprehensive Total Quality Management (TQM). For high impact, such a roadmap towards TQM must be clear in terms of its objectives, incrementally achievable, and objectively measurable, as opposed to a make-or-break approach.

Capability Maturity Models (CMMs) are known for measuring an organisation's current status, identifying improvement areas, and supporting development. This research paper reports on the development of a roadmap in the form of a Manufacturing Capability Maturity Model (MCMM) that leans on the philosophy of the Capability Maturity Model Integration (CMMI) [2] to address the need for objective measurement and visualised growth.

The primary research challenge is thus derived from the need for an MCMM that allows for visualised growth and objective measurement towards the final goal of TQM. The context of this research project is shown in the diagram below:

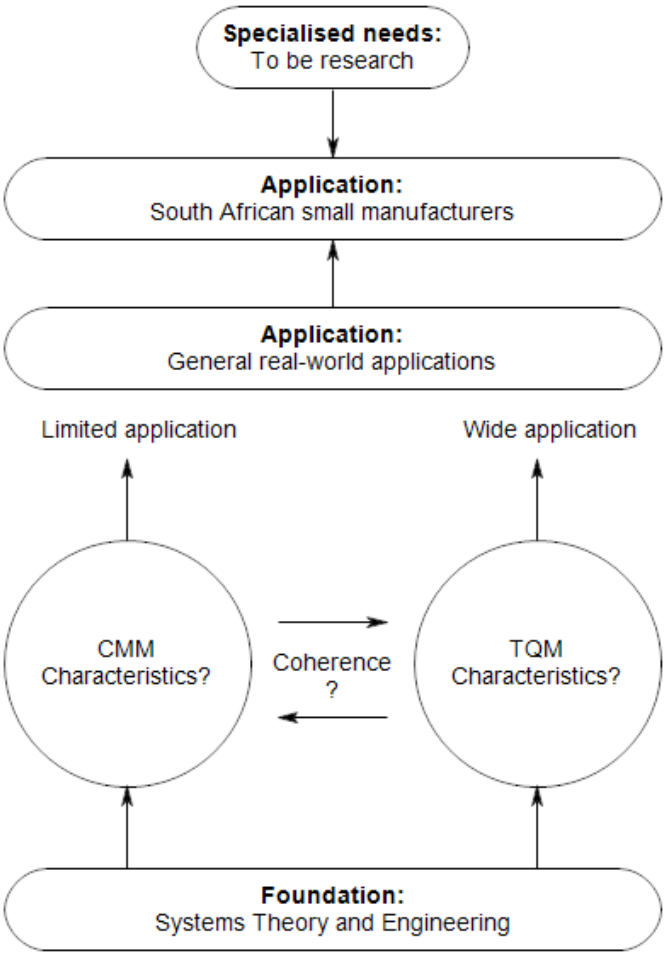

Figure 1 - Research context [1]

A number of focused research challenges were derived from the primary research challenge addressed in a Design Science Research (DSR) paradigm using an Action Design Research (ADR) method [3], [4]. Derived research challenges were defined using different sources, including

real-world observations (by a quality practitioner), informal interviews with industry experts, and an initial literature review [1]. Take note that ISO 9001, referred to below, is a standard that defines the requirements for a Quality Management System (QMS).

The **research challenges** include the following:

1) From the researcher's observation in practice, there is a need for Quality Management contextualisation among South African small manufacturers;
2) A detailed definition of need must be defined for small South African manufacturers in the context of Quality Management;
3) Questions that had to be answered are as follows:
    a) Could CMM be repurposed to general real-world applications other than information technology systems?
    b) Could CMM and QM be combined or integrated to meet the requirements of accepted standards (e.g. ISO 9001)?
    c) Would it be possible to define a progressive growth path, with feedback, to meet ISO 9001 compliance requirements realistically?
    d) Would a CMM framework specifically meet ISO 9001 requirements for small South African manufacturers?

As discussed in the sections below, the research challenges above were addressed in a research project. The paper is outlined as follows: Section 2 addresses the first two research challenges above, namely, to contextualise QM in the small South African manufacturing sector and to analyse the need of this sector in more detail; Section 3 discusses the road to quality using Capability Maturity as a reference and establishing its relevance in the ISO 9001 system; Section 4 shows how Process Areas were adapted or designed to align with needs in the manufacturing space; and Section 5 closes out with validation of this research.

2 DEFINING THE NEED FOR SOUTH AFRICAN SMALL MANUFACTURERS

The initial research challenge speaks to two important aspects, namely the contextualisation of QM in the small manufacturing space and an analysis of the need for it in the small manufacturing space in South Africa. To this end, the following was done:

1. Qualitative archival research: The literature review focused on QM philosophies and principles to define TQM in the small manufacturing space and to understand the characteristics of a relevant QMS. The history of QM and current interpretations were revisited, and desired characteristics and best practices were defined;
2. Industry survey: An exploratory mixed-method questionnaire survey was conducted in a cross-sectional way to better understand the current state of QM implementation in the South African small manufacturing environment. The cross-sectional view was used to define the TQM characteristics in this environment and ensure that the underlying need was analysed, defined, and understood.

2.1 Archival research on quality

The development of QM follows a path from the acknowledgement of artefact repeatability through the industrialisation of production processes to meet quality requirements, followed by the definition of Quality Management [5], [6] and Total Quality Management.

TQM focuses on achieving quality through total organisational involvement, an attribute it owes to its seminal theory: Deming's fourteen points, which can be summarised as follows [1].

1. Limit dependence on inspection activities and focus on the quality of the production process;
2. Adopt a new philosophy that supports QM in the broad sense, as opposed to the often-limited view of repeatability;
3. Institutionalise leadership and recognise the role of people in the overall QM effort and ensure organisational human development;
4. Create and sustain the focus on purpose and the principles and advantages of continuous improvement in QM;
5. Create a unanimous sense of accountability with the involvement of the entire workforce in the organisational transformation.

Further to this, the TQM philosophy stipulates eight primary elements that reflect the principles of QM, such as fundamental beliefs, values, and approaches. The eight primary elements, notably, include [7]:

1. Customer focus to include the need, expectations, and all requirements;
2. Employee involvement as a critical element for active involvement and commitment;
3. Process focus as the foundation for functions and capabilities;
4. Integrated systems to ensure comprehensive collaboration across resources;
5. Strategic approach to ensure appropriate direction and motivation;
6. Continual improvement to address changes and performance increase;
7. Fact-based decision-making to ensure an unbiased risk-based approach;
8. Communication to complement employee involvement and collaboration.

The role of Systems Thinking in the context of QM becomes evident when referring to the "unitary whole" [8]. This is important as it underscores the need for process and system analysis, performance management, validation and verification, and other essential considerations in systems. Systems Engineering and Thinking thus form part of the discussion as it provides common ground between QM and CMM.

The institutionalisation of QM principles is typically achieved through systems that provide frameworks for decisions, activities, and approaches that are typical of a QMS [9]. Lakhal *et al*. [10] provided an important researched and refined interpretation of the TQM framework to result in a TQM model that is particularly useful in the context of QM in SME manufacturing.

In the manufacturing environment, specifically, the best practices were extracted from further study by Doss *et al*. [11] to provide a set of **six high-level TQM facets**:

1. Customer focus with specific attention to requirements, quality objectives, market intelligence, customer satisfaction analysis, and integration of requirements;
2. Top management commitment is required for policy-level definitions, resource allocation to meet quality objectives and management availability;
3. Organisational commitment for comprehensive dissemination, employee contribution and motivation, supplier quality, assurance protocols, and product testing;
4. Employee training to establish an aligned training program, education in quality and QMS, succession management, and government assistance (where applicable);
5. Process management to ensure processes are defined, standardised procedures are followed, performance metrics are applied, and risk management is done;

6. Information and analyses for interpretable information from data, dissemination of information to relevant employees, and quantitative/factual decision-making.

The South African small manufacturing environment had to be defined in the context of the best practices facets– the questionnaire used in the industry survey was aligned with these facets.

2.2 Exploratory industry survey

As part of the initial needs analysis, the industry survey's primary focus was to contextualise the South African small manufacturing environment using a questionnaire to establish the presence of institutionalisation rather than a quantitative measurement. This survey was used to analyse and validate the research need, and to direct the in-depth study that followed.

2.2.1 Participants

South African manufacturers falling within the Small, Medium, and Micro Enterprises (SMME) definition [12] were considered, and 27 participants took part in the survey. The representatives of participating companies were selected to include owners, senior managers, or QM consultants who provide informative responses; using a questionnaire to acquire contributions from experienced practitioners is accepted in QM research [10].

2.2.2 Data collection

Using the 6 TQM facets above as focus areas in the questionnaire, the questionnaire measured the institutionalisation of QM within the participating organisations [1] using a Likert-type scale. Meta-data was used to organise the results according to industry type, ISO 9001 certification, and the presence of a quality manager. Questionnaires were answered using a web-based system called QuestionPro, which adhered to the constraints of ethical responsibility.

The data showed that 8 participants had been ISO 9001 certified, with 1 participant certified for less than 2 years (also without a dedicated quality manager). 26% of the participants were both ISO 9001 certified and managed by a dedicated quality manager/consultant. Among the 19 participants without certification, 6 had a dedicated quality manager.

The majority of participants were from the metal and mechanical industries, accounting for 66% of the responses. 11% were from the automotive industry, 8% from the food or medical industries and 15% from other industries.

Three groups were identified from the data:

1. Group 1: Certified companies that have both mature QMS certification (> 2 yrs) as well as a dedicated quality manager;
2. Group 2: Managed companies that have a dedicated quality manager but do not have any QMS certification;
3. Group 3: Unmanaged companies with no QM initiatives in the form of certification or a quality manager.

2.2.3 Results of the exploratory survey

Details of the results and their validity can be found in [1], with important findings reported. The independent t-test was used to ensure the results were valid from the survey, where sample means were used to test three null hypotheses relating to different groups [13].

The Cronbach Alpha test was used to validate the results for each of the six QM facets discussed, with all facets resulting in scores of 0.7 or above, showing their relevance in an exploratory survey [14].

The three null hypotheses are as follows:

1. **Ho1**: System certification does not offer any additional presence of TQM practices if there is a dedicated quality manager.
2. **Ho2**: A dedicated quality manager does not offer any additional presence of TQM practices when compared to a system without any QM initiatives.
3. **Ho3**: System certification does not offer any additional presence of TQM practices as compared to a system without any QM initiatives.

From the exploratory survey, it was found that [1]:

1. The null hypothesis is accepted for all six facets: "QMS certification did not offer a statistically significant difference in the presence of TQM facets when compared to managed, yet-to-be-certified systems."
2. The null hypothesis is rejected for four of six facets: "A quality manager thus significantly influences the presence of TQM facets in a manufacturing QMS."
3. The null hypothesis was rejected for all six facets: "This suggests a significantly larger presence of TQM-aligned practices within a mature certified QMS than in an unmanaged QMS."

The results provided evidence that QMS adoption would add significant value in terms of TQM-aligned practices, with evidence showing that almost 50% lacked active quality management, while around 70% of the participants lacked a formal quality system. Hence, a much-needed improvement is possible, but mostly absent, in the SMME manufacturing space as sampled in this survey.

It is important to note that formal certification (e.g. ISO 9001, providing both validation and certification value) is not the definitive consideration when considering quality, but rather the value of implementing QM principles in the small manufacturing space. Formal ISO 9001 adoption is often limited due to its costs and the high rate of implementation failures [15, 16].

The real value of QM becomes evident when a systemic embedment is done. That is, to truly transform the organisational culture to become inherently quality-managed, for which true organisational commitment is required. In addition to the findings from the survey, it is thus prudent to understand the need for a roadmap towards formal QMS adoption that is clear in its goals, time, process, and cost. This is necessary to both motivate and support small manufacturers on this important journey.

3 THE ROAD TOWARDS QUALITY – A CAPABILITY MATURITY PERSPECTIVE

3.1 Overview

Maturity models (MMs) allow organisations to measure maturity on a standardised scale with the ability to sustain their operations in a changing techno-economic landscape [17]. Mature organisations manage their operations, risks, opportunities, and requirements to meet the expectations of all stakeholders by being conscious of their own capability and maturity.

Maturity modelling is not a new concept in the QM environment, with Crosby's maturity grid being an early example of this concept [17]. However, there is still a lack of attention to MM integration in the TQM and ISO 9001 spaces.

A specific example of a comprehensive Capability Maturity Model is found in the Carnegie Melon CMMI framework [18], defined as follows: "The CMM is a framework representing a path of improvements recommended for software organisations that want to increase their software process capability". This demonstrates the mission of a CMM as a means to improve

process capability along a structured path, albeit for IT systems - this framework thus aligns with the need identified for South African small manufacturers.

CMMI process areas provide focus on specific aspects of an organisation, with a capability maturity scale from levels 1 to 5 [1], [18]:

Level 1: The initial level describes an organisation as being unpredictable with poorly defined processes, and the consistency of outcomes is mainly achieved through individual heroics and experienced managers.

Level 2: The managed level implements basic project management to achieve repeatability of outcomes in a foundational structure for governance, such as the definition of policy and standard operating procedures.

Level 3: A defined level is characterised by standards with documented core business processes and integrated functional areas, with the operation of processes according to organisational definition rather than individual discretion.

Level 4: Quantitatively managed levels use defined processes to affect control, where the quality and performance of processes and products become measurable metrics used to classify various system characteristics.

Level 5: An optimising level focuses on continuous improvement using best engineering practices to exploit system information to identify opportunities, weaknesses, and risks.

Evidence of the applicability of CMMI in other areas (as a CMM) is given in Wendler [19], where more than 20 application domains were identifiable by 2010. This implied that CMM has applications in other domains, which warranted further investigation into the application of CMM in small manufacturing spaces.

In the period 2017 to 2023, additional instances were identified in the manufacturing domain with applications including optimisation of a remanufacturing process, continuous process improvement, and intelligent manufacturing [20], [21].

The area in which a gap was identified early in the research specifically relates to the “as is” transferability of CMM to a manufacturing domain. Researchers who achieved the most success used informed reasoning to select or discard process areas and specific and generic practices [20], [21], [22], [23].

CMM uses 23 Process Areas to define its high-level functions, with Process Management, Project Management, Engineering, and Support as the categories inside which Process Areas are hosted. The use of Process Areas allows for the focus on relevant aspects of an organisation and simplifies the application of CMM as a measurement framework.

The following table was obtained from the CMMI Product Team [24] to show the different categories and Process Areas of CMMI:

Table 1 - CMMI Categories and Process Areas with maturity levels.

	Common Features			
	Process Management	***Project Management***	***Engineering***	***Support***
Maturity Level	**Process Area Mapping**			
5. Optimising				**CAR** *Causal Analysis & Resolution*
4. Quantitative	**OPP** *Organisation Process Performance*	**QPM** *Quantitative Project Management*		
3. Defined	**OPF** *Organisation Process Focus* **OPD** *Organisation Process Definition* **OT** *Organisation Training*	**IPM** *Integrated Process Management* **RSKM** *Risk Management* **IT** *Integrated Teaming* **ISM** *Integrated Supplier Management*	**REQD** *Requirements Development* **TS** *Technical Solution* **PI** *Product Integration* **VER** *Verification* **VAL** *Validation*	**DAR** *Discission Analysis & Resolution*
2. Managed		**PP** *Project Planning* **PMC** *Project Monitoring & Control* **SAM** *Supplier Agreement Management*	**REQM** *Requirements Management*	**MA** *Measurement and Analysis* **PQA** *Process Quality Assurance* **CM** *Configuration Management*
1. Initial				

3.2 Alignment of CMMI with ISO 9001

Upon first inspection, CMMI appears to be more comprehensive than ISO 9001 regarding its scope and depth, which had to be investigated to use CMMI as a base for deriving a QMS that supports incremental growth, measurement, and minimum performance levels. At the time, this was a subjective opinion that had to be investigated and validated.

Considering the 10 ISO 9001 clauses in conjunction with the CMMI Process Areas is imperative to form a complete picture of the alignment between the two domains. The ISO 9001 clauses are as follows [1]:

Table 2 - ISO 9001 clauses.

Nomenclature	**Clause 1:** *Scope*	Describes the scope of the International Standard as well as the expectations for certification.
	Clause 2: *Normative References*	References the normative documents that describe the fundamentals and vocabulary used in the International Standard.
	Clause 3: *Terms and Definitions*	References the normative documents that describe the terms and definitions used in the International Standard.
QM Requirements	**Clause 4:** *Context of the organisation*	Requirements detail the alignment of the organisation's business environment with the QMS.
	Clause 5: *Leadership*	Involvement of top management and integration of ISO requirements into operational processes. Alignment of policy and objectives with strategic direction.
	Clause 6: *Planning*	It focuses on planning and incorporates risk-based thinking to establish quality objectives that can be measured and/or evaluated.
	Clause 7: *Support*	Focuses on establishing support functions through resources, competence, and communication.
	Clause 8: *Operation*	Details requirements that enable processes to achieve quality objectives, customer expectations, and organisational requirements.
	Clause 9: *Performance evaluation*	Incorporation of both quantitative performance measures (process measurements, data analysis) and qualitative performance reviews (management reviews, internal audits).
	Clause 10: *Improvement*	Harness system information, management reviews, and risk-based thinking to identify and realise opportunities for improvement.

In the table, only clauses 4 to 10 apply and must be aligned with CMMI's Process Areas. Researchers attempting to compare or align CMMI and ISO 9001 found that a CMMI approach aligns with ISO 9001 in the following ways [1]:

- CMMI and ISO 9001 are complementary, and an integrated implementation reduces the overall risks and cost of QMS development rather than straining it;
- CMMI is a much more comprehensive and detailed representation of QM that encapsulates the requirements of the standard [25], [26];

- Comparing CMMI to the requirements of ISO 9001 suggests that CMMI level 2 already aligns the organisation with most of the ISO 9001 requirements [27], [25];
- CMMI offers significantly more depth in terms of quantitative management, process definition and control, as well as organisational enablement [26], [28];
- The ISO 9001 standard emphasises customer focus, specific documentation requirements, and the establishment of QM authority within the organisation [27].

A systematic comparison of CMMI and ISO 9001 supports the findings from other researchers ([25], [26], [27], [28]) with the following diagram (as an original contribution) showing the synergy between CMM and ISO 9001:

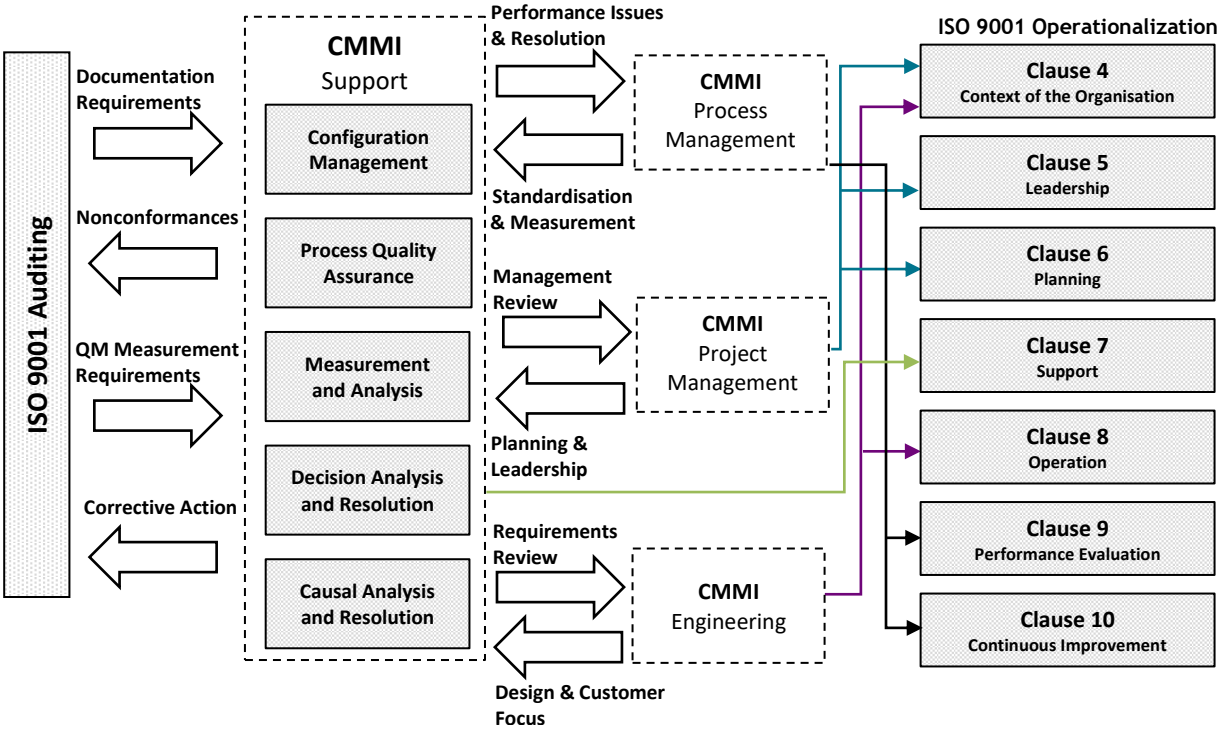

Figure 2 - Synergy between CMMI and ISO 9001:2015 [1]

The diagram shows that there is significant synergy between ISO 9001 and CMMI, with the understanding that ISO 9001 would provide an explicit set of requirements, as shown on the left of the diagram. The implementer and auditor subjectively determine implementation specifics and certifiability. CMMI lends itself to implementing operational systems (processes, procedures, resources, etc.) to meet the ISO 9001 operationalisation requirements, shown on the right of the diagram.

Most notably, the link between ISO 9001 Auditing and CMMI relies mainly on the CMMI Support Process Areas, with Engineering, Project Management, and Process Management providing the link to ISO 9001 Operationalisation. This result was not apparent at the onset of this research and required careful consideration and reflection.

Therefore, if CMM could align with ISO 9001 requirements on both ends (that is, the audit side and the operationalisation requirements), this integrated method would achieve the end goal of providing a roadmap for measurable progress. This was the focus of the last research challenges, as listed in Section 1.

The adapted CMM requirements, from a QM perspective, are addressed as follows [1]:

Table 3 - Adapted CMM requirements.

Requirements	CMM	TQM	ISO 9001
Provide a structured framework	X	X	X
Be progressive for incremental growth	X		
Be pragmatic and systematic	X		
Be measurable to allow feedback	X		X
Based on TQM and ISO 9001 principles		X	X
Verified to meet ISO 9001 comprehensively	X		X
Institutionalise QM best practices sourced from TQM, ISO 9001, and CMM	X	X	X

With the ISO 9001 alignment evident, additional requirements to be addressed relate to small manufacturing in South Africa. The research challenges can be successfully addressed if CMM can be adapted to meet the South African small manufacturing ontology by testing and retaining CMMI Process Areas relevant to a manufacturing application.

Some Process Areas had to be adapted to meet the terminology of the manufacturing domain, while other Process Areas had to be redefined in a novel manner to meet manufacturing characteristics not sufficiently addressed in the existing CMMI.

4 THE MANUFACTURING CAPABILITY MATURITY MODEL

To align the CMMI framework with the characteristics and requirements of a manufacturing environment in the South African context (the scope was limited to the survey and thus only to South Africa – further studies may test the adjusted model in different environments). Such a model is called a Manufacturing Capability Maturity Model (MCMM), as shown below:

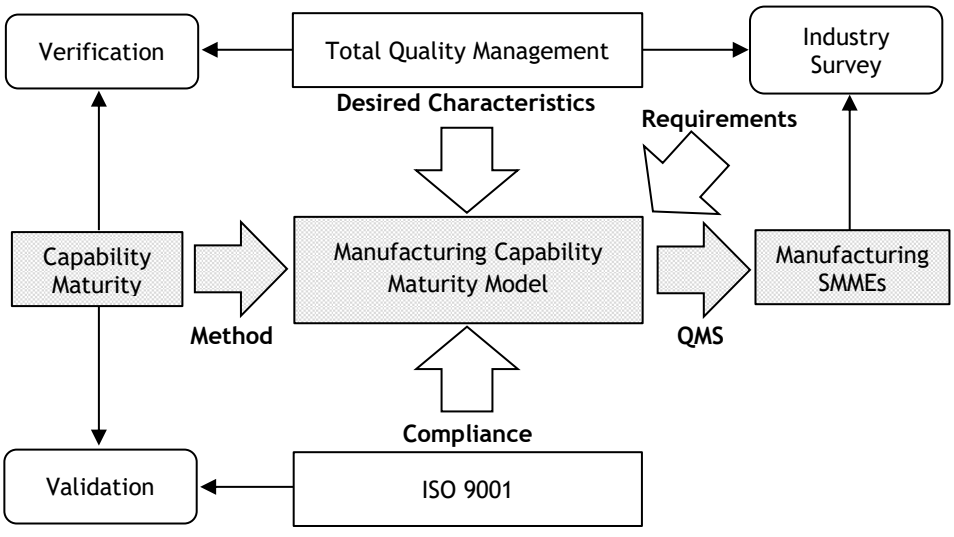

Figure 3 - Solution design validation, requirements, and constraints [1].

The diagram shows how different inputs and constraints were considered in the design of the MCMM, specifically focused on manufacturing. In line with CMMI, the MCMM model defines manufacturing categories that align with the manufacturing environment's capability

characteristics, as verified from personal participation in the SMME manufacturing space in the spirit of Action Research (refer to Table 4):

Table 4 - Manufacturing CMM Capability Categories.

CMM Categories	*Manufacturing Capability Categories*
Project Management	**Objectives**
	Institutionalisation
	Reflection
Support	**Infrastructure**
	Enablement
Engineering	**Engineering**
Process Management	**Process Management**

For each of the Manufacturing CMM categories, Process Areas were derived (adopted) or Novel (designed) based on experience in the South African manufacturing space. For brevity's sake, the following list contains the novel Process Areas:

1) **Objectives**
   a) Strategic Direction – Used to inform the organisation at all levels, from top-level policies to lower levels, using leadership inspired by commitment of time and effort;
2) **Institutionalisation**
   a) System Implementation – To ensure principles of Systems Engineering are used for the successful implementation of new systems, including the actual QMS to be implemented;
   b) Organisational Commitment – Aligned with the Process Focus Area of CMMI, this Process Area focuses on the primary use of a process-driven system for manufacturing;
   c) Resource Management – To ensure best practices for the systematic allocation of resources to meet requirements in a way that supports effective use of resources;
   d) Knowledge Management – This focus allows the management of information and knowledge necessary to execute core organisational processes with a business continuity focus;
3) **Engineering**
   a) Manufacturing Processes – Used to clearly define, document, and disseminate manufacturing processes and other requirements for successful process implementation in the manufacturing space;

4) **Process Management**

   a) Information and Analysis – To develop and establish methods for gathering, analysing, and disseminating organisational process data and information;

5) **Enablement**

   a) Asset Management – To establish, develop, and maintain a full life cycle asset management capability that preserves all process, physical, and people-related assets;

6) **Reflection**

   a) Sustained Customer Focus – For a sustainable customer-oriented approach to ensure the customer is managed in a customer relationship management manner;

   b) Organisational Decision Making – A recursive capability for utilising information from the QMS to make informed decisions;

The maturity levels were revisited to align with the ISO 9001 framework as follows:

1) **Level 1: Initial** – Assuring product quality unknowingly or on an ad hoc and reactive basis, with the need for more advanced methods present at higher levels;
2) **Level 2: Managed / Repeatable** – Performing processes in a repeatable manner without the presence of a formally managed baseline but under management control;
3) **Level 3: Defined / Baselined** – Standardised manufacturing processes are placed on record/configuration management, implemented, and controlled;
4) **Level 4: Measured / Auditable** – Manufacturing processes are performance measured and used to analyse variance as well as efficacy and to direct decisions;
5) **Level 5: Optimising / Improving** – Manufacturing is done only according to established processes, controls, and measurements and used to improve efficacy.

A comprehensive analysis is available in [1] with each CMMI Process Area and its corresponding Manufacturing CMM Process Area aligned, and novel Process Areas defined in broad detail.

5 VALIDATION AND CONCLUSION

The research challenges were *validated* from the initial literature survey to agree with the perspectives of other researchers. The research challenges were successfully addressed as follows:

- There is a need for Quality Management contextualisation among South African small manufacturers – *Addressed by means of a questionnaire survey that provided more detailed needs for the South African small manufacturing environment*;
- A detailed definition of need must be defined for small South African manufacturers in the context of Quality Management – *A valid TQM interpretation was obtained from research and used in a questionnaire survey*;
- Could CMM be repurposed for general real-world applications other than information technology systems? – *Answered from a literature study to show relevance in applications other than Information Technology environments*;
- Could CMM and QM be combined or integrated to meet the requirements of accepted standards (e.g. ISO 9001)? – *A systematic comparison and subsequent alignment were done to show how CMMI fits into the ISO 9001 framework (original contribution)*;

- Would it be possible to define a progressive growth path, with feedback, to meet ISO 9001 compliance requirements – A Manufacturing CMM realistically *was defined with its own categories and Process Areas (original contribution)*;
- Would a CMM framework specifically meet ISO 9001 requirements for small South African manufacturers? – *A pragmatic approach was followed to synthesise an ISO 9001-aligned manufacturing practices framework within an appropriate SMME context (original contribution)*.

It is thus *concluded*:

- From the exploratory industry survey that there is a need for a simplistic, measurable path towards TQM;
- A CMM provides sensible measures in the form of CM levels for incrementally improving quality practices, which simplifies the implementation of QM;
- A cross-validated customised CMM for small manufacturers was developed and is available for use in the small manufacturing space.

The main research challenge, namely, to provide a roadmap towards TQM, was addressed by synthesising a Manufacturing Capability Maturity Model that is tailored to the South African small manufacturing environment.

The following limitations are acknowledged:

- The study and design focused on *specific constraints and requirements from South African SMME manufacturers* using the best TQM characteristics from literature, the requirements for ISO 9001 certification, and the methods of a Capability Maturity framework;
- The model is validated as it meets requirements when cross-validated against literature, requirements, and existing standards, but it *has to be fully implemented and refined in an Action Design Research environment in future studies*.

Future work should focus on the refinement of the developed MCMM by physically implementing the model and learning from its guided emergence. Small manufacturers would benefit from the MCMM as it is relevant and instructive.

