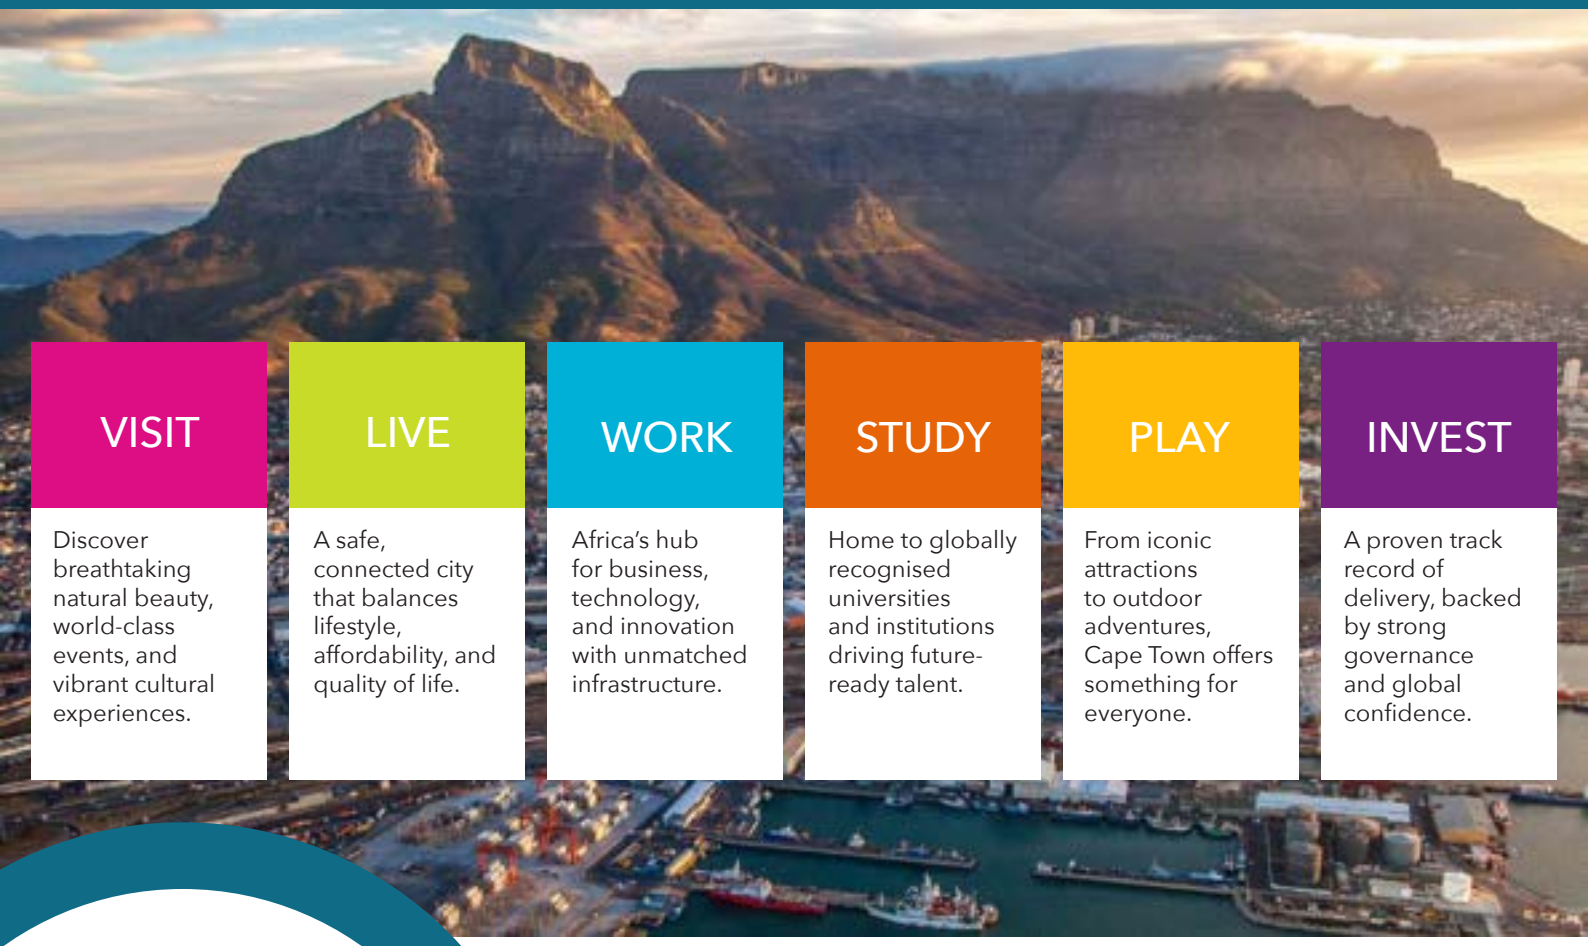
CITY OF CAPE TOWN AND THE SOUTHERN AFRICAN INSTITUTE FOR INDUSTRIAL ENGINEERING (SAIIE)

Recognised globally for its innovation, service delivery and resilience, the City of Cape Town continues to lead the way in infrastructure development and municipal excellence. Whether you're looking to Visit, Live, Work, Study, Play or Invest, Cape Town is a city of opportunity, culture, and growth.



VISIT

Discover breathtaking natural beauty, world-class events, and vibrant cultural experiences.

LIVE

A safe, connected city that balances lifestyle, affordability, and quality of life.

WORK

Africa's hub for business, technology, and innovation with unmatched infrastructure.

STUDY

Home to globally recognised universities and institutions driving future-ready talent.

PLAY

From iconic attractions to outdoor adventures, Cape Town offers something for everyone.

INVEST

A proven track record of delivery, backed by strong governance and global confidence.

CAPE TOWN
A DESTINATION FOR PEOPLE AND BUSINESSES SHAPING THE FUTURE.

CITY OF CAPE TOWN
ISIXEKO SASEKAPA
STAD KAAPSTAD

Making progress possible. Together.

Preface

The Southern African Institute for Industrial Engineering (SAIIE) annual conference continues to be a vital platform for connecting academia, industry, and government through the shared mission of advancing the field of Industrial Engineering. Over the years, this gathering has grown into one of the most anticipated events in the discipline, bringing together professionals, researchers, and students to exchange ideas, showcase innovations, and contribute to the body of knowledge that strengthens our profession.

The 35th SAIIE Conference carries the theme "Making Waves", reflecting the power of Industrial Engineers to create meaningful impact, whether through bold innovations that redefine industries or small, steady improvements that ripple across organisations. Just as waves represent motion, disruption, and connection, this year's theme invites participants to share how their work is shaping industries and communities through creativity, resilience, and collaboration.

The submission and review process

This year, we received a record total of 183 full paper submissions and 10 presentation-only abstracts, representing contributions from 15 academic institutions and multiple industry partners. Notably, no single institution contributes more than 30% of the total papers published, a reflection of the diversity and inclusivity of the Industrial Engineering community across the region.

Following the double-blind peer review process, 165 papers were accepted, of which 144 are included in these proceedings and 17 were selected for publication in the special edition of The South African Journal of Industrial Engineering (SAJIE). These papers reflect a diverse spectrum of topics spanning operational excellence, sustainability, data-driven decision-making, human-centred design, and digital transformation.

Abstracts for the full-paper track were screened for suitability, and successful authors were invited to submit full-length papers. These were screened using Turnitin plagiarism software to uphold academic integrity before being reviewed through a double-blind peer review process. The review process was managed via the online conference management system, which enables reviewers to provide feedback and ensures that all editorial decisions are transparently recorded. Each paper was reviewed by at least two reviewers, often pairing experienced academics with industry experts to facilitate a credible and developmental process. Only papers that passed this rigorous review were included in these proceedings.

We extend our sincere gratitude to the authors for entrusting us with their work, to the reviewers for their generous time and expertise, and to the editorial and technical teams whose commitment made this publication possible. Your collective efforts ensure that the SAIIE conference remains a credible and enriching forum for advancing Industrial Engineering research and practice in Southern Africa and beyond.

Finally, as we gather at Lagoon Beach Hotel, Cape Town, with Table Mountain on the horizon and the Atlantic Ocean at our doorstep, may this year's conference inspire us to continue making waves through innovation, collaboration, and the pursuit of excellence.

Dr Philani Zincume (Dr Zee)

Shaping the currents of tomorrow

At the Graduate School of Technology Management (GSTM), we lead change in engineering. Our internationally recognised postgraduate programmes in **Engineering Management, Technology and Innovation Management**, and **Project Management** equip industrial engineers to transform systems and drive innovation.

At SAIIE35, we celebrate Making Waves, highlighting how engineers stir progress, whether through monumental tsunamis or subtle ripples that reshape industries and inspire transformation.

Join our postgraduate community to drive the kind of change that disturbs the status quo, challenges norms, and reveals the hidden icebergs beneath the surface.

Be part of a learning environment where ideas matter, research drives impact, and technology powers progress.

Make waves. Make a difference. Study at GSTM.

GSTM proudly supports the SAIIE35 Annual Conference, championing engineers who innovate and influence industry.

For more information on our programmes, fees and application deadlines, visit **www.up.ac.za/gstm**

Make today matter

www.up.ac.za

Help us build the future

Technology creates opportunity.

But turning opportunity into real-world supply chain impact needs innovators and engineers to get the best out of the Internet of Things, robotics, digitization, big data and 3D printing.

Our solutions make a difference in many ways. They enhance workflows and optimise storage, deliver near-zero-error warehousing management and streamline monthly profit and loss and reporting. And much more.

We create smarter, faster, and more profitable supply chain solutions for our customers wherever machine, material, and methods come together.

If building the future excites you, then we want to talk.

THE DEPARTMENT OF INDUSTRIAL ENGINEERING AND ENGINEERING MANAGEMENT

About the University of South Africa

Unisa is the largest open distance learning institution in Africa and the longest-standing dedicated distance education university in the world. UNISA enrols nearly one-third of all South African students. Given our rootedness in South Africa and the African continent, Unisa today can truly claim to be the African university in the service of humanity.

UNISA offers an unparalleled range of study choices, ranging from short courses and certificate programmes to three- and four-year diplomas, advanced diplomas and degrees. It further offers postgraduate diplomas, master's and doctoral degrees, with close to 400,000 current students. The Department of Industrial Engineering and Engineering Management, located within the School of Engineering in the College of Science, Engineering and Technology (CSET) offers a range of undergraduate industrial engineering programmes which are accredited by the Engineering Council of South Africa. The Department of Industrial Engineering and Engineering Management also offers post graduate qualifications.

The globally respected and widely referenced Times Higher Education (THE) World University Rankings **2025 (www.timeshighereducation.com),** which rates over 1700 universities across 104 countries and regions, has placed UNISA's Engineering disciplines across the board in joint first place in South Africa. UNISA joins North-West University and Stellenbosch University in the top spot.

About the Industrial Engineering Profession

The domain of industrial engineering is concerned with the design, installation, and continuous improvement of integrated systems of people, materials, information, equipment, and energy. The discipline draws knowledge and skills in mathematical, physical, and social sciences together with principles and methods of engineering and analysis, and design to specify, predict, and assess the outcomes to be attained from such systems.

About the Department of Industrial Engineering and Engineering Management

The Department of Industrial Engineering and Engineering Management offers the following flexible and inclusive programmes:

Diploma in Industrial Engineering (NQF6), Advanced Diploma in Industrial Engineering (NQF7), Bachelor of Engineering Technology Honours (NQF 8), Master of Engineering (MEng) (NQF 9) by research, and Doctor of Philosophy in Engineering (NQF10).

Research focus in the Department of Industrial Engineering and Engineering Management

The research interests in the Department of Industrial Engineering and Engineering Management include, amongst others:

Systems Thinking, Systems Engineering, System Dynamics, Lean Manufacturing, Quality Engineering, Digital Transformation, Productivity and Optimization, Safety Engineering, Supply Chain Engineering, Advanced Manufacturing, Technology Adoption, Process Optimisation, Facility design and Material Handling, Additive Manufacturing,

Postgraduate offerings

Postgraduate Diploma in Industrial Engineering

FOCUS: DATA SCIENCE

Develop innovative optimisation and machine learning techniques to produce novel, efficient and robust data science technologies, for use in Industrial Engineering, Engineering Management and related applications.

- Structured module-based degree on NQF level 8
- Part-time and full-time study options available
- 8 core modules
- 1/2 year commitment

For more information contact Dr Martina Frei at mfrei@sun.ac.za

Masters in Industrial Engineering

FOCUS: DATA SCIENCE (STRUCTURED)

Develop an in-depth understanding of machine learning models and learn applications in real-world problems.

- Structured module-based degree on NQF level 9
- Part-time and full-time options available
- 8 modules (5 core, 2 electives, and 1 specialisation module) and a research assignment in industry relevant topics.
- 2/3-year commitment

For more information contact Dr Martina Frei at mfrei@sun.ac.za

Masters in Industrial Engineering

FOCUS: LOGISTICS AND SUPPLY CHAIN SYSTEMS (STRUCTURED)

The logistics and supply chain systems programme focuses on enabling students to develop forward-thinking strategies to enhance the global competitiveness of supply chains, making significant contributions to logistical frameworks and ensuring these systems are resilient and future ready.

- Structured module-based degree on NQF level 9
- Part-time and full-time options available
- 8 modules (6 core, 2 or 3 elective modules) and a research assignment in industry relevant topics
- 2/3-year commitment

For more information contact Dr Frei mfrei@sun.ac.za or Prof Goedhals-Gerber leila@sun.ac.za

Masters in Engineering Management

(STRUCTURED)

Educating innovative, future-focused leaders to solve the world's complex sociotechnical challenges.

- The MEM is composed of 7 core modules to enhance engineering and management skills.
- The curriculum can be customized with an elective and special interest research assignment, to support individual professional goals and curiosities.
- Designed with early to mid-career engineers and scientists in mind.
- 2-3 year part-time programme with a hybrid online delivery mode that allows students to study from anywhere in the world.

To find out more send an email to masterseng@sun.ac.za or visit https://mem.sun.ac.za/.

Masters in Industrial Engineering / Masters in Engineering Management

(RESEARCH)

The luxury of two years' dedicated skills development on a topic of your choice, with a topic guru as supervisor.

- Deliverables: 180 credit Thesis and finalized journal paper
- Thesis hand-in due dates:
- End August for December graduation
- Middle November for March graduation
- NQF level 9 qualification
- Full-time or part-time registrations possible

For more information contact Melinda Rust mrust@sun.ac.za

PhD Industrial Engineering and Engineering Management programmes

- Industrial Engineering offerings includes PhD studies.
- Research programme comprising 240 project-work credits in the form of a research dissertation.
- Minimum residency of 2 years.

For more information contact Dr Megan Forster meganforster@sun.ac.za

ABSTRACT

The ability of Posts to be effective and efficient in a 21st-century world driven by complexity, uncertainty, and ambiguity (VUCA) is a challenge that the postal sector must confront with determination to expand its reach, become resilient, remain relevant, and assure service reliability. The recent coronavirus contagion has exposed vulnerabilities in the postal sector's ability to respond to uncertainty. At the same time, the pandemic's consequences in bringing it to a halt have resulted in improvements in the natural environment as pollution on land, air, and waters receded. Therefore, sustainability is a crucial dimension of a sustainable Post, which demands adopting lean thinking and green thinking principles for greater humanity. A literature review focused on lean thinking and green thinking in the context of the postal sector in South Africa, which operates in the 21st century. The insights from the literature review were used to develop a lean-green dynamics conceptual model through a causal loop diagram, which illustrates the interaction of lean-green variables in a dynamic setting for postal sustainability. The research culminated in two reinforcing loops, which begin with lean thinking principles and green engineering principles, which reduce or even best eliminate the eight and environmental wastes, respectively, creating value that drives operational performance and reinforces a sustainable Post. A sustainable post that pursues the four sustainable development goals bolsters value creation for stakeholders.

Keywords: Lean Thinking, Green Thinking, Green Engineering, Value Engineering, Lean-Green

1 INTRODUCTION AND BACKGROUND

The world is changing rapidly and is driven by VUCA (Volatility, Uncertainty, Complexity and Ambiguity). These drivers force companies to become more efficient and competitive in order to remain in business. Uncertainty denotes a lack of certainty and momentous likelihood of surprise. The word complexity is denoted by an array of determinants underlined by disarray and confusion, and the word Ambiguity is characterised by fuzziness, a high likelihood of misconstruing conditions [1]. The current health crisis in the form of coronavirus, better known as COVID-19, is another uncertain prospect that no one has seen coming, and it has squeezed out businesses, resulting in their closure. It has put enormous financial pressure on companies and organisations. Climate change, which is wreaking havoc worldwide, has necessitated the international community to adopt Agenda 2030 with a set of Sustainable Development Goals (SDGs), which address an array of social, environmental, and economic challenges facing humanity in the 21st century.

Ranganathan and Dey [2] postulate that the postal service is the most elementary and common means of communication in most countries. The postal service sector is caught in a vicious cycle of poor financial performance, which triggers a lack of investment, thereby inhibiting either improvements in the quality of service or expansion, which generates even lower usage of the sector and mail volumes, further perpetuating the downward spiral. [2]. The haulage of materials, resources and products throughout the postal value chain has a considerable impact on businesses from a financial perspective due to costs associated with moving an array of materials, which includes letters which are currently on the decline, parcels which are exponentially rising due to e-commerce which has prompted a high demand for parcels, and distribution of social grants, resources. These movements across the postal value chain enormously impact the environment due to direct and indirect emissions generated from operations. Operations include a massive fleet operated by the postal sector and massive buildings operated by the postal industry, with the postal network present in almost all areas in the country, including even the remotest areas. Customer centricity, which is one of the core tenets of a lean system, demands that organisations, and in this context, the postal sector, respond to new customer demands from environmentally conscious customers in addition to complying with international, continental, regional, national, and local environmental laws and regulations. This requires organisations to have a complete mental shift in conducting business on the strategic, tactical, and operational levels.

Gupta [3] postulates that green thinking aims to manage consumption and reduce ecological impacts and burdens, while lean thinking seeks to eliminate waste; there seems to be a natural synergy between these two approaches. However, research on integrating these approaches is still progressing. This paper presents a literature review on the postal sector, lean manufacturing, and green engineering to develop a theoretical framework. To develop the theoretical framework, the main research question addressed in this study is:

1. What are the core determinants that underpin the postal sector?
2. What are the dimensions and constructs of lean thinking?
3. What are the dimensions and constructs of green thinking?
4. Can a causal system dynamic model be developed that illustrates the dynamic relationship between lean and green thinking principles in the postal sector in South Africa?

This article aims to determine how the postal sector in South Africa can improve its business performance to improve its reach, reliability, resilience, and relevance to attain its socio-economic imperatives through an integrated Lean-Green approach. To achieve this, the article establishes that combining Lean and Green thinking to leverage their strengths and bolster

each other. The article will develop a causal loop conceptual diagram that assimilates Lean and Green thinking for the postal sector in South Africa.

In the subsequent part of the article, a literature review is presented on Lean and Green thinking as individual approaches. The logic for integrating the two approaches as an assimilated approach is presented. Subsequently, the research methodology part of the article articulates how this study was conducted. The results part of the article articulates the analysis and the key findings. The discussion part of the articles articulates the intricacies and dynamics of the proposed Lean-Green framework. The article concludes with insights that a lean-green approach offers superior benefits such as cost reduction, improvement of process flows, reduced lead times, compliance with environmental laws and policies, meeting customer expectations and reduced environmental burden.

2 LITERATURE REVIEW

2.1 The postal sector and its evolution

DTPS [4] postulates that globally, the traditional postal services sector is undergoing reform prompted by the introduction of the digital society and the Internet. The proliferation of electronic mail, as well as other communication media, poses both challenges and opportunities for the postal services sector. Post Offices worldwide are transforming and innovating to include providing such services, given the decline in traditional mail volumes. [4]. To offer sustainable digital postal services, Posts must rely on their competitive advantages and transform key aspects of their business [5]. This view is supported by researchers who argue that Information and Communication Technologies (ICTs) have transformed social and business communications and have engendered a substantial decline in the traditional letter-mail business. In response, postal operators diversify and provide new e-services to their clients [6].