The insight obtained from the research and development conducted in this study will affect studies in other disciplines, adding value to the methodology used for Capability Maturity Model development that aligns with Quality Management for its inherent value.

EVOLUTION OF MANUFACTURING TOOLING TECHNIQUES IN A CHANGING GLOBAL ENVIRONMENT

S. Chikumba[1]

[1]Department of Industrial Engineering and Engineering Management
School of Engineering and Built Environment
University of South Africa, South Africa
chikus@unisa.ac.za

ABSTRACT

Tooling refers to the process whereby a manufacturer acquires, makes and use the appropriate equipment to produce a component or product. It is important in product design and industrialization and must minimize defects from variation in dimensions and tolerances, shapes, and forms. Using a concurrent approach, product design, prototype development and manufacture of a product is an integrated with tooling and process design. Injection moulding, casting and metal forming requires tooling for each component. In this paper processes to manufacture parts, tools such as dies, moulds, and inserts and parts using machining, rapid prototyping and newer techniques such as 3D-Keltool are explained and how tool making have evolved from traditional tooling was made from alloys such as tool steels to other materials such as powders based on advances in technology. Direct and indirect tooling are discussed. Benefits of and factors affecting the uptake of rapid tooling and limitations are discussed.

Keywords: Tooling, Tool making, rapid prototyping, rapid tooling, direct tooling, indirect tooling

1 INTRODUCTION

Industrialists refer to tooling as the acquiring of manufacturing equipment and accessories and components to enable production of goods [1] while in manufacturing technology it is devices directly used to produce a part which include dies and moulds. Tool making is practice or task of fabricating or manufacturing of the mould and dies which are often used to mass produce consistent quality components using injection moulding, casting and forming operations [2]. Mould and tooling are interchangeably used terms [3, 4]. Traditionally, machining has been used to fabricated moulds out of a block of metal alloys such as steel and non-ferrous alloys. To improve properties of moulds and dies, such as hardness and wear resistance they are heat-treated and, in some cases, coated after machining [3]. A typical mould design comprises a female (negative cavity) into which a material fills to produce a part by flowing inside under gravity or applied pressure. Injection moulding forces a molten material into the die e.g., molten plastic or metal to form a consolidated part. In forming operations such as forging or drawing sheet, solid or a heated metal blank is formed into shape by a huge forcing it into a die [5]. The temperature and pressure at which forming and moulding is conducted depends on material properties of the blank and the final product properties [4]. The total cost of tooling which include the design, development, fabrication and maintenance are important in manufacturing costing and estimation [6, 7]. Tooling costs are distributed across the part production volume throughout its lifespan and are allocated to part per-unit cost [6, 7]. The demand for cost effective products from a manufacturer's perspective and cheap products by the customers have been the main drivers of tooling technology [8, 7]. Advances in manufacturing technology, integration of physics and chemistry as well as material science have fuelled innovation in new machining methods, non-traditional manufacturing and materials for tooling. With emerging economies there is a rise in global manufacturing competition, while increasing customer standards of living and aware is fueling demand for mass customization to suit individual tastes, shorter product life cycles leading to accelerated product obsolescence and continued demands for cheaper easily replaceable products [8, 7].

Traditional machining processes are a mature technology using machine tools lathes, milling and grinding machines, electrode discharge machining and more recently chemical methods to produce dies and moulds [4, 9]. In die cast and plastic injection mould tooling, Computer numerical controlled (CNC) machining is now standard mould and die manufacturing methods since the 1990's [10]. They are used in most toolrooms to manufacture metal working tooling for stampings, forgings and include moulds, dies, mandrels, jigs, fixtures, punch dies, perforated forms [5]. However, machining methods are subtractive manufacturing methods requiring solid substrate material on which the tool is carved leading to material loss. Highly skilled artisans such tool and die makers are required for process set up and operation of the machine tools. The machine set up procedures are often complex and time-consuming and require fixtures for accurately holding the workpiece during fabrication [10]. In the last few decades methods of rapid manufacturing of tools and dies have been developed and are report in many research papers to potentially reduce cost and lead times of tool manufacture [11, 9, 12, 7]. These may be divided broadly into those involving material addition or the removal of material [11, 9, 7]. High-speed CNC machining is now the most efficient machining method for milling, turning, drilling and grinding among other subtractive methods. Additive manufacturing techniques based on layer-by-layer manufacturing of metallic composites and ceramic alloy parts show enormous potential in tool making [13]. Rapid prototyping is a key part of the new industrial movement [13] or Fourth industrial revolution which focuses future manufacturing on advanced manufacturing technologies to improvement of efficiency and reduce production lead times, product innovation, automation and integration with information technology creating cyber physical systems [13, 14]. Manufacturing sustainability aims to reduce energy consumption, waste production and maximize process efficiency [15, 16]. This paper discusses how tool making has evolved over the decades from traditional and

nontraditional machining methods right through to rapid prototyping and rapid tooling technologies. Their present and future applications are also discussed and how their adoption can impact productivity, efficiency, quality and market competitiveness.

1.1 Aim of this paper

The aim of this paper is to discusses advances in tooling technology from traditional machining processes to present day additive manufacturing. Traditional tooling methods are discussed, their technology and weakness that justify adoption of innovative tooling methods. Direct and indirect tooling methods are explained as part of rapid tooling techniques. Different applications and materials used in rapid tooling are explored together with their design considerations, merits, and limitations. The importance of rapid tooling and factors affecting its adoption of rapid tooling by industry are explored. Applications of novel materials and additive manufacturing as the future for tooling, with their design considerations, merits, and limitations are explored.

2 METHODOLOGY

This paper is a literature study from journals, books and other online sources to review the evolution of tooling used in manufacturing. The key drivers of innovation of tooling are investigated by studying appropriate tooling for different manufacturing processes and products. Factors affecting the selection and cost implications of different dies are studied as well as material selection considerations for tool making. Different traditional, nontraditional and rapid tooling materials and tool making techniques and their different applications are discussed.

3 LITERATURE REVIEW

The design of a product, manufacturing selection and tooling design, today occurs in a virtual design environment [17]. Feasibility and functionality of distinctive design concepts as well as the selected or design manufacturing process and tooling can be tested [18]. Once validated the physical tooling and other accessories are then manufactured and deployed [17]. Prototyping a product during development allows different stakeholders like engineering, sales and marketing, manufacturing, parts suppliers, and subcontractors to understand its functionality. This has been enabled using computer simulation with can create a virtual prototype. By creating a virtual prototype preliminary studies of the physical prototype can be done reducing cost. Techniques of virtual prototyping include CFD (computational fluid dynamics) which replicates a wind tunnel and assess fluid flow and FEA (finite element analysis) to determine load-carrying capacity. Other simulation tools can be applied to manufacturing and assembly processes [19]. Figure 1 shows a schematic of traditional prototyping [19].

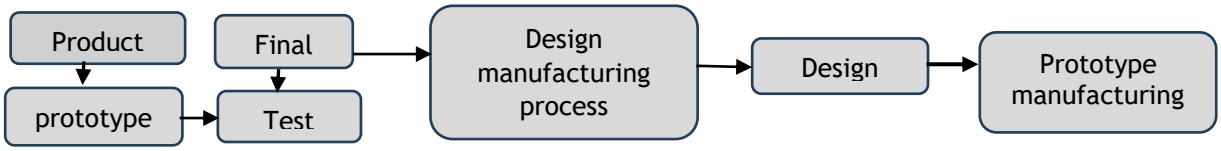

Figure 1. Traditional tooling development

The modern approach using virtual prototyping follows a concurrent engineering approach to both product and manufacturing and tooling design as illustrated in Figure 2.

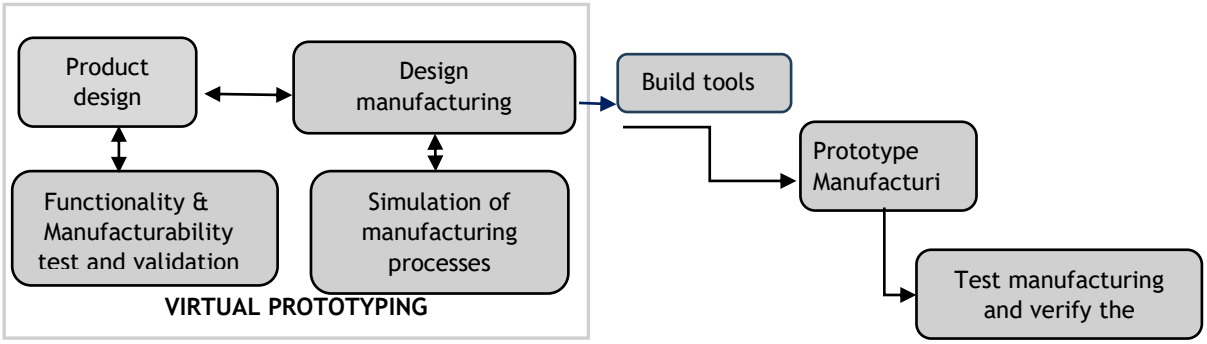

Figure 2. Modern tooling developing involving virtual prototyping

3.1 Mould material and components

Material selected for a tool material and the manufacturing techniques selected depend on component design and application requirements. For die casting permanent dies zinc alloys, aluminium, magnesium, and copper alloys are often used [20]. Moulds comprise fixtures that guide material flow during plastic moulding, sintering or die casting processes [19, 21]. Different mould designs include those consisting of two-plate and three-plate molds with or without stripper or rotary plates [22]. Insert molds incorporate metal inserts into the plastic mould before injection [23]. Other types of moulds include tandem or stack molds [24], parting line molds, hot runner molds, multicavity molds, cam action and multislide molds, lost core molds, and collapsible core molds [20]. These moulds require several inserts to control the filling and solidification process which can be fabricated using rapid prototyping [20]. Machining is used for high quality and precision components and involves machining, polishing, hardening, and heat treatment [1].

3.2 Traditional and nontraditional tool making

Traditional mould and die making uses conventional machine tools such as turning and milling to cut profiles and cavities. Their problem is limited quality and accuracy in reproducing profiles due to their mechanical spindles which produce unstable spindle speeds depending on operating conditions. Their drives cause mechanical impedance in gears, and thermal stress affect cutting forces, part surface quality and tolerances [25]. CNC machines have improved performance compared to conventional ones. One such type is a 5-axis CNC machine which is able to machine complex profile required for integral cavities on moulds due to the ability to manipulate the cutting tool and work piece [26]. An Illustrations of a 5-axis milling machine tool is in Figure 3(a) and a 5-axis lathe machine in Figure 3(b). Machining accuracy depends on spindle speeds and operating conditions, e.g., thermal stress affects cutting forces [25].

Other nontraditional tool making methods use different forms of thermal energy, such as electric discharge spark and plasma arc [27]. Electro discharge machining (EDM) is one method using spark discharges to machine electrically conducting materials regardless of its mechanical properties [27]. The metal workpiece is formed by discharges which take place in the gap between the tool, which serves as an electrode, and the workpiece [28].

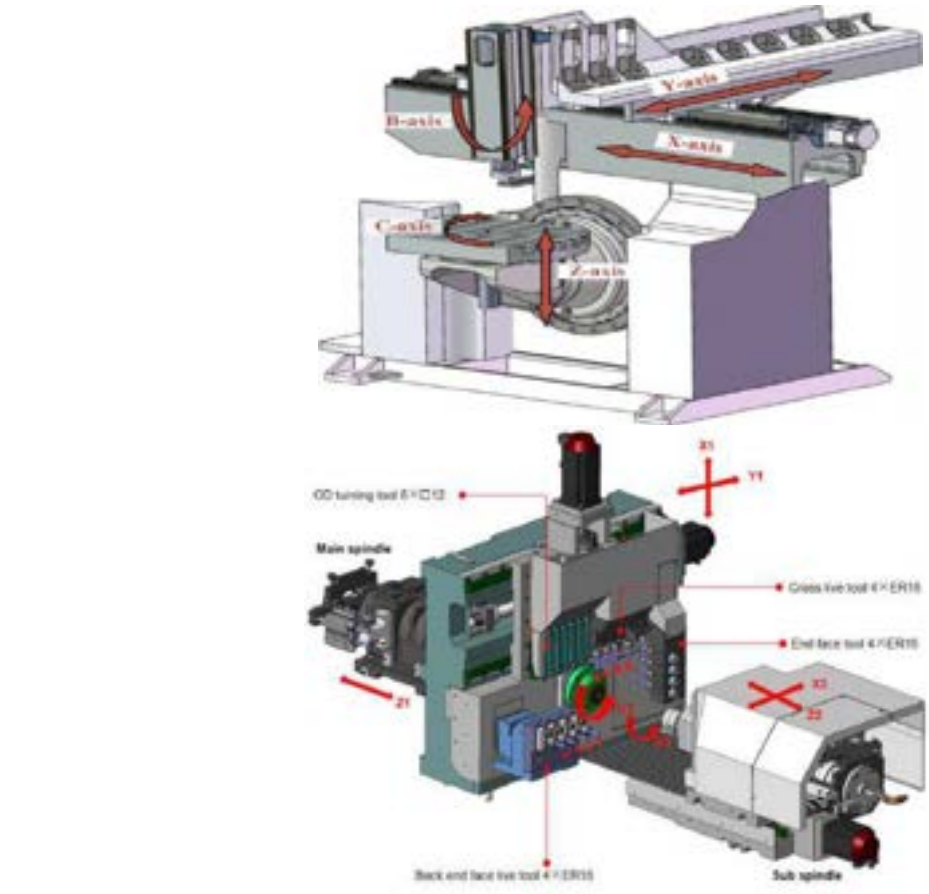

Figure 3 (a) five-axis CNC Milling machine (Jiang, et al., 2020) (b) 5-axis Lathe [29]

A variant of electrode discharge machining is Wire Electro Discharge Machining (WEDM) which uses a wire to cut a profile in conductive hard materials. Plasma arc manufacturing (PAM) uses plasma from a high energy electrical source to cut material and technology available today include High Tolerance Plasma Arc Cutting, Hydro-magnetically confined plasma arc cutting, Plasma Arc Machining using Hybrid plasma torch, CNC plasma arc cutting and underwater plasma cutting [27]. Principle of electro discharge machining is shown in Figure 4(a) and plasma cutting in Figure 4(b).

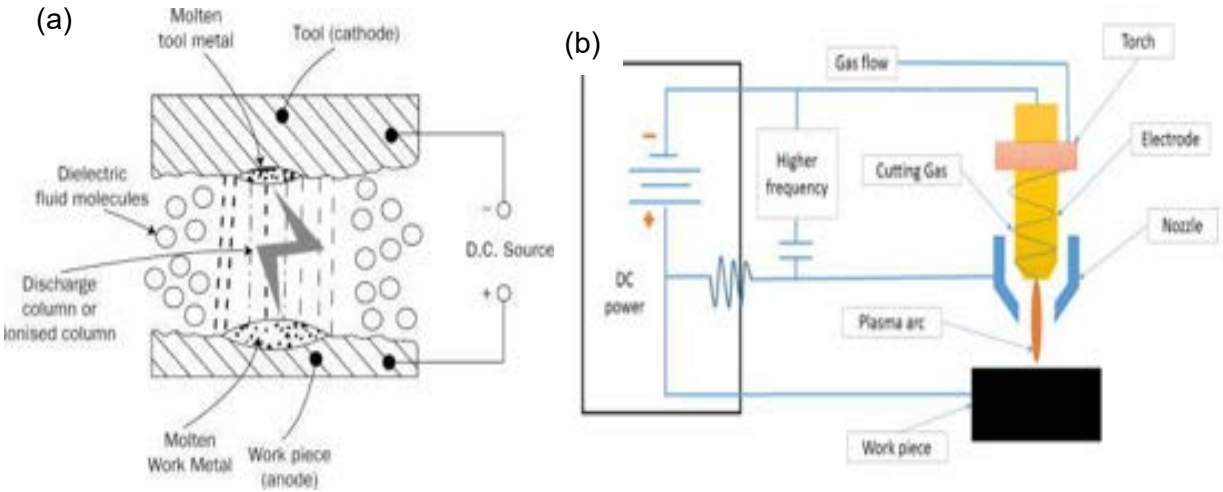

Figure 4. (a) Electro discharge machining [28] (b) Plasma discharge machining [30]

For non-conductive materials lasers can be applied for machining [31, 32]. Fundamentals of laser generation for five distinct types of lasers such as Nd: YAG Laser, Fibre Laser, CO2 Laser, Excimer Laser, and Diode Laser [27, 32]. Lasers in principle convert or process electrical energy first into light energy which then transformed into thermal energy. When controlled and directed onto a workpiece it melts and evaporates material effecting the machining process [31, 32]. During a laser machining (LM) process, the substrate material interacts with a laser beam resulting in its melting and material removal form the focus area [19, 32]. It can accurately cut titanium [19], and nickel alloys such as hardened Inconel 718 [32] and hard materials, such as advanced ceramics and composites, into intricate shapes and geometries with greater precision and minimal damage, vibration, and stresses [27].

The arrangement of laser machining process is shown in Figure 5.

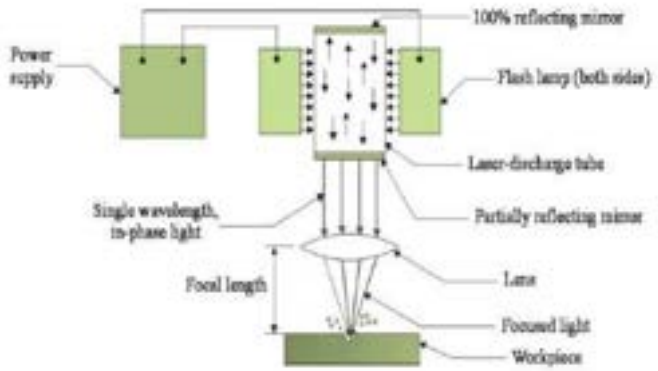

Figure 5. Arrangement of Laser beam machining [31]

3.2 Rapid prototyping and additive manufacturing

Rapid prototyping can be achieved using high speed machining using advanced CNC machines such as 5 axis machines [25]. However, additive manufacturing or 3D printing emerges as a fast way to develop a finished part directly from a design [8, 33]. It is also referred to as additive fabrication, processes, techniques, layer manufacturing, layer manufacturing [34], solid freeform fabrication [33] and freeform fabrication [34]. It is also applied in manufacture functional prototypes for product designs and small production batches of real component parts for use in a product [7, 35, 36]. Additive manufacturing transforms a digital computer aided design (CAD) model stored on a computer into a physical object form using a 3D printer to which the digital model is directly sent. The CAD model contains the part design information saved in STL file format after drafting which is readable to the 3D printer [7]. A number of 3D printing machines have been developed by different manufacturers and are classified into different categories by ISO/ASTM 52900:2021 based on their processing mechanisms [34]. The CAD model communicates model data including a description of the 3D surface geometry with native support for colour, materials, lattices, textures, constellations and metadata and shows surface geometry as a triangular mesh, flat or curved [37]. In 3D printing the layer is the basic building block of this technology, and their formation and interactions in the building process depends on materials used and techniques employed [38, 7]. A flow chart of rapid prototyping process is shown in Figure 1.

Additive manufacturing can be applied for rapid manufacturing (RM) where it delivers a significant increase in speed and reduction in cost, for small production runs or finished components and rapid tooling to produce complex tooling as a substitute for machining processes [40, 41, 33]. When applied for RM additive manufacturing techniques can produce high quality end user parts manufacturing direct from digital designs without elaborate process

set up and complex tool and work piece holders required for machining [12, 40]. Rapid manufacturing is already used for making parts in industries such as aerospace, aeronautics, automotive, home appliances, industrial equipment, and electronic devices [10, 40, 42, 7]. Advances in technology are key drivers in additive manufacturing the structural integrity and strength of the parts and the performance parameters of cost, quality and time of manufacturing also depend on layer properties [19, 7].

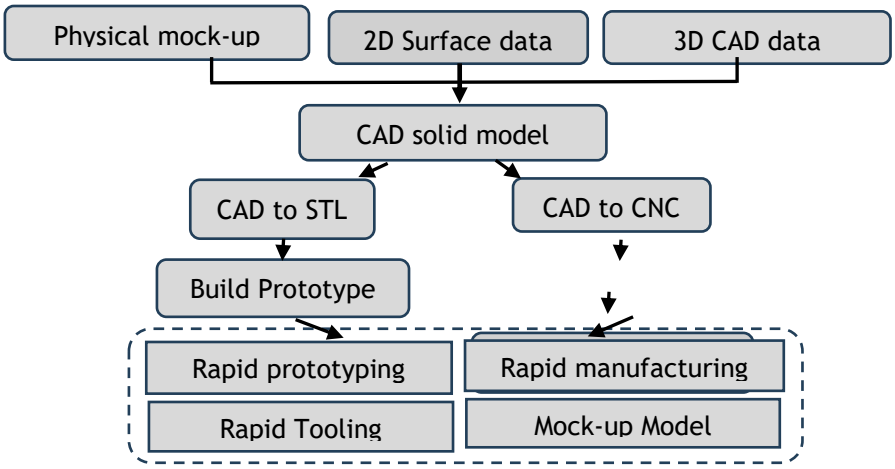

Figure 1. Rapid prototyping process [39]

3.3 Rapid prototyping techniques

Rapid prototyping methods based on additive manufacturing are categorized by the state of the prototype material before part formation, namely liquid, powder or solid sheets [8, 12, 42]. They can be classified according to the transferring data from the sliced three-dimensional models into physical structures [36, 43]. These are one-dimensional channels where a laser beam or material jet is employed, they use both polymer manufacturing, discrete particles solid particles and molten metal [35, 42]. Selective laser sintering, laminated object manufacturing and 3D welding are examples of these processes [36]. Multiple one-dimensional channels where two beams are independently controlled in a process such as laser sintering technology [7]. Two dimensional channels using masks in processes such as shape deposition manufacturing and direct photo shaping [8]. Liquid-based processes involve the solidification of a resin on contact with a laser, the solidification of an electro setting fluid [7]. Powder based processes aggregate substrate particles with a laser melting or by the selective application of binding agents [8, 4]. Processes involving melting and subsequent solidification of substrate material [7] include Ballistic particle manufacturing (BPM), MultiJet modelling (MJM), Fused deposition modelling (FMD), 3D welding, precision droplet-based net-form manufacturing (PDM) and Shape deposition manufacturing (SDM) [7, 42]. BPM builds parts by ejecting a stream of molten material from a nozzle whose stream separates into droplets that hit the substrate and immediately cold-weld to form the part [19, 42]. MJM builds models using techniques like inkjet or phase change printing but applied in three dimensions [19, 7]. FDM equipment comprises two movable heads, one of which deposits the material through a nozzle while the another supports the substrate [35, 42]. PDM uses a droplet-based net-forming manufacturing technique by exploiting capillary instability phenomenon of liquid jets which results in uniform liquid metal droplets [19, 7, 42]. By controlling the thermal state and mass of the droplets the desired microstructure develops [19, 7]. Powder bed fusion techniques involve locally melting metal powder using a leaser on a substrate to create layers and after a layer is formed, a new layer of powder is distributed by means of a roller [7, 42]. 3DW system uses an arc-welding robot to deposit material onto platform build complex structures [36]. Selective deposition modelling involves spraying molten metal in a near-net shape on to a

substrate and then removing unwanted material via numerically controlled (NC) operations [19, 7]. Liquid thermal polymerization (LTP) can form layers of thermosets instead of photo-curable materials. jetting heads feed the materials in liquid form on the surface [44, 42]. The liquid polymer and use a UV light to cure successive layers droplets form a deposition layer [36, 44]. Stereolithography is a method using curing of a liquid polymer in a vat using a UV light passed through its bottom causing successive solidification [45]. The laser engineering net shaping (LENS) is a process that feeds powder through a nozzle on to the part bed while simultaneously fusing it with a laser on one side of the bed or coaxial with the laser [19, 7]. Coaxial powder feeders often cause inaccuracies in the geometry of the part and the layer thickness due to beam and the powder misalignment [46, 42, 7]. Selective laser sintering (SLS) uses an infrared laser to trace a component onto a powder material [7]. Direct metal laser sintering (DMLS) is another powder sintering technique that shapes and solidifies metal powders using a fibre laser [35, 42].

4 DISCUSSION

Rapid prototyping technologies are now evolving toward rapid tooling RP devices generally build up a tooling prototype layer by layer, rapidly generating a fully three-dimensional free form, requiring no part-specific tooling [33, 36]. Rapid tooling refers to a process that allows a tool or mould to be manufactured in a short amount of time thereby shortening the duration execution of a product development project from design conception, creation to the fabricated product [5, 50]. Using rapid tooling evaluation of the tool's or product's processing performances before going into production is facilitated [5]. Multiple prototypes can be made in a given timeframe compared to conventional methods. Rapid tooling can be classified into direct whereby the design is directly send to a machine for additive such as 3D printing or subtractive manufacture such as CNC machining of stock material to produce a tool [50] and indirect methods involving creation of a pattern used to create the die through casting or other moulding methods [50].

4.1 Rapid tooling

Rapid tooling and rapid manufacturing facilitate production of test prototypes, and production of tooling and end-use parts even with complex geometries. Its flexibility allows easy personalization and customization of product design. In cases where blueprints of a machine part or equipment are missing a part can be printed for use as a replacement part needed for repairs [40, 7, 42]. Rapid tooling is based on the adaptation of ceramic, composites, polymer and metal alloy to create mould and other tooling components such as inserts and cores. When fabricating tooling, rapid prototyping techniques direct and indirect tooling can be produced [10]. To make direct tooling, additive manufacturing methods produce a mould directly form the design in one step [51]. Methods used include selective laser sintering [7], 3D printing tooling [4, 36], laser-engineered net shaping (LENS) tooling [7], direct metal laser sintering (DMLS) tooling [41], and electron beam melting (EBM) tooling [52].

4.1.1 Indirect tooling techniques

Indirect tooling involves the making of moulds and dies by first producing patterns, whose imprint undergoes further steps to create a mould cavity e.g., pattern making for sand casting around which sand is covered and compacted before the pattern is removed leaving a mould cavity [53]. In casting processes additive manufacturing methods using metals, polymers and composites reduce the time required for pattern making, reducing lead time for casting production. Other indirect tooling techniques which will be discussed in this paper are used for prototypes or short-run production tooling [54]. These methods include 3D Keltool [7], Polysteel [54], the ExpressTool process [55], and silicone room temperature vulcanization (RTV) tooling [51]. Indirect tooling is when the mold is made through more than one intermediary step, by using AM model as the first step [10]. Table 1 explains these methods including the materials used, principles and applications of each one.

Table 1.

Process	Description
3D Keltool	Core and cavity patterns with stereolithography or some other rapid prototyping process. After finishing core and cavity patterns silicone rubber is cast against them to create moulds into which a mixture of metal powder and binder is poured, packed, and cured [9, 54, 56].
Metal copy	Metal copying involves creating a master pattern or mold. Selective laser sintering (SLS) is used to fuse powdered pattern material together, creating solid patterns. However, it uses a binder that is less viscous, making it suitable for small features such as narrow, deep slots. It makes patterns for high volume production runs [9].
Polysteel	A 3D-printed model made of PolySteel is used as a master pattern to create a mold, rather than directly forming the mold cavity. Polysteel is a polymer filles material comprising of 90% steel and can be molded by deposition modelling to the right shape [9, 57]. The polymer reduces porosity [55, 57].
ExpressTool process	Powder-based additive manufacturing and electroforming techniques are used to create injection moulding tools. It uses chromium carbide and tungsten powder to create core and cavity mold inserts [55].
Silicone room temperature vulcanization (RTV)	An accurate master pattern is made by additive manufacturing SLA or SLS or even CNC machining or direct metal laser sintering and finished it to the desired appearance before silicone rubber is then cast around the pattern to form the mould. Moulds are used for thermoset materials such as urethane and epoxy materials are unsuitable for high-volume manufacturing and have life of less than 50 parts [54].
Spray metal tooling	Metal such as zinc-aluminum alloy (Kirksite), Nickel, or steel is applied by a gas arc or metal arc spraying on a pattern to create a mould [9]. A rubber or urethane material is then cast onto it as back up. Typical runs are 50–1,000 pieces, although some Kirksite molds have produced up to 200,000 pieces [54].
Rapid Solidification Process Tooling	A ceramic pattern is made of a component. To make the mould a 5-axis manual gripper holds the ceramic pattern as a spray system deposits in a vacuum chamber. The heated metal spray from a fixed nozzle directed onto the ceramic pattern onto which it coats

	form the mould [54, 58].After the spray is solidified over the pattern, the ceramic material is sand blasting leaving the metallic mould. It is applied to hard-to-machine alloys [54, 58].
Ford Sprayform	Special freeze-casting process is used to produce a ceramic pattern which is sprayed with a metal to form a shell about 19 mm thick. The shell backed up with epoxy fill. It is applied for producing stamping tools [54].
PHAST (Prototype Hard and Soft Tooling)	A pattern used for a mould master pattern in a soft, accurate, and reusable material. From the master pattern , ceramic moulds inserts are produced and used to cast wear-resistant Metal Matrix Composite of tungsten and bronze [54, 59].
Epoxy-based composite tooling	Epoxy-based composite tooling requires a master pattern created using AM process. Used for wax and polymer materials injection [53]. The pattern is finished and then embedded in a parting line block to create the parting line of the mould and metal inserts in high pressure areas during the injection molding process [54, 60].
Aluminum-filled epoxy tools.	Can be formed and machined to the ASTM standard according to cold stir casting [60]. Cold stir casting is a process used to create metal matrix composites (MMCs) by mechanically stirring reinforcement particles into a molten metal matrix. monolithic counterparts. Apply surface coats of epoxy to the pattern and run-off consisting of 35% epoxy and 65% aluminum composite material to complete the mold [54, 61].