UPU [7] argues that the upsurge of digitalisation, paired with other long-term socio-economic transformations, has triggered Posts to grow their services well beyond the physical delivery of mail. The postal sector substantially contributes to promoting socioeconomic development. This is because affordable, efficient and universal postal services substantially reduce transaction costs between economic agents, giving them access to an extensive communications and infrastructure network. In this sense, the postal sector actively contributes to the achievement of the United Nations Sustainable Development Goals (SDGs) [8].

UPU [9] asserts that the UN Sustainable Development Goals (SDGs) are ambitious universal agendas to achieve a better and more sustainable future for all. The SDGs aim to address urgent global challenges that humanity faces in the context of poverty, inequality, climate change, environmental degradation, prosperity, peace, and justice. The UPU (Universal Postal Union) asserts that its assessment revealed that four SDGs show high correlations for postal development and are measurable in the context of the postal sector. The four goals identified as having a high correlation with postal development are goals 8, 9, 11, and 17, which are decent work and promote economic growth, build resilient infrastructure, make cities and human settlements inclusive, safe, resilient, and sustainable, and partnerships for the goals [10].

Taking the above SDGs into perspective, It is clear that to make the postal sector sustainable from an economic, social and environmental standpoint; it is essential for the postal sector at national levels to take urgent and appropriate steps to implement activities that will result in lessening the environmental burden, continuing to play a role that the Post has played for more than 100 years which is socio-economic development, and rendering affordable yet cost-effective postal services to ensure financial sustainability of the postal sector. The socio-

economic role played by the postal sector cannot be overemphasised, and this is reinforced by the report of [11], which asserts that with approximately 677,000 post offices, 5.3 million staff and physical infrastructure covering 192 countries, the postal sector plays a critical socio-economic role. According to [12], the regional landscape of the Southern African postal sector comprises 50 sorting centres and a delivery infrastructure of 16,064.394 delivery points; South Africa accounts for 26 sorting centres and 14,106.896 delivery points. This makes South Africa the most extensive network, accounting for 52% of sorting centres and 88% of the delivery points.

The Post in South Africa is responsible for managing its operations efficiently and ecologically for the benefit of society, pursuing its historical mandate of socio-economic development, and connecting people.

2.2 Lean thinking as a standalone approach

Sundar et al. [13] assert that Lean concepts progressed from Japan, particularly Toyota. Lean manufacturing is a waste elimination method, as several authors have advocated [14];[15]; [16]. However, lean manufacturing amplifies the product's value by eliminating waste [13]. Lean manufacturing is built on the concept of producing products without waste. Waste can take many forms and shapes and can be found anywhere throughout the organisation's business processes. It may be hidden in standard operating procedures (SOPs), systems, methods, designs, and business processes. Waste devours resources without adding value to the goods, services and business processes [17].

Bicheno and Holweg [16] argues that the best way to represent Lean is through the difference between load and capacity, which triggers a gap. They say that Load is the amount of work imposed on a system and is composed of two types of demands which are the failure demand, which is triggered by failure to act or failure to execute an action correctly, first time every time and value (true) demand made up from runners, repeaters, and strangers which have an impact on levelling demand. On the other hand, capacity is defined as the resources available to do the work. Understanding the nature of demand is the initial aim of Lean because shifting and levelling demand frees capacity [16].

Prasad and Sharma [17] Suggests that to cultivate the culture of lean thinking in organisations, it is imperative to implement a set of lean tools to support the endeavour; this notion is supported by [18], postulating that to put Lean Production into practice, organisations must implement various tools and techniques that support Lean Production. Leksic et al. [19] identified 5S, Bottleneck Analysis, VSM, Continuous Flow, Heijunka, Muda, Andon, OEE, PDCA, Poka-Yoke, SMED, Root Cause Analysis, Visual Factory, Gemba, Six Big Losses, Standardised Work, Tack Time, and TPM as the most applied techniques to deal with an array of waste, which their research revealed [16] Reinforces this assertion and includes seven quality tools, SOPs, Kaizen, Kanban, and 5 Whys, to the arsenal of techniques that enable a culture of waste elimination in organisations.

Coetzee [20] proposes that improving operational performance in organisations is a key success factor in sustaining and growing the organisation, and suggests that lean manufacturing is generally considered a philosophy underpinned by ongoing improvement. Thangarajoo and Smith [21] argue that lean thinking is an approach to define value from a customer’s perspective, implement value-creating activities in the correct sequence, execute these activities without interruption when customers demand, and perform the activities efficiently and effectively. They suggest that the principles that underpin lean thinking could be articulated as (a) specify value from the viewpoint of the customer, (b) categorise the value streams, (c) ensure uninterrupted flow of value, (d) ensure implementation of a pull-based system, and (e) strive for ongoing improvement continuously.

The key goal of the five principles is to establish a flawless value stream by incessantly recognising and eliminating activities deemed wasteful and concentrating on endeavours that create value [21]. These principles are used in conjunction with specific Lean tools and methods to maximise the value-adding components in an organisation by using less human effort, space, and time to produce high-quality products and render high-quality service as efficiently and economically as possible while being highly responsive to customer demand [22].

Dekier [23] argues that one principal fundamental tenet of Lean Thinking is ceaseless endeavouring for excellence, owing to which the system incessantly progresses. An organisation that endeavours to implement lean should have robust customer centricity, be passionate about continuously eradicating waste from business processes, and have the incentive for sustainability [24]. The waste streams to be eliminated by a lean management approach are (a) Overproduction, (b) waiting, (c) Unnecessary transporting, (d) Over-processing, (e) Excess raw material, (f) Unnecessary movement, (g) Defects, and (h) Unused employee creativity (Talent).

Beitinger [25] postulates that lean is a philosophy aimed at bringing the ensuing benefits: (a) Produces a vigorous inter-dependent support system, (b) Lessens the organisational costs involved in other popular methods, (c) Emphasises waste elimination, (d) Particularly highlights unnecessary cost generating points, (e) Conveys an improved control over daily events, (f) Lessens the cycle time, (g) Implements socially answerable techniques, (h) Encourages environment-friendly practices, and (i) Act as a powerful tool for competitive co-existence.

The complete offerings can be summed up as an enhanced production system that optimises the utilisation of resources and deliveries. Lean manufacturing is about “delivering the extraordinary through ordinary resources by building extraordinary processes” [25]. According to [16] sustainability has become an essential topic in Lean. Sustainability is certainly important from an environmental point of view, and the idea of optimising resources and reducing emissions matches more significant lean ideas exceptionally well [16].

2.3 Green thinking as a standalone approach

Kozień [26] argues that mainstream thinking concerning sustainability is grounded in sustainable development, which is underpinned by an interlocking circle comprising environmental, social, and economic sustainability dimensions. Sustainable development was coined in the Brundtland Report commissioned by the United Nations’ World Commission on Environment and Development, which defined sustainable development as “development that meets the needs of the current generation without sacrificing the needs of future generations. [27]. This report rings alarm bells about an interlocking crisis facing humanity, characterised as an environmental, developmental, and energy crisis threatening humankind [27]. Green thinking is an attempt to address the environmental crises currently facing humanity, which have devastating effects on society.

Mokgohloa [28] suggests that the concept of environmental sustainability ranks high on the legislative agendas of most governments, and sustainability issues are of increasing concern due to global warming resulting from the exploitation of fossil fuels, which results in climate change, which is one of the biggest challenges of the 21st century. Environmental sustainability is maintaining the qualities valued in the physical environment [29]. This is reinforced by [30], postulating that environmental sustainability as meeting the resource and service needs of current and future generations without compromising the health of ecosystems that provide them. As a condition of balance, resilience and interconnectedness allows human society to satisfy its needs while not exceeding the capacity of its supporting ecosystems to continue to regenerate the services necessary.

Patel et al. [31] hypothesise that it is impractical to visualise life without the products produced by businesses because they are used in every facet of modern life. Green thinking, or rather environmental sustainability thinking, on the other hand, is articulated in this paper as a notion of Green Engineering. Green Engineering is designing, unearthing, and applying engineering solutions with cognisance of prospective benefits and difficulties from the ecological, economic, and societal perspectives throughout the design lifecycle [32]. On the other hand, Graedel and Allenby [33] describe Green Engineering as the design and application of engineering solutions that contemplate environmental sustainability concerns throughout the life cycle of the design.

According to Prasad and Sharma [17], green manufacturing is defined as a method of production that reduces waste and ecological pollution by applying research and process design. It is also a practice which supports and sustains a renewable way of manufacturing products or rendering services in a way that protects the environment. Green manufacturing aims to conserve and protect the environment and conserve resources for future generations. This goal supports the definition in the Brundtland Report, also known as "Our Common Future", which defines sustainable development as "development that meets the requirements of the current without sacrificing the capacity of future generations to meet their own needs" [27]. The assertion by [17] is reinforced by [34], postulating that the purpose of green thinking is to reduce environmental risks and impacts while improving the ecological efficiency of firms.

Mihelcic and Zimmerman [32] articulates the 12 Green Engineering principles, providing a framework to comprehend the concepts and practices essential to ensure sustainable engineered solutions to problems. These key principles are (a) Integral rather than incidental, (b) Prevention rather than treatment, (c) Design for ease of separation, (d) Maximization of mass, (e) Energy, space, and time efficiencies, (f) Output-pulled rather than input-pushed, (g) Conserve complexity, (h) Durable rather than immortal, (i) Meet needs and minimise excesses, (j) Minimization of material diversity, (k) Integrate local energy and materials value streams, and (l) Design for commercial after-life. This view is complemented by [35], proposing that the key principles of green chemistry, which is an approach to the design, manufacture and use of chemical products to reduce or eliminate chemical hazards intentionally are (a) Prevention (b) Atom economy, (c) Less hazardous chemical synthesis, (d) Design for safer chemicals, (e) Safer solvents and auxiliaries, (f) Design for energy efficiency, (g) Use of renewable feedstocks, (h) Reduce derivatives, (i) Catalysis, (j) Design for degradation, (k) Real-time analysis for pollution prevention, and (l) Inherently safer chemicals for accident prevention. There is a perfect correlation between green engineering and green chemistry principles as articulated by the respective principles. The twelve principles provide a framework to guide engineers in considering suitability through all design stages. They encourage the redefinition of the task by considering the entire lifecycle, inputs, and outputs [36]. Mihelcic and Zimmerman [32] asserts that the tools and techniques that are used to implement green engineering are lifecycle analysis (LCA), design for the environment (DFE), material flow analysis (MFA), environmental risk management and systems thinking.

Florescu and Barabaș [37] proposes that wastes associated with green manufacturing include air pollutants such as carbon dioxide emissions, energy use, wastewater discharges and solid waste generation. In the postal context, IPC [38] suggests that delivery efficiency, fuel consumption, and electricity consumption are directly proportional to carbon emissions due to the massive fleet and infrastructure in which the postal sector operates.

Pejic [39] postulates that the green thinking paradigm is realised by implementing green initiatives supported by tools and methods, including green operations, environmental management systems, green buildings, sustainable value stream mapping, life cycle assessments, and ecological design. IPC [38] asserts in the quest to become environmentally

sustainable, the postal sector has identified Sustainable Development Goal 9 (Industry, innovation, and infrastructure), Goal 11 (Sustainable cities and communities), Goal 12 (Responsible production and consumption), and Goal 13 (Climate action) as key Sustainable Development Goals (SDGs) that the global postal. These four SDGs are linked with priority areas: resource efficiency, waste management and air quality, procurement, and climate change mitigation and adaptation.

2.4 Rationale of Lean-Green thinking as an integrated approach

Cherrafi [40] suggests that the Lean and Green concepts have gained popularity recently, even though their underpinning principles and tools are not new. Lean and Green are compatible strategic approaches because they focus on reducing waste and efficiently using resources. Lean thinking and the green thinking approach, as standalone systems, have different measures and objectives to make organisations effective and efficient by eliminating waste and optimising costs across the value chain. While lean thinking is underpinned by five principles that strive for flow and perfection, green thinking, as espoused by green engineering, is underpinned by 12 principles encompassing the sustainability component in good engineering design of products and processes. While lean thinking is geared towards improving operational performance by eliminating waste, green thinking, on the other hand, is geared towards minimising waste and pollution [17].

Wei Dong et al. [41] proposes that the Lean and Green Thinking approaches have demonstrated a common cause focused on reducing and eliminating non-value-added activities for the final product or service. The synergy of Lean and Green thinking will eliminate the non-value-added activities in the process and reduce implementation time in attaining their common outcome. As lean tends to emphasise waste elimination or reduction, it offers a conducive environment to implement green thinking paradigms, approaches, and tools. In this case, the similarity between the two paradigms is logical, which is waste reduction. However, green thinking goes deeper than waste reduction as it is also immersed in process efficiency, reduction of material consumption, 3Rs (Reduce, Reuse, and Recycle), and customer satisfaction. From this perspective, it is possible to identify several synergies between the lean and green concepts: waste reduction, lead time reduction, and using different approaches and techniques to manage people, organisations, and supply chain relations. [42].

Faydy and Abbadi [43] argue that the benefits of the lean-green approach are cost reduction, improvement of process flow, reduction of lead times, reduced risk of non-compliance with regulations, meeting customer expectations, improved quality of the natural environment, and improved employee morale and engagement. They argue that barriers to implementation of lean-green initiatives are not short and suggest that fear of failure, lack of expertise, poor quality of human capital, lack of stakeholder support in to integrate lean-green practices, lack of top management involvement in adopting lean-green initiatives, poor corporate culture that separates environmental and continuous improvement decisions, and lack of environmental awareness amongst employees and even managers.

3 RESEARCH METHODOLOGY

Research methodology is a general research process that determines the shape and form of the research to be undertaken and starts from the philosophical worldview, research approach, research choice, research strategy, time horizons, and research techniques and procedures [44]; [45]. This paper adopted a pragmatic philosophical worldview, which is grounded on the research question which guides the research, an inductive approach, which is grounded on a building research approach, a qualitative research choice, a literature review as the chosen research strategy, time horizon of 10 years for relevant literature reviewed, and data collection was conducted through identification of relevant literature and analysis of the relevant literature was used to extract pertinent insights to develop an artefact in the

form of a conceptual framework. A literature review is a chronological means to accumulate, understand, comprehend, use, examine, integrate, and appraise quality literature to provide a solid ground for a topic and research method [46]. The system dynamics approach was then applied to develop a causal loop conceptual model to articulate the interaction of lean and green thinking variables in pursuit of organisational performance.

The research model that underpins this study is depicted in Figure 1. The research model culminates with articulating the research question that guides the research, followed by locating, selecting, and assessing relevant literature that relates to the research question, followed by synthesis and analysis of selected literature. The chosen literature's synthesis and analysis culminate in insights used to develop a causal loop conceptual model and conclude by reporting the findings that respond to the research questions.

The search method was completed with a desktop search of the body of material already published on the topics of investigation. To ensure that the reviewed articles were relevant to the field under study, the criteria also included limiting the reviewed papers to those written in English and performing a general overview of the research area. The search followed the requirements that were used to search open-journal sites and industry sites, and focused on the following topics:

- Lean Thinking
- Green Thinking
- Value Engineering
- Sustainability
- Green Engineering

One hundred fifty-five (155) articles came up in our initial search with the search terms. We reviewed the abstracts of all the chosen papers for primary evaluation, which allowed prioritisation to concentrate on the most relevant material. Table 2 lists the evaluation criteria in detail. Fifty (52) publications were found by applying the inclusion and exclusion criteria, and these were used for the literature evaluation.

Table 1: Inclusion and Exclusion Criteria

ID	Decision Type	Assessment Criteria
EX1	Exclusion	Duplicated papers
EX2	Exclusion	Informal literature
EX3	Exclusion	Papers not written in the English language
IN1	Inclusion	Recent publications (Papers not older than 10 years)
IN2	Inclusion	Papers categorically mentioning business process management, maturity models, strategy alignment, and information technology in the postal sector.
IN3	Inclusion	Relevance concerning the area under study

4 RESULTS AND DISCUSSIONS

The postal sector operates a massive fleet of delivery vehicles, mail centres, delivery depots, and retail outlets responsible for the end-to-end process from collecting mail items and parcels to their sortation and transportation to their destination. Articles reviewed suggest that while lean thinking and green thinking differ in their respective objectives, the former focuses on value addition and elimination of waste, and the latter focuses on reducing environmental impacts and environmental burden to the natural environment and utilising natural resources effectively and efficiently. It is apparent that while they have respective goals, they have a similar objective, waste reduction, as both approaches are geared towards reducing and eliminating waste across the product and business value chains.

Leksic [19] asserts that Lean was developed for the manufacturing environment, and its importance is related to operational and strategic mindset shifts, while [47] It asserts that the concept of green thinking in manufacturing applies green strategies and innovative techniques, including products and processes that consume less material and energy to reduce environmental waste and environmental burden to the planet.

The overall argument amongst the articles reviewed is centred on the potential benefits of implementing an integrated approach to attain efficiencies in the context of organisational and environmental objectives within the firm's operations and business processes. In essence, the papers suggest that while lean thinking and green thinking practices have been around as standalone approaches, there has been an upswing in research to integrate the two methods in recent years. The literature review points to a meeting of minds between lean thinking and green thinking, in which the concept of waste reduction can characterise, ideally, waste elimination. Literature suggests that integrating the two approaches would substantially benefit the organisation and, in this case, the postal service. The substantial benefits can be summed up as the eradication of waste, which leads to improved efficiencies, which suggests improved bottom-line and reduced environmental burden through the reduction of environmental wastes.

A value engineering methodology was applied, as depicted in Figure 1 and described in Table 2, to synthesise the literature associated with the two approaches into the purpose, which answers the question of why; an objective, which answers the question of where; functions, which answer the question of what; and activities, which answer the question of how. The information-gathering stage is characterised in this research by the detailed literature review. The information-gathering stage incorporates articulating the purpose or, put simply, the reason for existence. This approach was adopted to streamline the insights extracted from the literature review. The purpose of the approaches is to facilitate streamlining, the functions that underpin the principles pertinent to the approaches, and the activities that articulate how the two methods are applied. As a result, only three tenets of the value engineering methodology are utilised to streamline the insights of the literature review.

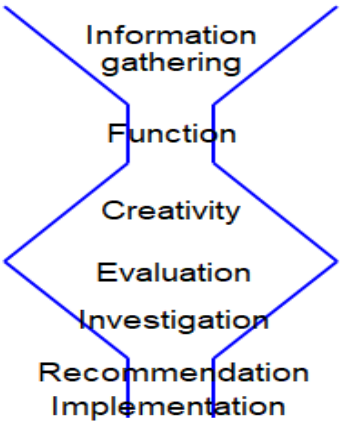

Figure 2: Value Engineering Methodology [48]

Table 2: Synthesis of concepts and variables on lean and green thinking

Underpinning Philosophy	Lean thinking	Green thinking
Purpose (Why?)	Lean Thinking establishes a flawless value stream by incessantly recognising and eliminating activities that are deemed wasteful and concentrating on endeavours that genuinely create value [21].	Green Engineering is the design, unearthing and application of engineering solutions with cognisance of prospective benefits and difficulties from the ecological, economic, and societal perspectives throughout the design lifecycle [32].
Functions (What?)	(a) Specify value from the viewpoint of the customer, (b) Categorise the value streams, (c) Ensure uninterrupted flow of value, (d) Ensure implementation of a pull-based system, and (e) Strive for ongoing improvement continuously [23].	(a) Integral rather than incidental, (b) Prevention rather than treatment, (c) Design for ease of separation, (d) Maximization of mass, (e) Energy, space, and time efficiencies, (f) Output-pulled rather than input-pushed, (g) Conserve complexity, (h) Durable rather than immortal, (i) Meet needs and minimise excesses, (j) Minimization of material diversity, (k) Integrate local energy and materials value streams, and (l) Design for commercial after-life [29.
Activities (How? Wastes)	Reducing or, at best, eliminating the eight wastes. (a) Overproduction, (b) Waiting, (c) Unnecessary transporting, (d) Over-processing, (e) Excess raw material, (f) Unnecessary movement, (g) Defects, and (h) Unused employee creativity (Talent). [14]	Reducing or, at best, eliminating the environmental (ecological wastes. (a) Solid waste (b) Wastewater discharge (c) Air pollution (d) Resource wastage [37].
Activities (How? Tools)	5S, Bottleneck Analysis, VSM, Continuous Flow, Heijunka, Muda, Andon, OEE, PDCA, Poka-Yoke, SMED, Root Cause Analysis, Visual Factory, Gemba, Six Big Losses, Standardised Work, Tack Time, and TPM [19].	MFA, DFE, environmental risk management, and systems thinking [32]. EMS, Green Buildings Ratings, sustainable VSM [36].
Lean-Green Benefits	Cost reduction, improvement of process flow and lead times, reduced risk of non-compliance with regulations, meeting customer expectations, improved quality of the natural environment, and improved employee morale and engagement [43].	