4.2 Application of rapid tooling techniques

Today it is widely used in automotive, mechanical designs, consumer products, software engineering, entertainment, microchips, chemicals, and electronics [39].Its steps involve data capture using a scanning process, data segmentation and then 3D model development using modelling software [38]. After creating an STL file, various rapid prototyping methods fabricate the physical model [35] [47]. Computer aided engineering (CAE) analysis in the development of tooling for manufacturing facilitates concurrent engineering and time-compression technologies during the industrialization process [39]. Virtual prototyping employs computer models, from which design options are tested and analysed [47]. Software tools based on finite element analysis (FEA), are employed in the initiating visual presentation and design optimization of tooling and products under development [19]. After detailed design of products or tools, rapid prototyping can be used for producing prototypes for testing their behaviour, visualizing appearance, and mechanical strength [35] [50]. Functional tests use selective laser sintered polyamide-based models [8]. SLS production of polyamide parts is a cost-effective method for small number of parts [58]. Another growing application is in art and design allowing artists and other designers to experiment and visualize with complex artworks [19]. Rapid prototyping technologies quickly build patterns for foundry applications. For investment and vacuum casting patterns, selective laser sintering and fused deposition modelling are applicable [59]. In the medical/surgical domain, rapid prototyping technologies can build models that provide visual and tactile information [19]. These models can assist in operation planning, surgery rehearsal and training [62]. Unusual medical deformities once modelled facilitate surgery and training. The procedure of data acquisition involves making a CT scan whose data can be exported to an STL file format exported to the rapid prototyping machine [36] [38]. A model for medical applications, rapid prototyping methods such as stereolithography, fused deposition modelling print the model [38].

4.3 Future of rapid tooling

Quality, cost, and lead times of dies and moulds determine the economics of producing a very large number of components, subassemblies, and assemblies in industries such as automotive and aerospace [4, 63]. Creating tooling for prototype and production components is one of the most time consuming and costly phases in new product development [46, 64]. Cost depends on the complexity of the design, material selection, production volume and customization needs [6, 65]. Complexity and customisation of design result in higher costs of tool making compared to standard tooling and such an expense is justified by the profitability of an intended manufactured final product and its demand [6]. With the advent of industry 4.0 (4IR) which is

revolutionising manufacturing through automation linked to cyber physical systems and advanced manufacturing such as rapid prototyping rapid tooling will play a key role in improving efficiency [13, 66]. Incorporating 3D printing into pattern and mould making will time to market and increase customisation in a market where product life cycles are shortening, and customers are demanding innovative products [67]. There are also broader applications of 3D printing for tooling required for highly specialised applications such as biomedical engineering [68]. Adoption of rapid tooling in companies where tooling has been produced by conventional machining methods requires a technology focus, management that is informed and committed to research and innovation and capital expenditure. However, the adoption of rapid tooling in traditional manufacturing environments is influenced by the financial resources, investment in product and process technology development within the individual companies as well as the existing infrastructure.

4.4 Comparison of different tooling

In manufacturing, tooling is compared in terms of cost, ease of manufacture, pressure it can with stand, mould life, part material. and accuracy [61]. Table 2 shows a comparison of the different rapid tooling techniques and their associated attributes.

Table 2. Comparison of 3D printing, CNC machining, and conventional hard tooling [69]

	Additive manufacturing (such as 3D printing)	CNC machining	Silicone rubber	Aluminum alloy	Soft steel	Hybrid of aluminum & soft steel	Hard tooling
Mold Cost	N/A	N/A	$1000	$4000	$3000	$3500	$5000+
Speed to first part	< 1 day	2-3 days	5 days	25 days	40 days	32 days	60 days
Mold life	1 to 5 shots	1 to 5 shots	20 shots	10000 shots	50,000 shots	35,000 shots	up to 1m shots
Texture	Limited	Limited	Very good	Limited	Very good	Very good	Very good
Accuracy	Medium	High	Low	Medium	Medium	Medium	High
Clamp pressure	N/A	N/A	N/A	Up to 100 tons	Up to 600 tons	Up to 100 tons	Up to 2,000 tons
Part material	Filament/resin	Stock	Silicone	Actual	Actual	Actual	Actual
Cycle time	5-24h	5-24h	24h	Seconds or mins	Seconds or mins	Seconds or mins	Seconds or mins

5 CONCLUSION

Moulds, dies, mandrels, jigs, fixtures, punch dies are among the commonly used tools in manufacture of component parts that are assembled into final products. Quality, cost, and lead times of dies and moulds determine the economics of producing a very large number of components. Traditional manufacturing methods such as conventional machining, electrode discharge machining have over the decades been replaced by 3-axis CNC machining. However, the two techniques do not produce complex profiles on one machine easily. To overcome this problem 5-axis CNC machines have been developed able to machine complex profiles on one machine. This reduced process time and productivity in tool making. Machine tools still require highly skilled operators, and the processes are subtractive leading to high material loss and ultimately the tool cost. Laser machining, plasma cutting and electrode discharge machining methods are subtractive, and energy intensive. Where subtractive methods are used for tooling manufacture stock material must have high quality and free of internal defects.Intricate, and narrow shapes, with high accuracy present challenges to die makers. This is often solved by multi component die assemblies leading to high cost of the tool assembly. Additive manufacturing or 3D printing is a fairly new method developed in the last 4 decades and by producing diverse materials such as metal alloys, ceramics and composites are replacing machining in component manufacturing. Techniques such as direct metal laser sintering are being utilised in tool manufacturing. Manufacturing is moving towards direct

tooling as opposes to indirect tooling to minimise lead times, tooling costs and increase productivity. 3D printing technology for fabrication of hard materials, and tooling of complex geometries without the need for expensive jigs and fixtures is the future of tool making industry.

ABSTRACT

Steel is a key industrial product in any economy impacting industrialisation, survival of other downstream and upstream businesses. While primary large scale producers use iron ore as a raw material, small to medium scale producers use scrap metal and other ingredients to produce mostly produce such as channels, reinforcing, columns, and beams. Steel manufacturing involves collected, sorted, and fed into furnaces, continuous cast and drawn to the required profile and sawmilled to size. Material handling equipment like cranes, cooling beds, stackers, oxygen plant, cooling water purification and cooling plant, air pollution control systems and machine tools are ancillary equipment in the operation. Steel manufacturing faces high defects, high down time, breakdowns, high idle time due to material shortage, low labour productivity and excessive material handling. This paper investigates how lean principles can be applied to eliminate the problems faced in medium scale steel manufacturing and how to sustain continuous improvement.

Keywords: recycled steel, operational efficiency, productivity, quality

* Corresponding Author

1 INTRODUCTION

Steel is an important raw material in the manufacture of consumer products, farming, mining, manufacturing, construction machinery and automotive components [1, 2, 3]. It is key in infrastructural development which accounted for nearly half of the total steel usage in the last decade [4]. Global steel production and export market is dominated by China and India where producers are subsidized their governments allowing their steel to be cheaper on the saturated market [3]. In developing countries such as South Africa, a surge in imports of primary carbon and alloy steel products is creating the potential market overstocking [3]. Steel industry is facing escalating operational costs, and uncertainty due to recently introduced US tariffs on steel [5]. A report by South African Iron and Steel Institute reports decline in the total national production for Q3 2024 was 1,292,700 tonnes from 1,359,900 tonnes in Q3 2023 [6] due to declining demand and decreased economies of scale and uncompetitive prices [5, 7, 3], power shortages interrupt production schedules, forcing plants to use expensive alternative energy sources leading to increased production costs [5, 7]. The continuing export of steel scrap limits available scrap for local industries and reimported finished products leading to increased competition [2] which limits availability of raw materials for local industries [2]. Logistics bottlenecks due to poor rail and port infrastructure cause forcing companies to resort to road transportation of material and finished products [5, 7]. For steel producers there is growing pressure for local steel producers offer competitive responsiveness, price and quality and to deliver the products on time to their customers [3]. However, small scale producers face high production costs, low efficiency in production and quality challenges [4] as well as poor environmental compliance due to poor emission control during scrap handling, storage, smelting and forming operations [8, 9]. Measures are required to systematically identify and quantify the challenges faced particularly by small scale steel producers using scrap steel as raw materials. In this study lean manufacturing principles, quality assurance and cleaner production principles are chosen as tools to develop manufacturing best industry practices using a case study of a medium scale recycled steel manufacturer to improve production and quality processes, and shop floor management as well as logistics operations. Lean manufacturing is a production philosophy focused on maximizing productivity and value for the customer while minimizing waste or any activities that does not add value to operations [10, 11]. Quality control is a system of maintaining standards in manufactured products by testing a sample of the output against the specification according to Oxford dictionary. Quality assurance focuses on building quality into the production process itself to prevent defects from occurring in the first place, rather than relying solely on inspection to catch them [12]. Cleaner production principles aim to identify waste and implementing ways to prevent its production during manufacturing while improving efficiency in resources utilisation efficiency [13, 14].

1.2 Aim and objectives of study

The investigates current procedures equipment and procedures in material handling, manufacturing practice as well as quality control and logistics in a medium sized steel manufacturing plant to identify challenges which are hampering process and operational efficiency. Lean management and cleaner production principles are then applied to improve operational efficiency, reduce pollution and environmental compliance in the steel making operations of the plant. The objectives are to achieve increased operational efficiency through improvement of material handling, quality assurance and achieve standardization of operations. Another objective is to reduce in occurrence of defects, and product returns, and subsequently financial losses due to quality failures. The last objective is to identify sources of pollution during processing and finding ways of mitigating harm to employees and the environment.

2 METHODS

The study was conducted using a field study on the shop flow by observing production processes and actively participating in operations. Studies were conducted on the current and documented processes to identify the factors affecting operational efficiency of s equipment and material movement. Quality management and control activities and processes throughout production was studied as well. Costs of production was evaluated to identify opportunities for cost saving. Quality measurements. were contacted experimentally in the Quality Control department. Problem solving techniques including fish bone analysis, failure mode and effect analysis and plan-do check act were applied to tackle challenges in production. The advantage of a field study on the shopfloor is to investigate production in real time in its natural setting. Lean principles were applied to improve productivity and eliminate waste while cleaner production methods were applied to identify physical waste reduction handling and treatment. Top management practices by managers were not studied as part of this research.

3 LITERATURE REVIEW

Steel is primarily made of iron and carbon with other elements as chromium, nickel, manganese, carbon, silicon and zinc are added to achieve required properties [8]. It is durable, ductile, workable, corrosion resistant and versatile in its applications [8]. Virgin steel manufactured from iron ore by primary producers accounts for the bulk of global steel production [9, 10] while recycled steel produced by secondary producers from collected ferrous scrap accounts for about 25% of steel produced but its share is growing [11, 9, 10]. However, globally recycled steel demand is growing at a faster rate than scrap which is fixed in the way it is being released from steel in use [10]. The steel industry produces steel billets, further rolled into sections and sheets [12]. Depending on use the quality requirements for steel products are varied and are determined by manufacturing industry standards [8].

3.1 Recycled steel production process

The input for recycling steel processing is heavy melting steel (HMS) [13]. HMS 1 is recyclable steel and wrought iron with less than 0.05% carbon recovered from items demolished or dismantled at the end of their life [13, 14]. HMS 2 contain galvanized and blackened steel [13]. Induction Furnaces use steel melting scrap, sponge iron & Pig Iron/Cast Irons at an average the ratio of 40% sponge Iron + 10% Cast Irons or Pig Iron [14]. Collected and sorted scrap is charged into an induction furnace which uses electrical induction heating of the metal until molten [9]. Steel impurities such as copper can be diluted during melting since it leads to a loss of ductility and resulting surface defects [15]. Induction heating is a clean, energy-efficient and is well controlled melting process as compared to other metal melting such as coke blast furnaces [11]. Induction furnace does not require an arc like electric arc furnace [14]. Electric Arc Furnace Process uses an electrode dipped into the furnace which melts the scrap through arcing [16, 9]. Charging is done as per scrap availability and impurities are removed as slag [14]. The metallic charge melts to form liquid steel and as soon as the liquid bath achieves a temperature of around 1650°C tapping starts in the ladle for further processing [9]. The scrap melting process using arc melting is shown in Figure 1.

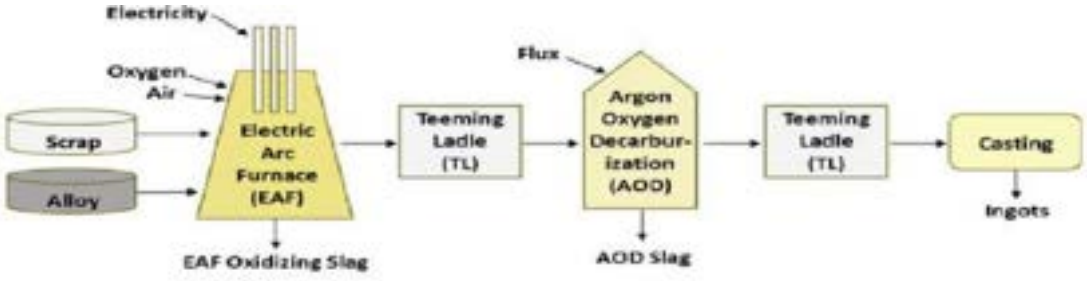

Figure 1. Melting of scrap and processing into billets [9]

Continuous casting is the process metal is poured continuously from a tundish or molten metal reservoir into a water-cooled metallic mould and solidified while being continuously withdrawn into a billet [17] . Steps in steel processing in Figure 1.Rolling is the metal forming process in cast billets are converted to the finished product by passing through rolls to reduce the thickness and make it uniform [12]. After rolling the product range sections produced includes reinforcing steel bar, IPE sections, angles, and channels [18]. Before rolling, billets are heated or soaked, in furnaces soaking pits util they achieve a uniform temperature of 1200°C [19]. Semi-finished billets are subsequently processed into final sections using cold rolling below recrystallisation temperature which is 650 to 700°C [12, 20, 18] or hot rolling mills above 930°C [21, 22, 23]. After rolling, scarfing is done to slab surface through a thermochemical process to remove a 2-6 mm layer with the aim of eliminating surface defects, like inclusions, pitting and cracks. Heating and blowing oxygen allow the melting of the metal layer [24] . The steel billet finishing process into sections is in Figure 2.

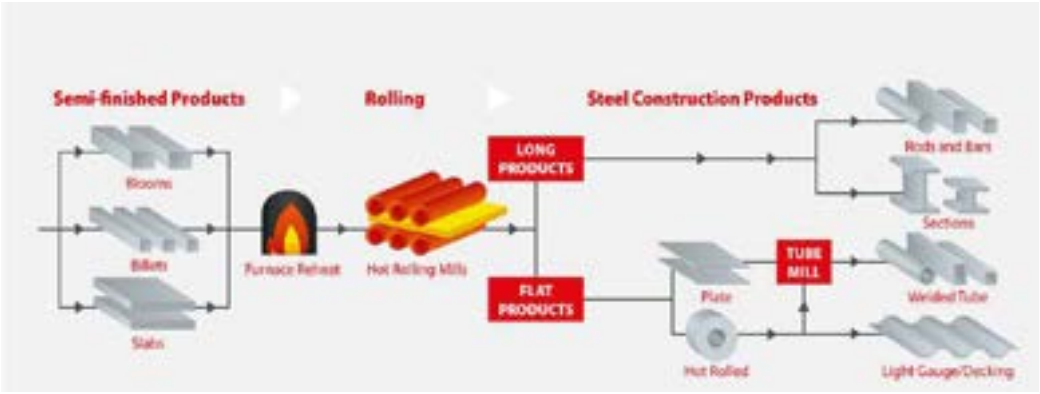

Figure 2. Finishing of continuous cast steel into final products [23]

A hot and cold sawmill, cooling beds, stackers, bundling machines and conventional and computer numerical controlled (CNC) lathes to maintain the many rolls used in the processing of steel into various shapes and sizes are also included in the capital equipment. Ancillary equipment in steel production includes an oxygen plant for onsite generation of oxygen used in steel scarfing [24], cooling water purification and cooling plant, air pollution control systems and a coal gasifier as well as material handling & lifting equipment (cranes). Material handling includes grabs for scrap handling, scrap and billet handling magnets, scrap pusher for induction melting furnaces, ladle and tundish pre-heating systems, tundish tilting and deskulling [25].

3.2 Lean manufacturing concepts and tools

The lean production concept seeks to improve efficiency by eliminating waste and has its origin in automotive assembly industry although it is widely used in the manufacturing sector [26, 27, 28, 29]. According to lean manufacturing philosophy waste includes excessive procedure (overproduction); delays/ waiting time; transportation that is not necessary;

excessive processing (inappropriate processes); excess inventory; excessive movement; and defective products [26, 30, 31]. Lean views manufacturing operations as a value stream [26, 28, 18] encompassing all the activities (both value-added, and non-value added). These activities bring materials through the production flow through to the customer [32]. Other sectors and industries such as mining and metallurgy also face similar challenges due to physical and lean waste generated during processing [18, 26]. In metal processing physical material waste includes emissions, and by products from extraction processes, while lean waste comes from excessive handling, idle time during processes, defects in products, excess inventory, and overproduction [31, 5]. Lean manufacturing systematically identifies and eliminates waste through process improvement and creating a smooth flow of production processes with fast lead times and little waste [32]. Central to lean manufacturing is problem solving. A problem exists when there is deviation from a standard in process performance, efficiency, and product quality [33]. A number of tools are available for problem solving. Root cause analysis , fishbone or cause and effect diagrams identify and trace the origins of a problem [33]. ABC analysis classifies the impact of identified problems to quantify their contribution and cluster them as the vital few or those with highest impact and important many as less impactful ones which still warrant solving to improve performance. These techniques are useful for preliminary evaluation of the impact of a problem [34]. For more detailed examination of a problem tools such as Failure Mode and Effect Analysis (FMEA) [35] and DMIAC (Define, Measure, Analyse, Improve, and Control) [33, 34]. FMEA defines each possible failure mode, its effect, criticality and ranks it using weighted scoring [35]. DMIAC methodology defines a problem, systematically analyse it to identify its main causes, and develop a feasible solution and implementation for sustainable continuous improvement [33, 34]. Collaboration between functional teams and teamwork within function departments is important in brainstorming and solving problems encountered within an organisation. Upskilling and training of equipment operators and staff creates awareness of lean management initiatives and technical skills which are key to achieving continuous improvement and a learning organisation. Upper and lower management must drive and be committed to sustain improvements [35]. They support and implement plans through budgeting for process redesign and acquiring of new equipment and enlisting shareholder approval for such initiatives for funding [34]. Through lean improvements production costs can be reduced, while product quality, material handling, and overall equipment and manpower utilisation improved together with process output waste management by tackling it at source and its handling [32].

3.3 Foundry quality control

Quality assurance of steel manufacturing ensures processes adhere to the standard manufacturing procedures during the entire process from scrap to the final rolled form. The melting temperature in the electrical arc furnace is up to 1600^{o}C, depending on iron compositions as determined by the Iron-Carbon diagram [43]. Hot rolling is at done at 800^{o}C to 1200^{o}C.The metallurgy of steel is charecterised by resultant phases with distinct properties namely austenite which gives high ductility and toughness [44], cementite consisting of carbides which gives hardness [45], and ferrite which gives ferromagnetic properties [46]. Properties are modified by adding alloying elements such as chromium, vanadium and silicon among others [47]. Non-alloy steels are low alloying addition content, for general use or for heat treatment, welding or forging. Stainless steels contain up to 1.25 carbon and up to 10.5% chromium for corrosion resistance [48]. Alloy steels have higher alloying element composition. During melting the molten steel is sampled at regular intervals and tested for elemental composition using spectrometry whose principle is derivation of masses within a chemical sample through their mass-to-charge ratio [49]. The phases can be modified by adding alloying elements to modify properties. After casting, billets and rolled steels are cut to produce samples which are ground polished etched and tested through micrography to identify phases

present [44, 45]. Some samples are machined and finished then tested for tensile strength [52], microhardness [53], impact strength, bending strength wear [54] and corrosion resistance [48].

3.4 Cleaner production and waste management

Cleaner production (CP) is a preventive environmental protection initiative focussing on reducing waste and emissions at the source rather than managing them after they are emitted [14]. The foundry industry faces environmental constraints due to requirements for waste management and hazardous waste disposal and compliance to minimum requirements for the handling, classification, and disposal of hazardous waste [55]. Different emissions from smelting operations include (a) dust furnace loading (b) dust and gases such as carbon and sulphur dioxide pouring emissions (c) gaseous furnace emissions (d) storm water runoff (e) dust from shotblast and baghouse dust (f) discharged control water. Burning loss is the proportion of the material loss to that charged into a furnace due to chemical reactions and volatilisation [55]. Solid waste such as slag is discharged as a byproduct of the smelting process (Beyerstedt, 2021; Adegoloye, et al., 2015; Gurumoorthy & Arunachalam, 2016). Life cycle analysis (LCA) is used to evaluate environmental impact of any product and in practice standards such as ISO14040 can be applied to study effects of smelting operations [61, 62]. Principles of cleaner production include (a) Prevention over end-of-pipe treatment (b) Integrated approach of entire production cycle (c) Resource efficiency or material, energy and water (d) Pollution prevention (f) continuous improvement (g) Stakeholder involvement including employees, management, customers and suppliers [63, 62]

3.5 Operational logistics

During steel processing there is considerable material handling throughout the process or manufacturing logistics [64]. It involves the planning, implementation, and control of the movement and storage of materials and finished goods within a manufacturing environment [65]. Material handling efficiency determines overall productivity and safety of workers [66]. Reverse logistics is also important in operations and is the process of managing the flow of goods from the point of consumption back to the point of origin. It includes returning products, such as for repair, refurbishment, recycling, or disposal [64].

4 RESULTS AND FINDINGS

A medium scale recycled steel manufacturing company was studied. Its raw material is recycled steel from one supplier who does the collection and sorting before delivery to the plant. The steel is stored onsite, before loading into electric arc furnaces for melting before secondary metallurgy i.e., modification of alloy compositions to ensure quality compliance. Once the quality is passed the molten still undergoes continuous casting into semi-finished steel billets. The billets are rolled before rolling into sections of different sections before finishing. Finishing involves cutting to size and straightening of the steel sections. Main products include reinforcement steel (rebar) and other sections such as angle iron and channel iron produced according to customer orders. The steel quantity, length, and type depend on its intended applications from customer orders. Production is based on make to stock or make to order. The value chain of the operation is below in Figure 4.

To support production a number of functional departments ensure smooth coordination and running of the business. The marketing and sales department communicates with customers to collect customer orders and demand forecast information based on historical demand trends. This information is sent to the Planning and Scheduling department where production schedules and lead times are generated for production and communicated to the sales team who liaise with customers. Planning and Scheduling does production capacity planning and identifies what raw materials and bill of materials based on product sizes ordered. It is done

for the sequencing the order of production tasks by ensuring to deliver products on expected due date as per customers' orders. Currently, scrap metal availability determines if orders are put onto the production schedule. Additional customer orders are accepted only if they can be accommodated into the already planned production. Production plans are checked against the availability of raw materials in inventory records in the Stores Department and this impacts production flow and order fulfilment. Planning is done on Excel spread sheets.

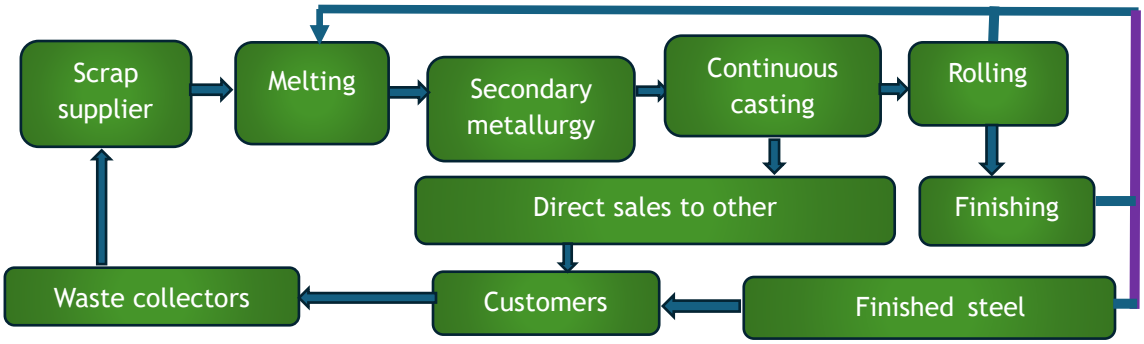

Figure 3. The steel production value chain and functional

The core business unit is the Production Department through which the scrap undergoes smelting, casting and rolling to the final product. Quality control and certification department ensures quality control of the process steps and the final steel sections. Plant maintenance ensures equipment functions optimally dealing with electrical and mechanical engineering. Other functional departments include Accounting, Human resources and admin, Logistics and transport, Stores and Inventory management and Safety department. The stores department through stock controllers keeps records of the material that includes scrap material, steel quantity, dimension sizes, and weights. Stock controllers colour code the finished material according to type, grade, section sizes and keeps the records of material section sizes, lengths calculated weights before loading truck and logistics department dispatches in trucks to customers.

4.1 Production facility and material handling

The plant has an external yard for scrap storage which received incoming scrap from trucks. Transfer to storage areas using overhead cranes, transfer trolleys and shutting trucks. The steel production process begins at the scrap yard where the scrap metal arrives for smelting. Cranes are also the main material handling equipment from the time raw materials (scrap) enters the company and gets dispatched from the company in the form of finished products. A crane is required to unload this scrap at the plant as they arrive in tonnage and in different shapes and sizes. Electric overhead cranes are used for scrap handling, and a host of cranes are used during smelting of scrap metals. The smelting area of the plant is exposed to extreme temperatures, hot liquid metal and flames. Cranes used during smelting are made to lift and carry buckets of liquid metals safely. Overhead, tundish, and ladle cranes are attached with additional equipment to lift ladles with liquid metal. The billets that come out of the smelters are hot and malleable and are moved to the rolling mill for rolling. As the steel is hot for shaping, the cranes used for lifting needs to be equipped with additional load handling capabilities like detachable magnets and tongs. Rotating trolleys or rotating beam cranes are used to move billets to storage areas. Electric Overhead cranes are used to move around steel sections and rebars to the storage bays. Forklifts are also used to stack steel products on the high storage racks. It gives the ability to reach anywhere around the rack, where crane and the operator cannot go through. There is a lot of material handling during steel processing and often accounts for roughly 30 to 60% of the production cost. The layout of the

manufacturing plant is in Figure 4 and shows the relative positing of different production and support departments.

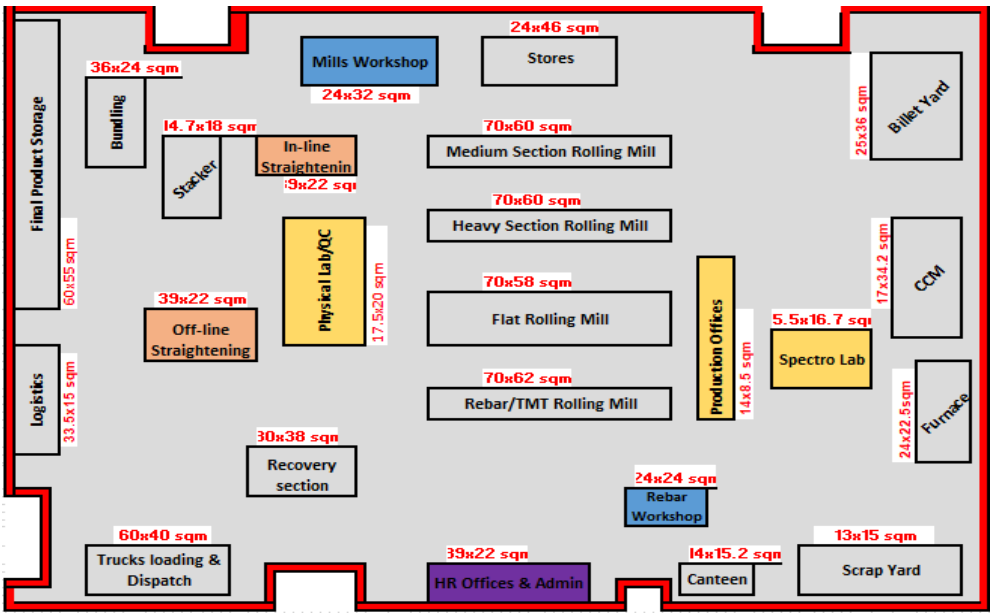

Figure 4. Steel production facility layout

4.2 Activities in quality department

In collaboration with production departments, they conduct research and investigations on material and heat balances, calculating total tonnage and scrap tonnage and chemical analysis of different furnace outputs and steel alloy produced, composition , properties and charge calculations. Charge calculations are the relative composition of ingredients fed into a furnace for melting [9]. Quality Control Department conducts sample collection, preparation and testing. Samples are cut, ground and polished if hardness tests are required. Where tensile testing on the Universal Testing Machine is required, they are cut and machined to the required shapes and sizes. The quality department also manages laboratory facilities and ensures testing instruments are calibrated to standard. Inspection, documentation and testing of products is done according to the ISO Standards and ASTM standards [68]. The Quality standards used to ensure steel produced meets minimum quality and safety standards by specifying (a) Chemical composition (b) Mechanical properties (c) Test methods and (d) Product dimensions [68]. Quality check of the final product includes conduct visual inspection of finished steel and calculate weight per meter of channels, angles, and reinforcing bars.

Spectro laboratory is responsible chemical composition analysis during the melting and casting of the steel to correct amount of alloying elements or scrap is added. The tests ensure cast billets are of correct quality prior to reheating and rolling processes. Physical Laboratory is tasked with ensuring that rolled products from mills conforms to the specification and meets what the customer ordered. This is established by destructive tests using tensile tests on a Universal Testing Machine, bend tests to measure the ductility and resistance to bending forces [33], impact strength tests using Charpy-V-notch Testing Machine [68] and hardness tests Rockwell, Vickers and Brinell [35, 36, 37]. Universal Testing Machine which determines the yield point, ultimate tensile strength, and percentage elongation of the sample [38]. Rolling quality inspection involves verifying the steel is of correct quality; comply with specification and dimensions during rolling. Should dimension discrepancies be observed on the hot rolled steel, rolling will stop, and adjustments made before rolling can resume. This

is a continuous check done on 30 minutes intervals during rolling. Finishing quality inspection checks are done by a quality inspector who checks if the products are free of any defects, product is straight.

4.3 Problems encountered in the steel making operation

A number of factors were observed to affect the steel making operations often leading to disruption of production, idle time, and low productivity. The problems encountered and their recurrence were recorded through study of production records, direct observation over a 12 month period. The results are tabulated in Table 1 and were categorised in terms of priority using ABC analysis.