The insights from Table 1 were used to develop a system dynamic causal loop model and depicted in Figure 2.

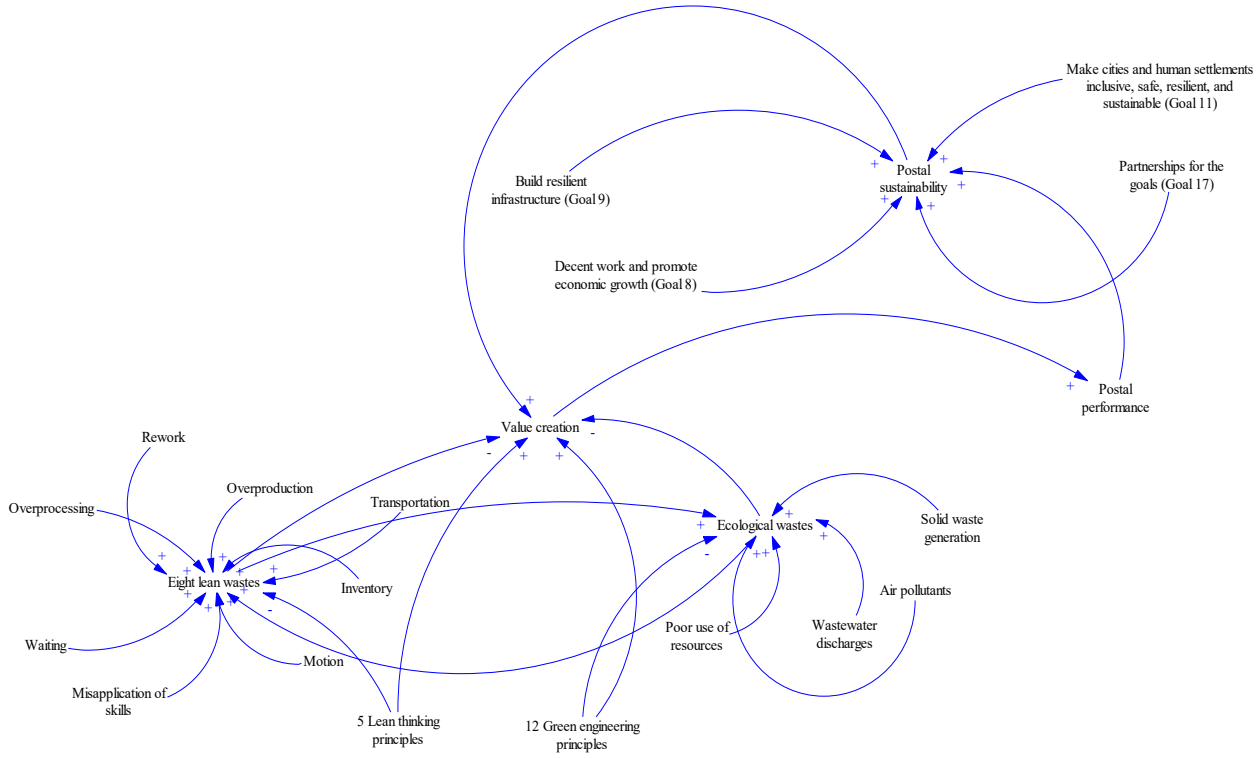

Figure 2: Lean-Green Dynamics

To demonstrate the effects of reduction or, even better, elimination of waste and creating value from a customer perspective, a system dynamic causal loop conceptual model is presented in Figure 2. The causal loop diagram demonstrates the variables that interact in a dynamic setting and articulates the five lean principles, which are (a) value, (b) value stream, (c) flow, (d) pull systems, and (e) striving for perfection are fundamental is reducing and at best eliminating the eight lean wastes (waiting, motion, inventory, misapplication of skills, overproduction, transportation, overprocessing, and rework). The propagation of the eight wastes within the business value chain reinforces the eight waste types and ultimately reduces value creation. On the other hand, adopting lean thinking principles reduces or, at best, eliminates the eight wastes, leading to improved value creation, resulting in improved performance of the postal organisation and ultimately leading to postal sustainability, which reinforces value creation for stakeholders.

The causal loop diagram further explains the 12 principles of green engineering (a) Integral rather than incidental, (b) Prevention rather than treatment, (c) Design for ease of separation, (d) Maximization of mass, (e) Energy, space, and time efficiencies, (f) Output-pulled rather than input-pushed, (g) Conserve complexity, (h) Durable rather than immortal, (i) Meet needs and minimise excesses, (j) Minimization of material diversity, (k) Integrate local energy and materials value streams, and (l) Design for commercial after-life are crucial in preventing environmental waste throughout the lifecycle of products, systems and processes are fundamental in reducing or at best eliminating ecological wastes.

The proliferation of ecological/environmental wastes ultimately diminishes value; green consumers increasingly demand environmentally friendly products and services, and businesses must implement both product and process green strategies. Contrastingly, adopting

green thinking principles reduces or, at best, eliminates environmental/ecological waste by designing products and services that are less harmful to the natural environment over their lifecycle, triggering the creation of value. Creating value leads to meeting the demands of green consumers prevalent in the 21st century, as sustainability is a leading global issue. The value created by green engineering initiatives leads to postal sustainability, which reinforces value creation for stakeholders in the postal sector.

Adopting the four sustainable development goals by the postal sector and their attainment reinforces postal sustainability, which sequentially creates value for the industry and society at large, which it is mandated to serve.

Two reinforcing loops (R1 and R2) are identified in Figure 2, which demonstrate the following dynamics:

R1: Lean thinking practices ⟶ Value creation ⟶ Postal performance ⟶ Postal sustainability ⟶ Value creation

R2: Green thinking practices ⟶ Value creation ⟶ Postal performance ⟶ Postal sustainability ⟶ Value creation

R1 asserts that implementing lean practices creates value for the stakeholders, which improves the performance of the postal sector, drives postal sustainability and further reinforces the value creation continuum. R2, on the other hand, suggests that implementing green engineering practices creates value for the stakeholders, which improves the performance of the postal sector, drives postal sustainability and further reinforces value creation, creating a value creation continuum.

5 CONCLUSIONS

The decline in traditional mail due to digitalisation has forced the Postal Sector to re-examine its business model and transition into the digital era. Digitalisation is aimed at integrating vertical and horizontal value chains, digitalisation products and service offerings, and digitalisation business models and customer access. Digitalisation can be viewed from a lean and green thinking perspective as it reduces the costs through the end-to-end processes and, at the same time, removes inefficiencies due to wastage. The raging concerns on climate change and the planet's sustainability have given rise to the demand for companies to be responsible corporate citizens who put the earth first by minimising their impact on the natural environment and reducing the environmental burden.

While lean thinking was not aimed at reducing ecological impacts in its inception, it can provide environmental benefits while improving organisational efficiencies through the reduction or, at best, elimination of waste in organisations' operations and business processes. The research highlights pertinent relations between lean thinking and green thinking; the first and foremost relationship is that both approaches share a common goal: waste reduction and, at best, waste elimination. The second relationship, as articulated in the causal loop diagram, is linearity in that an increase in lean waste will increase green waste. In contrast, a decrease in lean waste will reduce green waste. An example is that overprocessing items, a form of lean waste, will lead to resource wastage (electricity) and unnecessary carbon emissions in scope two or indirectly due to electricity use.

The causal loop diagram reveals that implementing green and lean thinking principles creates value for the postal organisation by eliminating lean and environmental/ecological wastes and creating value for customers. Creating value leads to postal organisation performance, which drives postal sustainability. Postal sustainability reinforces value creation for stakeholders, thereby creating a value continuum. As captured in the causal loop diagram, the interrelations demonstrate how the Post can improve its performance by implementing a system approach that integrates lean thinking and green engineering principles. The causal loop diagram is a

starting point on which the postal organisation may build and deepen its complexity to represent the real world and use the model to optimise its performance and, ultimately, its sustainability.

The literature points out that it is beneficial to combine the two approaches as costs are guaranteed to be optimised, business processes are set to be improved, lead times will be shortened, and the risk of non-compliance with environmental regulations will be reduced. The benefits of the lean-green approach are cost reduction, improvement of process flow, reduction of lead times, reduced risk of non-compliance with regulations, meeting customer expectations, improved quality of the natural environment, and improved employee morale and engagement.

ABSTRACT

The South African Post Office (SAPO) has struggled to maintain market relevance due to strategic misalignment, over-reliance on procurement-driven projects, and neglect of core business processes. This study proposes a Business Process Management (BPM) conceptual framework to realign SAPO's strategy with operations, strengthen governance, and enhance service reliability. Using an interpretivist, inductive, and qualitative archival research approach, literature on BPM, postal sector transformation, and maturity models was reviewed, alongside analysis of the Universal Postal Union's Integrated Index for Postal Development (2IPD). Results indicate SAPO's BPM maturity is low, with critical weaknesses in relevance and reliability, despite moderate resilience and reach. The proposed BPM framework integrates strategic alignment, process modelling, governance structures, technological enablement, and workforce capability development to drive agility, process standardisation, and customer-focused service delivery. Implementation is expected to improve SAPO's 2IPD score, operational efficiency, and competitiveness, offering a replicable model for postal sector transformation in emerging markets.

Keywords: Business Process Management, postal sector, strategy alignment, governance, maturity models

1 INTRODUCTION

Companies in the postal sector operate in an environment that demands continuous improvement in products and their associated business processes, as Mokgohloa et al. [1] explained that compounded emerging technologies broadened the industry scope and brought the postal sector to near collapse. As a result, companies' business models and strategies are constantly in flux. This postal sector fluidity was articulated in [1], who saw that its value proposition was evolving in communities. This has resulted in conflict between the static and the dynamic business process maturity models.

This study was conducted in the context of the South African Post Office (SAPO) beginning a journey of investigating a way to survive. In the context of evolving customer demands in this age of volatility, uncertainty, complexity, and ambiguity, mentioned by [2], SAPO's loss represents one-third of its revenue [3]. SAPO's international obligations have compounded this. As an implementation agent for South Africa in meeting its universal postal service obligation [4], SAPO must deliver to all citizens of the country and collect postal items for citizens of the world. Hence, it can be described as an international company operating nationally. In such a case, SAPO has to be a world-class organisation (WCO). WCOs position themselves to improve continuously and achieve sustainable results [5].

Successful organisations in this era require a culture capable of radical or breakthrough change, coupled with continuous improvement, if classified as a WCO. In the search for a business model that enables continuous improvement and sustainability based on [6], SAPO has fallen victim to a permanent turnaround project paradigm. This project orientation is explicit in its implementation roadmap. As postulated by [7], projects by nature are detached from present reality. Therefore, it is unsurprising that a purist project approach leads to radical innovation and misalignment with daily operations. Major revenue generators are in the scenario for SAPO business processes rather than projects. Considering the inherent high failure rate of projects [7], this approach has led to financial disaster reported in [3].

Tunc [7] identifies two approaches for strategy implementation, namely the project approach and the process approach. The problem in SAPO was a disproportional emphasis on projects, resulting in neglecting the business processes when implementing a strategy. This led to a misalignment between the strategic corporate plans and daily operations. The evidence of the misalignment is in the company's dismal strategic failure and financial unprofitability [3]. Moreover, the inflexible or stagnant business processes eroded its ability to deliver on the new value proposition. Strategy performance measures were biased towards project completion over business process relevance and compliance [6].

2 LITERATURE REVIEW

2.1. Strategy Implementation and Business Process Management

As business processes are critical factors in implementing the strategy and are one of the aspects of achieving a WCO, it must be understood. According to [8], a process is a sequence of events to produce value. It is also defined as a set of transformative activities that interact with each other [7]. With this level of strategic importance, processes should be managed appropriately as they interact [7] [8]. This interaction of many processes might create chaos and cloud clarity. At this point, Business Process Management (BPM) comes into play. BPM is defined as the definition, improvement and management of a firm's end-to-end enterprise business processes to achieve outcomes crucial to a performance-based, customer-driven firm [9] [10]. According to [7] it is a discipline and [8] views it as a methodology that assists in identifying, designing, executing, measuring, monitoring and controlling business processes to achieve the targeted results.

In choosing an appropriate strategy, companies use an industry view, a resource view or a combination of both perspectives [7]. The output of strategy is products that meet market requirements and capabilities to deliver value defined in the product. A capability is composed of processes, people and technology. Therefore, BPM as a tool to implement a process orientation is vital in developing capabilities for a successful strategy [11]. Interestingly, BPM is a capability, meaning it has a process to implement process orientation, professionals to optimise processes and technology for processes. Therefore, there is a measurable maturity level for BPM in a company or ecosystem of companies. [11]. In Figure 1, [11] Portrays six capability areas that are utilised to measure BMP maturity.

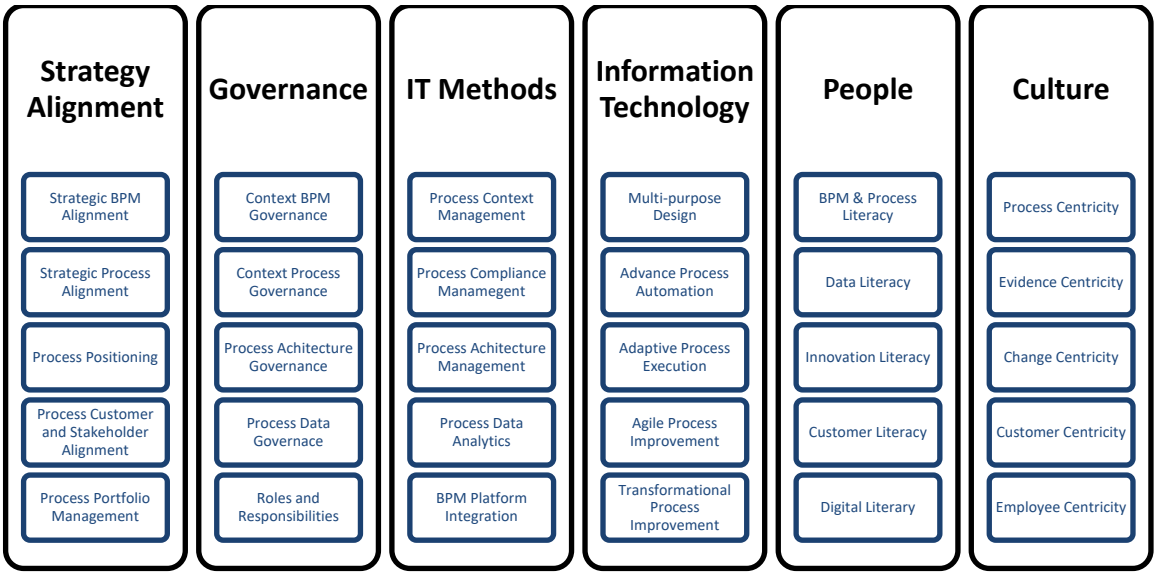

Figure 1: BPM Capability Framework [12]

2.2. Strategy Alignment

Competition pressures and technological advancement in the business environment force organisations to revise their strategies to remain competitive and relevant [13] [2] [11]. Every organisation operates in the environment that surrounds it. Therefore, a management team must ensure that their organisation is closely aligned with the environmentally critical elements [14]. For this reason, improving an organisation's internal processes should be guided by a vantage point that reflects the reciprocal relationship between an organisation and its environment [15]. Aligning the portfolio and services with the needs of the core business (processes) leads to maximum added value for the company. It contributes optimally to the overall performance of the organisation [13]. The strategic plan is to contain the strategy maps, themes, and the balanced business scorecard for performance measurement.

2.3. Governance

BPM governance is implemented through an architectural approach from the strategy context [11]. Business process architecture is defined as the type of processes within the organisation and the relationship among them [16]. Organisations must understand their business processes better and, in more detail, to be more agile and react faster to market changes [17].

Nelis in [18] argues that process architecture is an essential step in an organisation as it ensures that processes designed or developed meet its objectives and fit within its strategy. He further states that processes are aligned with how the business is performed and can provide the products/services to customers. He explains that processes are to be aligned with the IT architecture and applications, as the IT has to support the current and future processes.

There is more to consider beyond a process flow when designing and modelling a process [19]. A process model must describe the definition of tasks, the sequence of tasks, the resources needed to operate them, the environment in which they operate and the business objectives they fulfil.

Dijkman et al. [20] further states that in the framework, processes are both organised and identifiable by creating a hierarchical breakdown of the business functions in an organisation; the breakdown does not go deeper than two or three levels. The author [9] further recommends that the process maintain top-down traceability across the various process levels, and a process defined at any level must be traceable to the highest level [12]. The multiple levels of the process, the target audience and purpose are indicated in Table 1, below.

Table 1: Process Level Approach

Level	Description
L0 Enterprise Contextual	This level targets the executive, strategies and board members. The purpose is to provide the context of the organisation's business model, depicting the business aligned with the mission.
L1 Macro Conceptual	This level targets the executive, strategies and board members. It defines the cross-functional macro processes within the business. It can also be referred to as the value chain.
L2 Business Process: Logical	This level targets the business owner, architects, information office and general management. This level defines the unique business process per macro process. The processes can be assigned to a business owner and can be measured.
L3 Sub-Process: Logical	This level targets the business owner, architects, information office and general management. It depicts the breakdown of the business process into sub-processes and the process flow with individual operational steps.
L4 Activity Logical	This level targets the trainer, business analyst, and accountable manager. Defines the operational view of each sub-process, depicting the inputs, outputs and role accountability for each activity. At this level, the documents used are Manuals, Standard Operating Procedures and Work Instructions.
L5 Task Physical	This level targets the responsible role user. Depicts the procedure level of the process where a step-by-step guide is defined at the task level for each activity.

According to [21] there are six primary business process modelling techniques which can be used for various process levels: Object Oriented Model (OOM), Data Flow Diagram (DFD), Petri Net (PN), Flow Chart, Role Activity Diagram (RAD) and Integration Definition for Function Modelling (IDEF).

2.4. Information Technology with Associated Methods

In the era of hyper automation identified by [2], BPM is not left behind. As BPM has a strategic intent on increasing customer value, digitisation requires agility in changing business processes. [7]. Beyond the strategic intent, successful implementation of BPM requires technology to facilitate process modelling, process design, process mining, process orchestration, process interoperability, model management and process mining [22].

Kemsley [23], identifies mobile applications and cloud computing as influential technologies in developing BPM as a discipline. Data-producing events, big data and analytics methods further empower these technologies. Emerging technologies and methods enhance BPM

systems to facilitate building social collaboration and distributed co-creation that make employees, customers and suppliers interact at a whole new level [23] [22].

2.5. People: Competence and Culture

BPM drives organisational agility to speed up service delivery to stakeholders, which is vital [7]. According to [24] Agility enables the firm to respond quickly to unanticipated changes in the marketplace, and change is managed as a matter of routine. It allows the organisation to thrive and prosper in an environment of constant and unpredictable change[24]. Over and above, BPM is a change catalyst, and its implementation and maintenance impact employees' lives. It is considered a prerequisite for sustainable competitive advantage so that it can quickly and effectively adjust to environmental changes [25] [26].

BPM, in its essence, transforms an organisation into a change organisation [26]. Tumbas and Schmiedel [27] emphasise that there should be a link between an organisational culture supportive of BPM and a BPM culture that is encompassed by values of customer orientation, excellence, responsibility, and teamwork [28]. Appropriate managerial approaches play a vital role in the development of organisational cultures [29].

In order to handle the social and emotional side of people and improve their competencies and culture, a change administration model has to be chosen to increase the probability of success. Dijesh and Roseline [26] Identify the ADKAR Change Model, Lewin's Three Stage Model and Kotter's Eight Steps Change Model as the widely used or dominant change models. There are no substantial differences between these change models, and the choice depends on the competency of the change leader on a particular model. Organisations should instead choose a human resources management strategy for consistent upskilling.

2.6. BPM Maturity Assessment

To undertake a BPM implementation program, a company must comprehend its maturity. Fourie and Schoeman [24] Observe that the successful implementation of agility was greatly enhanced by prior implementation of ISO 9000, total quality management (TQM) and business process redesign (BPR), rooted in sustained competitiveness. Many key business processes form the basis of business capabilities. A business requires a mature discipline that drives corporate success through effective and efficient business processes. [11]. The maturity model presented in [12] is helpful in this assessment. This model (Figure 2) has three perspectives for consideration: maturity levels, management factors and process domains. The model's sophistication arises from the possibility that management factors at different levels of development and process domains may develop at a varying pace. As BPM maturity level is a cultural matter, organisations with other cultures will require other interventions. Pinto and Santos [30] mention the following steps a company can take to climb the maturity ladder in BPM implementation to attain success as defined in a predetermined culture and predestined strategy goals.

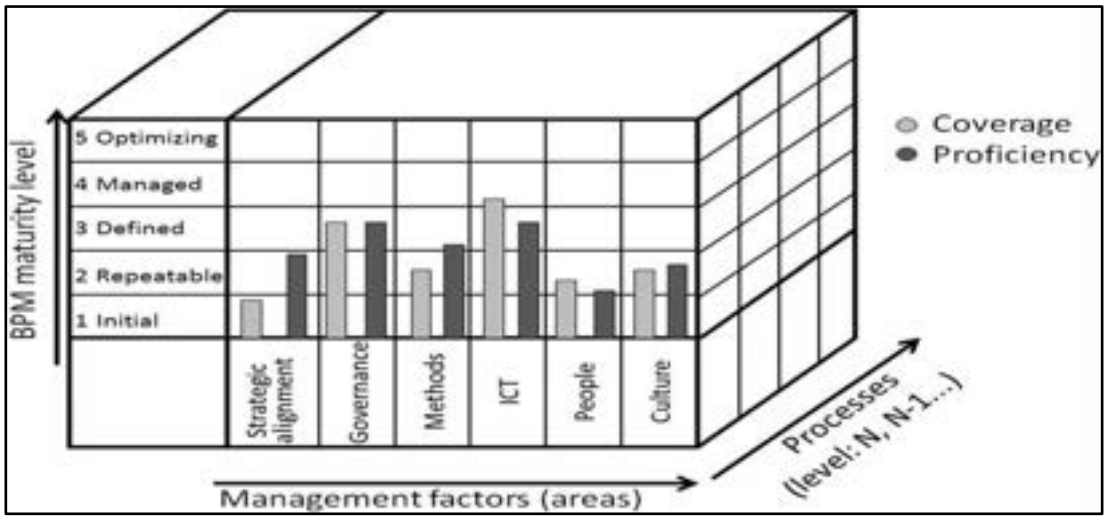

Figure 1: BPM Maturity Model

3 RESEARCH METHODOLOGY

This research adopted an interpretivist philosophical worldview, an inductive research approach, a qualitative methodological choice, and an archival research strategy, which entailed a critical review of the literature to crystallise insights on BPM for the conceptualisation of the Business Process Management conceptual framework for the South African Post Office. An analysis of the literature is necessary for a critical review. To maximise the breadth of the examined literature, the initial step was to highlight the core concepts connected to the study. Expanded to guarantee comprehensive and extensive coverage, the study encompasses concepts such as BPM, the Postal Industry, Digital Ecosystems, and Digital Disruption.

The search method was completed with a desktop search of the body of material already published on the topics of investigation. To ensure that the reviewed articles were relevant to the field under study, the criteria also included limiting the reviewed papers to those written in English and performing a general overview of the research area. The search followed the criteria that were used to search open-journal sites and industry sites, such as the Universal Postal Union on the following topics:

- Business Process Management (BPM)
- Strategy Alignment
- Information Technology
- Maturity Models

One hundred and fifteen (115) articles came up in the first search with the search terms. The abstracts of all the chosen papers underwent primary evaluation, which allowed prioritisation to concentrate on the most pertinent material. Table 2 lists the evaluation criteria in detail. Fifty (50) publications were found by applying the inclusion and exclusion criteria, and these were used for this preliminary literature evaluation.

Table 2: Evaluation criteria

ID	Decision Type	Assessment Criteria
EX1	Exclusion	Duplicated papers
EX2	Exclusion	Informal literature
EX3	Exclusion	Papers not written in the English language
IN1	Inclusion	Recent publications (Papers not older than 10 years)
IN2	Inclusion	Papers categorically mentioning business process management, maturity models, strategy alignment, and information technology in the postal sector.
IN3	Inclusion	Relevance concerning the area under study

4 RESULTS AND DISCUSSION

SAPO's failure to implement and execute a strategy that fulfils a market-appropriate value proposition was expected to positively correlate with its business processes management maturity in line with the [12] views. It was reported in [33] that South Africa (ZA) was in the fourth of ten levels of the Index for Postal Development (2IPD). 2IPD results in Figure3 represents a maturity ladder based on similar management factors or measures of organisational success in [12] [30].

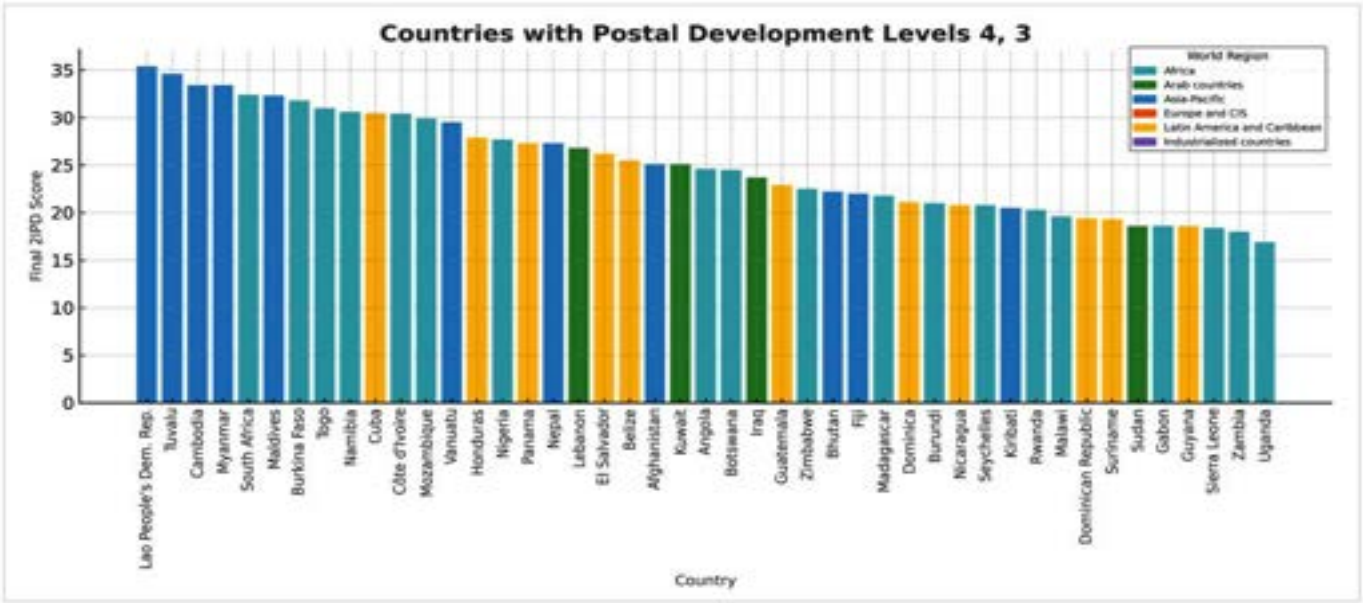

Figure 3: Index for Postal Development

SAPO should review their strategies to remain relevant to competition pressures and technological enhancements, as organisations should, as argued by [13] [1] and [11].

Cicerone et al. [14] encourages organisations to improve their internal processes. This should be guided by a vantage point that reflects their typical relationship with their environment. However, SAPO does not strive to maintain a relationship with its external and internal environment, thus creating a misalignment between the organisational levels; hence, the strategy evolves at the strategic level and remains static at the operational level.

Appel-Meulenbroek et al [15] indicates that strategic planning at the corporate level is crucial as it induces strategic thinking at all levels and helps align the portfolio and services with the core business. Sapo does not have a track record of inducing strategic thinking at a lower level in the organisation's portfolio, and its services are not aligned. As a result, Sapo does not obtain maximum added value as the business and optimally contributes to its overall performance.

SAPO's failure to implement and execute a strategy that fulfils a market-appropriate value proposition was expected to correlate with its BPM maturity positively [12]. 2IPD results represent a maturity ladder based on similar management factors or measures of organisational success [12] [30].

2IPD measures resilience, relevance, reach and reliability. South Africa scored 4 of 10 levels or 38.7 over 100 points [33]. This meant that South Africa, through SAPO, was approaching conditions necessary to serve customers. It did not fulfil all requirements of repeatability in BPM maturity, which emphasises compliance with standards.

The overall score was 65.7 over 100 for resilience, 2.7 over 100 for relevance, 40.9 over 100 for reach and 35.7 over 100 for reliability. The resilience results reinforce the argument that procurement projects undertaken by SAPO strengthen its ability to survive external environment shocks. The relevance score reinforces its misalignment with revenue sources. The procurement projects undertaken do not build a business model that responds to customer requirements. The postal connectivity had a broad international reach. This indicator was driven by the spread of countries receiving goods from South Africa via SAPO. There was an opportunity for SAPO to be the preferred small goods logistics partner for all South African trade partners. Lastly, the reliability score illustrated the unpredictability of the service.

Considering the results of 2IPD, BPM implementation support service repeatability in the short term must be introduced, and the journey must be initiated towards a definable level of maturity or a minimum of 60 out of 100 on 2IPD. This would be in line with [14], who encourage organisations to try to improve the internal processes guided by a vantage point that reflects the typical relationship with their environment.

BPM as an implementation philosophy and 2IPD as a performance indicator demand a systematic approach towards maintaining a relationship with SAPO's external and internal environment, thus providing an appropriate vantage point for strategic alignment at all organisational levels. This provides an outline of the strategy to be developed from the strategic level to the operational level. As acknowledged by [15], implementing strategic thinking at all levels within the organisation helps to align the portfolio and services with the core business. The entirely project-focused approach to strategy implementation did not induce strategic thinking at a lower level to deliver the SAPO portfolio and services. As a result, SAPO did not gain maximum added value as a business or optimally contribute to its overall performance.

Sabuhari et al. [25] and Dijesh and Roseline [26] argue that to achieve competitive advantage and maintain business sustainability, companies need their employees' flexibility and ability to adapt to the changing environment. SAPO cannot preserve its sustainability because of the misalignment within the organisational levels. BPM will assist SAPO in introducing interventions to increase employee competencies in its core business to respond to changes.

The proposed Business Process Management conceptual framework is depicted in Figure 4.

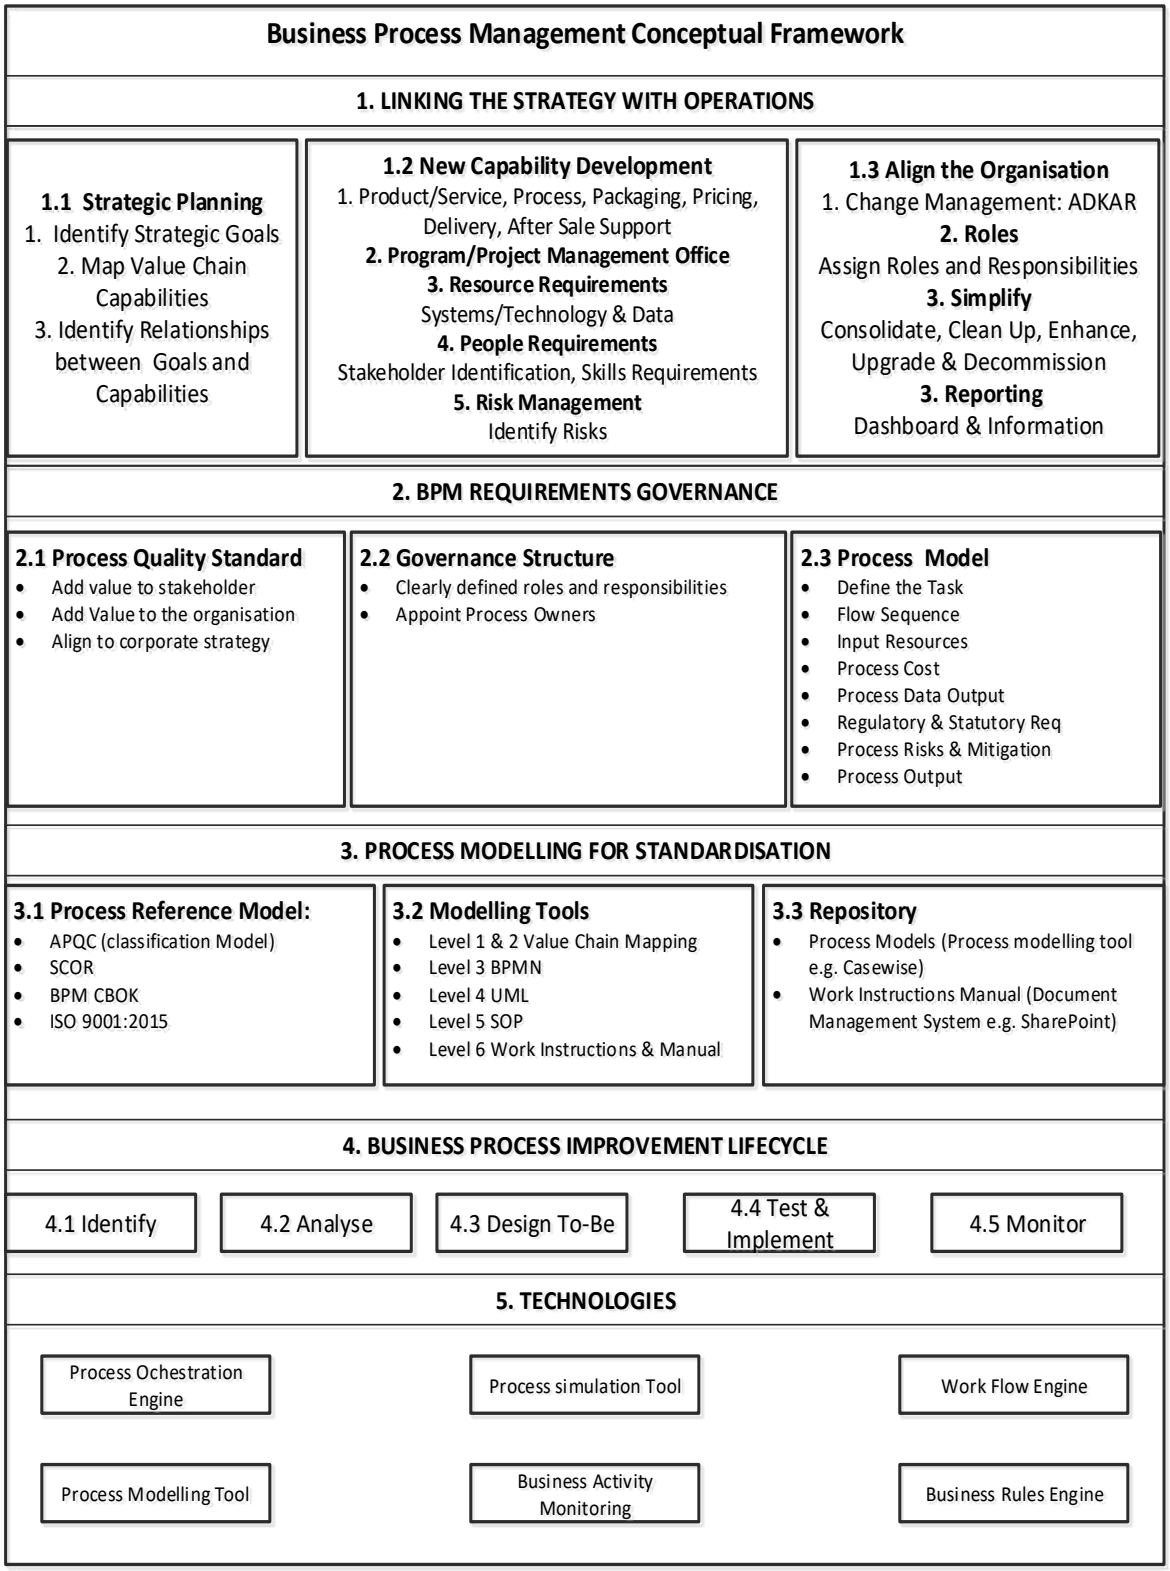

Figure 4: BPM Conceptual Framework

The Business Process Management (BPM) Conceptual Framework depicted in Figure 4 outlines how SAPO can systematically link strategy with operations, ensure governance, standardise processes, and drive continuous improvement through technology. The SAPO BPM conceptual model is explained in detail below:

1. Linking the strategy with operations

This section ensures that SAPO's high-level strategic goals translate into practical, operational actions.

1.1 Strategic planning

- Identify strategic goals**:** For SAPO, this means setting clear objectives aligned with restoring market relevance, improving reliability, and capturing e-commerce logistics opportunities.
- Map the value chain: Identify every step from parcel acceptance to delivery, including payment processing, to find where value is added or lost.
- Identify relationships between goals and capabilities: Link goals such as "increase reliability" to capabilities such as "real-time parcel tracking."

1.2 New capability development

- Products/services: Diversify beyond traditional mail into parcel logistics, last-mile delivery, and financial services.
- Processes: Standardise sorting, tracking, and customer service workflows.
- People and technology: Train staff in BPM methods and deploy tracking & automation tools.
- Risk management: Address threats from competition, technology disruption, and declining mail volumes.

1.3 Align the organisation

- Change management (ADKAR): Prepare SAPO staff for changes in processes, culture, and technology.
- Role assignment: Make process ownership explicit at all levels.
- Reporting: Introduce dashboards showing real-time performance (delivery times, customer complaints, process bottlenecks).

2. BPM requirements governance

This ensures SAPO's processes add value, are managed effectively, and meet strategic priorities.

2.1 Process quality standard

- Align all processes to corporate strategy and customer expectations.
- For SAPO, this means delivery times, payment processing, and tracking updates must consistently meet standards.

2.2 Governance structure

- Assign process owners for logistics, payments, customer service.
- Define roles to avoid duplication and accountability gaps.

2.3 Process model

- Clearly define tasks, inputs, outputs, risks, costs, and compliance requirements for each core process.

- Example: The “Parcel Delivery Process” should specify timelines, technology used, resource allocation, and quality checks.

3. Process modelling for standardisation

This is about creating consistent processes SAPO can repeat and improve.

3.1 Process reference model

- Adopt industry frameworks like **SCOR** for supply chain processes.
- Adopt ISO 9001:2015 quality management standards.

3.2 Modelling tools

- Value chain mapping: Identify end-to-end postal and logistics processes.
- BPMN and UML: Standardise process documentation for clarity.
- SOPs and work instructions: Ensure consistent execution.