Table 1. ABC analysis of production problems in the plant

Item category	Overall value	Classification	Action
Lack of resources for production	60%	A	Material requirements planning
Insufficient budget for production resources			Accurate medium range planning
Poor teamwork			Automation of processes
Unrealistic deadlines	30%	B	Regular review of production schedules
Overloading of workers			Use of standard operating procedures
Poor communication			Line balancing of production line
Lack of accountability	10%	C	Team building
Poor coordination of tasks			Effective delegation and communication

4.3.1 Quality problems in production

Customer complaints were often received on finished products come from the shopfloor or from external customers. They include material cracking and bending for sectional universal structural beams lengths after rolling. Some beams were returned from customers. Visual inspection of returns was conducted on the material, and it was found that the material showed cracking, and materials and claim was accepted. Some quality defects identified in rolled steel produced after rolling are in Figure 5. Root cause of the cracking and bend materials was investigated and found that it was due to the steel beam straightening machine [39] having wrong settings. It was found that the force pressure applied on the top and bottom machine rollers were too high and after reducing them the material showed no sign of cracking and bend/twist of material. Cracking was further confirmed through a non-destructive testing method called penetrant dye test, and there were no traces of cracks observed.

Cracking rebar material during bend test and investigation revealed it was due to high Silicon content added during casting and the team was informed to reduce and monitor Silicon content during casting and melting. Work instructions were created for improvement on operations and in the process of developing the standard operating procedures (SOP).

Figure 5.(a) Rejected beams due to non-conformance (b) Beam material showing cracks (c) rebar cracking and bending

4.3.2 Cost of rejected returns

Customer returns were often observed on some finished products. Reverse logistics is costly to the operation. Quality control sampling is used for quality certification of a batch. Although the sample may pass the test a batch may contain defective products. For example, rebar steel was tested using the non-destructive tests before a batch is supplied to a customer. One bundle is worth R40, 000 while a batch of 6 bundles is sold for R240, 000. Transport costs currently amount to R8000 per bundle. If a bundle is returned die to poor quality the company bears the transportation is cost amounts to about R8,000 when transportation and labour overtime are considered. Returns cost the company in terms of money and lack of customers reputation.

4.3.3 Inconsistent quality

A study of the defect rate of rebar on a month to month (MTM) basis from January to April 2023 was conducted from quality reports. During the 4 month period, variation of defective bars according to diameter are shown in shown in Figure 6.

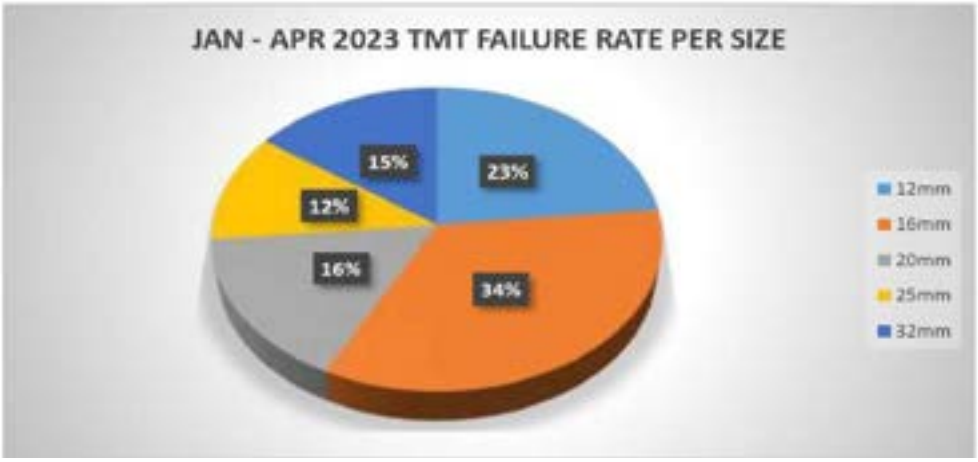

Figure 6. Failure rate of rebar based on diameter

The highest defect rate was observed in the 16mm rebar which can be attributed to the tooling used. From studying the tensile strength of different steel sections produced there was inconsistency of tensile strength test results of different batches tested from October 2022 to July 2023. The trend is depicted in Figure 7.

Figure 7. Mechanical strength test results trend from Oct 2022- Jul 2023

4.3.4 Costing

A study of distribution of costs in relation to steel making operation was conducted. Fixed and variable costs were evaluated including regular and overtime costs. Regular and overtime labour rates are in Table 2. These costs were used to estimate product costs. The distribution of fixed and variable costs is in Table 4.

Table 2.Labour rates for overtime for operators of different equipment

Description	Labour used - Hrs	Rate/Hour	Applied cost
Laser cutting	2.5	R40	R160
Machining	4	R66	R528
Welding	1.5	R70	R210
Fabrication	1	R68	R136
Sample preparation	2.5	R58	R290

Table 3. Distribution of variable and fixed costs.

	Section Mill Cost Structure		Accumulated Total
Fixed Costs	Direct Labour	8.96%	20.58%
	Depreciation	2.62%	
	Other	1.10%	
	Information Technology Services	0.09%	
	Maintenance Repair Services	2.52%	
	Maintenance Spare Parts	1.47%	
	Subcontracting	3.82%	
Variable Costs	Raw Materials	71.10%	79.42%
	Refractories	0.25%	
	Electricity	2.43%	
	Other Utilities and field operations	0.08%	
	Water	2.87%	
	Transport cost	1.09%	
	Other Consumables	0.33%	
	Petroleum products	1.27%	
	Total	**100%**	

4.4 Waste management in foundry and mill operations

Workers in plant face safety risks which include burns, cuts respiratory problems due to dust, hearing loss, trip and fall, or explosion of gases. The risks the operators were observed and documented in the table 4.

Table 5. Foundry and rolling mill waste and mitigation

Division	Solid/Liquid wasyes from process	Solid wastes from pollution control	Disposal method
Electric Arc Furnace	-Slag	-Flu dust	-
Steel making shop	-Slag -Broken refractory	-SMS dust	-
Rolling mills	-Random (End cutting) -Broken refractory	-Mill scale -Oily sludge	Designated steel bins & back to scrap
Raw material handling	-Fines	-Dust	-
Finishing & stacker	-Offcuts -Randoms	-Mill scale	-
Quality	-Acids & chemicals -Tested material	-Smoke -Dust	Tested material in designated steel bins & back to scrap

5 DISCUSSION

The plant was observed to be a traditional manufacturing environment with limited automation, high inefficiencies in planning, production and safety and environmental compliance.it can benefit by implementing principles of lean manufacturing and cleaner production.

5.1 Teamwork

Teamwork between various department and the production quality engineer was observed to be an essential approach to solving problems in product quality and meeting customer demand. Team building must be implemented, and management must understand team dynamics as a tool for team satisfaction influences how workers exert their effort in the work [47, 46, 40]. Studies have shown that through teamwork cause analysis in any production process can use collaboration in problem identification, root cause analysis and planning and implementing solutions [40, 41, 31]. On the shopfloor it was observed that long working hours/days were observed to lead to exhaustion absenteeism and unavailability of employees due to fatigue. Teams bring synergy between departments through information sharing and cross functional teams will ensure the company is effective in tackling production and quality problems. Top management commitment is essential in tackling budgeting shortfalls, quality projects and long term competitive strategy.

5.2 Standard operating procedures

Standard operating procedures in production and quality control specifications must be followed strictly to eliminate defects and to ensure productivity. Internal reporting and documentation can identify deviations from standards and recurring trends in production [42, 43]. Standard work scheduling, management of takt time i.e., daily demand/production capacity [48] and cycle time or the duration of time to process or produce a product from start to finish [49] using such techniques as line balancing to smooth production will distribute the workload evenly between workstations [32, 49]. Workflow can also be improved through efficient planning of material movement through sequencing, and scheduling procedures [30] and use of material handling devices such as cranes [50, 25]. In order to ensure standard operating procedures are followed, regular internal self-audits and strong organizing capability must be implemented [26, 31, 28].

5.3 Safety and material handling

Supervisors must be tasked with ensuring that the workplace is organised and tidy at all times applying the 5S principles [28] which will ensure improved workflow as well as easy access to materials and tools [26, 28]. The 5S principles (a) Sort reduces clutter and improves efficiency and safety (b) set in order organises tools and information to reduce unnecessary movement (c) Shine emphasizes good housekeeping of workstations (d) standardise emphasises standard operating procedures, process time and steps to reduce delays and improve productivity (e) Sustain through promoting training and discipline to ensure quality, productivity and 5S practices are a habitual part of the workplace culture. Compliance to health and safety, maintain ISO Accreditation as well as security procedures are also important in maintaining competitiveness of operations, safety and access to markets of the steel produced [44]. Lean principles can be applied to limit unnecessary handling and applying Kanban visual signals [51, 30, 29] to prioritise production of steel sections that are needed as per orders when they are needed leading to reduction of work in progress and inventory of semi-finished and finished steel.

A detailed study is also required to ensure handling of materials is be performed safely, efficiently, at low cost and in a timeously manner. Guidelines for improving material handling processes include analysing weight load, size and distance to minimise ergonomic risk factors,

optimize space and workflow, identifying required safety gear and processes, upgrading technology compatible with operations, providing correct training and getting employee feedback [52, 30]. It is recommended that in the foundry, overhead cranes should have sirens when moving so people around can be cautious at all times [53]. Visual signal in the mill section with the rolling process speed is exceedingly high. Interlocks can prevent equipment from starting and warning signals such as lights can flash red when material is coming and when green it is safe to cross over [53]. Process automation should be integrated to production and material handling to improve productivity and safety by reduce repetitive and unnecessary tasks, reducing operator error, increasing productivity with less manpower [54, 26, 47, 53].

5.4 Job design and reward management

Work environment and staffing matters such as reward management and amenities affect employee wellbeing and motivation [45, 46]. As a result, required staffing levels per workstation can be determined, efficiency improved and overtime .requests minimised [47, 46, 49].

5.5 Problem solving in quality control

Active use of problem identification and solving can assist in eliminating defective products and assist in root cause analysis. Product quality of semi-finished and finished products was studied, and a cause and effect of fishbone diagram was used for analysis . Problem solving techniques and charting as shown in Figure 8 can be employed to address all production problems. To improve quality control processes the following quality tools can be applied as ways of problem solving. Finished products must be colour coded according to the specifications or test results and ingots identified correctly. Correct scrap ratings must be available and high carbon steel separated. Material and heat balances according to total tonnage of scrap to optimise energy consumption. To improve product quantity in the short and long term the steel mill must commit to:

- Proper training is required especially for new employees and the risks, hazards and how to operate the machines they are to use.
- The lab efficiency can be improved by gin going digital as currently most things are done manually e.g. Reports are not automatically generated, one must sit and type them including the tested results are captured manually.
- Invest in quality suitable equipment for process efficiency to improve.

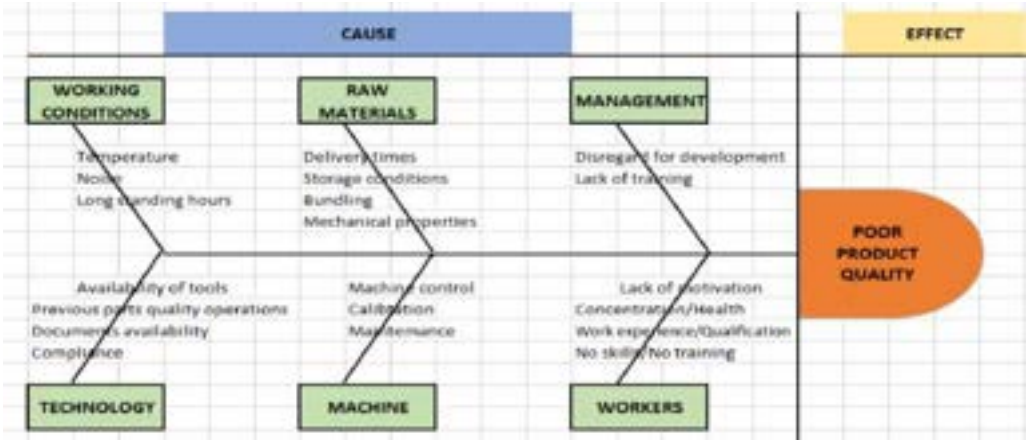

Figure 8. Root cause analysis of production problems

5.5.1 Cracking of steel samples

Other projects involved macro etching on the billet material prior to charging in the furnace to check for defects which can cause more problem during hot rolling, defective materials were isolated and not charged, sent back for rework. Material chemical composition and other parameters are important in quality control and resources must be given to the further research. The current rolling samples for laboratory testing are cut using Oxyacetylene torch after the sample beams are marked. The oxyacetylene torch is dangerous if gas leaks occur and heating the sample affects its properties changing microstructural properties [55, 56]. Sample collection may lead to weakening of the beam from which samples are collected causing it to be scrapping. The time for sample collection needs to be standardised because often oxygen is finished, and the gas cutter have to go collect one and this can take up to 1hr 30min. To improve sample collection, an automated blade sawmill machine to be purchased and the process will be faster and cheaper. This is easy to operate, safe and accurate than flame cutting. Grinding process will be reduced thus saving time and costs.

5.5.2 Maintaining accuracy of quality control equipment and processes

Adequate sampling for quality testing must be conducted to ensure quality assurance. All inspection, documentation and testing of products according to the ISO Standards and quality research must be done to improve quality. All quality equipment must be calibrated cleaned and be of good working order through routine maintenance. Test instruments can be contaminated by oxide films . dirt, be scratched and chipped on the indenters or improperly secured during testing leading to inconsistency of results. Replacement of chipped indenters, worn anvils, and use of proper standards and testing procedures can improve the performance of quality control. Quality controllers also require training on their daily tasks problem solving skills and documentation. They must also be experienced in production processes and equipment as well as their set up. They must be able to work in production teams and understand the formulation of different alloys produced in the plant.

5.5.3 Use of DMAIC methodology

The problem solving technique of DMAIC (Define, Measure, Analyse, Improve, and Control) methodology was implemented to research on the quality problems of rolled steel. The documentation of the study is in Table 7.

Table 7. Investigation of rolled steel quality using DMAIC methodology

PROJECT	DETERMINING THE CAUSE OF MATERIAL CRACKING ON FLANGE AND WEB CENTRE	
Definition of Terms		
Steel Melting Process	Industrial plant for the manufacture of steel	
Billet Process	Billets are produced by continuous casting or hot rolling processes	
Rolling Mill	machines used to roll hot or cold ferrous or non-ferrous strips, rods, wires, etc.	
Section	Standard dimensional properties of steel	
Chemical Composition	Identity and arrange chemical elements for easy traceability	
Test Certificate	Document verifying chemical and mechanical properties of material conforming to the standards and customers specific requirements	
Heat Treatment	Heating of steel to high temperatures to obtain desired results like hardening or softening of the material	
Normalising	Heating of steel to temperature below melting point and cool in air to relieve stress	
Straightening Machine	machine to make bar perfectly straight and removing any imperfections	
DMAIC	PROBLEM	DESCRIPTION
DEFINE	UB 254x146 rolled material cracking at straightening machine	After UB 254 x146 steel section material is rolled and cooled at cooling bed, the material will be in bend form. It is then passed through the Straightening Machine, where it is straight aligned.
MEASURE	Recording the activities as part of process	Analyse the frequency of problems and causes
ANALYZE	Root Cause Analyse to uncover causes	Chemical & Tensile test
		Penetrant testing
		Reduce high chemical elements e.g S & P
		Ensure straightening rolls are well aligned
IMPROVE	Using ideas to motivate people to work	Congratulate people when they are doing good work
CONTROL	SOP & 5S	

5.6 Waste management

The waste stream, disposal and recycling methods are important in pollution prevention in the plant and to the environment. Compliance to occupational health and safety standards such as OHSAS 18001 is legislated and mandatory in factory operations [44]. It demands routine protective equipment to people entering the plant, inspections and frequent audits [44]. Plant induction trainings alert new employees to risks and hazards in the plant. Waste management practices can be implemented to identify and mitigate the effects as shown in

Table 6.

Table 6. Waste streams, disposal and mitigation of pollution

Waste Stream	Disposal & Recycling Method	How can be reduced
Slag	West deposits sites & recycled for manufacturing cement and building materials industries, aggregates for road construction, fertilizers and landfilling	Use pneumatic slag stppers, slag darts, slide gates and eccentric bottom tapping for EAF
EAF dust	Collected by bag filters & recycled by processing it to recover metallic zinc element	By dust suppression
Mill scale	At waste plant	-
End cuts	Red bin & reused as scrap	Produce & Cut to exact length
Defects	Separate and sort from prime materials and sold at lower grade. If extreme scrap them	Reuse as scrap
Not Utilising talent	Use skills and talent in positions its suitable	Proper positions appointment

6 CONCLUSION

Increasing competition, logistics bottlenecks, rising production costs and outdated technology and practices are affecting small scale steel manufacturing operational efficiency and competitiveness. The steel industry is equipment and labour intensive suffering from a lot of lean waste. Lean manufacturing practices can be applied to investigate and eliminate physical wate and lean waste, Management of materials handling, individual processes and equipment as well as labour can reduce manufacturing costs. Steel production generates vast amounts of carbon and other types of pollution such as slag and requirement for environmental regulatory compliance. Steel making operations thus has to embrace more innovative and sustainable methods by investing in new technologies while adopting green manufacturing practices. Through understanding the metallurgy of steel, charge calculations, processing methods and equipment common defects such as bending, warping, inclusions, poor hardness and strength can be measured, tracked and eliminated in long term operations. Techniques such as cause and effect diagrams and DMAIC methodology which are simple problem techniques can be used to identify, document and manage production problems. Proper scheduling and production management can optimise material handling, reduce furnace and mill idle time and reduce unnecessary overtime in operations.

ABSTRACT

Student retention remains a significant challenge in South African Technical and Vocational Education and Training (TVET) colleges, particularly within the National Certificate (Vocational) [NC(V)] engineering programmes. Despite various interventions, dropout rates remain high, raising concerns about the effectiveness of current retention strategies. This study explored the student retention strategies implemented in selected public TVET colleges in Gauteng Province. A qualitative research design was adopted, with data collected through individual oral interviews with college management and senior academic staff across four college campuses. Data were analysed thematically using ATLAS.ti. Findings revealed that while some strategies, such as college support, financial aid and DHET attendance policy, are in place, their effectiveness is often limited by inconsistent implementation processes, under-resourced support systems and weak stakeholder engagement. The study highlights institutional gaps and operational challenges that limit the effectiveness of existing retention efforts, while offering guidance for optimising student support and improving persistence in NC(V) engineering programmes within the TVET college sector.

Keywords: TVET colleges, NC(V) engineering programmes, Retention strategies

* Corresponding Author

1 INTRODUCTION

Student retention remains one of the most pressing challenges in South Africa's public Technical and Vocational Education and Training (TVET) colleges, particularly within the National Certificate (Vocational) [NC(V)] engineering programmes. Despite several interventions to improve student success, dropout rates remain high [1]. This disrupts students' learning pathways and undermines the primary goal of vocational education: to produce vocationally trained graduates who can contribute to the country's economy.

Although several retention strategies, such as academic support and attendance monitoring, are currently in place, their effectiveness is often limited by inconsistent implementation and weak coordination across TVET college campuses [2;3]. This suggests that interventions exist in name but lack the structural and resource alignment required for consistent impact within the NC(V) programmes. Adding to these challenges, delays and administrative inefficiencies in the National Student Financial Aid Scheme (NSFAS) have further strained student well-being and retention, placing a disproportionate burden on low-income and rural students [4]. As a result, student support remains limited across TVET college campuses, with many NC(V) students navigating significant academic and personal challenges with minimal institutional assistance.

From an Industrial Engineering perspective, student retention can be seen as a process within the educational system, where inputs are student enrolments, processes are academic and college support interventions and outputs are successful completion of NC(V) engineering programmes. Inefficiencies such as inconsistent attendance monitoring and limited student support services reduce throughput and overall system performance [5]. Badroodien and Garisch [5] further note that strengthening support processes, including comprehensive orientation and ongoing academic and psychosocial support, can optimise resource use and improve workflow reliability, leading to more students completing their NC(V) programmes.

Given the practical and operational nature of vocational education, improving student retention in NC(V) engineering programmes requires targeted, efficient, and scalable strategies that can respond to the everyday realities faced by students and TVET colleges [6]. Assessing which retention strategies are currently in place and how effectively they are implemented is a necessary first step. This paper responds to that need by exploring existing retention strategies from the perspectives of TVET college management and senior academic staff. By doing so, this study contributes to ongoing conversations about institutional responsiveness, student success and educational equity within the vocational education system.

In line with the conference theme "Making Waves," this study presents a systematic, process-oriented analysis of student retention strategies, identifying operational inefficiencies and providing evidence-based insights to guide more responsive and coordinated retention practices in NC(V) engineering programmes. Specifically, it explores and analyses the retention strategies implemented at selected public TVET colleges in South Africa, focusing on their effectiveness and highlighting gaps based on the experiences of college management and senior academic staff.

1.1 Research question

What student retention strategies are currently implemented in NC(V) engineering programmes at public TVET colleges, and how effective are they in supporting student persistence?

1.2 Purpose of the study

The purpose of this study was to gain a deeper understanding of the effectiveness of retention strategies implemented in NC(V) engineering programmes at public TVET colleges in South Africa. By exploring the perspectives of college management and senior academic staff, the study aimed to assess the effectiveness of these retention strategies, identify gaps and provide insights that can inform more effective institutional practices for improving student persistence in the TVET sector.

2 LITERATURE REVIEW

This literature review outlines the theoretical framework that guided the study and examines existing research on student retention strategies within higher education institutions.

2.1 Theoretical framework: Bean and Metzner's model of Non-Traditional Student Attrition

This study is grounded in Bean and Metzner's Model of Non-Traditional Student Attrition, as it aligns closely with the profile of NC(V) engineering students in public TVET colleges. These students often face financial hardship, limited academic preparation, family responsibilities, and minimal social integration opportunities, which are central to Bean and Metzner's theory. The model emphasises how external environmental variables (such as finances, family support, and work obligations) significantly influence students' decisions to persist or drop out [6]. Many NC(V) students are non-traditional because they commute, may have dependents and have limited access to campus-based academic or social support. Therefore, Bean and Metzner's theory provides a useful lens for understanding the challenges faced by TVET students and examining how institutional retention strategies respond to these challenges. Focusing on external and institutional factors makes this theory especially useful for assessing retention interventions and informing future retention practices in vocational education.

2.2 Retention challenges in higher education institutions

Retention challenges in higher education institutions often stem from personal and institutional factors. According to Dunn [7], personal challenges include physical and mental health struggles and the need to balance multiple life roles, such as studying, working, and fulfilling family responsibilities. On the institutional side, Dunn identifies inadequate academic support, low awareness of support services, challenges with learning technologies, and feelings of isolation or disconnection from the institution as key barriers to student persistence [7].

Nkutu and Seekoe [8] reinforce this by emphasising that students need sufficient academic and emotional support to complete their programmes successfully. Their research indicates that limited access to lecturers, facilitators and academic mentors can negatively affect student retention. Dlungwane et al. [9] identified key contributors to student attrition, including academic difficulty, heavy workloads, family pressures, and lack of support from dependents.

Further, Nkutu and Seekoe [8] point out that financial pressures, unfamiliar academic environments, family responsibilities, and career uncertainty contribute to student dropout. These issues are likely to be prevalent in the TVET college context, particularly within NC(V) programmes, where students frequently face academic and financial hardships that threaten their ability to persist. Badroodien and Garisch [5] highlight that engineering students are particularly at risk, with mathematics being a persistent barrier and many students dropping out before reaching Level 4. They also observe that many NC(V) students lack self-discipline and accountability, often finding it difficult to adjust to college life due to their socio-economic backgrounds [5].

Muchineripi et al. [10] identify additional institutional barriers affecting retention, including limited student accommodation, inadequate infrastructure for academic and non-academic purposes, and insufficient access to information about support services. These factors, combined with disparities in socio-economic status, further impede student integration, persistence, and academic success in TVET colleges [10].

The high dropout and low success rates among engineering vocational students call for an urgent review of current retention strategies and a deeper understanding of student perspectives in vocational education. Low throughput affects individual students and has institutional consequences, including reduced government funding, which limits the capacity of TVET colleges to invest in resources and student support [11].

Joja [12] stresses that student success should not be viewed solely as the institution's responsibility. Instead, a collaborative effort is required, including students, families, educators, communities, policymakers, and industry. Addressing these multidimensional factors is essential for developing sustainable retention interventions that enhance student success in higher education and TVET contexts.

2.3 Academic engagement through attendance

Class attendance is vital to student retention, especially in structured programmes such as NC(V) engineering. Nzembe [13] describes class attendance as a source of conflict in TVET colleges, noting that students frequently miss classes despite DHET policies requiring regular attendance. The Department of Higher Education and Training's Attendance and Punctuality Policy [14] mandates 80% attendance per subject for students to be eligible to sit for final examinations.

Although the policy aims to improve academic engagement and foster a professional culture, its implementation is inconsistent. Myataza and Mokoena [2] found that many colleges allow students with low attendance to write exams, weakening the policy's intended impact. Seroka and Sepeng [15] further reveal that violations of the DHET attendance policy often encourage unruly and disruptive behaviour, which undermines teaching and learning environments in TVET colleges.

The DHET policy draws a strong link between attendance, retention and academic performance, supported by Klein et al. [16], who found that chronic absenteeism correlates with lower academic achievement and reduced school completion rates. Chronic absenteeism is defined as missing at least 18 days in an academic year [17]. Gottfried [17] further highlights that chronically absent students not only fall behind academically but may also negatively influence the performance of their peers. Kirksey [18] and Nthako [19] further support this, highlighting that absenteeism hampers educational and social engagement and leads to long-term academic difficulties.

Therefore, TVET colleges must recognise the serious implications of absenteeism and take proactive steps to monitor and support student attendance. Doing so may improve performance, student engagement and retention outcomes.

2.4 Student support services and accessibility

Effective student support services are critical in promoting academic success and retention. However, several studies highlight significant challenges in the utilisation and visibility of these services within South African TVET colleges. Badenhorst and Radile [3] note that many students enrolled in NC(V) programmes are either unaware of available support services or fail to recognise their relevance in addressing academic and personal challenges. As a result, these services are often underutilised or viewed as inaccessible. Makibinyane and Khumalo [11] add that poor student understanding of the purpose and function of support services further limits their use, while operational inefficiencies make services less effective.

In addition, Cook and Rushton [20] found that students often perceive institutional support structures, such as lecturer consultation or academic counselling, as invisible or difficult to access. Creating a supportive college environment where students feel welcome, acknowledged, and actively engaged can significantly improve help-seeking behaviour and academic outcomes [21]. This suggests that support structures must be visible and student-friendly to contribute to TVET colleges' retention goals effectively.

Buthelezi [22] suggests that psychological support services such as counselling, peer tutoring, and interventions addressing socioeconomic difficulties improve both academic success and general well-being in TVET students. Students also advocate for more tutoring and the appointment of assistant lecturers, particularly in engineering departments, to improve performance and reduce dropout rates [15]. Additionally, Ramuthivheli [23] emphasises the

significance of enhancing teaching, mentorship, and institutional responsiveness to suit student requirements, highlighting the direct relationship between perceived academic service quality and student satisfaction and loyalty.

The reviewed literature highlights a combination of theoretical, institutional and practical factors influencing student retention in vocational education. Bean and Metzner's model offers a fitting framework for understanding the realities of NC(V) engineering students, particularly regarding financial and environmental barriers. Evidence also points to high dropout rates driven by poor attendance, limited access to support services, and inconsistent policy implementation. Addressing these issues through targeted, context-specific retention strategies can significantly enhance student persistence and institutional performance within the TVET sector.

3 METHODOLOGY

According to Creswell [24], qualitative research is an approach for exploring and understanding the meaning individuals or groups ascribe to a social or human problem. In line with this definition, this study adopted a qualitative research approach to explore and analyse the effectiveness of current retention strategies in TVET colleges in Gauteng province. This qualitative component forms part of a broader mixed-methods doctoral study involving students and senior academic staff. This paper presents a stand-alone inquiry focusing specifically on college-level retention strategies from college management perspectives.

3.1 Population and Sampling

The study was conducted across four public TVET colleges in Gauteng province. The target population included campus managers, Heads of Department (HODs), or senior lecturers responsible for academic and student support processes in NC(V) engineering programmes. Participants were purposively selected based on their strategic roles, operational responsibilities, and in-depth knowledge of retention strategies, challenges, and interventions implemented in TVET colleges. Purposive sampling is a technique used to identify cases or experts who have a wealth of knowledge that may be used to shed light on the research issues [25]. Four public TVET college campuses offering NC(V) engineering programmes were purposively selected, with two participants interviewed at each campus. Their insights were instrumental in understanding the effectiveness of existing retention strategies, institutional barriers, and areas that need improvement.

This paper focuses on the qualitative component of the broader doctoral study, which employed a mixed-methods design incorporating student and academic staff perspectives. Although quantitative survey findings from the wider study are not presented here, they provided complementary background during interpretation, helping to contextualise the management perspectives discussed in this study within the broader institutional and student context.

3.2 Data collection

Data were collected through semi-structured interviews using open-ended questions, enabling in-depth exploration of participants' perspectives on existing retention strategies and their effectiveness in TVET colleges. Interviews lasted an average of 35 minutes and were conducted in person at each college campus. The study engaged TVET college management staff to enhance the rigour of expert input by incorporating elements of the Delphi method. These participants were considered knowledgeable informants in student retention within TVET colleges, and their insights contributed to a deeper understanding of college retention strategies, implementation gaps and areas requiring intervention.

3.3 Data analysis

Thematic analysis was employed to identify key patterns in the interview data. ATLAS.ti software was used to support the coding and organisation of themes, ensuring that findings were directly

grounded in participants' narratives and closely aligned with this study's objective of analysing the effectiveness of retention strategies in TVET colleges.

Ethical clearance was obtained from the university's research ethics committee. The four participating TVET colleges also granted permission. All participants provided informed consent, and confidentiality and anonymity were strictly maintained for individuals and TVET institutions.