3.3 Repository

- Store all process documentation in a central, accessible location (e.g., SharePoint) to support training and compliance.

4. Business process improvement lifecycle

The five stages for continuous process improvement:

1. Identify – Find underperforming processes (e.g., delayed parcels).
2. Analyse – Determine root causes (e.g., bottlenecks in sorting).
3. Design to-be – Create an improved process model (automation, better routing).
4. Test and Implement – Pilot the changes, then roll them out.
5. Monitor – Use KPIs (on-time delivery, customer satisfaction) to track success.

5. Technologies

Technology enables process efficiency, consistency, and monitoring.

- Process orchestration engine: Automates workflows across departments.
- Process simulation tool: Test changes virtually before implementation.
- Workflow engine: Controls and sequences postal processes.
- Business activity monitoring: Tracks operations in real-time for rapid intervention.
- Business rules engine: Enforces compliance and consistency in decision-making.

Applying this framework would:

- Shift focus from procurement-heavy, project-centric strategies to process-driven, customer-focused operations.
- Standardise and automate logistics and payment processes for higher reliability and relevance.
- Improve governance by assigning ownership and accountability for each core process.
- Increase BPM maturity and raise SAPO’s 2IPD score (especially in Relevance and Reliability).

- Enable agility to adapt to e-commerce growth, technological shifts, and competitive pressures.

5 CONCLUSIONS AND RECOMMENDATIONS

For an organisation to be recognised as a world-class organisation and to remain competitive, it must acquire a culture capable of bringing a radical change. Strategic planning from the corporate level is crucial as it induces strategic thinking up to the lower levels of the organisation. The literature further recommends that they should be aligned with the core processes. Aligning the corporate level with the operational level ensures that the day-to-day activities support the organisation's core business. The misalignment within the different levels creates difficulties in the strategy implementation, and therefore, governance becomes crucial to implement. The organisation must adopt a business process management phase to ensure continuous process improvement. Business processes consist of the organisation's capabilities and assets, which need to be managed and controlled at all levels.

5.1 Strategic realignment to a market-oriented value proposition

- Shift from project-driven to process-driven strategy: Replace the heavy focus on procurement projects (which have high inherent failure rates) with strategies that strengthen logistics, payment processes, and customer-centric services—the real revenue engines of the postal sector.
- Adopt a customer value-driven model: Use market research to identify current and future customer needs, especially in e-commerce fulfilment, last-mile delivery, and financial services.
- Define a clear market position: Position SAPO as *South Africa's trusted small parcel logistics and payment solutions provider*, leveraging its broad international reach.

5.2 Business Process Management (BPM) Implementation

- Establish BPM governance: Create a dedicated BPM office responsible for process architecture, monitoring, and continuous improvement.
- Map and optimise core processes: Document all logistics, payment, and customer service processes; identify inefficiencies; redesign for speed, reliability, and cost efficiency.
- Embed process ownership: Assign process owners at operational and strategic levels to ensure alignment between daily operations and organisational strategy.
- Implement performance repeatability: Standardise processes to achieve at least a "Definable" BPM maturity level (minimum 60/100 on 2IPD metrics).

5.3 2IPD-driven performance improvement

- Resilience (current score: 65.7/100):

- Strengthen supply chain agility to absorb market shocks.
- Build redundancy in critical operations (e.g., backup logistics partners, IT systems).

- Relevance (current score: 2.7/100):

- Redesign services to directly respond to customer needs (e.g., trackable deliveries, flexible pick-up options, mobile payments).
- Partner with e-commerce platforms to create bundled shipping services.

- Reach (current score: 40.9/100):

- Capitalise on existing international connections to become the preferred small goods logistics partner for trade partners.
- Develop export-friendly packaging, pricing, and customs facilitation services.

- Reliability (current score: 35.7/100):

- Introduce strict service-level agreements (SLAs) with monitoring.
- Invest in tracking technologies to provide customers with real-time updates.

5.4 Strategic thinking and alignment across organisational levels

- Cascade strategy downwards: Ensure corporate-level strategy is broken into measurable, department-level goals and operational actions.
- Align services with core business: Review the portfolio to eliminate non-core activities and focus resources on logistics, payments, and customer trust-building.
- Foster cross-functional collaboration: Introduce cross-departmental process improvement teams to ensure operational and strategic cohesion.

5.5 Workforce capability and change management

- Upskill employees for agility: Provide training in customer service excellence, digital tools, and adaptive problem-solving.
- Introduce BPM culture: Embed continuous improvement as part of performance reviews and team objectives.
- Leadership development: Train managers at all levels in strategic thinking, process management, and change leadership.
- Internal communication: Maintain transparent updates on strategic changes to improve employee buy-in.

5.6 Digital and technological enablement

- Invest in process automation: Use workflow automation to speed up sorting, tracking, and payment processing.
- Digital customer experience: Upgrade the SAPO website and mobile app for easy parcel tracking, service booking, and payment processing.
- Data-driven decisions: Implement analytics dashboards to track performance across 2IPD dimensions and BPM KPIs.

5.7 Short-to-medium-term targets

- Short-term (0–12 months):

- Implement BPM governance.
- Map all core processes and identify “quick win” improvements.
- Increase 2IPD relevance score from 2.7 to at least 20.

- Medium-term (1–3 years):

- Achieve a minimum score of 60/100 on 2IPD.
- Position SAPO as the leading small goods logistics partner in the region.
- Maintain service repeatability and customer satisfaction ratings above 85%.

5.8 Key expected outcomes from implementing the conceptual framework

- Improved operational efficiency and service predictability.
- Clear market positioning that responds to competition and technological disruption.

- Enhanced organisational agility through process standardisation and workforce competence.
- Measurable improvement in all 2IPD performance dimensions.

OPTIMISING CUTTING ROOM EFFICIENCY: LEAN SIX SIGMA AND 4IR INTEGRATION IN CLOTHING MANUFACTURING

K.R. Ramdass[1*]

[1]Department of Industrial Engineering and Engineering Management
University of South Africa, South Africa
ramdakr@unisa.ac.za

ABSTRACT

The clothing manufacturing industry struggles with material waste and process inefficiencies. This impacts SA manufacturers' competitiveness against countries like China, India, Indonesia who benefit from lower labour costs and cheaper materials. This study applies lean six sigma and fourth industrial revolution (4IR) technologies to improve cutting room processes. Manufacturers can enhance their processes and sustainability by incorporating automated cutting systems and Lean Six Sigma methods. Using Saunders' research onion, the study systematically analyses cutting room processes through a case study analysis using direct observation as the method of data collection thereby identifying opportunities for improvement. The focus is on an organisation in Durban, Kwa-Zulu Natal.

Keywords: industrial engineering; process optimisation; lean six sigma

* Corresponding Author

1 INTRODUCTION

The clothing industry greatly contributes to the global economy, employing millions worldwide. In South Africa alone, the industry employs approximately 230 000 people, making it a vital sector for economic growth. However, the South African clothing industry faces numerous challenges, particularly from cheap imports brought into the market from overseas countries that have since disrupted local markets and threatened the livelihoods of many South African employees [1]. To remain competitive, South African manufacturers have to look at ways to optimise their production processes, particularly in the cutting room, where material wastage and production inefficiencies are prominent. This is where Lean Six Sigma and the Fourth Industrial Revolution (4IR) technology become relevant. These two innovative approaches will assist manufacturers streamline processes, reduce waste, and improve productivity [2].

Lean Six Sigma is a proven industrial engineering methodology that assimilates the principles of lean management and Six Sigma principles to eliminate waste and minimise process variation. 4IR technology, on the other hand, offers cutting-edge innovations like automation, artificial intelligence, and the Internet of Things (IoT) that can enhance efficiency and reduce production costs. By exploring the integration of Lean Six Sigma and 4IR technology, this research aims to identify opportunities for improvement in the cutting room operation of clothing manufacture. This case study will provide valuable insights into the potential of these innovative strategies to enhance the competitiveness of South African manufacturers in the global clothing market [3].

2 LITERATURE REVIEW

2.1. Lean Six Sigma

Lean Six Sigma is a popular approach for process improvement that is been widely adopted in various industries to increase efficiency and reduce waste. Lean principles eliminate non-value-added activities by continuously improving the product based on customer demand. On the other hand, Six Sigma methodologies focus on reducing variation and defects to ensure high product quality and customer satisfaction. Despite its limited use in clothing manufacturing, Lean Six Sigma holds significant potential for adaptation, especially in the cutting room. The industry's unique complexities and challenges, such as complex operations, high production variation, and short production schedules, have deterred its widespread adoption. However, it is essential to recognise that Lean Six Sigma can be tailored to intricate clothing manufacturing processes, such as pattern making, marker marking, and labour-intensive sewing operations. Moreover, the variation in apparel products can be managed effectively using Six Sigma methodologies, offering a promising path for process improvement in the clothing industry. The clothing industry operates on short production schedules to meet consumer demand and respond quickly to market or seasonal trends. Quick response to market demands is crucial for success in the apparel industry, as evidenced by companies like Zara and TFG in South Africa [4]. However, the short lead times limit the implementation of time-consuming Six Sigma projects requiring extensive data collection, analysis, and process optimization. In a fast-paced environment, there may be pressure to prioritize speed over process improvement initiatives, resulting in under-utilization of Lean Six Sigma methodologies. While Lean Six Sigma can bring significant benefits to the clothing manufacturing sector, it is equally important to address the challenges and limitations of its implementation [5].

2.2. Fourth Industrial Revolution (4IR) technology

The Fourth Industrial Revolution (4IR) has brought about transformative technologies that could potentially revolutionise manufacturing processes in the clothing industry. One such technology is the Gerber Paragon cutting system, launched by Gerber Technology in 2019. This cutting-edge technology has advanced features such as intelligent software, smart sensors, integrated control, and an intuitive interface, making it a game-changer for apparel manufacturers. The Gerber Paragon cutting system, combined with the Gerber spreader, is an automated machine that streamlines the fabric laying and cutting process. This system is significantly more efficient than traditional manual processes, producing higher quality output while reducing material waste by up to 30%. This is substantial, considering fabric costs account for 40% to 60% of the total apparel production cost. Gerber's comprehensive ecosystem supports the Gerber Paragon, offering market-leading hardware and software solutions that streamline the process from CAD files to cutting [6]. This ecosystem includes advanced CAD software for pattern design, automated spreading machines for fabric preparation, and a network of cutting machines that can be controlled and monitored remotely. This technology leverages 4IR advancements like automation, robotics, artificial intelligence, and advanced data analytics to optimise operations, improve decision-making, and enhance productivity. Integrating 4IR technology like the Gerber Paragon into apparel manufacturing processes can potentially revolutionise the industry. These automated systems far surpass traditional labour-intensive processes, which require hundreds of man-hours to produce a fraction of what automated systems can produce. This transformative potential inspires a new era of efficiency and sustainability in the clothing industry [7].

However, it is crucial to consider the expected output volume when selecting technology to avoid under-utilization. Most cut-make-trim (CMT) factories produce a few thousand units weekly, while the Gerber cutter can produce a few thousand units daily. This underscores the importance of careful evaluation and planning to ensure the technology is utilised to its full potential, leading to efficiency and resource optimization [8]. Therefore, apparel manufacturers must carefully evaluate their production needs and consider the potential of 4IR technology like the Gerber Paragon to optimise their operations and improve sustainability. However, it is crucial to carefully consider the expected output volume and ensure proper implementation and utilisation to avoid under-utilisation and maximise the benefits of this technology [9].

2.3. Sustainability in the Apparel Industry

The clothing industry alone is a R14.8 trillion industry, producing around 150 billion garments yearly, nearly 19 items for every human being [10]. Enes and Kipoz [11] surveyed 130 companies to raise awareness about waste management and investigate their methods. The study revealed that manufacturing companies employ various waste management strategies to minimise environmental impact. These methods include waste avoidance (such as using digital patterns to reduce paper waste), reduction (by optimising production processes to reduce excess fabric), reuse (by repurposing fabric scraps for other products), recycling (by sending fabric waste to recycling facilities), and environmentally friendly disposal (such as using waste-to-energy technologies). Although none of the companies could eliminate waste completely, they did find ways to minimise or reduce it. From production to consumption, the industry's waste management practices have a substantial impact on the environment [12].

2.4. 3D Printing of Garments

3D printing in the fashion industry has gained momentum recently, with several researchers and designers exploring its potential for garment production. The advantages of 3D printing lie in its ability to create complex designs and structures that cannot be achieved through traditional manufacturing methods. Additionally, 3D printing allows for customisation and

personalisation of garments, which is a growing trend in the fashion industry. However, there are still several limitations and challenges associated with 3D printing of garments. One of the main limitations is the lack of suitable materials that are flexible, absorbent, and comfortable to wear [13].

2.5. The future of the clothing industry

The fourth industrial revolution is characterised by the combination of physical, digital, and biological systems. This revolution is expected to transform the clothing industry in various ways, including using advanced technologies such as artificial intelligence, robotics, and the Internet of Things (IoT). One of the key trends in the future of the clothing industry is the use of sustainable and circular business models. This includes using recycled materials, upcycling, and closed-loop production systems [14]. Another trend is the increasing use of digital technologies such as 3D printing, as discussed above, virtual reality, and augmented reality (VR/AR)). Artificial intelligence (AI) and machine learning (ML) are also expected to play a significant role in the future of the clothing industry. In addition, the clothing industry is expected to become more global and connected, using blockchain technology and IoT sensors to track production and supply chains [15]. However, the future of the clothing industry also poses several challenges, including the need for workers to develop new skills and the potential for job displacement due to automation. Overall, the literature suggests that advanced technologies, sustainable and circular business models, and increasing globalisation and connectivity will characterise the future of the clothing industry in the fourth industrial revolution [16].

3 RESEARCH METHODOLOGY

The research onion was adopted to guide this study. This onion illustrates the range of choices, paradigms, strategies, and steps the researcher follows during the research process. This research study adopted an ontological approach, capitalizing on the data available in the organisation that can be quantified and enhanced. The research methodology adopted an inductive approach. This involves analysing theories around existing information regarding lean Six Sigma and 4IR technology and applying them in the apparel industry cutting room context. The research strategy involved collecting data from cutting room processes and analysing the impact of Lean Six Sigma and 4IR technology in process improvement [17]. The research employed a case study approach. Data collection methods involved observation of cutting room processes, secondary data from industry specialists and analysis of production data. The cutting room process depends on demand planning, where textile material is received in bales and spread on a table. Paper patterns are then placed on the fabric and cutting takes place using a band knife.

4 RESULTS AND DISCUSSION

The garment manufacturing process begins in the cutting room, where fabric is transformed into components, namely garment panels. These panels form the foundation of various garment parts like fronts, backs, sleeves, and collars. In mass production, workers arrange multiple layers of fabric on a cutting table. This process is called laying or spreading, and then they cut these layers. The cutting process involves several intricate procedures to ensure accuracy, efficiency, and quality.

4.1. Demand Planning

The Master Production Schedule (MPS) is a critical planning tool used in manufacturing and production management. It serves as a detailed timetable outlining the production requirements for finished goods over a specific period, typically covering several weeks to months ahead. The MPS is critical in coordinating and synchronising production activities with

customer demand, inventory levels, and overall business objectives, ensuring the system's efficiency. The MPS fulfils the following functions.

- Demand Aggregation: The MPS aggregates demand from various sources, such as sales forecasts, customer orders, and inventory requirements. It consolidates this demand into a unified plan that guides production activities.
- Time Horizons: It typically spans a medium-term planning horizon, breaking down production requirements into specific periods (e.g. weekly or monthly).
- Product Details: The MPS details the specific products or product families to be manufactured, along with their quantities and timing. It categorises products based on attributes like style, colour, size, or SKU (Stock Keeping Unit), depending on the complexity of the production process and the level of detail required.
- Resource Allocation: Based on the MPS, production managers allocate resources such as labour, materials, and equipment to ensure that production schedules are feasible and efficient.
- Integration with Other Systems: The MPS is closely integrated with other planning systems and processes within the organisation, such as Material Requirements Planning (MRP), inventory management, and sales forecasting. This integration ensures that production plans are aligned with broader business goals and operational capabilities.
- Flexibility and Adaptability: The MPS, while providing a structured plan, also allows for adjustments in response to changes in customer demand, production disruptions, or shifts in market conditions. This adaptability of the MPS reassures production planners that they can continually review and revise the plan to maintain alignment with evolving business needs [18].

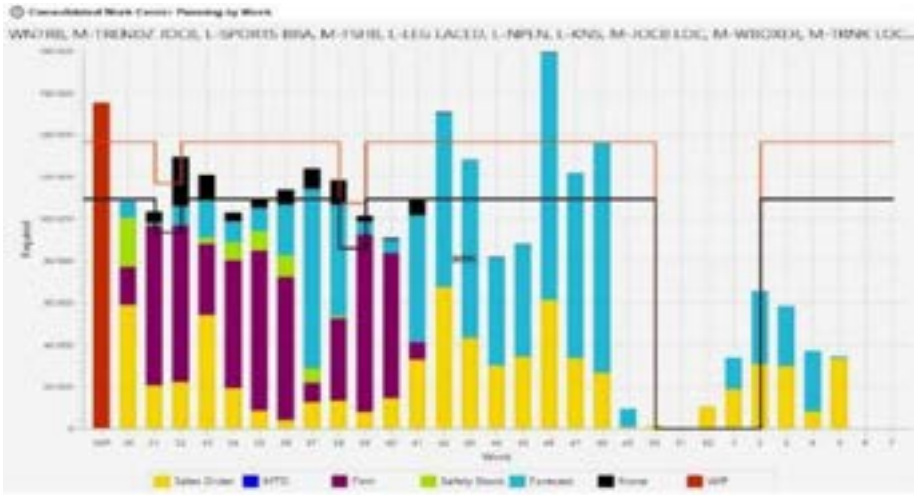

Figure 1. Erratic nature of demand in the clothing industry

4.2. Demand Grouping

Within the MPS, demand is grouped into categories such as basic cotton stretch panties, men’s vests, woven boxers, men’s pouch trunks, ladies' seamless panties, men’s and ladies' undershirts, and winter tops and bottoms. There is also a sub-group under each garment type that separates demand by colour and size. This structured grouping facilitates streamlined production planning and resource allocation. Due to machinery and skills, the product types are not inter-changeable and each category represents a sewing line on the production sewing floor that is set up for that product/garment type. Following the organisation of demand in

the MPS, sales coordinators create work orders that align with the identified production needs both to fulfil customer orders and keep supply to the cutting room and sewing floor. Each work order is designed to accommodate specific garment styles, sizes, colours, and their respective lead times [18].

4.3. Fabric and Sewing Trims Warehouse

The fabric and sewing trims are stored offsite due to limited space within the building premises. When a work order is created, a detailed sewing trim picking instruction or picking list is automatically generated. This instruction triggers the process of gathering and delivering the necessary trims from the dedicated storehouse. Each order precisely outlines the quantities of trims required for production, ensuring that the exact amounts are retrieved and transported. To mitigate delivery costs, work orders are created once a day. The delivery schedule is then aligned accordingly accommodating 1 to 2 trips per day based on the volume of fabric pieces and trims that must be transported. Multiple trips are often necessary as fabric pieces occupy significant space within the delivery trucks and other sewing trims also need transporting as per the picking instructions [19].

4.4. Pattern and marker-making

A pattern is a template or design used to create a specific garment. Patterns are typically created on paper or digitally using computer-aided design (CAD) software. A pattern includes essential details such as the garment piece's shape, size, layout, and any necessary markings, such as grain lines, fold lines, or cutting lines. There are different types of patterns, including basic patterns, master patterns, and variant patterns. Basic patterns are simple patterns used to create essential garment pieces, such as fronts, backs, sleeves, and collars. Master patterns are more complex patterns used to create a complete garment, including pockets, buttonholes, and zippers. Variant patterns are modified versions of basic or master patterns used to create different garment variations.