4 FINDINGS

4.1 Participants' profile

The study engaged eight participants across four public TVET college campuses in Gauteng province. These participants held strategic roles in delivering and managing NC(V) engineering programmes. Their professional experience ranged from one to fifteen years. The participant group included campus managers and HODs or senior lecturers. Most participants held education-related qualifications at diploma, degree, or postgraduate level, including master's and honours qualifications. This diversity allowed for informed perspectives on student retention strategies, challenges, and institutional dynamics.

4.2 Retention strategies in practice

The analysis of existing retention strategies in NC(V) engineering programmes was structured using three approaches: (1) a word cloud analysis to visualise the most frequently mentioned terms; (2) a thematic concept map to categorise key strategies and their relationships; and (3) an analysis of selected participant quotes to deepen the understanding of college retention practices and their effectiveness. These approaches provided a comprehensive picture of how retention strategies are perceived, implemented and experienced within TVET college settings.

4.2.1 Analysis of findings from the word cloud on student retention strategies

Figure 1 presents a word cloud highlighting the most commonly mentioned terms from interview responses, including 'students', 'lecturers', 'attendance', 'support', 'financial', 'policy', and 'assist'. These terms indicate a dominant focus on academic support, student monitoring, and institutional assistance. The prominence of 'financial' and 'support' highlights their importance as retention strategies, addressing immediate needs and long-term student support. This finding aligns with Xu and Webber [26], who identified financial stress as a significant barrier to student persistence in higher education. The word cloud suggests that effective retention strategies in NC(V) engineering programmes require a combination of classroom-level interventions, such as lecturer engagement and attendance monitoring, and institutional measures such as policy enforcement and financial assistance.

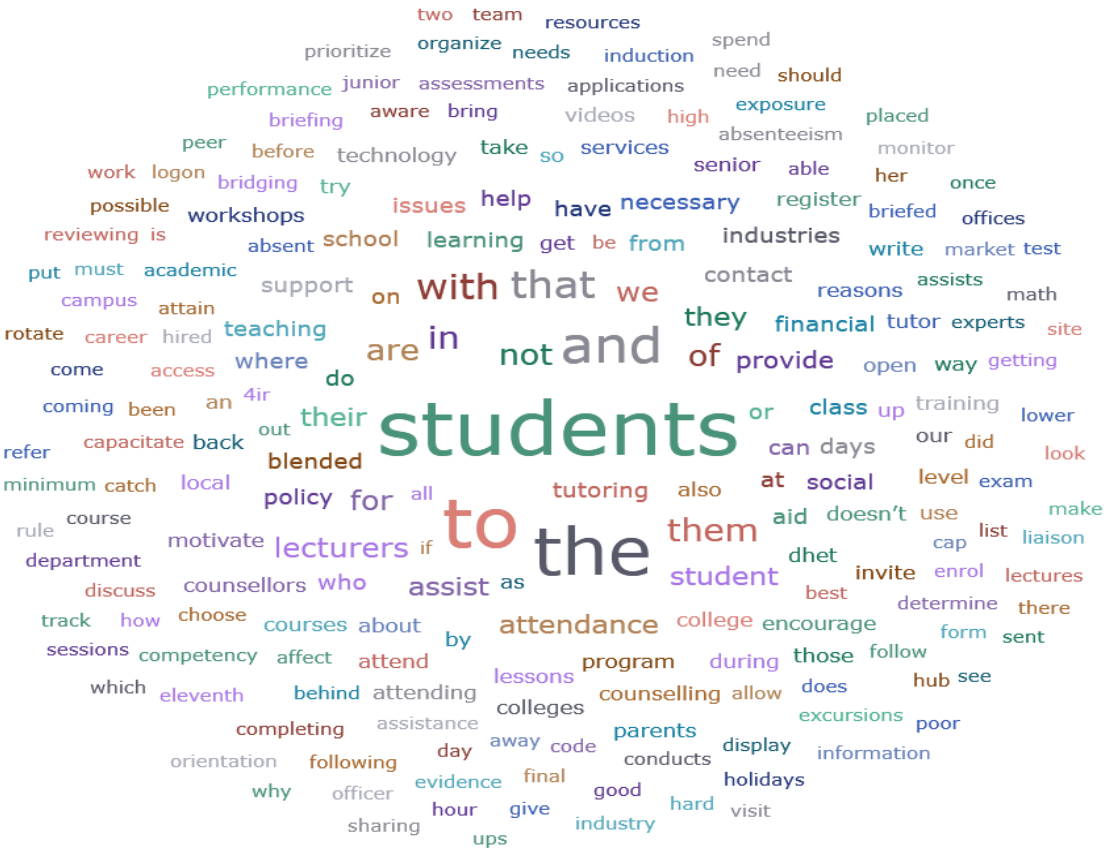

Figure 1: Key themes on existing retention strategies in TVET colleges

4.2.2 Analysis of the concept map for student retention strategies in TVET colleges

Figure 2 presents an overview of key retention strategies currently implemented or under discussion in TVET colleges. These include college-level interventions such as attendance monitoring, tutoring, counselling, financial aid, career day sessions, industry visits, technology integration, selective admissions, and the 80% attendance policy. The map shows how these strategies are interconnected, showing that student retention in NC(V) engineering programmes results from coordinated actions rather than isolated interventions. The findings suggest that attendance monitoring supports policy enforcement, while tutoring and counselling address academic and personal challenges that may lead to student dropout. The concept map also highlights that effective retention requires alignment between academic, personal, and institutional support and coordination between national policies and college initiatives to address the realities faced by NC(V) engineering students.

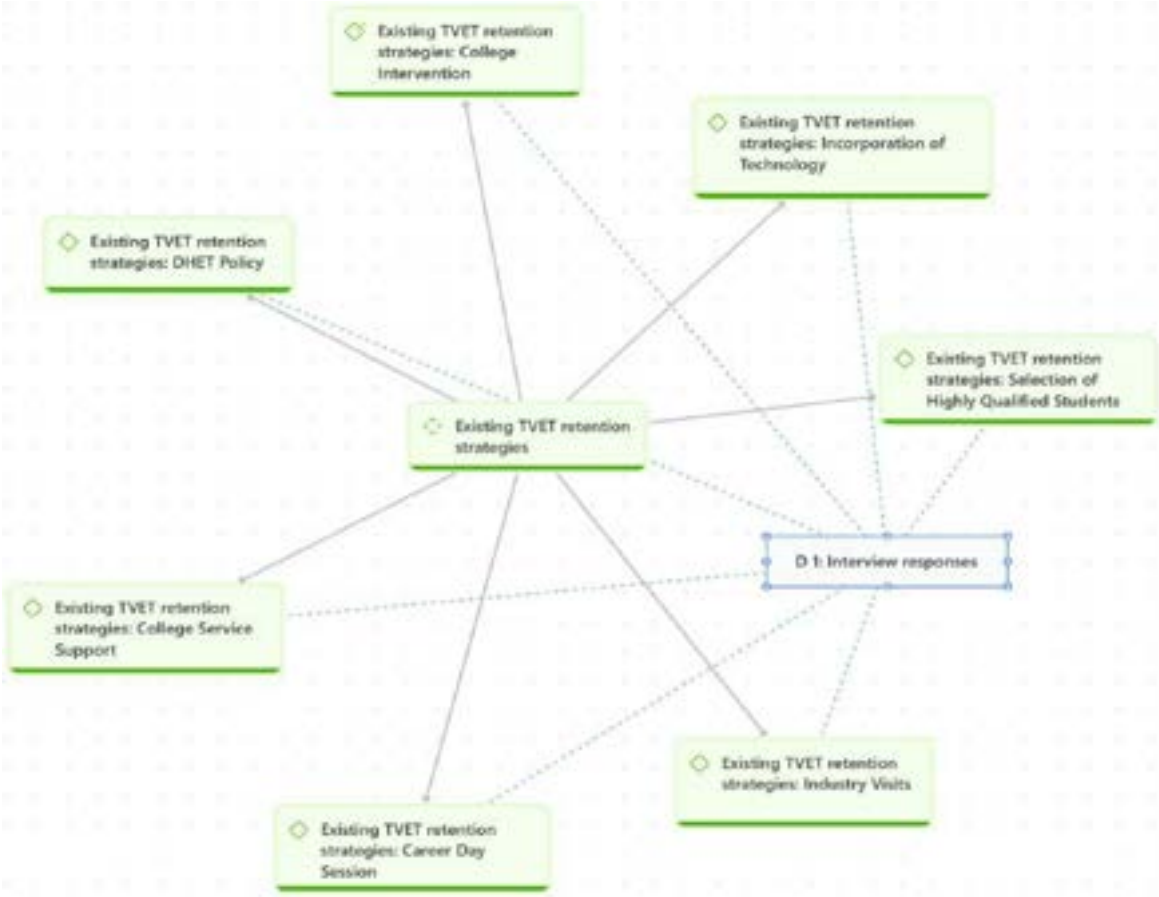

Figure 2: Thematic map for existing retention strategies in TVET colleges

4.2.3 Analysis of participants' quotes on retention strategies

A thematic analysis of participant quotes revealed key strategies and limitations shaping student retention in NC(V) engineering programmes in public TVET colleges. Eight key themes were identified and are discussed below, supported by selected participant quotes and relevant literature.

I. Career day sessions

Career day events were noted as a proactive but underutilised strategy for improving student awareness about NC(V) programmes and related career prospects. Participants emphasised the value of these sessions in helping students make informed study choices. Participant 3 stated, *"A career day would assist with sharing information about TVET colleges in high schools. We visit neighbouring schools once a year and conduct briefing sessions."*

However, the infrequency of these events was raised as a limitation. Participant 8 noted, *"Currently, we only have speakers from industry once every two years, but this should happen annually, or even twice a year."*. This suggests a need for consistent outreach activities to align student expectations with the realities of NC(V) engineering programmes. This is supported by Garcia [27], who notes that students need guidance and support from administrators, lecturers and support staff to navigate the new college environment and achieve their academic goals.

II. Financial support and NSFAS funding

Financial aid was consistently identified as a key retention strategy; however, delays in NSFAS payments and a lack of alternative funding were reported as significant concerns. One participant stated, *"NSFAS must pay students timeously, because most students come from households*

where parents are not working.". Such delays contribute to financial instability, absenteeism and dropout risk. These challenges are consistent with Bean and Metzner's student attrition model, highlighting the impact of external factors such as financial hardship on student persistence [28]. Matsolo, Ningpuanyeh and Susuman [29] also report that 35% of students fail to complete their qualifications due to financial difficulties. These findings highlight a need for DHET and TVET colleges to ensure timely and reliable NSFAS disbursements, particularly for transport, food and accommodation support.

III. College-level interventions

Participants described a range of interventions such as attendance tracking, academic support, tutoring and bridging programmes as potential retention strategies, but they suffered from inconsistent implementation. For attendance, class registers are used to monitor attendance of NC(V) engineering students; however, effective communication with parents remains a challenge due to students providing their own contact details during registration. Tutoring initiatives exist on some TVET college campuses, particularly in subjects like mathematics and drawing, but they are underutilised by students who need them most. Bridging programmes were also mentioned to have been implemented by some TVET colleges to support students transitioning from high schools into the NC(V) engineering programmes. However, opinions on their effectiveness differed, with some participants questioning whether they provide sufficient support or prolong the NC(V) study period.

IV. College support services

Support services were reported as an essential retention strategy for addressing both academic and personal challenges faced by NC(V) students. Participant 2 shared, *"We have a student support services department, where we have social workers to assist with their social issues, and we have financial aid offices that help students with their financial aid issues."*. Participant 3 added, *"We refer students experiencing personal difficulties, such as family instability, to counsellors hired by DHET and placed in colleges"*. However, the limited availability of these services and staff shortages hinder the effectiveness of this retention strategy. Another participant noted, *"We have a learner support department that can assist, but it takes time to respond to the needs of students. I think the challenge is that the learner support department is understaffed"*. These findings echo Badenhorst and Radile's [3] earlier research, which found that support services in TVET colleges may be dysfunctional, underused or poorly marketed. Dunn [7] similarly points to institutional issues such as poor support from academic staff, feelings of isolation and limited awareness of support services as key barriers to retention.

V. DHET policy implementation

The DHET 80% punctuality and attendance policy is recognised as a retention strategy that promotes student accountability, but implementation was described as inconsistent. Participant 8 shared, *"Students who fail to meet attendance requirements are given a chance to explain their absence, and in most cases, they are eventually allowed to write exams."* This suggests that while DHET policies exist to promote student engagement, their impact depends heavily on how consistently they are implemented at the TVET campus level. The literature supports these findings. Nzembe [13] found that although the policy clearly states that the minimum attendance requirement is 80%, students still attend irregularly, often without any consequences. Myataza and Mokoena [2] similarly reported inconsistent policy implementation, where students with poor attendance are still allowed to write the final exams

VI. Integration of technology in teaching and learning

Technology-enhanced learning was identified as an emerging retention strategy by one participant. Participant 7 remarked, *"Management encourages the use of technology in teaching to keep students engaged. However, some lecturers resist due to age or a lack of motivation.*

Resources like laptops and monthly data are available, but adoption remains slow". Resistance to technology use and infrastructural constraints hinder efforts to make blended learning a reliable support strategy for retention. These challenges are echoed by Dunn [7], who identified limited learning technology as a significant obstacle in student retention and institutional innovation.

VII. Industry visits

Industry exposure was highlighted by one participant as a valuable engagement strategy for motivating students and demonstrating the relevance of their NC(V) engineering studies. Participant 2 explained, *"We organise academic excursions, allowing students to visit industries. Senior students are also placed in industries for short-term exposure"*. Although this strategy can potentially motivate students, it appears limited or underdeveloped in TVET colleges. There is a need for TVET colleges to strengthen their partnerships with the industry to improve relevance and student motivation.

VIII. Student admission practices

Only one participant mentioned adopting stricter student admission criteria for NC(V) engineering programmes as another strategy to improve retention. Participant 9 stated, *"We try to admit students who have performed well in Grade 10 or 11, as previous data shows that they perform better than those with only Grade 9 qualifications"*. This approach may improve academic outcomes; however, it risks excluding underprepared students who might succeed with adequate support. Badenhorst and Radile [3] observed that academically weaker students often struggle in mixed-level classes, highlighting the need for inclusive support strategies.

5 CONCLUSION

This study explored existing retention strategies in NC(V) engineering programmes across selected public TVET colleges. The findings revealed that interventions such as attendance monitoring, academic support, NSFAS funding, career day sessions, and DHET policy enforcement are in place; however, their effectiveness is limited by fragmented implementation, inconsistent monitoring, and operational inefficiencies. In most cases, these interventions exist only on paper, remain informal or are unevenly implemented, which reduces their ability to meaningfully support student persistence in NC(V) engineering programmes.

Insights from campus managers and senior academic staff highlighted operational gaps, including delays in financial aid disbursements, under-resourced support services and inconsistent enforcement of the 80% attendance policy. Although initiatives such as industry exposure and technology integration in some TVET colleges reflect emerging innovation, their limited implementation has yet to produce a broader impact across TVET campuses.

Viewing retention as a process system highlights how inefficiencies in attendance monitoring and student support services reduce throughput and compromise NC(V) programme completion. Strengthening these processes through comprehensive academic support systems and psychosocial interventions can improve resource utilisation and successful student outcomes within the TVET sector.

The findings suggest that most current strategies lack the scale, structure and coordination required for lasting retention improvement. To truly *make waves* and achieve sustainable impact in the TVET sector, retention strategies must be formalised, aligned across campuses and continuously reviewed and improved. A more structured, student-centred and efficient retention system grounded in continuous improvement and process integration can enhance student outcomes and build long-term stability in NC(V) engineering programmes.

ABSTRACT

This review investigates the evolving challenges and solutions related to railway capacity, with a particular focus on infrastructure-related constraints and the application of data-driven technologies. By analyzing literature from 2017 to 2025, the study identifies four core infrastructure domains, telecommunications, signaling, electrification, and permanent way-as central to capacity optimization. It highlights the impacts of defects, maintenance inefficiencies, cyber threats, and climate-related disruptions on system performance. The paper evaluates the role of smart maintenance approaches, including predictive analytics and digital twins, in enhancing resilience and reliability. It further explores emerging paradigms such as dynamic capacity modelling, intelligent routing, and the integration of real-time data into operational planning. The study concludes that a shift from reactive infrastructure expansion to proactive digital management offers a sustainable path to capacity optimization. Insights provided aim to support infrastructure managers, policymakers, and researchers in the transition to smarter and more resilient railway systems.

Keywords: Railway capacity, Infrastructure optimization, Predictive maintenance.

* Corresponding Author

1 INTRODUCTION

Railway infrastructure plays a pivotal role in supporting national and regional economies through the efficient movement of goods and passengers. As demand for rail services continues to grow, optimizing infrastructure utilization has become a critical concern. Infrastructure utilization refers to the effective use of railway assets, such as tracks, platforms, and rolling stock, often measured by the ratio of train paths operated to the maximum capacity the infrastructure can accommodate. Inadequate utilization not only represents inefficiencies in resource deployment but also results in significant economic losses, particularly in countries heavily reliant on rail freight. In South Africa, this inefficiency is clearly reflected in the sharp decline in rail freight volumes, which dropped from 226 million tonnes in 2017 to just over 150 million tonnes by 2023, largely due to infrastructure failures, maintenance backlogs, and operational disruptions [1]. Globally, similar issues have been reported. For instance, in Sweden, a study of over 225,000 scheduled maintenance activities revealed that frequent but inconsistently documented trackwork had a considerable impact on capacity availability and scheduling reliability [2]. The lack of integrated digital maintenance records was highlighted as a key barrier to effective capacity planning. Railway capacity utilization is essential not only for minimizing delays but also for enhancing the resilience and service quality of rail systems. Emerging research has demonstrated that well-managed infrastructure utilization can lead to more stable network operations, improved safety outcomes, and better long-term cost efficiency [3]; [4]. Conversely, infrastructure-related failures, whether due to outdated signaling systems, telecommunications outages, electrical faults, or permanent way degradation, undermine operational efficiency and compromise system robustness [5].

Recognizing these challenges, the present review seeks to investigate the factors within railway infrastructure that influence capacity utilization, with a specific focus on four interdependent disciplines: telecommunications, electrical systems, signalling, and the permanent way (track). These infrastructure elements form the backbone of railway operations, collectively determining the reliability, safety, and throughput of the network. The objectives of this review are fourfold. First, it aims to identify the critical infrastructure components that directly impact railway capacity utilization. Second, it examines the common failure modes associated with these components and assesses their operational consequences. Third, it evaluates the effectiveness of various maintenance strategies specifically, reactive, preventive, and predictive maintenance in mitigating infrastructure-related disruptions. Lastly, the review synthesizes recent literature concerning the definitions of capacity, the role of digital transformation, and the adoption of system-level management approaches that enable data-driven decision-making and long-term capacity optimization.

2 METHODOLOGY

This study employed a structured literature review to explore current trends, challenges, and innovations in railway capacity and infrastructure management, focusing on publications from 2017 to 2025. Academic databases such as Scopus, ScienceDirect, IEEE Xplore, and Google Scholar were searched using Boolean operators to refine the results. Key search strings included combinations like "railway capacity" AND "infrastructure," which yielded 95 records; "railway maintenance" AND ("predictive" OR "preventive"), with 62 records; 54 records for "railway digitalization" AND "smart systems"; and 39 records for "railway signaling" AND "telecommunications." Inclusion criteria encompassed English-language peer-reviewed journal articles and conference papers addressing railway capacity, technological advancements, or smart maintenance strategies. Exclusion criteria excluded non-academic sources, non-English texts, and studies not focused on the railway sector. From an initial yield of approximately 250 records, 120 were shortlisted after title and abstract screening, with 42 selected through full-text review based on thematic relevance and methodological rigor.

Extracted data included author, publication year, geographic focus, rail type (passenger, freight, or mixed), infrastructure domain (track, signaling, telecoms, or electrification), and the nature of the capacity or maintenance approach discussed. The final selection was subjected to thematic analysis to synthesize patterns, draw comparative insights, and identify emerging strategies aimed at enhancing rail system performance and resilience

3 RESULTS AND DISCUSSION

3.1 Railway Capacity

Railway capacity, a critical determinant of operational efficiency and service reliability, refers to the number of train paths that can be scheduled over a defined rail infrastructure segment within a specific time frame. Capacity is inherently dependent on a variety of factors, including train heterogeneity, route design, operational headways, and the desired level of robustness within the system [4]. Rather than a fixed value, capacity is dynamic and context-sensitive, influenced by technical, organizational, and environmental conditions. [4] emphasize that capacity is best understood as a function of how infrastructure is used, rather than a singular, static metric. This aligns with contemporary approaches that define capacity in multiple layers: theoretical, maximum, and practical. Theoretical capacity refers to the ideal scenario of uninterrupted and homogeneous train operations, while maximum capacity introduces real-world diversity in train types and operations, albeit without including buffer times. Practical capacity, on the other hand, incorporates scheduled buffers, dwell time, and allowances for disruptions, making it the most realistic and usable form of capacity in modern operations [6].

Recent research prioritizes real-time and data-driven models to redefine capacity estimation. For instance, [7] demonstrate how reinforcement learning algorithms can dynamically adjust train schedules to improve network fluidity, thereby increasing practical capacity without major infrastructure upgrades. This reflects a paradigm shift from infrastructure-heavy expansion to intelligent network optimization. Similarly, [8] propose a data-driven framework to identify bottlenecks and evaluate station-line capacity interactions using transit performance datasets. Their work reveals that digital models can identify systemic inefficiencies invisible to traditional planning methods. In parallel, digital twin's virtual simulations of railway systems are gaining traction for capacity scenario testing and resilience modeling [9] These tools allow for predictive responses to demand variability and disruptions, enhancing overall network agility.

Smart maintenance strategies further support practical capacity enhancement. Predictive maintenance, underpinned by Internet of Things (IoT) sensors and machine learning, allows railway operators to anticipate and prevent failures before they impact scheduling [10] [11], This reduces unplanned downtime and preserves the buffer allowances built into practical capacity models. Moreover, capacity utilization metrics are increasingly framed within safety and service quality thresholds. [12] emphasize that overutilization exceeding 85% may compromise schedule reliability, while underutilization signals inefficiencies. Their study found that coordinated routing strategies can reduce overutilization risks by balancing train flow across alternative paths and time windows, maintaining capacity within optimal thresholds. Advanced signaling and control systems also play a crucial role. Modern implementations of Communication-Based Train Control (CBTC) and European Rail Traffic Management System (ERTMS) have proven effective in reducing headways, increasing line throughput, and improving responsiveness to demand changes [13]. These systems enhance the interoperability of trains and infrastructure, contributing directly to the flexible management of capacity. Furthermore, capacity planning now incorporates multimodal integration and climate resilience. According to [14], climate-induced disruptions such as extreme heat or flooding must be included in capacity planning algorithms to ensure long-term sustainability

and robustness.

In summary, recent literature frames railway capacity not only as a physical constraint but as an outcome of real-time data integration, smart maintenance, and digital control. The focus is shifting from adding new infrastructure to optimizing existing assets through intelligent systems and predictive analytics. This evolution reflects a broader transition toward smart mobility and sustainable railway operations.

3.2 Railway Capacity Challenges

While the theoretical and practical frameworks of railway capacity provide essential benchmarks for network planning, real-world operations are often constrained by a range of persistent and emerging challenges. These challenges, both technical and systemic, have a direct and measurable impact on the ability of rail infrastructure to operate at or near its designed capacity. This section presents a categorized summary of the most pressing capacity challenges currently facing the railway sector, with emphasis on recent findings from international and regional studies published between 2017 and 2025. The table synthesizes five primary challenge areas track defects, maintenance scheduling instability, security-related disruptions, overutilization thresholds, and environmental factors highlighting their descriptions, impacts on capacity, and supporting literature. Understanding these barriers is critical for developing more robust, adaptive, and data-informed strategies for capacity optimization.

Table 1: Key Railway Capacity Challenges and Their Specific Impacts (2017–2025)

Challenge Area	Description	Impact on Capacity
Track Defects [15]	Structural failures, such as inadequate strength and rail buckling, reduce track integrity and require temporary speed restrictions or line closures	Reduces operational speed, introduces delays, and limits train throughput.
Maintenance Scheduling Instability [16]	Frequent last-minute changes to schedule maintenance activities lead to reduced capacity and train delays.	Decreases available train paths and increases operational unpredictability.
Security Breaches and Vandalism [17]	Theft, vandalism, and signal tampering result in derailments, collisions, and service disruptions	Interrupts service delivery and lengthens repair response times.
Overutilization of Capacity [12]	Utilization beyond 85-90% reduces network flexibility and increases the risk of cascading delays.	Strains network reliability and reduce the ability to absorb minor disturbances
Environmental Disruptions [14]	Extreme weather events such as heat waves and floods degrade infrastructure and disrupt planned operations.	Forces reactive rerouting and increases the need for buffer time in timetables.

As table 1 illustrates, railway capacity limitations stem from a multifaceted combination of infrastructure degradation, operational inefficiencies, and external threats. Technical failures such as track defects and unstable maintenance scheduling remain fundamental obstacles to maintaining reliable throughput. Meanwhile, socio-economic challenges, including theft and vandalism, continue to disproportionately affect networks in regions such as South Africa. Moreover, the risks associated with both under- and overutilization of capacity underscore the need for dynamic and context-sensitive management frameworks. Climate-related disruptions further compound these issues, signaling a need for resilience-based planning.

Addressing these challenges requires an integrated approach that combines predictive maintenance, real-time monitoring, digital planning tools, and investment in system-wide resilience. Informed by current evidence, these insights should guide infrastructure managers and policymakers in their pursuit of a more reliable and high-capacity rail system.

3.3 Railway Infrastructure

Following the discussion on capacity challenges, it is essential to examine the core infrastructure systems that directly influence railway performance.

Railway infrastructure comprises several interdependent components that enable safe, efficient, and high-capacity operations. Railway infrastructure is a complex system that integrates physical and digital components to support the safe and efficient movement of trains. As demand for speed and capacity grows, modern networks rely on interconnected subsystems such as track (permanent way), signaling, electrical systems, and telecommunications to maintain reliability and performance [4]; [18]. The permanent way includes rails, sleepers, ballast, and switches, forming the structural backbone that guides train movement [19]. Signalling systems manage train separation, enforce safety, and optimize track utilization [20]. Electrical systems, including overhead traction and substations, supply power and are increasingly supported by smart monitoring technologies to enhance reliability [21]; [1] Meanwhile, telecommunications infrastructure now evolving to 5G and FRMCS enables real-time communication, control, and diagnostics essential to modern operations [22]. Because these systems are interdependent, a failure in one can disrupt the entire network. Holistic infrastructure management through integrated planning, digital systems, and predictive maintenance is therefore essential to sustaining capacity and service delivery [9].

3.3.1Telecommunications (Telecoms)

Telecommunications systems are essential to modern railway operations, enabling real-time communication between control centers, trackside equipment, and rolling stock. The transition from legacy systems such as GSM-R to advanced platforms like 5G and the Future Railway Mobile Communication System (FRMCS) reflects a shift toward more intelligent, high-capacity, and latency-reduced networks [23]. These systems support operational efficiency, safety signalling, passenger information, and data-driven maintenance protocols. However, increased reliance on digital infrastructure introduces new risks, particularly cyber threats. Recent studies highlight vulnerabilities to ransomware attacks, signal jamming, and communication failures that can lead to train delays or system-wide shutdowns [22]. Telecom failure not only disrupts train control but also undermines the performance of automated signalling and traffic management systems, thereby reducing network reliability and capacity.

3.3.2 Permanent Way (Perway)

The permanent way comprises the physical track infrastructure, including rails, sleepers, fastenings, ballast, switches, and crossings, that ensure the structural stability and alignment required for safe and efficient train operations [24]. Defects such as rail breaks, fastening fatigue, or misaligned sleepers significantly reduce permissible speeds and can cause derailments, resulting in capacity loss and safety concerns. Studies show that broken rails account for a substantial proportion of derailments in freight operations, with over 15% of such incidents linked to these defects [25].

Ballast degradation, caused by abrasion and fouling, leads to poor drainage and track instability. The mechanical properties of ballast are influenced by particle size, shape, and composition, directly affecting performance under dynamic loads [26]. Sleepers, when damaged, can lead to rail misalignment and necessitate temporary speed restrictions [27]. Similarly, turnouts (track switches) critical for train routing are susceptible to mechanical wear, especially under high-frequency traffic and complex vehicle dynamics [28]. Turnout failures in high-density networks can cause major operational delays; thus, redundancy and regular maintenance are essential for capacity assurance [29].

3.3.3 Signaling

Signaling systems maintain safe train separation and coordinate train movement across the network. Modern signalling uses both fixed-block and moving-block principles, with technologies such as centralized train control, interlocking, and automated route setting. Excessive headways, often resulting from conservative signal placement or system failures, limit throughput and degrade capacity [30]. Interlocking systems, whether relay-based or computer-based, manage routing logic and safe track occupancy by integrating data from signals, axle counters, and track circuits [31].

Failures in signaling systems due to equipment degradation, cybersecurity breaches, or software errors often lead to manual overrides, increasing response times and reducing line efficiency. For example, signalling failures in South Africa have been linked to chronic underfunding and inadequate spares and staffing, posing a threat to operational continuity [1]; [32] further emphasized that enhancing the reliability of sub-systems like axle counters and track circuits is crucial for improving train detection accuracy and, by extension, capacity reliability. Interoperability among subsystems remains a key technical challenge, requiring integrated systems engineering to ensure resilience and seamless operation.

3.3.4 Electrical Systems

Electrical systems are a critical backbone of railway operations, ensuring the uninterrupted supply of power for train propulsion and auxiliary systems. Core components such as overhead line equipment (OLE), catenary systems (OCS), pantographs, and traction substations work together to deliver consistent electrical current to moving trains. The OLE and OCS transmit power through contact wires, which must maintain mechanical and electrical integrity despite variable speeds, environmental stress, and vibration. Factors like wire tension, pre-sag, and gradient play crucial roles in performance [21]. Pantographs, mounted on trains, dynamically collect current, and their interaction with the catenary affects energy transfer efficiency. Failures in these systems due to wear, weather damage, or poor design can result in arcing, contact loss, and service delays [33]. Traction substations convert and regulate high-voltage grid electricity into usable power for trains. Substation failures can cause cascading delays across entire corridors, particularly in high-density urban systems [34]. While diesel locomotives can serve as backup during outages, electric traction remains more energy-efficient and environmentally sustainable, making its reliability a top priority [1] to enhance system resilience, smart monitoring systems are increasingly deployed to track load behavior, detect anomalies, and guide predictive interventions.

3.4 Railway Infrastructure Maintenance Management

Maintenance is essential for ensuring rail infrastructure reliability, minimizing downtime, and sustaining capacity. Poor maintenance leads to service disruptions, increased safety risks, and higher lifecycle costs. [35] established a direct link between high-capacity utilization and elevated maintenance demands, as heavily used infrastructure experiences accelerated wear. Proactive maintenance planning is therefore vital to preventing failures and preserving operational efficiency. Railway maintenance typically follows three approaches: reactive, preventive, and predictive.

3.4.1 Reactive Maintenance

Reactive maintenance, or run-to-failure, involves addressing faults only after breakdowns occur. While it reduces immediate staffing and planning demands, it increases the likelihood of sudden service interruptions and expensive emergency repairs. It is often associated with lower reliability and reduced capacity in the long term [36];[37].

3.4.2 Preventive Maintenance

Preventive maintenance (PM) adopts a scheduled, time-based approach to inspections and repairs, reducing the risk of unexpected failures. It improves asset longevity, ensures schedule reliability, and supports optimal capacity utilization [38]; [39]. However, PM must be carefully planned; overly frequent interventions can become costly, while poor scheduling may miss critical failure points [40; 41]

3.4 3 Predictive Maintenance

Predictive maintenance (PdM) represents the most advanced strategy, using data analytics, sensors, and machine learning to anticipate failures before they occur. By monitoring the condition of tracks, rolling stock, and components in real time, PdM enables timely intervention, reducing unplanned downtime and enhancing system reliability [10];[11].PdM not only improves asset performance but also contributes significantly to capacity optimization by minimizing operational disruptions [42].

This review demonstrates that railway capacity is a multifaceted and dynamic concept shaped by infrastructure design, operational strategies, and technological integration. Emerging digital tools such as predictive maintenance, data-driven scheduling, and advanced signaling significantly enhance practical capacity without expanding physical assets. Persistent challenges, including infrastructure failures, cyber threats, and environmental disruptions, necessitate resilience-based and intelligent planning. A shift from reactive to proactive management underpins sustainable railway efficiency. Ultimately, optimizing capacity requires systemic coordination across disciplines to ensure reliable, high-performance rail networks.

4 CONCLUSION

This paper reviewed the multifaceted nature of railway capacity, highlighting the integral role of infrastructure systems, namely telecommunications, signalling, electrification, and permanent way, in shaping operational performance. It has been shown that capacity is not a static metric, but a dynamic outcome influenced by technical reliability, maintenance strategies, and real-time operational responsiveness. Challenges such as infrastructure degradation, overutilization, cyber vulnerabilities, and climate-related disruptions continue to constrain system reliability and throughput. However, advancements in predictive maintenance, digital modelling, and intelligent control systems offer promising avenues for enhancing capacity without the need for extensive infrastructure expansion. The study underscores the necessity for integrated, data-driven approaches that enable adaptive planning and resilience across the rail network. Moving forward, stakeholders must prioritize investment in digital infrastructure, robust maintenance regimes, and cross-disciplinary collaboration to unlock the full potential of modern railway systems. Such efforts are essential for creating agile, sustainable, and high-capacity railways suited for 21st-century demands.

ABSTRACT

Operational inefficiencies in the filling stations of a yoghurt manufacturing plant have resulted in production delays, product inconsistencies, and rising operational costs. Although filling stations play a critical role in dairy production, limited research has focused on their specific inefficiencies, particularly within yoghurt manufacturing. This study aimed to identify the root causes of these inefficiencies and propose practical solutions. A qualitative observational approach was employed to assess the plant's filling station processes. Findings revealed that key inefficiencies stemmed from inconsistent raw material flow, frequent machine calibration errors and inadequate maintenance practices. To address these challenges, the study recommends enhanced machine calibration, predictive maintenance scheduling, and integration of real-time monitoring systems. Implementing these strategies could improve productivity, reduce waste, and ensure consistent product quality. This research contributes to improving operational efficiency in dairy manufacturing and offers practical strategies for similar food production industries.

Keywords: Yoghurt manufacturing, Operational inefficiencies, Filling station

1 INTRODUCTION

In today's highly competitive and quality-driven food industry, optimizing business systems to enhance productivity is critical for maintaining both competitiveness and profitability [1],[2]. The yoghurt manufacturing sector faces unique operational challenges, such as the need for precise process control to ensure product consistency and compliance with food safety standards [3]. Industry studies have shown that inefficiencies in daily production, including outdated machinery, inconsistent quality control, and prolonged equipment downtime, can lead to increased costs, reduced output, and lower productivity [4], [5].

Operational inefficiencies are especially apparent at the filling stage of yoghurt production, where the final product is packaged for distribution. Inefficiencies reported globally in similar settings include prolonged machine downtime, low employee efficiency, and a high proportion of off-specification products, all of which result in extended production cycles, material waste, and elevated costs [6],[7]. Although inefficiencies in food manufacturing have been the subject of several studies, there is limited research focused specifically on yoghurt plant filling stations, even though these stations are crucial for determining throughput, product quality, and overall profitability.

Addressing these challenges requires a systematic, holistic approach using industrial engineering techniques, such as preventive maintenance, workflow optimization, and real-time quality monitoring, to improve resource utilization, enhance productivity, and reduce waste [8]. Therefore, it is evident that inefficiencies in filling stations not only represent a considerable economic loss, but also reduce the operational profitability, resource utilization and the overall production efficiency. This study responds to the gap by analysing the root causes of inefficiencies at yoghurt filling stations and proposing strategies to improve performance.

1.2 Aim of the research

This research aimed to analyse the root causes of operational inefficiencies in the filling station of a yoghurt manufacturing plant in South Africa and to propose strategies for improving overall efficiency. By addressing these inefficiencies, the study seeks to enhance productivity, minimize waste and improve profitability within the dairy production sector.

1.3 Research Question

In the filling station of the yoghurt manufacturing plant under study, operational inefficiencies such as prolonged machine downtime, inconsistent product quality have been observed to cause delays, increased waste and higher operational costs. These challenges reduce overall productivity and negatively impact the plant's profitability and resource utilization. To investigate these issues and identify solutions, this study was guided by the following research questions:

What are the root causes of operational inefficiencies in the filling station of the yoghurt manufacturing plant in South Africa, and how can these inefficiencies be addressed to improve production efficiency?

2 LITERATURE REVIEW

2.1 Understanding Operational Efficiency in Production Processes

Operational efficiency refers to the optimization of organizational processes to achieve higher productivity while minimizing costs and sustaining quality performance. According to Araujo [9], operational efficiency is an organization's ability to produce goods and provide services in the most economical way, while maintaining high standards of excellence and customer satisfaction. Operational efficiency is fundamental, as it enables output-to-input assessments that determine productivity and profitability [10]. According to Chen et al. [11], in today's

manufacturing environment, technological innovation and the adoption of Industry 4.0 technologies are recognized as major drivers of efficiency, enabling real-time monitoring, automation, and data-driven decision-making.

2.2 Theoretical Frameworks of Operational Efficiency

Theoretical frameworks provide the foundation for understanding and improving operational efficiency. Cagliano, Grimaldi, and Rafele [12] emphasize that selecting appropriate management models and tools is essential for sustaining improvements in organizational processes. These frameworks often draw from methodologies such as Lean Manufacturing (LM), Total Quality Management (TQM), and Six Sigma, which are widely acknowledged as proven approaches for enhancing efficiency and eliminating waste in production systems [13].

2.2.1 Overview of Lean Manufacturing and Its Principles

Lean manufacturing (LM) is a production philosophy centred on doing more with less by reducing waste and maximizing value creation [14]. Womack and Jones [15] define LM as a systematic approach to eliminating non-value-added activities while improving responsiveness to customer demand. Dhiravidamani et al. [16] note that the primary goal of LM is to deliver high-quality products with minimal waste in terms of resources, time, and effort. Waste reduction is considered the cornerstone of LM, targeting excess inventory, unnecessary motion, waiting times, overproduction, and defects [17].

Practical tools within LM include pull production systems, 5S workplace organization, Total Productive Maintenance (TPM), Just-In-Time (JIT), Standard Work, Value Stream Mapping (VSM), Kanban, and Kaizen [18]. These methods not only reduce inefficiencies but also foster a culture of continuous improvement.

According to Moen & Norman [19], The Plan-Do-Check-Act (PDCA) cycle, originally developed by Shewhart and later refined by Deming, is often integrated into lean thinking to support iterative, evidence-based improvements. According to Deming [20] PDCA emphasizes continuous problem identification, experimentation, and refinement, making it highly relevant for qualitative research focused on uncovering root causes of inefficiencies. By combining LM tools with the PDCA cycle, organizations can systematically identify, analyse, and eliminate sources of waste, leading to sustained operational efficiency.

2.2.2 Utilizing Total Quality Management (TQM) and Root Cause Identification

Before proposing any solution, it is necessary to understand the primary issue and its causes. To make the task simpler, a systematic approach should be used to identify and eliminate the root source of the issue. Another key framework in addressing operational inefficiencies is Total Quality Management (TQM), which emphasizes continuous improvement and customer satisfaction through systematic quality control. Rehman et al. [21] highlight that TQM incorporates seven fundamental quality control tools: check sheets, cause-and-effect diagrams, flowcharts, histograms, control charts, Pareto charts, and scatter diagrams. These tools provide a structured means of identifying and addressing the root causes of inefficiencies at all stages of the production process.

By applying TQM principles, manufacturers can eliminate non-value-added activities, reduce variability, and improve process stability, thereby enhancing both productivity and quality [22]. TQM therefore complements lean approaches by focusing not only on waste reduction but also on fostering an organization-wide culture of problem-solving and continuous improvement.

2.3 Factors Contributing to Operational Inefficiency in Production Processes

Identifying the drivers of inefficiencies is critical for designing effective improvement solutions. Research shows that factors such as lack of a continuous improvement culture,

frequent changeovers, inadequate decision-support systems, and resistance to adopting new technologies significantly undermine productivity [23], [24]. Moreover, Cai & Yang [25] added that the absence of structured methodologies for root cause analysis often results in recurring operational bottlenecks.

Therefore, early identification and mitigation of these factors are essential for sustaining efficient operations. If left unresolved, inefficiencies accumulate into systemic problems that erode long-term sustainability and competitiveness [26], [27]. A structured approach to analysing and managing these contributing factors is critical for maintaining operational excellence in manufacturing environments.

2.4 Impacts of Operational Inefficiencies and Mitigation Strategies

Operational inefficiencies have wide-ranging consequences for production processes, including excessive downtime, quality defects, increased waste, and higher costs, all of which reduce profitability and competitiveness [28], [29]). Choomlucksana et al. [30] specifically identify motion and process wastes as critical obstacles, highlighting the importance of adopting comprehensive strategies to minimize waste and optimize processes.

Research indicates that Lean manufacturing, particularly when integrated with Industry 4.0 technologies, is highly effective in mitigating inefficiencies by reducing cycle times, enhancing resource utilization, and improving quality control [31], [32]. Similarly, continuous improvement methodologies such as Kaizen and PDCA provide the structured mechanisms for sustaining long-term operational efficiency [33]. These approaches demonstrate that sustainable improvements require both technical interventions and human factors, including employee engagement and organizational culture [34].

2.5 Conclusion of Literature Review

The reviewed literature demonstrates that operational efficiency in production processes is a multidimensional concept that combines technological, managerial, and cultural factors. Lean manufacturing and TQM frameworks offer structured methodologies for eliminating waste and identifying root causes of inefficiencies, while the PDCA cycle reinforces continuous and iterative improvement. Factors contributing to inefficiencies, such as a lack of a continuous improvement culture, frequent changeovers, and weak decision-support systems, must be systematically identified and resolved to prevent long-term performance declines. Finally, adopting mitigation strategies grounded in lean principles, TQM tools, and continuous improvement philosophies ensures not only cost reduction but also sustainable competitiveness in manufacturing environments such as yoghurt production.

3 METHODOLOGY

3.1 Study Setting

This study employed a qualitative research approach to explore the root causes of operational inefficiencies in the filling stations of a yoghurt manufacturing plant. The qualitative approach was chosen for its ability to provide in-depth insights into complex operational dynamics, human factors, and technological challenges that contribute to inefficiencies [35]. A case study design was adopted to facilitate a focused investigation within a real-life industrial context, allowing for rich, contextualized understanding of the production environment [36].

Observations were conducted over a twelve-week period (three months), five days a week, across three production shifts (morning, afternoon, and night). This duration provided sufficient time to capture variations in production processes and operational patterns.

3.2 Focus Areas and Variables

The focus areas were derived from the operational efficiency framework discussed in Section 2 below and represent critical determinants of production efficiency:

1. Machine Performance: Variables included downtime frequency, maintenance requirements, and cycle times. Machine efficiency affects throughput and overall operational effectiveness [37].
2. Employee Efficiency: Variables included task completion rates, adherence to procedures, and coordination/communication issues. Human factors play a crucial role in workflow consistency and productivity [38].
3. Product Quality: Variables included the occurrence of off-specification products, rework frequency, and deviations from quality standards. According to Choomlucksana [39]. Product quality impacts both customer satisfaction and operational profitability.

Focusing on these areas enabled the study to systematically investigate inefficiencies in the filling station and establish a basis for root cause analysis.

3.3 Population

The target population comprised the machinery operations and production workflows at the filling stations of a major yoghurt-producing plant in South Africa. This included all mechanical functions, human interactions, and system-level processes that directly influence operational efficiency, productivity, and product consistency.

3.4 Sampling Method

A purposive sampling strategy was used to select operational settings most likely to reveal critical data on inefficiencies. Observations were conducted across all three shifts to capture variations in machine performance, workflow patterns, and process consistency. Purposive sampling is widely recognized as suitable for qualitative industrial research because it targets the most relevant operational areas [40].

3.5 Data Collection

Data were collected through non-participant direct observation using structured observation sheets and checklists. Observation data included the following variables:

- Machine performance: downtime, maintenance activities, and cycle times
- Employee efficiency: task completion rates, adherence to procedures, coordination, and communication issues
- Product quality: off-specification incidents, rework frequency, and deviations from standards

Secondary data sources, such as maintenance logs, production reports, and quality control records, were used to validate observations and strengthen data reliability. This combination ensures comprehensive coverage of variables and aligns with best practices in qualitative manufacturing research [41].

3.6 Data Analysis

Thematic analysis was employed to code observation notes systematically, identifying recurring patterns and inefficiencies. The themes were categorized into technological, human, and process-related causes, which were derived from the focus areas described above, ensuring a clear link between observations and analytical categories.

The analysis also applied the Plan-Do-Check-Act (PDCA) cycle as a framework for iterative assessment and continuous process improvement. The PDCA cycle supports root cause analysis by enabling systematic identification, testing, and refinement of corrective actions [8].

Data triangulation was performed by comparing findings across shifts and cross-referencing secondary data (maintenance logs, quality reports), enhancing validity and reducing observer bias.

3.7 Ethical Considerations

Ethical research principles were strictly adhered to. Permission to conduct observations was obtained from plant management. Observations were conducted without interfering with daily operations. Confidential information unrelated to the study's focus was excluded from analysis.

3.8 Methodology Flowchart

Figure 1 illustrates a flowchart summarizing the research design and methodology employed in this study.

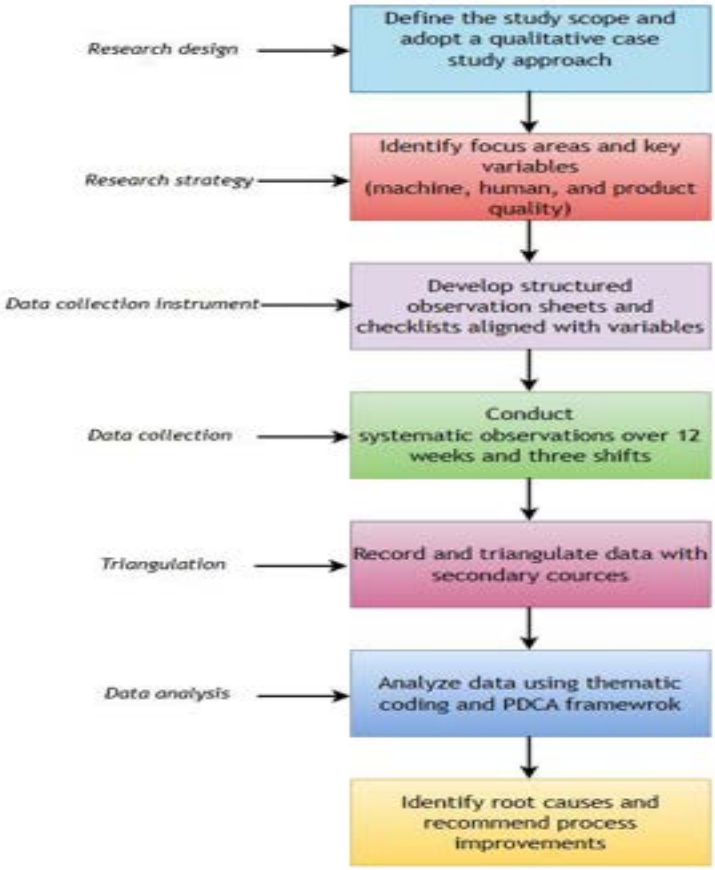

Figure 1: Flowchart of research design and strategy

4 FINDINGS

4.1 Overview

The study conducted a comprehensive analysis of the observational data collected over a 12-week period (three months) at the filling stations of a yogurt manufacturing plant in South Africa. Observations were conducted five days a week across three production shifts (morning, afternoon, and night) to capture variability in operational performance. The primary focus

was on machine performance, employee efficiency, and product quality, as these factors were identified through the literature review and research objectives as the key determinants of operational efficiency [9],[6].

The PDCA root cause analysis approach, combined with thematic coding, was used to systematically identify patterns and factors contributing to inefficiencies. Themes were categorized into technological, human, and process-related factors, reflecting the interdependence of equipment, workforce, and workflows in the production process [12].

4.2 Summary of Observational Data

Although observations were carried out over three months, five representative days were selected for presentation in Table 1. These days were chosen because they reflect typical operational patterns, including examples of high and low efficiency, ensuring that the sample captured the variability of operations, and the table remains concise.

Table 1: Summary of observational data

Day	Machine Downtime (Minutes)	Employee Efficiency (% of tasks completed on time)	Off-Spec Products (%)	Detailed observations of machine issues, employee performance, and their impact on production quality for each shift.
Day 1	45	85%	25%	Machine breakdown occurred early in the shift; employees had to wait for maintenance to fix the issue.
Day 2	30	78%	22%	Minor machine issue, leading to a delay in filling operations; some confusion during shift change caused miscommunication between operators.
Day 3	50	80%	28%	Major machine downtime due to an equipment malfunction; operators struggled to maintain quality during the restart phase.
Day 4	20	90%	18%	Fewer issues with machines, but some employees were slow to adapt to a change in product specifications, leading to higher off-spec rates.
Day 5	35	88%	20%	Maintenance resolved most machine issues, but there were still some qualities control challenges during peak production hours.

From Table 1, the machine downtown throughout the five days averaged 36 minutes per day with the highest being 50 minutes on day three and resulted in decrease in both productivity and product quality. The machine experienced the lowest downtime of 20 minutes on day four, which coincides with the highest employee efficiency. The worker's efficiency is, therefore, linked to machine performance and communication. Proper coordination and reduction of equipment downtown time are the essential ingredients of maintenance of high levels of workers' productivity.

For employee efficiency, the average completion of a task / order on time over the five days was 84.2%, The best efficiency observed was in day four at 90% of the days had the lowest machine downtime, which suggests that equipment reliability positively affects worker efficiency. The lowest efficiency observed was on day two at 78%; this justifies the point made above that proper co-ordination along with minimizing equipment downtimes are essential to maintain high levels of worker productivity.

On the plot of days against off-spec, there is a clear correlation between machine downtime and product quality; the highest off-spec rate is on day two with 28% due to major machine downtime. This clearly shows that the performance of the machines affects product quality.

From this observational study, it can be concluded that machine performance is related to employee efficiency and product quality. For instance, machine downtimes mostly affect

production, since both worker efficiency and product quality will be low, meaning more rework. The enhancement of operational efficiency at the filling station can be pursued by minimizing machine downtime through better maintenance practices and improving communication at shift changes. The implementation of real-time quality control systems is anticipated to minimize off-spec products, improving production efficiency while delivering significant cost savings.

4.3 Discussion of findings

Observations from the filling station were used in gathering qualitative data to understand the root causes of the operational inefficiencies. These observational data showed that machine downtime, employee efficiency, and product quality are indeed interrelated in such a way that production output and quality are being much affected by machine downtime. This finding aligns with the literature, which emphasizes that inefficient equipment utilization and frequent downtime are major contributors to production delays and quality defects in manufacturing systems [28], [30].

High machine downtime on day one and three directly impacted employee efficiency, leading to increased rates of off-spec products and rework products. These results highlight the importance of effective preventative maintenance and better communication during shift changeovers. This is consistent with Lean manufacturing principles, which advocate for Total Productive Maintenance (TPM) and workflow standardization to minimize waste and variability [17], [18]. Furthermore, real-time quality monitoring systems can also come in handy to improve processes through issuing early warnings for quality issues that will, in turn, reduce rework and wastes. The integration of real-time quality monitoring aligns with Industry 4.0 approaches, which enable early detection of deviations, reduce rework, and enhance overall product quality [11], [31].

Frequent machine downtimes were also associated with reactive maintenance practices, poor raw material quality, and breakdowns in communications during shift changeovers. These qualitative insights support the adoption of proactive strategies, including structured maintenance schedules, improved quality monitoring, and robust communication systems to greatly enhance productivity while reducing waste. Ergonomic improvements and workflow design, as observed, may ease operator strain and increase process efficiency, Lean principles that target both technical and human factors to optimize productivity [14], [34].

The production process observed was not always operating within the required specifications, particularly during the initial stages of the production run. This highlights a critical need to refine operational processes within the filling station to maintain high quality and minimize financial losses. Such process refinement is supported by Lean and TQM methodologies, which emphasize reducing process variability and eliminating non-value-added activities to enhance both operational performance and financial outcomes [16], [22], [17].

The analysis demonstrates that operational inefficiencies at the yoghurt filling station can be addressed through proactive strategies that include preventive maintenance, real-time quality control, improved communications, and ergonomic improvements. These strategies are consistent with established frameworks in Lean manufacturing, TQM and continuous improvement philosophies, including PDCA cycles, which collectively emphasize the systemic elimination of inefficiencies to improve productivity and reduce operational costs [19], [33].

5 CONCLUSION

This study identified the root causes of inefficiencies in the filling stations of a yoghurt factory in South Africa. Using qualitative observations, it was found that the main contributors to inefficiencies were inconsistent raw material flow, machine calibration issues and lack of

preventative maintenance. These inefficiencies resulted in machine downtime, product rework and resource wastage, directly impacting operational performance.

To address these challenges, the study proposed three integrated solutions: a preventative maintenance program, real-time quality monitoring and redesigned workflow communication structures. Implementing these strategies is expected to increase productivity by minimizing machine downtime and streamlining workflows, reduce costs through waste elimination and optimized resource utilization, and support continuous improvement by creating a data-driven feedback loop that identifies and addresses inefficiencies in real time.

The study demonstrates how targeted interventions can enhance efficiency and profitability in dairy production. The findings provide practical guidance for the studied plant; however, it also contributes to the broader understanding of managing operational inefficiencies in yoghurt manufacturing and similar environments. Future studies could evaluate the effectiveness of the proposed strategies and explore their applicability across other production stages.

ABSTRACT

Three-dimensional (3D) printing has revolutionized the manufacturing landscape, offering unparalleled flexibility, customization, and speed. However, despite its vast potential, 3D printing is not without its challenges and limitations. This paper explores the technical, material, design, economic, environmental, and regulatory hurdles that hinder the widespread adoption of 3D printing. We discuss the limitations of current 3D printing technologies, including resolution, accuracy, and speed, as well as the restricted range of available materials and their inherent properties. Furthermore, we examine the economic and environmental implications of 3D printing, including high upfront costs, energy consumption, and material wastage. Finally, we highlight the need for standardized regulations and guidelines to ensure the safe and responsible development of 3D printing technologies. By acknowledging and addressing these challenges, we can unlock the full potential of 3D printing and usher in a new era of innovation and technological advancement.

1 INTRODUCTION

3D printing technology has revolutionized various industries, enabling the production of complex designs and shapes. However, despite its advancements, the technology still faces significant challenges and limitations [1]. These include high costs, low printing speeds, limited part sizes, and strength issues ([1]. One of the primary challenges in 3D printing is the need for continuous innovation and refinement to overcome current limitations and facilitate patient-specific healthcare with on-demand tailored medications [2]. The customizability of 3D-printed devices introduces new complexities when drafting a design control model for FDA consideration of market approval [3]. Additionally, maintaining consistent material powder properties and optimal printing parameters such as build orientation and laser power is crucial for ensuring quality builds [3]. In conclusion, while 3D printing offers tremendous potential, several challenges must be addressed to advance the technology further. These include improving material properties, increasing printing speeds, expanding part sizes, and addressing regulatory hurdles ([1] [3] [2]). Overcoming these limitations will be essential for the widespread adoption of 3D printing across various industries and applications.

Recent advancements in 3D printing materials have significantly expanded the technology's applications and capabilities. Plastics remain the most widely used material due to their low cost and ease of printing, while metals are gaining popularity for their superior mechanical properties [4]. However, research is now focusing on developing new materials to overcome existing limitations such as high costs, low printing speeds, limited part sizes, and strength [1]. Ceramics and biomaterials have emerged as promising materials for 3D printing, opening up new possibilities in industries like aerospace, healthcare, and electronics [4]. The development of 4D printing technology, which allows for the fabrication of self-transforming materials in response to external stimuli, has garnered significant attention in biomedical engineering [5]. Additionally, advancements in vat photopolymerization have enabled the creation of complex multi-material geometries with excellent printing resolution and high dimensional accuracy [6]. In conclusion, the research on 3D printing materials is focused on expanding the range of printable materials, improving their properties, and developing novel technologies like 4D printing. These advancements aim to address the current limitations of 3D printing technology and unlock its full potential across various industries. As materials continue to evolve, the prospects for 3D printing to revolutionize manufacturing and other sectors remain promising [6].

There has been a significant increase in the acceptance and usage of AM technology is the global space in recent years. The number of 3D-printed devices increased from 665 000 in 2020 to about 1248 000 in 2023 and has been estimated to rise to 2837 000 by 2030, worldwide. In the manufacturing sector alone, the number of 3D-printed devices rose from 102 000 in 2020 to 206 000 in 2023 and is expected to increase to 644 000 by 2033, globally (Figure 1) [7].

2 3D PRINTING TECHNOLOGY IN THE ERA OF 4IR

The advent of 3D printing technology has transformed the manufacturing sector and allows cutting-edge production of parts and substructures thereby advancing the course of the Fourth Industrial Revolution (4IR) in the following ways.

2.1. Reduction of Production Costs and Material Waste

By adopting 3D printing technology, there is a significant reduction in the setup time, production costs, and assembly requirements in the manufacturing of parts and substructures. This is due to the elimination of complex supply chains, greater customization, better design, and improved flexibility, resulting in a faster and cheaper production process when compared with the traditional subtractive manufacturing process. Since there is adequate product design, optimization of production parameters, innovative product design, material waste, and product rejection are significantly reduced in the era of 4IR. The process of 3D printing gives opportunities for iterative product and process design, reduction in scraps, elimination of overstock, efficient materials handling, effective material recycling and conversion, reduction in waste generation, and reduction of the environmental impact of manufacturing processes [8].

2.2. Customization and Flexibility

Manufacturers can eliminate the high cost, material wastage, expensive tooling, and other challenges associated with the fabrication of small quantities of complex and customized products when they adopt 3D printing technology in the wastewater treatment sector. With adequate product design, it is easier and cheaper to accommodate and respond to customer needs and preferences regarding size, shapes, material selection, etc. when working with 3D printing technology. Unlike traditional manufacturing techniques, 3D printing technology gives room for improved responsiveness, creativity, and flexibility [9]

2.3. Innovation and Product Design

3D printing technology allows manufacturers to deploy innovative technology to achieve variety in product design. This motivates innovative prototype creation and customization that fits existing pipelines or treatment systems, allows process expansion, and ensures reliability and safety. Also, the deployment of 3D printing technology encourages innovation and product design which facilitates the production of complex geometries, cost reduction, and timely response times which ultimately eliminates long production time associated with traditional subtractive manufacturing plants. Greater flexibility and optimization of wastewater treatment plant and operation [10]

Notwithstanding the undeniable advantages of 3D printing, the layer-by-layer deposition of materials takes a longer time, especially for products with complex geometries when compared with traditional manufacturing techniques. The huge initial financial investment required for 3D printing technology including printers, materials, and other infrastructural requirements results in high cost per part, particularly for complex objects remains a major drawback. Though 3D printing allows a wide range of materials, certain specialized alloys and composites are not readily workable with 3D thereby limiting the application of the technology [11]. Some of the post-production processes like polishing, painting, etc., to achieve the required surface finish, accuracy, quality, and other specifications add to the production costs and duration. Unlike traditional manufacturing methods, there are size and structural limitations associated with 3D printing, particularly at the industrial stage. The strength, porosity, durability, and other mechanical properties of 3D printed products might be different from those manufactured through traditional methods. This often affects the performance of such products in specialized applications. The advent of 3D printing technology has led to a surge in the circulation of fake and counterfeit products and copyright infringements [12] [13].