Markers, a crucial tool in the garment creation process, come in various forms, each with its unique benefits. Manual markers, for instance, are created by hand, using a pencil or pen to draw the patterns onto the fabric. On the other hand, computer-aided markers are created using computer-aided design (CAD) software, automatically fitting the panels on the set length and width of paper as efficiently as possible, while allowing for enough space for the cutting tools operators to manoeuvre when cutting. Plotter markers, another type, are used to plot digital markers onto fabric, offering a high level of precision in the cutting process [20].

4.5. Cutting works order

The fabric requirement for an order is calculated based on the average consumption of fabric from the marker. This calculation considers the specific fabric usage for each garment piece, fabric grams per square meter (GSM), and fabric yield, ensuring that the correct amount of fabric is allocated for cutting in a particular work order. In cases where an order involves multiple colours, the fabric requirement is calculated separately for each colour, ensuring that the correct quantity of each coloured fabric is allocated.

In addition to calculating fabric requirements and issuing fabric to cutting, the fabric department also ensures that fabric quality standards are met. This includes inspecting fabric for defects, ensuring that the fabric is appropriately stored and handled, and maintaining accurate fabric inventory and usage records [21].

4.6. Fabric spreading or laying

In the fabric layering or laying stage, multiple fabric sheets are carefully layered on top of each other, maintaining a pre-defined marker length, fabric ply height (i.e. the number of fabric plies layered on top of each other) and precise ply tension to achieve fabric plies. This

step ensures the fabric is aligned correctly and stacked to achieve optimal cutting quality. The fabric sheets are layered up to a certain height to avoid any cutting quality problems that may arise, primarily caused by the fabric plies being too high or too low. The layering process can be done manually, where skilled operators carefully place each fabric sheet on top of the other, or automatically, using a specialised layering machine or a spreader. The length of each fabric lay is determined by the marker or works order, influenced by factors such as order size, garment style, and fabric colour. Optimal lay lengths typically range from 5 to 8 meters, balancing efficient machine operation and minimising equipment wear and tear [22].

Figure 2. Fabric laying process

4.7. Fabric Cutting

The cutting process involves precisely cutting layered fabric into individual garment components. This process carefully cuts along marked lines on the fabric, ensuring that each piece meets precise specifications. Various cutting methods are used based on the fabric type, pattern complexity, and desired accuracy.

Straight knives are commonly used for cutting straight lines and simpler shapes, offering versatility in handling various fabric types. Rotary blades are used to precisely cut curved lines and intricate shapes. Laser cutters and water jets provide unmatched precision for complex designs.

Block cutting involves dividing the fabric lay into smaller, more manageable blocks, making it easier to handle and transport to shaping tables where individual panels are cut out according to the pattern's outline. Shaping tables is where operators use stationary saws specifically designed to cut through layered fabric, ensuring stability by increasing the number of plies or using clamps for slippery fabrics with fewer plies. In cutting, skilled operators carefully separate garment components and remove excess fabric. This stage requires careful attention to detail to avoid errors that could lead to defective garments, emphasising the importance of precision throughout [23].

Figure 3. Fabric cutting Process

4.8. Sorting Processes

Cut components are organized and prepared for the next production stage in the sorting process. The sorting method depends on the specific production system, such as make-to-order, progressive bundle, or one-piece flow system. Two sorting methods are used at the organisation: size-wise sorting and colour sorting. These two methods are used in conjunction with each other in the sorting process. Size-wise sorting involves grouping components by size, ensuring that all components for a particular size are together. This makes assembling garments of the same size easier, reducing errors. Colour-wise sorting involves grouping components by colour, ensuring that all components of the same colour are together. This is particularly important when producing garments with multiple colours, as it ensures that the correct colours are used for each component. Garments are grouped by size, colour, garment type and destination, i.e. which sewing line those garments are going to. This ensures that all components are correctly routed to the correct sewing line or production area, streamlining the production process, and reducing errors.

4.9. Bundling Processes

Several garment panels are tied together to form a bundle in the bundling process. These bundles contain all the panels required to make a set number of garments. To create these bundles, the ERP systems generate a bundle breakdown sheet based on the number of units cut in the cutting process [24].

Once the bundling is done, a sticker or coupon for that bundle is generated with all the necessary information for that bundle, including the following:

- Bundle number: A unique identifier for the bundle
- Style Name: The name of the garment style
- Size number: The size of the garments in the bundle
- Quantity of pieces: The number of garments in the bundle

This information is used in tracking and managing the production process, ensuring that the correct components are sent to the correct production line for sewing.

5 RECOMMENDATIONS AND CONCLUSION

The Lean Six Sigma methodology was employed to conduct a comprehensive analysis of the cutting room operations and identify critical areas for improvement. This involved a systematic approach to process mapping, data collection, and statistical analysis. Through the application of Lean Six Sigma tools and techniques, such as value stream mapping, root cause analysis. The following recommendations have been identified in the study.

5.1. Styles Combinations

As mentioned previously, the planning department typically creates work orders per style. However, it was discovered that grouping work orders by fabric quality and colour would be significantly more efficient. This can be achieved by creating works orders with the same style, fabric quality, and colours in one single work order. Style combinations on work orders can be done by creating combination markers and the pattern-making stage since that is the feed into the automatic marker-making system.

The image above shows a marker created with two distinct patterns for two different garment types. This type of marker is ideal for orders comprising multiple styles or garment types that utilize the same fabric quality and colour. The size ratio of the marker can be adjusted to accommodate specific order requirements. Tests conducted on six different markers using the same format achieved an average efficiency rate of 82-87% (see Table 6). However, there are limitations to this method. The total marker length cannot exceed 9 meters, as this is the maximum usable length on the laying table. This restriction is due to the presence of laying machines on either side of the 22-meter-long cutting table. Notably, the longest average length for an underwear marker is 7 meters, leaving a significant portion of the table underutilized. In contrast, factories working with larger garments may require marker lengths of up to 20 meters, which would effectively utilise the marker format for combining their smaller unit orders, while getting the most out of their laying machine and available fabric. The other notable drawback is the possibility that the garment panels might get mixed up during the soring process however the panels can be tagged after laying, before cutting to indicate which style they belong to. Through this method, the following could be achieved:

- Improved fabric utilization: Grouping work orders by fabric quality and colour enables us to create longer lays, making the most of the fabric's length and reducing waste by reducing the fabric end allowance, i.e. which is the fabric allowance given at the beginning and end of each fabric marker as well the edges of the marker.
- Increased productivity: By marking different styles next to each other, one can create longer lays that supply multiple sewing lines, maximizing the use of the laying table and the speed of the laying machine.
- Reduced setup time: Instead of setting up the machine twice for two separate lays, one can do it once for two lays, saving time and increasing efficiency.
- Enhanced flexibility: Grouping work orders by fabric quality and colour allows us to accommodate changes in production demand or fabric availability more easily.
- Better resource allocation: By optimizing the laying process, one can allocate resources more effectively, reducing labour costs and improving overall productivity [26].

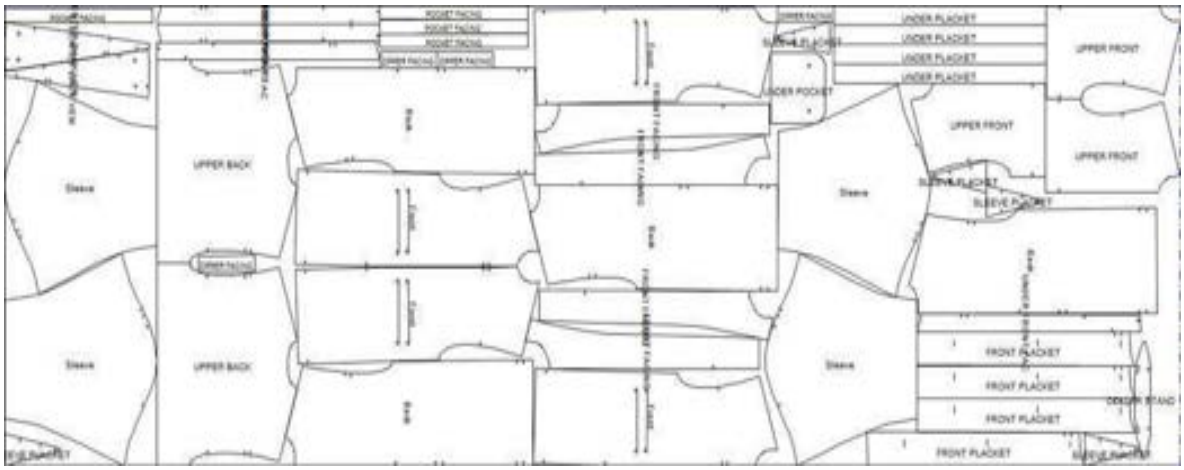

Figure 4. Combination of styles

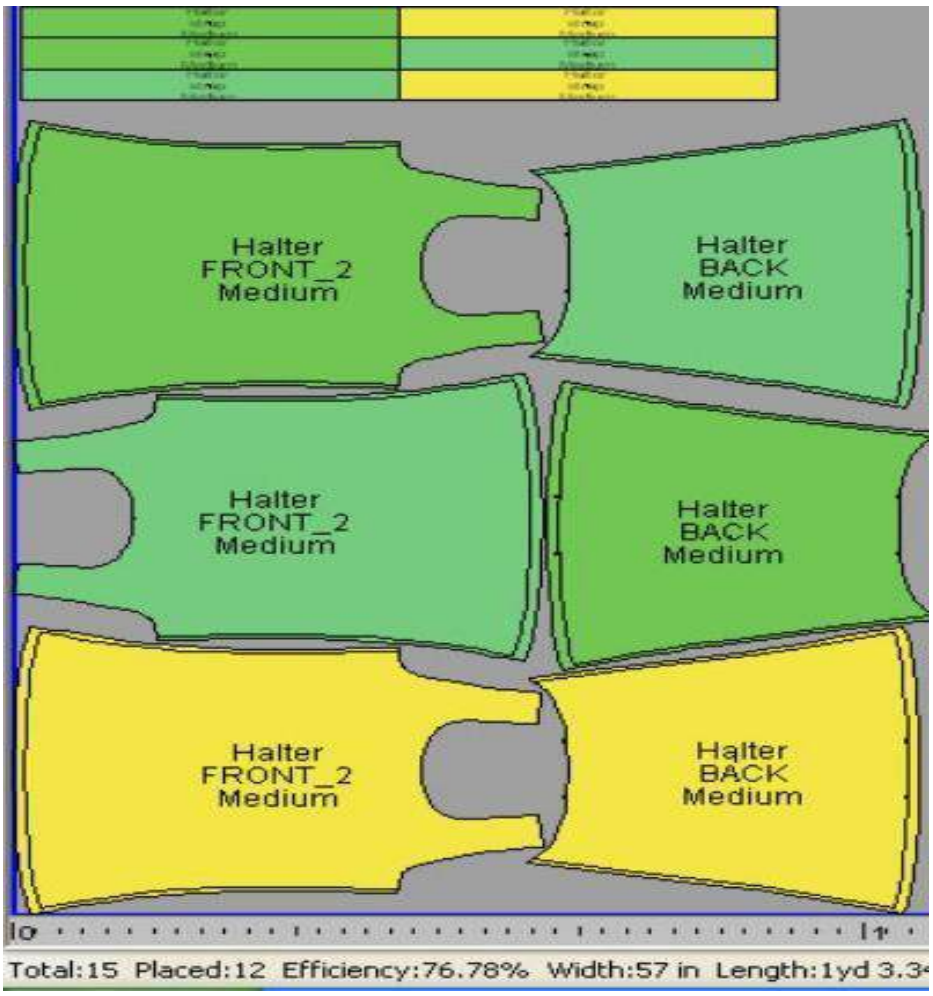

Figure 5. Current marker application

Table 1: Marker efficiencies from combination markers

Fabric Item	Item Description	Saving %	Plies	Quantity	AWO Id	Cost Length	Marker Efficiency	Fabric Width
9833	95/5% COMBED COTTON LYCRA BCI CERTIFIED	0,147	40	200	AW485015	0,68	84,8	166
9833	95/5% COMBED COTTON LYCRA BCI CERTIFIED	2,927	10	30	AW485015	0,41	82,21	166
9833	95/5% COMBED COTTON LYCRA BCI CERTIFIED	3,017	50	400	AW485035	1,79	87,07	166
9833	95/5% COMBED COTTON LYCRA BCI CERTIFIED	-7,768	40	200	AW485035	1,12	87,08	166
9833	95/5% COMBED COTTON LYCRA BCI CERTIFIED	-34,556	20	80	AW485035	0,9	86,33	166
9833	95/5% COMBED COTTON LYCRA BCI CERTIFIED	-2,208	40	280	AW485038	1,54	87,07	166

An alternative method involves creating separate work orders and patterns, marking them individually, but plotting them side-by-side on the automated making system. This approach eliminates the risk of panel mix-ups during sorting, as each marker cuts separately. However, the average fabric recovery percentage is 82%, which is lower than the previously suggested method. Note that this method still requires identical fabric quality and colour for all involved work orders, and is subject to maximum lay length limitations.

5.2. Automated Fabric Calculation

Fabric is one of the most significant cost factors in the clothing industry as it represents the highest cost of a garment. Determining how much fabric will be utilised based on fabric parameters gives manufacturers an edge over their competitors. Assyst Automarker has an AutoCost module that allows manufacturers to calculate fabric costs accurately, considering factors like fabric width, thickness, and grain and generating optimised markers that minimise fabric waste and reduce costs. Using AutoCost, clothing manufacturers can significantly reduce fabric waste and costs, improve cutting efficiency and productivity, and enhance accuracy in cost estimation and fabric calculation, ultimately streamlining their production process.

5.3. Laying Process Efficiency: Data capturing

The study identified that laying operators dedicate a substantial amount of time to paperwork throughout the laying process. Time studies revealed that 23% of the laying process is spent on data capture tasks. Operators manually capture data to calculate fabric efficiency, marker efficiency, fabric consumption, machine utilisation, and fabric recoveries on a recovery sheet document. This process involves manual calculations of fabric utilisation as well as transferring of information from three distinct documents, i.e. the works order report detailing with units required and garment specifications, the marker report containing marker length, ratio, and costed width, and the fabric picking list detailing fabric quality, dye lot information, weight, and width onto the recovery sheet. Once the laying operator completes data entry on the recovery sheet and finishes the laying process, the document is handed over to a clerk to capture the information on the recovery sheet and send it to the ERP system. This study proposes automating the data capture directly onto the ERP system. All three documents

already exist within the ERP, allowing seamless transfer to a device such as a scanner or tablet to be used by the laying operators. Instead of manually entering data, operators scan or input necessary information into the device. The tablet or scanner would then automatically calculate marker efficiency and fabric recoveries, reducing the manual workload significantly. Each document mentioned above is already equipped with a QR code for all the information to be captured. By having laying operators input data directly into the scanner or tablet, all information would flow directly into the ERP system without requiring manual input from a clerk [27].

According to the cutting room manager, this streamlined approach enhances operational efficiency by reducing paperwork and manual calculations, which often involve calculation errors. It also minimises the potential for other errors inherent in manual data entry. By leveraging existing ERP capabilities and integrating modern scanning technology, one can optimise the laying process, improve overall productivity, and ensure more accurate data management throughout production. In addition to the immediate benefits of reducing paperwork and manual data entry, implementing scanners or tablets for data capture during the laying process offers several strategic advantages. These include:

5.3.1. Real-time Data Integration

By integrating scanners or tablets with the ERP system, data captured by laying operators is instantly fed into the centralised database. This real-time integration ensures all stakeholders access up-to-date information regarding fabric efficiency, marker efficiency, and other critical metrics. The ERP system plays a crucial role in this process, enabling managers to make informed decisions promptly based on accurate and current data.

5.3.2. Enhanced Accuracy and Consistency

Manual data entry is prone to errors, which significantly affect production planning and cost management. Automated data capture decreases the likelihood of errors due to human input. Consistent and reliable data improve the quality of production metrics and financial reporting.

5.3.3. Operational Efficiency

The time saved from manual data entry and calculations allows laying operators to focus more on their core responsibilities—ensuring precise fabric cutting and layout. This efficiency speeds up the laying process, reduces lead times, and consistently meets production deadlines.

5.3.4. Cost Savings

While the initial investment in scanning technology may be required, the long-term savings from reduced labour hours, improved process efficiency, and minimised errors more than justify the expenditure. Additionally, eliminating the clerk's role in data entry post-laying further reduces operational costs and frees up resources for other value-added tasks.

5.3.5. Scalability and Flexibility

As our manufacturing operations grow, the automated data capture system can quickly scale to accommodate increased production volumes and additional product lines. Integrating scanners or tablets allows flexibility and adaptability to future technological advancements and operational needs.

5.3.6. Employee Satisfaction and Training

Simplifying data capture through user-friendly devices like tablets or scanners enhances the user experience for laying operators. Training on these devices is typically straightforward, minimising downtime during implementation and ensuring quick adoption by the workforce.

5.3.7. Compliance and Audit Trail

Automated data capture provides a robust audit trail for compliance purposes. Detailed records within the ERP system enable easier traceability and accountability, seamlessly supporting regulatory requirements and internal audits.

5.4. Fabric waste eliminations: Stabilisation

The fabric undergoes significant tension during the rolling process, leading to stretching and potential shrinkage. If left unchecked, this tension can cause garments to lose shape or improperly fit after production. For fabrics with this shrinkage problem, an additional 2 cm allowance is added on either side of the lay with a length. This additional fabric cost adds fabric waste to the garment, making manufacturing less cost-effective. To prevent this, the fabric is carefully unrolled and spread out to its full width, allowing it to relax and stabilise. This enables the fabric to recover from its stretched state and return to its natural dimensions. This process, known as fabric relaxation or stabilisation, prevents fabric distortion and ensures optimal garment production. The fabric is left to rest for an extended period, typically 24 hours, to ensure complete relaxation. This step is particularly critical for knit fabrics, which are more prone to stretching and shrinkage than woven fabrics. By allowing the fabric to relax and stabilise, manufacturers can ensure that their garments retain shape and size throughout the production process.

5.5. Cut Room Efficiency

As mentioned, cutting room operations lack standard measuring tools or methodologies widely used in the industry, like how sewing operations have Standard Minute Values (SMVs). This is primarily due to the complexity of the cutting operations. However, implementing the following methods can significantly improve efficiency and accuracy in the cutting room operations:

5.5.1. Develop a standardised cutting room methodology

Establish a consistent approach to measuring cutting room efficiency, considering factors like garment complexity, fabric type, and garment group types. Garments that use similar fabrics are cut the same way. Garments that use slippery fabric will need clamps when cutting; garments with bigger panels do not need to be cut on the stationery saw table.

5.5.2. Create a garment Cutting Room Standard Time system

Similar to SMVs, develop a standardised time measurement system for cutting operations. This involves conducting time studies on garment group types based on pattern similarities. This will give an average cycle time for cutting each garment type, and this cycle time can be applied to the master pattern, meaning that all garments that use a specific master pattern would take approximately that amount of time to cut.

5.5.3. Implement a complexity rating system

Assign a complexity score to each garment design, considering factors like pattern pieces, fabric types, marker efficiency and cutting techniques. This helps normalise efficiency metrics across different garments.

5.5.4. Use technology and data analytics

Leverage cutting room software, sensors, and data analytics to track operator performance, garment complexity, and production times provides valuable insights for optimisation and efficiency improvement. It could also be used on stationery saw tables, equipped with sensors that measure saw revolutions per second, visual recording devices like cameras, and other machine utilisation measures.

5.5.5. Continuous monitoring and feedback

Regularly monitor cutting room efficiency, provide feedback to operators, and adjust the standard times as needed. This ensures accuracy and fairness in our operations, giving everyone a level playing field.