The operation of advanced manufacturing is governed by information, automation, computation, software, sensing, and networking. The main goal of the advanced manufacturing process is to boost value, enhance flexibility, improve responsiveness to the market, and reduce time to market [14]. The upgrading of the conventional manufacturing process to an advanced manufacturing process leads to lower scrap generation, a reduction in inventory and material content, and an increase in added value [15]. Consequently, advanced manufacturing process leads to health competitiveness, quality improvement, and significant workforce development. Common examples of advanced manufacturing processes include additive manufacturing, cloud computing, smart manufacturing, the Internet of Things, artificial intelligence, digital manufacturing, robotics, virtual reality, nanotechnology, laser machining/welding, and advanced/composite materials [16]. Table 1 compiles the benefits and challenges of the advanced manufacturing process.

Table 1: Benefits and challenges of advanced manufacturing process *[17]*

Benefits of advanced manufacturing process	Challenges of advanced manufacturing process
• Eco-friendly • Cost effective • Improvement in quality standards • Reduction work in process inventories • Reduction in waste generation • Increased productivity • Scalable • Innovative and strategic process • Stimulated the production process • Reduction in downtime • Reduced scraps and defective products • Nearly error-free process • Improvement in the work environment	• High initial cost of investment technology • High cost of training and retraining of personnel • Require integration of advanced manufacturing techniques • Tedious methods of organization and management • Likelihood of breach of data security • Privacy and security concerns • High cost of technology to ensure relevance and sustainability • Need for constant adapting to technological changes • Process is mostly industry-specific • Improving manufacturing plant efficiency. • Limited flexibility and adaptability

• Better accuracy • Customization • Improvement in the response to the variability of the product mix • Optimized supply chain • Improvement in management control • Part reliability	• Skilled labour shortage • Supply chain disruption • Material selection • Regulatory compliance • Design complexity

Notable areas of application of 3D printing technology in South Africa include medical, sport, pharmaceutical, manufacturing, etc. South Africa has developed and manufactured a 3D printer, under a monitored homegrown solution to reduce the country's reliance on imported 3D printers and accessories.

Without a doubt, 3D printing is a promising technology in the Fourth Industrial Revolution (4IR) and will continue to transform manufacturing in the coming decades. As the technology advances, the materials that can be used to create objects are also expanding, from plastics and metals to biodegradable materials and even living cells. Overall, AM is a transformative technology that has the potential to revolutionize the manufacturing industry [18].

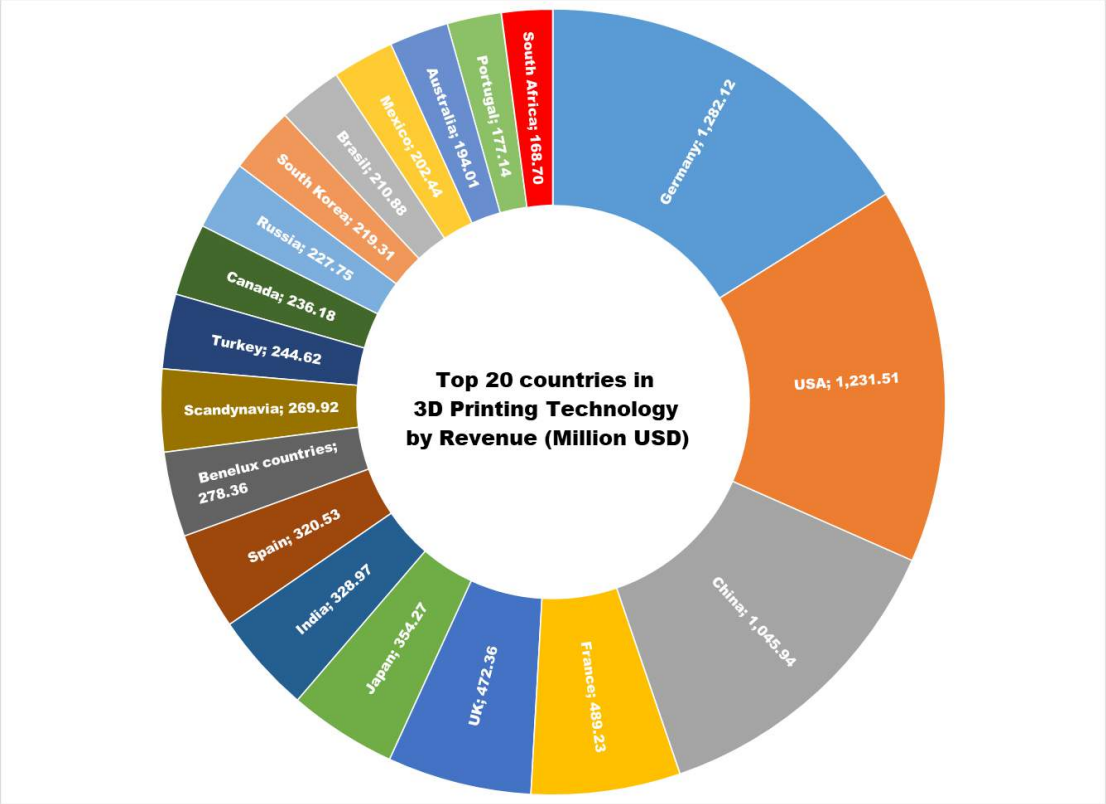

Figure 2: Top 20 countries in 3D printing technology by revenues (Million USD). Data from [151].

3 TECHNICAL LIMITATIONS OF 3D PRINTING

3D printing is promising an uprising manufacturing process, with many benefits, however it is important to be aware of its technical constraints. It is noted that 3D printing is slower in production rate when compared to traditional manufacturing such as injection moulding, this limitation is a big challenge to industries that rely in high volumes of production. [19] . The traditional manufacturing has mastered the use of different types of materials. The range of materials available for 3D printing is limited [20]. Furthermore, the cost of 3D material remains high, for any development the industries concern is always focusing on reducing the

cost, this makes it difficult to adopt 3D printing material because of its increased cost [21]. The 3D printing machines are required to be calibrated, if not calibrated properly it may affect the quality of final product or can cause inconsistency in production. This is very critical in industries that requires high accuracy such as Aerospace and medicine. The manufacturing of big sizes is already accounted for in traditional manufacturing, however with 3D printing the big printers are not easily accessible and they are highly expensive. 3D printing is perfect for small scale production.

Table 2: Summary and limitations of recent work. *[22]*

Focus	Technical Adopted	Limitations
Metals made using lasers and 3D printing are resistant to bending.	Analysis of the metal materials' data	The bending behaviour may limit the strength and durability of 3D-printed metal items during manufacture.
Heat transfer pipes made of 3D-printed metal filaments are being tested.	Stainless steel porous structures are made using additive manufacturing, and the time is measured by passing liquid through the pores.	Insufficient sample size and inability to generalize to different materials.
dental crowns that resemble the multi-scale structure of natural tooth enamel in terms of structure.	Direct ink writing and 3D printing.	restricted to various materials.
Composite microstructure and 3D-printed material performance.	Toughened semi-interpenetrating polymer network—thermoplastic polymer bi-matrix composite fused filament fabrication technology.	Experimental approach
Configuration of several 3D printing techniques that impact the characteristics.	3D printing and tensile testing.	Microstructure and chemical composition were not taken into account.

4 CONCLUSION AND RECOMMENDATION

Features and limitations of conventional manufacturing technology that necessitated the introduction, development, and adoption of AM techniques are important. The current status, trend, research activity, and utilization of 3D printing techniques globally and in Africa are necessary and further detailed studies need to be conducted. The benefits of 3D printing technology will continue to be evident through the ongoing research efforts that must be undertaken to understand and address the limitations that hinder the use of this technology. Key aspects that need to be addressed include life cycle cost design tools, Additive manufacturing-oriented Computer Aided Design (CAD) systems with more user-friendly and advanced simulation capabilities. An obvious advantage of 3D printing is mass customization. This means it produces a range of bespoke goods, allowing each product to be different whilst keeping the price low through mass production.

ABSTRACT

The evolution of financial technology (Fintech) has significantly transformed the global financial landscape, enhanced accessibility and promoting financial inclusion, particularly in Sub-Saharan Africa, and notably in Niger. Thus, a resilient Fintech is supported by strong adoption. This study aims to develop a new conceptional model contextualised to foster the adoption of mobile money in Niger. A systematic literature review of Fintech adoption was conducted, evaluating various adoption theories using the PRISMA method. These theoretical foundations further aid in framing the hypotheses and suggesting the conceptual model based on select determinants. The literature review highlights the importance of understanding various theoretical frameworks and their determinants, which are crucial in shaping user behaviour and adoption intentions to influence mobile money adoption in Niger positively.

Keywords: Mobile Money Niger, Fintech, Innovation, Adoption

* Corresponding Author

1 INTRODUCTION

Adoption is critical to the sustainable growth of the Fintech sector. Hence, the evolution of Fintech has transformed the global financial landscape, offered innovative services and improved accessibility for consumers. According to [1], only 40% of the adult population in sub-Saharan Africa uses cash instead of formal financial services. Mobile phones provide people, including those in rural areas, access to financial services. Thus, the rapid growth of financial technology promotes financial inclusion, enabling individuals without bank accounts to access banking services through mobile applications.

Nevertheless, according to [2], adoption remains low in most West African countries, such as Niger. Similarly, a comparative analysis revealed that Kenya, Lesotho, and Botswana saw improvements in their digital financial inclusion rankings. In contrast, [3] stated that Egypt, Sudan, Tunisia, and Niger experienced declines, signifying restricted access. Hence, these challenges are mainly due to restricted access to mobile phones, inadequate financial resources, and the high costs of digital financial services [3]. According to [4], people generally use mobile money accounts to make or receive payments, send money to family and friends, and pay bills.

The literature review focuses on mobile Fintech services, considering that most of the unbanked population in West Africa owns mobile phones, which have become the primary platform for financial services, and particularly mobile money. It encompasses money transfer, bill payment, e-wallets, savings, and loans. In Niger, [5] reported that the adoption of the first mobile transfer application (m-transfer) in 2010 resulted in a 20% reduction in transfer costs compared to manual cash distribution. Thus, households in the Zap m-transfer group were more likely to use cash to purchase goods such as protein- and energy-rich foods. However, [5] suggested that the increased adoption of m-transfer and other Fintech services faces challenges, including limited infrastructure, weak mobile networks and mobile money agents, and lower financial literacy. According to [6], the advancement of mobile Fintech also introduces new challenges, such as outdated and complex regulatory frameworks, cybersecurity risks and data privacy concerns. Using the PRISMA guidelines helped assess the determinants of mobile money adoption in Niger through a theoretical framework. By synthesising the findings from 14 theoretical articles and 20 relevant studies, the proposed mobile money adoption framework includes analysing the barriers and theorising the adoption drivers for Mobile Money in Niger. Thus, the findings emphasised that most of the determinants in [7]'s TAM's [8] UTAUT2, [9] Frugal Innovation, [10] Institutional Theory, and [11] integrated financial services offerings drive mobile money adoption. Hence, considering the similarities between the key determinants in UTAUT2 and those in the abovementioned theoretical frameworks, we defined the following conceptual framework based on UTAUT2: Performance Expectancy, Effort Expectancy, Facilitating Conditions, Social Influence, and Price Value. Finally, the study is expected to contribute to the work of researchers, policymakers, and the private sector in promoting a more significant and sustainable adoption of Mobile Money in Niger, thereby leading to enhanced financial inclusion, increased efficiency, and economic growth.

2 LITERATURE REVIEW AND HYPOTHESES

Behavioural research in information systems has created numerous theories about technology adoption. The assessment of the studies focusing on the adoption characteristics can help understand the determinants influencing the adoption and use of mobile money. It will also shed light on the rationale for contextualising these theories based on geographical location, demography, and socioeconomics. Considering the scarcity of research on mobile fintech adoption in Sub-Saharan Africa and a singular publication about Niger, the literature study encompassed 34 articles, including 14 related to adoption theory. The 17 analysed publications

primarily focus on mobile uptake in Sub-Saharan Africa, while the remainder concern research on emerging nations. The pertinent articles represent a diverse array of research agendas and methodologies. Those studies primarily relied on the following adoption theories: the Technology Acceptance Model (TAM), the Unified Theory of Acceptance and Use of Technology (UTAUT2), the Diffusion of Innovation Theory (DOI), the Theory of Planned Behaviour (TPB), Frugal Innovation (FI), and Institutional Theory (IT). Since UTAUT2 [8] encompasses key determinants from behavioural, frugal innovation, institutional, and socio-economic theories, we formulated our hypotheses based on key constructs in UTAUT2, including insights from other theories in the literature review for mobile money adoption in Niger as follows: (A) "Performance Expectancy", (B) Effort Expectancy", (C) Facilitating Conditions", (D) "Social Influence", and (E) "Price Value".

2.1 Theorical frameworks

The following section describes the key determinants of technology adoption in the following streams: behavioural, Frugal, and institutional.

Behavioural

2.1.1 Technology acceptance model (TAM) – related determinants (Behavioural)

The Technology Acceptance Model (TAM) [7] aims to explain how users adopt and use new technologies. It is based on Perceived Usefulness (PU) and Perceived Ease of Use (PEOU).

Perceived Usefulness (PU): Various research avenues support the theoretical significance of TAM's [7] "perceived usefulness" and "perceived ease" of use as factors that impact Individuals' intention to use technology. However, Davis [7] also acknowledged the need to enhance metrics to gain a deeper understanding of the TAM determinants and their functions as predictors of computer use. He states that perception, usefulness, usability, and user innovation can influence technology adoption. The same factors can influence consumer adoption of Fintech solutions in general, including in the context of Mobile Money in West Africa. For example, in Niger, Aker et al. [5] found that the mobile money cash transfer (Zap) experiment in rural areas demonstrated easier and less costly mobile transfer (m-transfer) for recipients to collect their transfers, despite having fewer Zap agents. Hence, program customers went shorter distances to receive their transfers than their manual cash counterparts [5].

Perceived Ease of Use (PEU): The more consumers perceive how easy a Fintech service is, the more likely they will trust that service and continue using it. In contrast, system complexity will discourage its usage. Ultimately, simplicity and ease enhance the user experience, leading to increased Fintech adoption [5] .

These findings [5] support TAM's [7] Perceived Usefulness and Perceived Ease of Use. Thus, Akinyemi and Mushunje [12] examined the adoption of mobile money in rural regions of Africa where the population lacks access to traditional financial services. The data was collected through random sampling of individual census data from ten African nations: Ghana, Kenya, Lesotho, Mozambique, Nigeria, Rwanda, Senegal, South Africa, Tanzania, and Uganda. They performed an empirical investigation using the determinants of the Technology Acceptance Model (TAM) and Two-Part Model [13], a statistical approach that examines datasets containing numerous zero values alongside nonzero values that are either discrete or significantly skewed. They concluded that mobile money users find it easy, safe, trustworthy, convenient, rapid, and cost-effective compared to alternative payment methods in rural Africa [12]. The findings support [7] theories on Perceived Usefulness (PU) and Perceived Ease of Use (PEOU) within the Technology Adoption Model (TAM).

Finally, studies (5) across several countries have leveraged TAM to analyse the determinants which influence the use of mobile Fintech. With the adoption of mobile money, both studies

[4] and [5] used, respectively, randomised experiments and empirical studies to conclude that the TAM's determinants, "perceived ease of use" and "perceived usefulness" [7], positively influence the adoption of mobile money. These findings are corroborated by [14] and [15] in the context of mobile banking adoption. Similarly, following a quantitative analysis, the study in [16] concluded that the same determinants positively influence the adoption of e-wallets. In conclusion, "perceived usefulness" and "perceived ease of use" can positively influence adoption. In the context of Niger [4]"Perceived ease of use" and "perceived usefulness" can be key drivers for money adoption.

2.1.2 Diffusion of innovation (DOI) – related determinants (Behavioural)

According to the research [17], "Diffusion of Innovations" refers to the process by which new ideas or technologies spread across different population segments. The diffusion of innovations encompasses innovation, communication channels, time, and the social system. The Diffusion of Innovation theory explains how Fintech innovations spread within communities. Accordingly, the study [18] leveraged the diffusion of innovation to examine how the adoption of Fintech can help enhance financial inclusion in rural and remote areas of emerging economies. The research utilised a quantitative design and the drop-and-pick approach to collect 275 valid and reliable responses. It used structural equation modelling to evaluate the reliability and validity of the measurement model. The findings indicate that compatibility, agent trust, perceived risk, and facilitation have a significant impact on Fintech adoption [18]. The research also determined that effective use of communication channels (awareness) influences the correlation between observability, Fintech adoption, and trialability. Following stratified and simple random sampling, they finally determined that compatibility, agent trust, perceived risk, and facilitation — the means through which information about the innovation spreads — significantly drive the adoption of mobile money [18] .

2.1.3 Technology planned behaviour (TPB) – related determinants (Behavioural)

The Theory of Planned Behaviour (TPB) [19] is a psychological framework that incorporates subjective norms, attitudes, and perceived behavioural control, influencing human behaviour. The application of TPB to technology adoption encompasses (i) individual attitudes towards the technology, (ii) subjective norms or perceived social pressure influencing adoption, and (iii) individuals' perception of their control over adopting the technology [19]. The study [20] examined the impact of the Theory of Planned Behaviour (TPB) on the behavioural intentions of Fintech usage. The model includes perceived behavioural control, attitude, subjective norms, perceived risk, and perceived trust. The research examined the factors affecting Jordanian attitudes towards FinTech among 158 respondents, emphasising the TPB constructs of subjective norm, perceived behaviour control, perceived risk, and perceived trust. Their findings indicated that those constructs positively affect behavioural intention [20]. Thus, the study [12] employed empirical analysis to investigate the adoption of mobile money based on the determinants of the Theory of Planned Behaviour (TPB). They concluded that determinants such as an individual's perceived behavioural control and attitude, as well as factors like ease, safety, trustworthiness, convenience, speed, and cost-effectiveness compared to other means of sending or receiving payment in rural areas of Africa, strongly impact adoption. Similarly, the same determination was made [15] while conducting a convenience sampling analysis of mobile banking adoption. Thus, the study [16] on e-wallet adoption concluded that individuals' adoption of mobile technologies facilitates their participation in relevant programs and alignment with changes in the agricultural system. Therefore, the TPB's determinants [19] — attitude, subjective norms, and perceived behavioural control — positively impact e-wallet adoption.

Frugal

2.1.4 Frugal innovation (FI) – related determinants (Frugal)

Frugal principles emerged in developing markets to create affordable products and services for low-income consumers. Accordingly, Frugal Innovation is defined by cost reduction, functionality, and performance [9]. It significantly saves costs while prioritising essential features and enhancing performance. The characteristics of frugal innovation can differ based on context, requiring different criteria for emerging nations compared to developed markets due to varying infrastructure, environmental, and consumer behaviour factors. In emerging economies, attributes such as resilience and the ability to cope with frequent power outages are critical in specific markets [9]. Thus, the case study [21] on frugal innovation, focused on societal issues, resource limitations, and institutional gaps in the adoption of mobile money in sub-Saharan Africa. Their research, which included both quantitative and qualitative analyses, found that mobile money addresses cost and resource constraints while reducing institutional gaps [21]. Similarly, the study [5] surveyed nearly 100 villagers, using randomised data to demonstrate that mobile transfer (m-transfer) systems are easier and less costly for recipients to collect their transfers.

Finally, similarly to [5], the research [21] used both quantitative and qualitative analyses to determine that mobile money, as a frugal innovation, alleviates cost and resource constraints while reducing institutional gaps in resource-limited environments, utilising the frugal innovation framework. Accordingly, simplicity, affordability, and resourcefulness have a positive impact on the adoption of mobile money.

2.1.5 Unified theory of acceptance and use of technology 2 (UTAUT2) -

The Unified Theory of Acceptance and Use of Technology 2 (UTAUT2) [8] builds upon the previous theory - UTAUT [22]. UTAUT2 is contextualised through (i) three fundamental dimensions from previous research on both general and consumer technology adoption and usage, (ii) an update of some relationships in the original UTAUT framework, and (iii) the addition of new relationships. Integrating hedonic motivation enhances UTAUT's primary predictor, which focuses on utility [8]. Furthermore, this indicates that UTAUT2 incorporates the fundamental linkages of UTAUT while offering additional constructs and interactions that expand the framework's applicability to the consumer context. The framework (UTAUT2) includes performance and effort expectancies, social influence, facilitating conditions, hedonic motivation, price value, and habit. In the context of the agrarian economy, the research [23] involved 40 participants to assess the robustness of extending UTAUT 2 to the agricultural economy of developing countries, based on statistical analysis. The findings demonstrated a significant positive correlation between social influence (SI), which entails the impact of others on an individual's decision to use technology and the prevalence of behavioural intention to adopt agricultural Fintech products and services (BIAFPS) among Indian farmers [23]. The study also indicated that farmers are more likely to adopt technology based on the influence of others in their social settings. Accordingly, this social engagement should concentrate on rural regions of the country where social media remains an elusive concept, particularly in the lives of farmers [23]. Similarly, in Egypt, there was research [24] on e-payment products and services, such as mobile wallets, virtual cards, and mobile and online banking. It used convenience sampling to collect and perform quantitative analysis on 399 questionnaires to examine the applicability of the UTAUT2 theory regarding consumers' intentions to accept e-payment [24]. The findings indicated that performance expectancy, facilitating conditions, effort expectancy, and social influence affect customers' intentions to accept e-payments [24]. Accordingly, these factors contribute to the growing number of individuals using e-payments to the extent that e-payment eventually becomes a preferred medium for economic transactions [24]. Furthermore, the study [24] assessed that Hedonic

motivation, price value and habit are insignificant in encouraging consumers' e-payment acceptance. Thus, the research [25] conducted a systematic review and meta-analysis of 67 relevant studies on mobile Fintech, finding that, among the UTAUT2 determinants, social influence is crucial for adopting mobile money in Sub-Saharan Africa. Hence, the facilitating conditions are crucial as mobile money relies on agents' networks to provide cash-in and cash-out services [25]. Similarly, the study [26] investigated the effects of the Ghanaian government's charge (levy) on electronic transactions, incorporating Venkatesh et al.'s (2012) UTAUT2 factors for validation. The data (417 replies) was obtained via research questionnaires distributed among several segments of Ghanaian residents. The study used the structural equation modelling (SEM) technique to demonstrate that the current fee structure for mobile money transactions does not encourage sustained adoption [8]. Although effort expectancy did not significantly affect the sustained adoption of mobile money transactions, performance expectancy and enabling variables were key determinants of this ongoing adoption [8]. Ultimately, the findings [26] provide strong evidence for policymakers and the government to incorporate a comprehensive tax policy into mobile money systems, thereby achieving widespread usage and enduring acceptance of mobile money transactions.

Finally, the studies [24], [26], [25] examined the adoption of mobile money based on the UTAUT2 determinants and determined that Social Influence impacts individuals' behaviour towards adopting mobile money. Thus, they concluded that Performance Expectancy (PE), Social Influence (SI), and Facilitating Conditions (FC) have a positive effect on the utilisation of mobile money services. Similarly, in Niger, the proximity of agent networks has a significant impact on mobile money adoption [5].

Institutional

2.1.6 Institutional theory – related determinants (Institutional)

The study [10] examines how institutional mechanisms foster trust during the early phase of industrial development in the United States. Institutional Theory focuses on rational bureaucratic organisations, professional credentialing, the service economy, and regulatory frameworks [10]. The paper identifies three trust generation methods: process-based, characteristic-based (linked to individual traits), and institutional-based (tied to social frameworks). Consequently, the institutional trust theory characterises public institutions as the trustee and citizens as the truster [10]. The research [10] further emphasised that normative pressures from external entities, such as the state, or internal dynamics, shape organisations. The study [27] employed institutional theory and Fuzzy-set qualitative comparative analysis to examine the interactions between enterprises and institutions regarding mobile money services across 110 services in 46 emerging countries. Their findings indicated that mobile money services, with a significant market share, could achieve high adoption rates regardless of the level of institutional support [27]. However, many depend on favourable conditions, such as regulations and adequate infrastructure. Moreover, advanced Fintech companies are better positioned to implement mobile money solutions in countries with developed financial markets [27]. In such environments, consumers are becoming more aware of security concerns in the digital realm, causing many to avoid electronic transactions. Hence, lots of potential digital payment users do not understand how transactions work and their implications, such as the sharing of data with third parties. Accordingly, [27] National Cybersecurity Commitment (NCC) influences digital payment use, with national culture as a moderating factor. Countries with collectivist cultures, strong governmental cybersecurity commitment, and low uncertainty avoidance tend to adopt digital payments despite risks. However, certain demographic groups, especially women, the elderly, and rural residents, are less likely to adopt these methods [28]. Thus, the modern global financial services sector is increasingly vulnerable to cybercrime, putting consumers' sensitive data at risk [29]. This rise in cyber threats has prompted regulators to implement new laws protecting personal data. In

South Africa, a key piece of legislation is the Protection of Personal Information Act 4 of 2013 (POPIA), which requires assessment for its alignment with the EU's General Data Protection Regulation (GDPR) standards [30] and [29] argue that POPIA represents a significant advancement in privacy and data protection in South Africa, which is expected to enhance personal data security in the financial sector. Thus, it offers the potential to reduce cyberattacks and foster Fintech adoption. Similarly, the study [31] assessed the legal and regulatory framework for mobile banking (M-banking) in Tanzania to identify and address legal gaps. Using a doctrinal legal methodology and comparative analysis with countries such as Kenya and the Philippines, the study found that compatibility, complexity, agent trust, perceived risk, and facilitation significantly influence the adoption of Fintech. Thus, favourable conditions enhanced the relationship between technological attributes and Fintech adoption [31]. Finally, the research [27], using fuzzy-set qualitative comparative analysis, determined that cognitive institutionalisation, normative institutionalisation, and regulative institutionalisation significantly influence the adoption of mobile money. Their study [28] on mobile also concluded that regulatory institutionalisation positively influences the adoption of mobile money. Similarly, the respective studies [29] and [31] also concluded that regulative Institutionalisation is a significant factor driving mobile money adoption.

2.1.7 Socio-economic factors

Socio-economic characteristics can also influence the adoption of mobile Fintech [11] conducted a study in nations under the Western African Economic and Monetary Union, including Niger, which found that obstacles such as cost, lack of trust, formal documentation, and religious considerations hinder the adoption of mobile money. Thus, the most marginalised demographic includes women, teenagers, the underprivileged, and persons with limited educational qualifications. These findings suggest that integrating mobile Fintech into banking services and enhancing financial literacy will accelerate adoption. The analysis of fifteen research studies of socio-economic factors to elucidate the utilisation of mobile Fintech in Sub-Saharan Africa [25]. Their findings suggest that education, female gender, high income, employment, marital status, and residence in rural areas can enhance the likelihood of adopting mobile Fintech services in Sub-Saharan Africa. Factors such as youth, female gender, divorce status, economic level, and household size may adversely affect mobile Fintech adoption in Sub-Saharan Africa [25].

3 RESEARCH METHODOLOGY

3.1 Data

The literature analysis examines the determinants of Fintech adoption in Africa, particularly in West Africa and Niger, with a focus on Mobile Money. This study develops a theoretical framework to enhance consumers' mobile Fintech adoption behaviour based on a systematic literature review (SLR) based on the PRISMA guidelines [32]. The findings from the systematic literature review (SLR) and related research contributed to a proposed conceptual model aimed at increasing mobile money adoption in Niger. A summary of the research methodology is presented in Figure 1, with further details in the following section. The review process is continuous, with outputs from one stage informing the next.

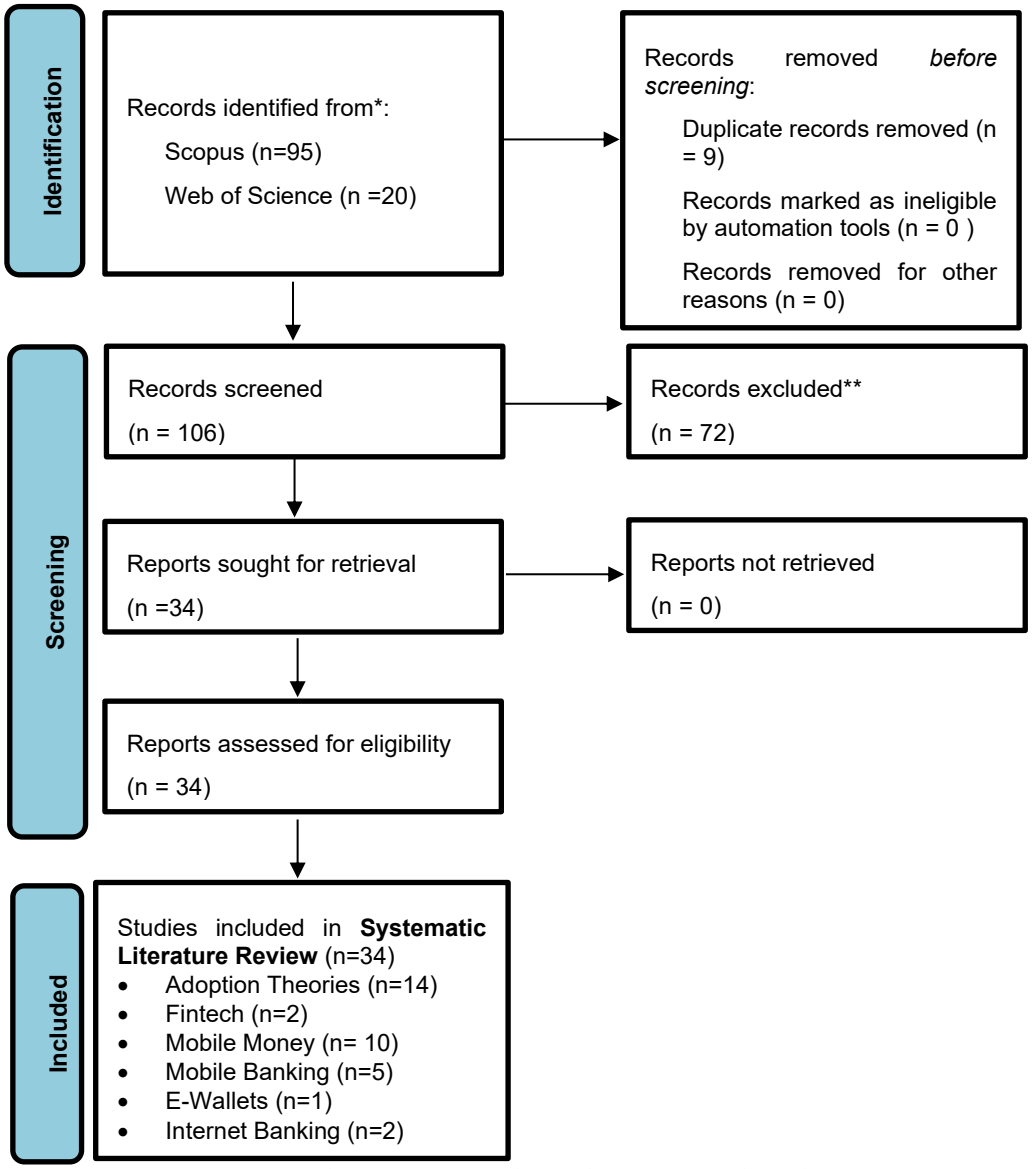

Figure 1: PRISMA Flow Diagram, based on a template by [NO_PRINTED_FORM] [32].

3.2 Method

We used the theorical method [33] for the systematic literature review. This includes defining core terms, establishing boundaries, identifying constructs (determinants), and making predictions that lead to a new conceptual theoretical model. The literature review's perspective encompasses the use of technology adoption theories (TAM, UTAUT, DOI, TPB, FI, and IT) as core terms. The study's boundaries pertain to Mobile Money, Mobile Banking, E-Wallets, and Internet Banking. The analysis identified key determinants (constructs) that were assessed against the pertaining adoption theories. Following the review of the determinants based on each theorical group, the objective is to draw hypotheses (predictions). Furthermore, the analysis leads to the formation of the conceptual framework for positively influencing mobile Fintech adoption in Niger. The theorical method provides a strong foundation of knowledge leading to the formulation of a conceptual framework. However, its findings cannot be observed or compared to outcomes from empirical research. Notwithstanding, the theorical findings can pave the way for empirical validation, leading to stronger evidence-based research.

4 RESEARCH RESULTS

The systematic literature review of 20 studies in Fintech, Mobile Money, Mobile Banking, E-Wallets, and Internet Banking emphasises key determinants that positively influence Fintech adoption. Thus, the findings suggest that key determinants in TAM, UTAUT2, DOI, TPB, FI, IT, and Socioeconomics collectively contribute to creating a conducive environment for mobile money adoption. The following table summarises the determinants of the findings about Mobile money:

Table 1: Summary of key determinants for Mobile Money adoption

Mobile Money Adoption Models	Key determinants	References
TAM	Perceived usefulness	[5], [12], [16]
	Perceived ease of use	
UTAUT2	Performance Expectancy	[24], [26],[25] [23]
	Effort Expectancy	
	Facilitating conditions	
DOI	Complexity	[17]
	Compatibility	
TPB	Attitude	[12], [15], [16], [20]
	Subjective Norms	
	Perceived behavioural control	
FI	Affordability	[5], [21], [34]
	Simplicity	
IT	Regulatory Forces	[27], [28]
	Isomorphism	
Socioeconomics	Consideration of socio-economic factors such as age, gender, and income	[11], [25]
	Integrated financial services offerings	

Table 1 summarises 11 studies on Mobile Money, with most of the research conducted in Sub-Saharan Africa. The analysis demonstrated that the drivers for adoption are almost the same across various Fintech solutions (Mobile Money, Mobile Banking, E-Wallet, and Internet Banking). From the consumers' perspective, determinants in TAM, UTAUT2, DOI, and TPB seem more relevant. However, most unbanked populations [12] reside in rural areas, and mobile money is often the primary means of accessing Fintech services. Therefore, they are more prone to the TAM, UTAUT2, FI, TPB, IT, and socio-economic determinants. Thus, in emerging markets (Table 1) [27], the factors influencing the adoption of mobile Fintech services are slightly nuanced. Hence, the determinants in IT seem important, followed by TAM, UTAUT2, and TPB, considering the presence of the facilitating conditions (UTAUT2) and the regulatory forces (IT).

It is also important to emphasise that the key constructs in UTAUT2 include similar determinants as compared to those in the other theoretical frameworks, as analysed in the literature review, as follows:

Table 2: UTAUT2 Comparison with the other theoretical frameworks

UTAUT2	TAM	DOI	FI	TPB	IT	Socioeconomics
Performance Expectancy (Belief that using a technology will improve performance)	**Perceived Usefulness (PU)**		Optimised Performance Level			
Effort Expectancy (Perceived ease of using the technology)	**Perceived Ease of Use (PEOU)**		**Core Functionalities Focus**			
Social Influence – (Impact of others on an individual's decision to use technology.)		**Social System** (Community or group influencing adoption decision)		**Subjective Norms** – Influence of social pressure		**Consideration of socio-economic factors**
Facilitating Conditions: Availability of resources and support for technology use, including regulations		Means through which information about the innovation spreads			**Regulatory forces Standardisation & Isomorphism**	
Hedonic Motivation: Enjoyment or pleasure derived from using the technology.						
Price Value: Perceived cost-benefit of using technology.			**Substantial Cost Reduction**			
Habit: The extent to which past behaviour influences future technology use.						

Considering that UTAUT2 encompasses most of the determinants of the behavioural, frugal innovation, institutional, and socio-economic theories, we drew the following hypotheses for mobile money adoption in Niger based on the UTAUT constructs in correlation with the findings from the other theories in the literature review:

Table 3: Hypotheses based on the UTAUT2 determinants

UTAUT2 (Constructs)	Hypotheses
Performance Expectancy	**(A)** The perceived performance improvement will increase user adoption of mobile money
Effort Expectancy	**(B)** The perceived ease of use will improve user adoption of mobile money
Facilitating Conditions	**(C)** The Availability of resources and support, including regulations, can increase the adoption of mobile money
Social Influence	**(D)** The Influence of social pressure can impact an individual's decision to use mobile money
Price Value	**(E)** Perceived cost-benefit can positively impact the adoption of mobile money

In summary, all the determinants in UTAUT2, except "habit", based on hypotheses (A), (B), (C), (D), and (E), can positively promote Mobile Money adoption in Niger.

5 MAJOR FINDINGS OF THE SYSTEMATIC LITERATURE REVIEW

Mobile money is an excellent case for integrated digital and financial innovation, positively influencing financial inclusion and reducing poverty. However, its adoption rate remains low, especially in peripheral sub-Saharan Africa and particularly in Niger.

The study critically evaluates current adoption theories and research on mobile money, as well as other mobile Fintech services, including mobile banking and Internet banking, with a specific focus on Sub-Saharan Africa and Niger. Utilising PRISMA principles for a systematic literature review of 34 pertinent studies on mobile money, e-wallets, mobile banking, and internet banking in Sub-Saharan Africa and Niger, identified the key factors that can facilitate the adoption of mobile Fintech in general and mobile money in particular within Niger. Accordingly, perceived usefulness and perceived ease of use (TAM) [7], facilitating conditions (UTAUT2) [8], attitude, subjective norms, perceived behavioural control (TPB) [19], and regulatory forces (IT) [10] can foster the sustainable adoption of mobile money in Niger. The literature review's findings should assist scholars, policymakers, and the business sector in promoting the adoption and sustainable use of Mobile Money in Niger, thereby enhancing financial inclusion, efficiency, and economic growth. Thus, it is essential to investigate further the impact of other socio-economic factors such as income level, age, and gender. Nevertheless, the literature review had limitations due to the low number of studies available on mobile money in West Africa, particularly in Niger. Thus, the analysis is limited to a systematic literature review, lacking a meta-analysis. Future research should consider conducting rigorous field experiments, including a quantitative study, as part of the systematic review process. Finally, it is essential to note that using Moher et al.'s [32] the PRISMA method to conduct a systematic literature review helped contextualise the determinants for Fintech adoption based on characteristics such as regions (emerging versus developing countries), context (infrastructure and social), and type of Fintech services (mobile money versus internet banking, for example). Despite the continuous growth of mobile money across regions, its adoption is still low in the peripheral areas of the African continent [12]. Hence, in the context

of Niger, the determinants of hypotheses (A), (B), (C), (D), and (E) can help form a conceptual model for influencing mobile money adoption.

6 CONCEPTUAL MODEL

The suggested conceptual model includes the following determinants, based on UTAUT2 [8]: "Performance Expectancy," which suggests that mobile Fintech can help increase user adoption in Niger. (hypothesis A). "Effort Expectancy" through perceived simplicity and ease of use can help increase adoption in Niger, where the adult literacy rate is only 38% [35] (hypothesis B). "Facilitating Conditions" through the availability of resources, support, and regulatory frameworks can help foster Fintech trust and adoption in Niger (hypothesis C). "Social Influence" can influence an individual's behaviour towards adopting mobile money in the context of Niger (hypothesis D). Finally, "Price Value" can be a good incentive for increasing Fintech adoption in Niger (hypothesis D).

The following diagram provides the conceptual model based on the hypothesis and determinants.

Figure 2: Mobile Money Adoption (Niger) – Conceptual Model

The suggested conceptual model is based on key determinants in UTAUT2. Accordingly, studies indicate that factors such as education, female gender, high income, employment, marital status, and rural residency can increase the probability of using mobile Fintech services in Sub-Saharan Africa. Youth, female gender, divorce status, economic status, and household size may negatively influence mobile Fintech adoption in Sub-Saharan Africa [25]. Additionally, religious beliefs can hinder the adoption of mobile money [11].

7 CONCLUSION

Mobile money is an excellent case for integrated digital and financial innovation, positively influencing financial inclusion and reducing poverty. However, its adoption rate remains low, especially in peripheral sub-Saharan Africa and particularly in Niger.

The study aimed to critically evaluate current adoption theories and research on mobile money, as well as other mobile Fintech services, including mobile banking and Internet banking, mainly in Africa, with a specific focus on Niger. Utilising PRISMA principles for a systematic literature review of 34 pertinent studies on mobile money, e-wallets, mobile

banking, and internet banking in Sub-Saharan Africa and Niger identified the key factors that can facilitate the adoption of mobile Fintech in general and mobile money in particular in Niger. Accordingly, the "Performance Expectancy", "Effort Expectancy", "Facilitating Conditions", "Social Influence", and "Price Value" of UTAUT2 [8] can foster sustainable adoption of mobile money in Niger. The findings of the literature review can assist scholars, policymakers, and the business sector in promoting the adoption and sustainable use of Mobile Money in Niger, thereby enhancing financial inclusion, efficiency, and economic growth. Thus, it is important to investigate further the impact of other socio-economic factors such as income level, age, and gender.

This literature review is limited by the scarcity of studies on mobile money in West Africa, particularly in Niger. The analysis is confined to a systematic literature review and does not include a meta-analysis. Future research should conduct rigorous field experiments and incorporate quantitative analysis into the systematic review process.

A SURVEY OF LOGISTICS SKILLS IN SOUTH AFRICA: IDENTIFYING LOGISTICIANS OF THE FUTURE

R.A. Dondofema[1*]

[1]Smart Mobility Cluster-Smart Logistics Management
Council for Scientific and Industrial Research, South Africa
radondofema@gmail.com, rdondofema@csir.co.za

ABSTRACT

South Africa faces major structural challenges, including an unemployment rate of 27%, which rises to 55% among youth. Although Africa's most advanced economy, it has underperformed compared to other middle-income countries, leading to a critical skills shortage, particularly in logistics. Results of this study show that while there are adequate traditional logistics skills, there is an increasing need for technologically adept logisticians due to rapid advancements, requiring expertise in data analytics, telecommunications, and environmental management. Future logisticians must understand value creation, identify market opportunities, and possess both technical and soft skills to succeed in the evolving logistics landscape.

Keywords: Logistics skills, Skills survey, Future logistician

1 INTRODUCTION

South Africa is facing significant structural challenges, including the delivery of quality education, a high crime rate, corruption, a high unemployment rate, and labour market rigidity. The large number of young people requiring training and the slow pace of expansion of educational institutions contribute to the high unemployment rate and difficulty in entering the labour market [1]. Despite being the most advanced economy on the African continent, South Africa has underperformed compared to its peers and currently lags behind other middle-income countries in these critical areas. As a result, the country is facing a significant skills shortage. According to Stats SA, the unemployment rate is 27%, with a youth unemployment rate of 55%. Various economic sectors need experienced technicians with relevant skills. According to the Logistics Barometer (2016) [2] and the Barloworld Supply Chain Foresight (2018)[3] , the shortage of skilled workers is a major constraint to supply chain efficiency in South Africa.

These inefficiencies result in a high cost of logistics that equals approximately 11.7% of South Africa's GDP, which is higher when compared to the USA and Germany, where it is estimated to account for 7% and 8.6%, respectively [2]. South Africa has a unique transport-intensive economy that is characterised by long distances between ports and economic centres [2]. This highlights the increased importance of efficient supply chain management. Efficient logistics and supply chain performance are critical for the smooth functioning of the economy and the Reserve Bank SARB has identified dysfunctional supply chains as one risk to economic growth [4].

The relationship between sector skills and sector performance has been widely recognised in academic literature and by numerous scholars [5], [6]. This study is part of a national initiative aimed at enhancing the competitiveness of South Africa's logistics network. This study assessed the current skills landscape and identified skills necessary for future logisticians in South African context.

Clarke (2018) [7] identifies the causes of the skills shortage as 1) an industry growing faster than workforce qualifications, 2) a shortage of educators, and 3) businesses struggling to identify competent individuals. The supply chain landscape is changing rapidly and, as a result, professionals need to acquire new skills to stay relevant. Despite having the most advanced economy on the African continent, South Africa has performed poorly relative to its peers and currently lags behind other middle-income countries in these critical areas hence the country experienced an amplified skills shortage. WEF has indicated that these skills cannot be developed through training alone, but require a combination of various approaches, including practical experience [8]. The aim of this study is to understand the skills gap in the logistics sector of South Africa. To achieve this goal satisfactorily, the following objectives will be met:

- Outline the skills gap within the logistics sector in South Africa.
- Identify the relevant skills for the future logistician; and
- Identify skills that are not easy to fill in the sector.

The skills gap can be defined as the discrepancy between the abilities that job seekers possess and the skills that employers need [7], [9]. The logistics skills gap refers to the shortage of trained people who can oversee intricate logistics operations and use technology to maximize productivity. Reasons for the logistics skills gap include the emergence of disruptive technologies such as the Internet of Things, Artificial Intelligence, and Blockchain, which has created a demand for unique skill sets. The competencies required to utilize these skills extend beyond traditional logistics and supply chain skills [7], [9].

2 BRIEF REVIEW ON LOGISTICS SKILLS AND TALENT MANAGEMENT

This literature review focuses on the definitions and categorisations of logistics skills. The section concludes with an examination of the significance of talent management in the context of skills development and retention.

There are different supply chain skills categorisations in the literature, for example, Dubey et al (2017) [10] group logistics skills based on where they are applied within the logistics chain. The study classifies them as purchasing skills and management skills, whilst Lutz and Birou (2013) [11] distinguish skills based on core competencies being applied. In the study by Lutz and Birou [11], in logistics, there are social skills, decision-making skills, problem-solving skills, time management skills, and general knowledge skills. Social skills include oral communication skills, the ability to manage relationships, listening skills, and other related skills. Decision-making skills include cross-functional coordination, globalisation of transport and logistics, material handling, material sourcing, warehouse design, and warehouse management. Problem-solving skills are applied in inventory management, maintenance and repair, tracking and tracing, and the ability to learn quickly. More recent studies have now focused mainly on digitisation skills, which is a paradigm shift from the traditional logistics skills in response to advances in information technology systems [12]. However, this classification of skills is consistent with the competence approach used by [11]. In this survey study, both paradigms of logistics skills definition have been used.

It is also important to understand the talent management strategies employed in the logistics sector. Identifying and acquiring talent with the necessary skills to perform essential job functions is fundamental to the competitiveness of the logistics sector in South Africa. Employees who lack the requisite skills may face a high level of incompatibility within organisations, leading to increased employee turnover and negative performance appraisals [6]. Failure to manage talent within the sector from acquisition to retention is akin to failing to manage the logistics sector effectively. A well-managed sector should be backed by skilled human resources that enhance performance and improve sector competitiveness.

Talent management is defined as the sum of experience, knowledge, skills, and abilities possessed and utilised by each employee in an organisation [6][5]. This encompasses various processes for identifying roles, responsibilities, and necessary skills, as well as establishing qualified resources for each position [5]. Talent management includes efforts to attract, onboard, develop, retain, and replace talent to achieve top performance emphasize the importance of establishing talent forecasts, roles, responsibilities, and critical capabilities and skills, as these foundational activities ensure that subsequent acquisition processes (such as onboarding, mentoring, and training) focus on the organizational needs vital for an effective talent management program [5], [6].

3 METHODOLOGY

The first step was to comply with the CSIR's research ethics requirements. Once the requirements were met, a questionnaire was developed and reviewed internally within the Smart Logistics Management research unit and externally with the South African Association of Freight Forwarders (SAAFF). After completing the review phase, the questionnaire was uploaded to Google Forms, and a test survey was conducted. After successfully conducting a test survey, a final questionnaire was distributed through various channels, including the SAAFF emailing list, LinkedIn, personal networks, and Transport Forum networks. Survey responses were analyzed using the tools provided by Google Forms and Google Analytics.

The steps followed in this study are summarised below:

- Research ethics application;

- Questionnaire development;
- Online survey distribution; and
- Response analysis.

3.1 Questionnaire development

When conducting a survey, it is essential to ensure validity and reliability. Validity refers to the accuracy of the survey and is determined by assessing the representativeness of the sample and the precision of the questions being asked [13]. This helps to ensure that the survey accurately measures what it is intended to measure. Questionnaire reliability refers to the consistency of questions and their ability to elicit information from respondents, regardless of changes to the structure of the wording [13]. To ensure validity and reliability, the developed questions were first discussed internally and were then sent for external review to industry experts and this aids reliability as a form of triangulation.

When distributing survey questionnaires, sampling bias must be considered. To ensure a diverse pool of respondents, the questionnaire was distributed through various channels, including email lists, professional networks like LinkedIn, and personal networks. SAAFF and Transport Forum emailed the questionnaire to their members and shared the questionnaire on their LinkedIn profiles. SAAFF members account for 80% of South Africa's international trade and Transport Forum indicated that they have more than 2400 active subscribers. The survey was open from the 6th of February to 25th of March 2024

The questionnaire was designed to gather information on the experience and exposure of the respondents. It consisted of questions that aimed to understand the availability of skills, as well as the talent management methods used. The final section of the questionnaire focused on the skills required for the future.

3.2 Sample size and its limitations

Surveys are structured to gather information about a specific population, surveys intend to draw a sample that can provide insights about the entire population based on the data collected. To achieve reliable results, the sample must be selected in a manner that ensures it is representative of the population. This is not always achievable, particularly when there is limited knowledge of the entire population. Consequently, studies may encounter challenges such as coverage errors and nonresponse errors which is a limitation acknowledged in this research project.

4 SURVEY RESULTS

While the number of responses was low (17 responses), several logistics sub-sectors were represented which include: transportation, warehousing & distribution, cold chain solutions, courier & express industry, freight forwarding, procurement, and manufacturing as shown in Table 1. Respondents in our study had varying levels of experience and authority, ranging from entry-level to executive management. Table 1 also shows the years of experience ranging from entry-level to more than 10 years of experience in the sector.

Table 1: Respondents profile

Respondent ID	Logistics subsector	Role	Years of experience	Organization number of employees
1	Transportation, Warehousing & Distribution, Freight forwarding, Cold chain solutions.	Executive management	More than 10 years	more than 100 employees
2	Courier & Express industry	Executive management	4 -10 years	more than 100 employees
3	Freight forwarding	Middle-level management / Operations managers	0 - 3 years	more than 100 employees
4	Transportation, Courier & Express industry	Logistics Administration & Finance	0 - 3 years	more than 100 employees
5	Transportation, Freight forwarding	Executive management	More than 10 years	1 to 5 employees
6	Transportation, Freight forwarding, Courier & Express industry	Entry level	4 -10 years	more than 100 employees
7	Warehousing & Distribution	Supervisor	4 -10 years	16-50 employees
8	Manufacturing	Technician/ operators	More than 10 years	more than 100 employees
9	Freight forwarding	Entry level	4 -10 years	16-50 employees
10	Transportation, Warehousing & Distribution	Logistics Administration & Finance	0 - 3 years	more than 100 employees
11	Procurement	Middle-level management / Operations managers	4 -10 years	more than 100 employees
12	Warehousing & Distribution	Logistics Administration & Finance	0 - 3 years	more than 100 employees
13	Manufacturing	Middle-level management / Operations managers	More than 10 years	more than 100 employees
14	Warehousing & Distribution	Supervisor	0 - 3 years	more than 100 employees
15	Transportation	Entry level	0 - 3 years	more than 100 employees
16	Freight forwarding	Logistics Administration & Finance	4 -10 years	more than 100 employees
17	Warehousing & Distribution	Executive management	More than 10 years	1 to 5 employees

Figure 1: Logistics skills survey respondents profile

Table 2 shows the results of the respondents on the skills that they think are abundant and enough in the sector. The following skill sets scored above 60% (when combined currently abundant and enough): forecasting and material handling, logistics financial management, facilities planning, project management, international logistics, reverse logistics, customer service, and telecommunication.

Table 2: Availability of skills in the sector

Logistics skills	Currently abundant	Enough	Lacking
Forecasting	35%	35%	29%
Inventory Management	35%	18%	47%
Material Handling	53%	18%	29%
Logistics financial management	24%	32%	39%
Production planning	35%	18%	47%
Facilities planning	59%	6%	35%
Procurement and purchasing management	35%	18%	47%
Project management	35%	24%	41%
International logistics	41%	18%	41%
Reverse logistics	29%	29%	41%
Green logistics	29%	29%	41%
Data analytics	35%	18%	47%
Business process improvement	41%	12%	47%
Customer service	47%	18%	35%
Traffic and transport management	53%	12%	35%
Telecommunication and information systems	35%	29%	35%
Community engagement	29%	29%	41%
Talent management	35%	24%	41%
Research and technology application	29%	24%	47%
Employee management	24%	29%	47%

According to the survey, over 40% of the participants stated that there are skill shortages in the following areas employee management, research and technology application, talent management, community engagement, business process improvement, production planning, data analytics, green logistics, reverse logistics, and international logistics.

Forty-seven percent (47%) of respondents indicated that onboarding and career development are poorly implemented in the sector. In addition, 41% of respondents indicated that leadership development, diversity and inclusion, talent analytics, and employee engagement are also poorly implemented in the sector.

Table 3: Talent management strategies application in the sector

Talent management strategies	Poor	Good	Excellent
Talent acquisitions	29%	41%	29%
Onboarding	47%	24%	29%
Performance management	24%	47%	29%
Learning and development	35%	41%	24%
Succession planning	29%	18%	53%
Career development	47%	18%	35%
Employee engagement	41%	29%	29%
Retention strategies	35%	41%	24%
Talent analytics	41%	29%	29%
Diversity and inclusion	41%	35%	24%
Feedback	35%	24%	41%
Continuous improvement	24%	41%	35%
Leadership development	41%	12%	47%

More than 60% of respondents reported effective implementation of the following strategies; talent acquisition, performance management, learning and development, succession planning, retention strategies, feedback management, and continuous improvement.

Respondents further indicated that future logisticians should possess skills in:

- Logistics value chain comprehension;
- Logistics finance;
- Opportunity identification in the market;
- Efficiency, sustainability, and innovation methods;
- Technology adoption and implementation;
- Entrepreneurship;
- Closed-loop logistics;
- Use of real-time data and live feeds;
- Benchmarking;
- Data analytics;
- Blockchain and Internet of Things;
- Automation;
- Sustainability practices; and
- Timelessly process shipments.

The respondents identified the following important emerging technical skills in the sector:

- Digitization and analytical skills;
- Data analysis, route planning, network optimization;

- Reporting and programming capabilities, as well as additional forecasting and data analytics tools;
- Management skills and planning skills;
- International trade;
- Research and Technology application;
- International logistics and data analytics;
- Artificial intelligence;
- Project management;
- Transport Management and task balancing;
- Automated documentation management; and
- Environmental management.

Respondents indicated that logisticians of the future require the following soft skills:

- Empathy, attentive listening, talent management;
- Time management;
- Situational awareness;
- Communication;
- Problem-solving;
- Leadership;
- Negotiation skills;
- Transparency;
- Adaptability;
- Critical thinking;
- Creativity; and
- People management.

The 4th industrial revolution is making certain tasks obsolete. Respondents indicated that the following skills will become less critical:

- Inventory management and warehouse management;
- Repetitive tasks that do not require logical decision-making;
- Administrative functions;
- Personnel management;
- Paperwork;
- Manual ordering;
- Fleet route monitoring; and
- Data capturing.

Respondents identified the following skills as being or becoming in demand due to the 4th industrial revolution:

- Data analysis;
- Clearance management;
- Creativity;
- Complex problem-solving;
- Communication;
- Planning;
- Fleet management;
- Cost management;
- Transport management;
- Project management;
- Inventory diagnostic;

- Effective collection of data;
- Cleaning and preparing data for analysis;
- Programming; and
- Data sciences, data engineering, robotics coding.

5 DISCUSSION

The survey responses are interpreted and discussed below. Note that the discussion represents responses from individuals in the subsectors indicated in Section 4. The framework in Figure 2, shows that the sector does not struggle with forecasting, material handling, facilities planning, customer service, traffic and transport management, telecommunication and information systems, procurement, purchasing and supply, and international logistics skills. Forecasting, material handling, facilities planning, customer service, traffic and transport management, procurement, purchasing and supply, and international logistics skills have long been recognised as traditional logistics sector skills, hence, it can be inferred that skills have been fully integrated into the sector. The positive trend can be attributed to initiatives between industry and skills development organisations that include vocational training, internships, apprenticeships, and collaborations between industry and educational institutions [1].

Figure 2: Logistics future skills framework

Vocational training is aimed at providing practical skills to job seekers. It covers a wide range of competencies required by the logistics and supply chain industry, such as inventory management, purchasing, distribution, and transportation. This has equipped more people with the necessary skills to enter the workforce and contribute to the industry's growth.

Promoting internships and apprenticeships has also aided in closing the skills gap in the logistics and supply chain industries. Young people have received on-the-job training and developed their experience in supply chain and logistics through internships and apprenticeships offered by businesses [14]. Collaborations between educational institutions and South African businesses have worked well, with schools developing logistics and supply chain curricula that are appropriate for the classroom and prepare students for the workplace. Various educational departments have been appointing industry-experienced individuals as course moderators to align institutional offerings with industry needs and trends.

The logistics industry still needs to adapt to the emerging trends of green logistics. The demand for these practices is primarily driven by the regulations and requirements of the European markets. By 2026, the European Union will implement the Carbon Border Adjustment Mechanism (CBAM), which will require logistics companies to prioritize green logistics skills and comply with carbon emissions measurement standards for all transport and logistics-related activities [15].

The skills gap within the logistics sector has partly been driven by the rapid pace of technological advancements. It has been highlighted that the future of logistics will require logisticians who are agile and technologically astute. To keep up with the demands of the future, logisticians will need to upgrade their skills and improve their competencies in areas such as data analytics, telecommunications and information systems, and logistics financial services.

Various stakeholders in the national logistics system are emphasizing efficiency and value maximization [16]. Therefore, the logistician of the future should possess key attributes of understanding value in the logistics value creation ecosystem. Additionally, the individual should be able to identify market opportunities and unprofitable relationships with stakeholders, including transporters, shipping lines, and other clients. The logistician of the future should also be an environmental steward and technology adopter.

The emerging skills trends in the sector are aligned with future demands. Respondents frequently mentioned skills associated with digitization, data analytics, environmental management, artificial intelligence, and international trade. Along with other technical skills, the logistician of the future should also possess soft skills such as people management, critical thinking, transparency, negotiating skills, and communication skills.

The adoption of the 4th industrial revolution is evident through the adoption of more efficient technologies. As a result, manual warehouse management activities, administrative functions, and data-capturing skills are becoming obsolete. However, it is important to note that technology is developed to augment humanity and not replace it. Therefore, skills associated with technology augmentation are in demand, as indicated by respondents.

The requirements for future logisticians, as illustrated in Figure 2, also encompass a diverse range of skills that align with the technologies currently being adopted in the sector. This diversity positions logistics as a competitor for talent alongside sectors that it previously did not compete with. For instance, the logistics sector will need to compete with the fintech industry for expertise in data analytics, blockchain technology, and the Internet of Things. The growing demand for these skills in logistics is also highlighted by emerging competencies. To attract and retain talent, organisations will need to implement various talent management strategies. This should include reskilling existing personnel who possess knowledge in areas that are becoming obsolete due to advancements in technology. The sector should strengthen some of its talent management strategies that include onboarding, career development, employee engagement, talent analytics, diversity and inclusion, and leadership development.

6 CONCLUSION

The sample size of this study was small compared to other skills surveys; however, respondents represented all sub-sectors of the logistics industry in South Africa. It is important to note that the conclusions of this study are anchored in the experience and authority of the respondents (respondents' profiles are shown in Table 1). The limitation of this study was the response rate, and this impacted the ability to draw statistical conclusions with an acceptable level of confidence. For future research, we will explore other data collection mechanisms beyond questionnaires. However, this limitation should not overshadow the findings of this study, as it represents a significant step in understanding the logistics skills landscape in South Africa.

The survey responses indicate that the logistics sector possesses adequate traditional skills in areas such as forecasting, material handling, and logistics management, largely due to initiatives like vocational training, internships, and industry collaborations. While these efforts have helped bridge the skills gap, the industry must adapt to emerging trends in green logistics, especially with upcoming regulations from the European Union. The demand for technologically savvy logisticians is increasing as the sector encounters rapid advancements, requiring skills in data analytics, telecommunications, and environmental management. Key attributes for future logisticians will include understanding value creation, identifying market opportunities, and possessing both technical and soft skills to navigate the evolving landscape of logistics and supply chain management.

Despite implementing most talent management strategies, the logistics industry is still struggling with employee retention, engagement, leadership development, and diversity and inclusion. In conclusion, respondents agreed that the logistician of the future should be familiar with new technology trends, be astute in terms of the management of green logistics and be able to identify opportunities in the ecosystem.