5.6. Future technology

The following list outlines potential machines for future development and research, informed by observations from the study. These machines aim to enhance cutting room operations, catering to the needs of smaller manufacturing companies. While cutting-edge technologies like the Gerber cutter/spreader can revolutionise high-volume production, their high cost and under-utilisation in low-volume environments make them less suitable for smaller factories. Instead, there is a need for affordable, operator-assisted technologies that improve quality and efficiency in these settings. Thought should be given to a cutting-room facility only, that works for several clothing manufacturers.

5.6.1. Laser-guided manual cutting machine

These machines will be equipped with a light or laser guidance system to monitor the cutting process and detect deviations from the pattern line. When an operator cuts outside the designated line, the machine will alert them with a visual or auditory signal, indicating a cut error and preventing further inaccuracies.

5.6.2. QR Codes on Printer Marker Panels

Implementing QR codes on printer marker panels can assist operators in sorting and bundling areas. By simply scanning the QR code on the top marker paper, the scanner will instantly identify the corresponding bundle assignment, eliminating manual errors and increasing efficiency.

5.6.3. Reject detecting sensor laying machine

During the literature review, no existing machine was found that could detect standard fabric rejects during the laying process in the cutting room. While quality control machinery is available for textile manufacturing, none specifically addresses the cutting room needs. An ideal solution would be a machine or attachment that can be integrated with any laying machine, detecting fabric rejects as the roll is unrolled and laid on the table. Upon detection, the machine would alert the operator and halt the process, allowing for the reject to be removed. A sensor-based attachment would be a preferred solution, enabling seamless integration with existing laying machines.

6 CONCLUSION

This analysis of cutting room operations, guided by the Lean Six Sigma methodology, has highlighted key areas for improvement and developed actionable strategies to enhance efficiency. Key findings include the benefit of grouping work orders by fabric quality and colour, which improves fabric utilisation and productivity. The study also recommended automating data capture during the laying process to reduce manual errors and streamline operations. Additionally, fabric relaxation techniques and potential future technologies, such as laser-guided cutting machines and reject-detecting sensors, offer significant opportunities for improving accuracy and reducing waste. Implementing these recommendations, including optimising work orders, automating data capture, and adopting advanced technologies, can help the cutting room achieve better fabric utilisation, enhanced productivity, and reduced costs. These improvements will streamline the cutting process and contribute to higher-quality and more efficient garment production [27;28].

ABSTRACT

The purpose of this study was to address Company XYZ's underutilized maintenance data, hindering the adoption of proactive maintenance procedures. Applying maintenance data to increase asset dependability and operational effectiveness was the key goal. To determine the underlying causes of downtime and data inconsistencies, a mixed-methods approach was used, combining quantitative analysis of maintenance records with qualitative insights from process observations. The study's conclusions showed that inadequate staff training, gaps in process standardization, and data inaccuracies were the main causes of poor maintenance management. As a result, the study created tools for data analysis, standardized maintenance procedures, created a framework for choosing strategies based on Reliability-Centered Maintenance, and integrated the concepts of Total Productive Maintenance. When these interventions were put into practice, downtime decreased, indicating operational gains. This study adds to the body of knowledge in maintenance management by providing empirically supported methods for enhancing decision-making and maintaining reliability gains.

1 INTRODUCTION

Cost-cutting measures are essential for maintaining supply and generating income in the cutthroat automobile parts manufacturing sector. This industry is heavily dependent on equipment, and reducing downtime gives manufacturers a significant edge in terms of increased operational effectiveness, lower costs, and the capacity to continuously satisfy client expectations. Original Equipment Manufacturers (OEMs) and Tier 1 suppliers in the South African market, as well as overseas export markets, receive a wide range of components from Company XYZ, a respectable and skilled maker of automobile parts. High-capacity equipment is the foundation of production and income in the asset-intensive operations of the company. However, these assets are vulnerable to unforeseen malfunctions because of their high utilization rates. Such malfunctions cause a great deal of downtime, which puts the company at a competitive disadvantage and consequently contributes to missed or delayed customer deliveries.

Frequent outages in Company XYZ's high-capacity assets cause delays and interruptions in customer delivery. Customer satisfaction and operational efficiency are compromised by this issue. It is necessary to reconsider current maintenance practices and implement more efficient methods of enhancing asset reliability rather than relying solely on expensive investments in new machinery. The company's downtime and its high-capacity assets lead to delays and disruptions in customer deliveries. This problem undermines operational efficiency and customer satisfaction. Rather than defaulting to costly investment in new equipment, there is a need to re-evaluate existing maintenance strategies and adopt more effective approaches to improving asset reliability. This study's major goal is to assess and suggest maintenance plans that reduce downtime and increase the dependability of Company XYZ's high-capacity equipment. By tackling these goals, the study hopes to provide useful insights into maintenance optimization in the automotive parts manufacturing sector and provide Company XYZ with doable tactics to improve asset competitiveness and reliability.

2 LITERATURE REVIEW

In this literature review, there was an exploration of how authors have developed aspects of their asset care excellence framework and have applied methodologies and concepts to develop Company XYZ's asset care excellence framework.

This literature will be relevant to developing an asset care excellence framework for Company XYZ, which will play a significant role in gaining accurate data that will be used in minimizing downtime, improving overall asset reliability, and selecting maintenance strategies, thus tackling the problem of underutilization of data to proactively respond to maintenance downtime and addressing data inaccuracies.

2.1. Maintenance Strategies

Equipment and systems deteriorate over time, which can lead to decreased operational efficiency and increased downtime [1]. Over time companies have identified this and have implemented maintenance practices and strategies to minimize downtime, improve overall asset reliability, and optimize the lifespan of equipment and systems. There are four common maintenance strategies that most companies employ: reactive maintenance, preventative

maintenance, predictive maintenance, and proactive maintenance. Each has its own advantages and challenges that will be explored in this section of literature.

2.1.1. Reactive maintenance

Historically one of the first maintenance practices and strategies was to run your equipment to failure [2], and then repair or replace that equipment [3]. During this time operations within companies consisted of mainly physical labour [2]. The run to failure maintenance method came about in the past when operations used equipment that was simple, equipment failures did not cause total operations stoppage, technology was limited, and there was limited knowledge available about maintenance [2]. This maintenance practice and strategy is ineffective as a breakdown can lead companies to unexpected downtime, thus hurting the business. This strategy is coined as reactive maintenance, whereby maintenance teams or third-party service providers will be requested to repair or replace equipment. Today, there are many companies that still use Reactive maintenance as its core maintenance strategy. If this strategy is used alone, it can lead to unexpected downtime, unexpected costs, extra wastage of time waiting for maintenance teams or third-party service providers to arrive and replace/repair, and lastly possible loss of business.

Although Reactive maintenance is not a suitable strategy for all equipment, it may be suitable to employing reactive maintenance to equipment with low consequences of failure and high availability [4]. In [4] paper, they had explored where Reactive maintenance can be applied as a maintenance practice, and had determined that it can be applied to equipment where the cost of applying more preventive or proactive or predictive maintenance strategies would actually cost more than allowing the equipment fail. In their paper, the equipment they used as an example to apply reactive maintenance was on a light bulb, which would be relatively cheaper to buy when the fuse is blown than to apply preventive or proactive or predictive maintenance strategies [4]. To determine if reactive maintenance is suitable for equipment, one must determine if the cost of preventive or proactive or predictive maintenance outweighs the potential risk and impact of that equipment's failure [4].

2.1.2. Preventative maintenance

As equipment and technology had developed and advanced during the 20th century, operations involved more complex equipment and systems, thus leading to failures having a greater impact to operations and line stoppages [2]. As a result of failures having a greater impact on operations, preventative maintenance was developed. Preventative maintenance was the first maintenance practice to consider the health of the equipment with the aim of prolonging its lifespan and preventing equipment failure. Preventative maintenance involves scheduling maintenance tasks and activities like inspections, cleaning, lubricating, and other servicing of the equipment ahead of time to prevent unexpected downtime due to failure. This allows for equipment to be in good working condition, thus minimizing downtime as issues with the equipment can be identified and dealt with before becoming a bigger problem [5]. Preventative maintenance assists in extending the equipment's lifespan and reliability, because when the equipment is regularly maintained, early failures can be identified, flagged, and prevented [5].

Preventative maintenance can also be referred to as time-based maintenance and scheduled maintenance, as it involves performing maintenance activities at predetermined intervals. Scheduling intervals of the preventative maintenance activities can be calendar based or usage based. Calendar based preventative maintenance scheduling involves performing maintenance activities on equipment every week, month, quarter etc., which can be planned in advance. Usage based preventative maintenance involves performing maintenance activities after a predetermined number of hours of operation [6;7].

Although preventative maintenance is an effective practice and strategy, it is very costly to set up spares, lubrication, tools, and a skilled maintenance team is required to conduct maintenance activities on a regular basis. It would also involve maintenance activities to be done on equipment on a regular basis irrespective of the health and condition of the equipment, which can cost a company money to replace spares that do not need to be replaced, cost the maintenance team time to carry out maintenance activities on equipment that is already in a good condition, and could disrupt operations by needing to commence maintenance activities on equipment that is a good condition [1]. This maintenance strategy alone is suitable for equipment that is not used in operations frequently or is used in operations seldomly. There would need to be a balance between choosing calendar based and usage based preventative maintenance to perform. To determine which time-based maintenance method should be used, one can develop a calendar schedule for the selected equipment, monitor the usage of the equipment, and perform maintenance activities at the earliest occurring method.

2.1.3. Predictive maintenance

As equipment and technology developed further, and more knowledge was available with a deeper understanding of the importance of maintenance was gained from implementing preventative maintenance and learning from information from reactive maintenance; predictive maintenance emerged as a valuable maintenance practice and strategy to further improve the reliability of equipment. Predictive maintenance uses predictive tools to analyze historical data and identify if a failure is likely to occur in the future by monitoring the equipment's condition [8]. By using predictive maintenance, companies can proactively address possible failures before they actually occur and become costly breakdowns or accidents. Predictive maintenance is a heavy data driven maintenance practice that relies on historical data such as past work orders with work done on equipment, schedule maintenance work completed, the downtimes that the equipment experienced, the breakdowns with its root cause analysis, the equipment's performance, and the equipment's parameter settings [5]. With this data artificial intelligence and machine learning can be applied to proactively address possible failures before they actual occur and can also provide the maintenance personal valuable troubleshooting information to repair equipment, thus minimizing downtime or improving overall reliability [5]. Although this is the most effective maintenance practice in minimizing downtime and improving equipment reliability, it requires sensors or people consistently recording data, storage of the data, processing of the data, analysis of the data, and lastly requires a predictive model which can become very costly and time consuming. This maintenance practice should be applied to critical equipment to operations and advanced equipment with built in sensors and systems like PLCs.

In [9] paper the author explored the use of predictive maintenance in the refractory insulation of high temperature units in the metallurgical industry. [9] used predictive maintenance by continuously monitoring high temperature equipment like furnaces and ladles to extend their lifespan, reduce downtime, and ensure efficient production. They performed experiments by monitoring damage of the high temperature equipment by visual assessment, temperature measurement, and mathematical modeling to make informed decisions on performing maintenance activities based on the data [9]. The experiment resulted in [9] establishing relationships between failure parameters and diagnostic signs, thus leading them to develop rules based on these relationships to predict failures based on the current conditions of the equipment.

With the development of industry 4.0 and technologies such as Internet of Things (IOT) and cyber-physical systems to collect and analyze data from equipment sensors companies are able to gain real-time insights to making data driven decisions. In [10] paper they explored using a data-driven approach of continuously monitoring and forecasting potential failures through predictive maintenance on an Engel Injection molding machine. Since the injection

molding machine was older, they explored retrofitting external sensors to the machine which would collect raw data and also explored using Supervisory Control and Data Acquisition (SCADA), Manufacturing Execution System (MES), or Enterprise Resource Planning (ERP) systems to store the raw data for analytics by combining edge and cloud based computer systems [10]. They used the edge-based computing (edge computing involves linking data from sensors to the SCADA/ MES/ ERP systems) to handle time-sensitive data processing to detect anomalies in real time whilst also reducing bandwidth, and cloud-based computing for more complex data analysis for predictive models [10]. They explored integrating data like barrel pressure, clamp force, cavity pressure, screw position, and strain from sensors to develop predictive models to detect maintenance issues more effectively [10].

With the emergence of Artificial Intelligence (AI) and Machine Learning (ML) companies are realizing that there is a vast number of applications for them including predictive maintenance. In [8] paper they explored using ML model for predictive maintenance which involved historical data selection, data preprocessing, model selection, training, and validation, and model maintenance. [8] explored the use of Random Forest (RF), Artificial Neural Networks (ANN), Support Vector Machine (SVM), and k-means ML models for Predictive Maintenance which resulted in cost reductions and process efficiency.

2.1.4. Proactive maintenance

As equipment and technology developed further, and information gathered from preventative maintenance and reactive maintenance was available, companies started learning from equipment failures and implementing solutions to prevent the same failure happening again, thus proactive maintenance emerged. Proactive maintenance involves anticipating potential equipment failures from historical data collected on equipment and system failures before they can lead to failure and downtime.

Root Cause Analysis (RCA) is applied to problem solving after a problem has occurred. Its purpose is to identify the causes of the problem. One commonly used tool is the fishbone diagram. The fishbone diagram uses the 4Ms which is: Man, Machine, Methods, and Materials to determine the possible causes of the problem from the perspective of each of the 4Ms. RCA methodologies aim to uncover the causes for the failure/ downtime. Once these causes are realized, countermeasures are brainstormed, developed, implemented, and then monitored for effectiveness on minimizing downtime. If the countermeasures prove to be effective, then they can be standardized and become part of the company's maintenance practice and would improve the overall reliability of the equipment.

2.2.Other Maintenance Strategies

In addition to the four common maintenance strategies mentioned in the previous section of the literature there are other effective maintenance strategies that uses a combination of these four common maintenance strategies, which can be employed by companies to minimize downtime and improve overall equipment reliability. There are two that will be covered in this section: Total Productive Maintenance (TPM) and Reliability-centered maintenance (RCM).

2.2.1. Total Productive Maintenance (TPM)

Total Productive Maintenance (TPM) involves reducing costs and downtime by having zero unplanned failures, zero product defects, and zero accidents. Its approach is slightly different to other maintenance strategies, where its focus is on effective training and skills development of employees, thus creating a culture of commitment to maintenance to improve equipment effectiveness, minimizing downtime, and improve product quality [11]. TPM consists of eight pillars and was built on the foundation of 5S. The eight pillars of TPM defined based on [12] paper are Autonomous Maintenance, Planned Maintenance, Quality Maintenance, Focused

Improvement, Development Management, Education and Training, Safety, Health, and Environment (SHE), and Office TPM.

In [11] paper they explored using TPM to improve equipment effectiveness, minimizing downtime, and improve product quality, by elimination of "main problems", Autonomous maintenance, schedule maintenance, and training. Elimination of "main problems" looked into identifying RCA, implementing solutions and standardizing procedures like in proactive maintenance [11]. Autonomous maintenance involved getting employees to perform **basic** inspections and cleaning activities of equipment, which where structured into employee's daily, weekly, and monthly tasks [11]. Schedule maintenance tasks that can only be completed by maintenance teams were scheduled taking into account of operations [11]. Lastly training of employees which involved them gaining theoretical and practical knowledge about equipment to prevent unexpected downtime, and creating supporting documents that they can refer back to if need be [11].

2.2.2. Reliability-centered maintenance (RCM)

Reliability-centered maintenance (RCM) is a maintenance practice and strategy that first came about in the aviation industry [13]. It involves systematically analyzing equipment components using failure mode and effect analysis (FMEA) to identify critical parts and potential failure modes, then selecting maintenance activities to reduce or eliminate failures [4].

Failure Mode and Effects Analysis (FMEA) involves determining potential failure modes of components, and determining their criticality based on the frequency of occurrences, detectability, and severity of the failure [13]. These are then scored on a scale (example 1-10), and a Risk Priority Number (RPN) is calculated from these scores, helping prioritize maintenance activities based on the criticality of each component's failure modes [13].

In [13] paper they explored the use of RCM in a subsystem of a Continuous Emissions Monitoring System (CEMS), they identified the main causes for component failure through FMEA and targeted maintenance strategies to be employed on components of the FMEA outcomes. They used mean time between failures (MTBF) to determine the intervals between faults in the CEMS to assist them in selecting a maintenance strategy to be used [13]. They were able to improve the reliability of the CEMS by targeting failing components and applying an appropriate maintenance strategy to these components [13].

2.3.Reliability metrics

Building on the maintenance strategies in the previous two sections of the literature, reliability metrics can be used to implement and evaluate the effectiveness of these maintenance strategies in improving equipment reliability and minimizing downtime. By analysing reliability metrics companies can evaluate the impact of different maintenance strategies on equipment performance. This allows companies to make data driven decisions on which maintenance strategies to prioritize and invest in, to improve overall equipment reliability and minimize downtime.

2.3.1. Mean time to failure (MTTF)

Mean time to failure (MTTF) is a reliability metric that is used to determine the average time it takes for non- repairable equipment to fail by calculating the average time between the equipment's start of operation and its failure [14]. MTTF is useful in determining the expected lifespan of equipment and allows for proactive maintenance strategies to be implemented, reducing the risk of unexpected failures and minimizing downtime.

2.3.2. Mean Time Between Failures (MTBF)

Mean Time Between Failures (MTBF) is a reliability metric used to determine the reliability of repairable equipment or systems by calculating the average time between failures [15]. MTBF

is the ratio of the total operational time of an asset to the total number of failures of the asset [16]. MTBF is useful to determine the overall reliability of the equipment or system and can used to determine the maintenance schedule for usage based preventative maintenance and expected downtime for the equipment or system so that operations can plan accordingly and minimize disruptions to productivity.

2.3.3. Mean Time to Respond/ Mean Time to Acknowledge (MTTA)

Mean Time to Respond or Mean Time to Acknowledge (MTTA) is a reliability metric used to determine the average time it takes for the maintenance team to arrive and carry out maintenance activities by calculating the average time between the start of the downtime to the arrival of the maintenance team [17]. MTTA is useful in determining the response time of the maintenance team and identifying any delays or gaps in the maintenance process.

2.3.4. Mean Time to Detect (MTTD)

Mean Time to Detect (MTTD) is a reliability metric that is used to determine the average time it takes to diagnosis the reason to an equipment failure by calculating the average time between equipment failures and failure diagnosis [15] [17]. MTTD is useful in determining how long it takes to identify and diagnose the cause of equipment failure.

2.3.5. Mean Time to Repair (MTTR)

Mean Time to Repair (MTTR) is a reliability metric used to determine the average time taken to repair an equipment failure by calculating the average time it takes to complete equipment repairs on a number of equipment failures [14]. MTTR is useful in determining how long it takes to restore equipment to a working condition so that operations can plan around potential downtime. This metric is also useful in determining the effectiveness of maintenance strategies and identifying possible gaps in the capability maintenance team, as a shorter MTTR indicates timely repairs and a strong capable maintenance team.

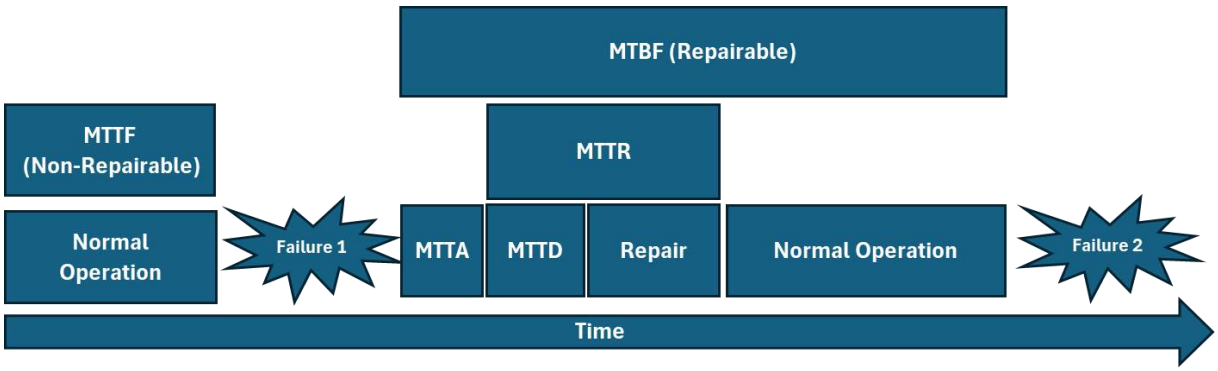

Figure 1: Reliability Metrics Sequence

These reliability metrics have been employed by many companies and can be highly effective in planning preventative maintenance with production, thus decreasing the chance of downtime during peak production demand. [18] has also used these reliability metrics to plan preventative maintenance which resulted in reduced downtime, improved overall asset reliability, and optimized maintenance strategies.

In [16] paper they used these MTBF and MTTR as a foundation to compare the improvement made before and after the Implementation of Autonomous Maintenance in a Beer Processing Plant, to determine the effectiveness of Autonomous Maintenance.

2.4.Framework to selection of maintenance strategies for Asset care excellence

Based on the explored maintenance practices and strategies in the earlier part of the literature, a method for choosing which strategy to use for equipment needs to be determined.

In [19] paper they explored a framework through RCM by selecting equipment, classifying the equipment as critical and non-critical, and then applied a maintenance strategy based on the equipment and their classification. This framework proved to be effective in identifying and implementing asset care excellence by providing a systematic approach to choosing a maintenance strategy. In Figure 9, an Asset Care Excellence Selection Framework based on [19] framework was developed, with the addition of equipment systems, and determining if minor or major before choosing a maintenance strategy. The framework will be discussed further in the recommendations of this paper.

3 METHODOLOGY

The research onion as explained by [20], serves as the methodological framework for this investigation. The research onion offers an organized framework for planning and carrying out research by outlining a number of levels, from data collection methods to philosophical presumptions, that the researcher gradually traverses to reach suitable methodological decisions. It is useful because it guarantees methodological consistency and openness all the way through the study process. The study's ontological position, which recognizes the reality of objective realities in the form of measurable production and maintenance data, serves as the philosophical foundation. This is consistent with the study's emphasis on quantifiable downtime, efficiency, and reliability metrics.

This study ensured methodological rigor, coherence between research philosophy and practice, and transparency in the decision-making process by methodically navigating the research onion. The framework improved the research's replicability and contribution to the maintenance and process optimization fields in addition to bolstering its internal validity. In this methodology, the research philosophy, approach, strategy, time horizons, and methodology choices are detailed and are based on the research onion by [25]. The selected methodology to solve the research problem of the organization’s inaccurate data and the underutilization of data to proactively respond to maintenance downtime is explained. In this research paper, the pragmatism philosophy was used as a guiding framework. This philosophy has allowed the selection and combination of different approaches to be used from multiple sources of literature, and tailor Company XYZ’s Asset care excellence framework to what would realistically work best for the organization.

In this research paper, the deductive approach was used. By using the deductive approach, the application of existing concepts mentioned in the literature review section was used and determined whether they could effectively address the research problem of the organization’s inaccurate data and the underutilization of data to proactively respond to maintenance downtime. Additionally, this approach aligned with the research objectives and questions, as it focused on exploring how the organization could use data analytics to identify patterns and trends to address maintenance challenges.

For this research project, the action strategy was used. Using the action strategy has enabled the planning and application of solutions from the literature to address the research problem of the organization’s inaccurate data and the underutilization of data to proactively respond to maintenance downtime. After implementation of the various solutions, enabling observation and reflection on the effectiveness of the solutions. Through observation and reflections of the various solutions, adjustments and changes were made based on the results of the solutions, which has assisted in bringing positive change with more practical solutions to addressing the problem. This strategy has allowed more active involvement and participation in the research which has assisted in convincing the staff of the organization to follow the suggested solutions.

The mixed-methods methodology was used to collect both quantitative and qualitative data. This mixed-methods approach provided a comprehensive understanding of contributing factors

to maintenance downtime and allowed for a more accurate analysis of the data. These mixed methods approach also gave a more accurate picture of the problem, as it considered a more holistic view of maintenance from a numerical perspective and a subjective perspective from the maintenance and production teams.

4 RESULTS AND DISCUSSIONS

Data was gathered from the organization's asset management records and Computerized Maintenance Management System (CMMS) to facilitate the methodical creation of maintenance performance reports. Extraction of precise, time-bound data on malfunctions and reactive maintenance work orders was the key goal. The necessity to monitor asset dependability, maintenance effort, and recurrent failure patterns served as the basis for data gathering. The data collected enables the establishment of reports in Figures 2 and 3, and data used in the development of the dashboard, i.e., data in 4.1.2 and 4.1.3.

4.1.Utilization of maintenance data

Previously, at the organization, maintenance data was too inaccurate and unreliable to be used for analysis. With the interventions put in place during this research, Company XYZ has seen a positive change in gaining data that can be used to complete maintenance downtime analysis.

4.2 Downtime and repair time analysis reports

To gain a view into the organization's asset failures, I decided to create reports that are used for analysis of breakdowns and reactive work orders created and completed over the year, and for the month. These reports would be routinely created every month to identify any trends and patterns of the various assets. These reports would then be printed and added to the KPI board for management to review in one of their weekly management meetings of the month. This includes the following Reports:

- Report 1: Breakdowns- Downtime versus Repair hours
- Report 2: Reactive- Downtime versus Repair hours
- Report 3: Breakdowns- Downtime versus Occurrences
- Report 4: Reactive- Repair Hours versus Occurrences.

Figure 2: Breakdowns- Downtime vs Repair hours report

Figure 3: Breakdowns- Downtime vs Occurrences Report

These reports are essential for the organization to gain a deeper understanding of asset reliability and to identify issues that can lead to further investigation. These reports assist the organization in comparing Downtime, repair time, and the occurrence of failures, which can assist in identifying trends and patterns, and be used for focused improvement initiatives.

4.1.1. MTBF and MTTR analysis reports

To analyse Company XYZ's data for MTBF and MTTR, I decided to create a robust tool through reports. These reports will also be routinely created every month and throughout the year, with the purpose of analysing MTBF, MTTR, downtime, and repair times. It will be printed and added to the KPI board for management to review in one of their weekly management meetings of the month. This includes the following 3 Reports:

- Report 5: MTBF vs MTTR
- Report 6: Interactive- Downtime vs MTBF
- Report 7: Interactive- MTTR vs Repair hours

These reports are essential to the organization as they can be used for further analysis and investigations of the asset's conditions, identifying root causes, and also assisting in the implementation and monitoring of the maintenance strategies mentioned in the literature.

4.1.2. Work order analysis reports

To gain a view into what type of work artisans were requested to do and to show progress of reducing the work orders backlog, I decided to create a maintenance work order KPI report. This KPI report will also be routinely created every month throughout the year. It will be printed and added to the KPI board for management to review in one of their weekly management meetings of the month.

- Report 1: Total Work Orders created.
- Report 2: Work orders backlog.

- Report 3: Predetermined Maintenance by Asset
- Report 4: Corrective Maintenance by Asset

These reports are essential to the organization as they provide an understanding into the types of work being requested of the maintenance team, the progress being made in reducing the backlog of work orders, understanding the total generated work orders, the current backlog, and comparing predetermined and corrective maintenance activities to help the maintenance managers make informed decisions about resource allocation, staffing, and determine overall maintenance effectiveness.

In addition to graphically presenting the reports, a dashboard design that incorporates derived KPIs and trends is established to provide management with quick access to actionable insights. The data collection process made it possible to produce structured reports that included early warning signs of asset reliability issues in addition to historical performance data. The regular production of these reports promoted proactive decision-making, guaranteed ongoing monitoring, and made it easier to align maintenance performance with organizational goals.

4.2.Application of Maintenance strategies

As one of the objectives of this research, I wanted to investigate maintenance strategies which can be implemented to reduce and prevent maintenance downtime. Through the literature I have identified the five main strategies that were applied and investigated.

4.2.1. *Total Productive Maintenance (TPM)*

As mentioned in the literature of this paper about TPM, it is proposed that Company XYZ's asset care excellence is built on the Foundation of TPM. Throughout this research the Education and Training, Planned Maintenance, Autonomous Maintenance, Safety, Health, and Environment (SHE), and Focused Improvement pillars of TPM have been applied. As mentioned in the literature that TPM's 8 pillars are built on the foundation of 5S, which is developing well at the organization through other initiatives in place outside of this research.

4.2.2. Preventative maintenance

Since the organization currently employs calendar based preventive maintenance as its main maintenance strategy, this strategy was not researched at length. However, investigating the possibility of moving away from calendar based preventive maintenance to usage based preventative maintenance did occur. It is propose that the organization uses the MTBF chart to determine the average time between failures for equipment within 24 hours (3 shifts) before or after this value, determine the lead time of the required spares for the preventative maintenance to order spares in advance, use the MTTR for preventative maintenance to determine how long the maintenance activities will take place- so that production a plan accordingly, and monitor the usage of the assets as it approaches the MTBF value. The MTBF value with the other factors mentioned can be used to determine the usage based preventative maintenance intervals, which should be updated regularly based on the updated data month to month.

4.2.3. Proactive maintenance

Since the organization has maintenance related data with much improved data accuracy, they are able to utilize their data from past failures. With the reports created on Power Bi, the organization can use their work order data and do further investigations of root causes of failures. The Power Bi reports would be key to proactive maintenance on past failures, and as more accurate data becomes available, it would be easier to identify patterns and trends of Asset failures. These reports are the cornerstone to shifting the organization to taking proactive measures to making assets more reliable, and also being able to initiate focused

improvements to where it is needed most, whilst also tracking the effectiveness of these improvements.

4.2.4. Reliability-centered maintenance (RCM)

As part of applying RCM at Company XYZ, it was decided to do a purpose sample asset of 533 which was an eccentric press. This press was chosen based on it being available to analyse and based on it being one of many eccentric presses of the organization. It was decided that an FMEA for asset 533 would be developed. As mentioned in the literature FMEA involves determining potential failure modes of components, thus requiring interviews with an experienced Artisan who knows the functionality of all components, and the role the components plays in the operation of the press. Before interviewing the artisan, all components of the press were listed, and then the artisan were interviewed on the functions of component and the possible failures based on his experience over the years. With the completed FMEA, it was duplicated and edited for the other eccentric presses. The purpose of the FMEA was to determine all possible failures that could happen, give an RPN based of the likelihood of occurrence and the risk, and also to be used as a guide to determine what the failure could be with the remedy to that failure. With the FMEA diagnostic times would decrease, thus leading to shorter downtimes.

4.2.5. Predictive maintenance

As part of a separate project for Company XYZ's Ecoating line, a system that takes inputs from users and plots these inputs into a Statistical process control (SPC) chart in real time was developed. Part of predictive maintenance, it was decided to use the water pressure parameter of tank two of the Ecoating line for predictive maintenance. Below is the SPC chart of tank two.

Figure 4: SPC chart for Tank 2 of the Ecoating line

By using the system designed and applying predictive maintenance to tank 2 of the Ecoating line, monitoring and tracking a continuous drop in water pressure was possible, thus leading the organization to predict that one of the nozzles of tank 2 would soon fall off into the tank. By continuously monitoring the SPC chart, it was able to predict that there would be a loss in water pressure soon. Since water pressure is not something you can see problems until it

actually becomes a problem, the SPC chart was used to be able to identify issues through recording and comparing historical data. The issue with the nozzle was easily fixed long before it could become a big issue, which could have resulted in rework of all parts processed, which would have only been identified five tanks later. This also saved the other tanks from contamination, as tank two plays an important role in washing off degreaser and debris.

5 RECOMMENDATION AND CONCLUSIONS

In order to increase dependability and operational performance, this study addressed Company XYZ's high-capacity asset downtime and maintenance inefficiencies. The integrated production data is used in conjunction with expert insights and observations, guided by the research onion technique. In order to facilitate trend analysis and management decision-making, monthly reports were created to track malfunctions and reactive maintenance.

The results showed that current maintenance procedures lacked uniformity and efficient data utilization, and that the majority of downtime was caused by a small sample of high-capacity equipment. The study suggested standardized maintenance procedures, data analysis tools, employee training, and the integration of Reliability-Centred Maintenance (RCM) and Total Productive Maintenance (TPM) by utilizing Lean Six Sigma and Fourth Industrial Revolution (4IR) principles.

Through KPI reporting, these actions enhanced operational visibility and reduced downtime. The study offers useful tactics for boosting competitiveness in equipment-intensive manufacturing, decreasing operational disturbances, and improving asset reliability. It provides a template for comparable firms looking to enhance maintenance using data.

From the accurate work orders data, I was able to create interactive reports on Power BI to be able to analyze downtimes and failures of assets at the organization. These reports consisted of data from various sources within the organization, thus creating a holistic view of maintenance's role within the organization and integrating maintenance data into other business systems, which was not possible in the past.

These reports visualize the data from the work orders and other data sources to easily identify patterns and trends for Downtime of assets, Repair hours used by artisans for maintenance activities, the number of occurrences of maintenance activities, show MTBF of the sample assets, and show the MTTR for maintenance activities. Furthermore, the organization was now able to identify and analyze patterns and trends of asset downtimes and failures with the ability to drill down deeper into the data when further investigations are required.

From the initiatives of this research, it can be concluded that Company XYZ has seen a reduction in its average downtime. Lastly, with the monitoring and tracking initiatives put in place for work orders, it was observed that Company XYZ has made outstanding improvements to reduce the backlog of work orders.

6 RECOMMENDATIONS AND FUTURE WORKS

6.1. Asset Care Excellence framework

From the literature review of the various means employed by other authors to maintain assets, improve data accuracy, as well as through the various investigations and initiatives of this research, a framework was developed which is recommended that the organization employ for its asset care excellence. This framework would greatly assist the organization improving its data integrity, allow for the utilization of maintenance data to proactively respond to and reduce maintenance downtime, assist the organization to choose a maintenance strategy to be applied for each asset, and lead to improved overall reliability of assets.

Figure 5: Asset Care Excellence Framework

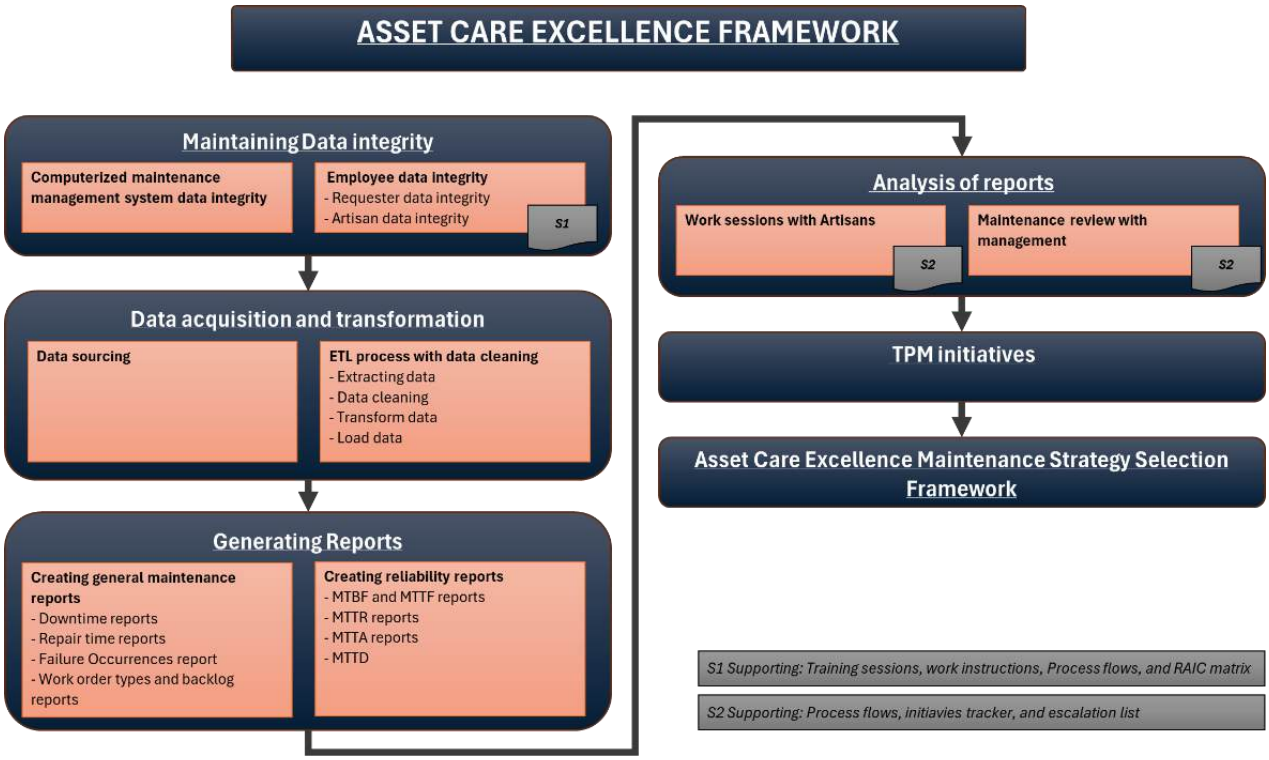

Figure 6: Asset Care Excellence Maintenance Strategy Selection Framework [19]

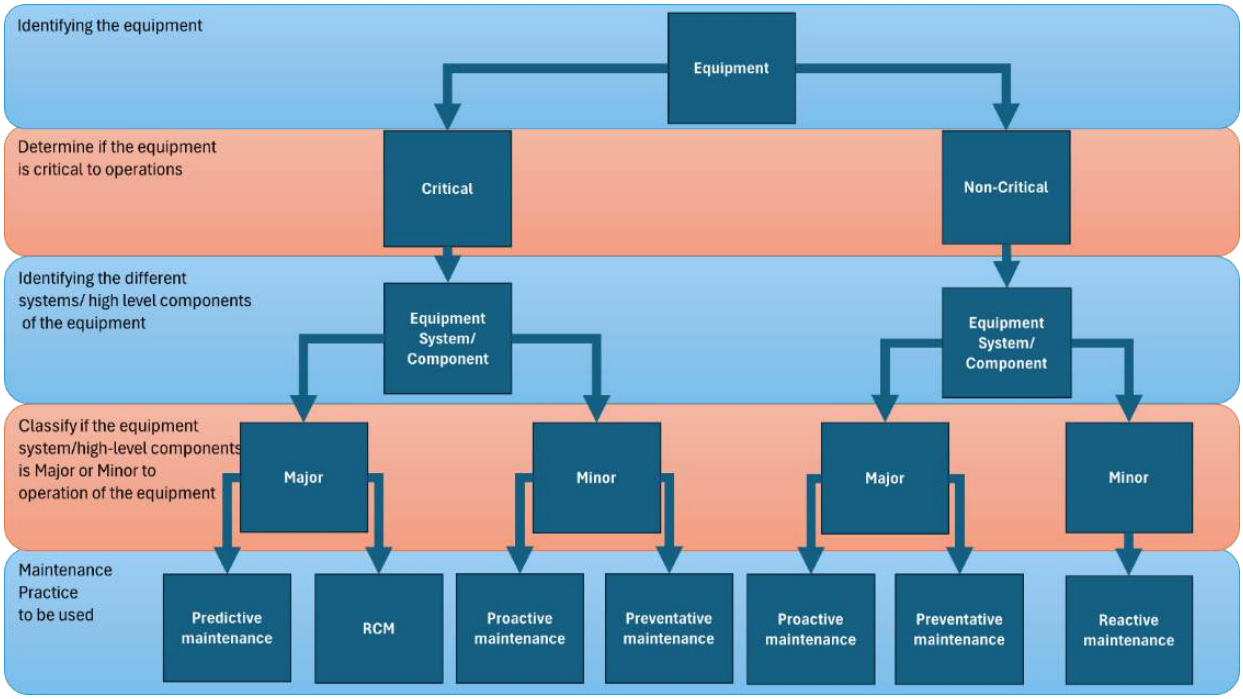

6.2. Predictive maintenance on technologically advanced assets

Many machines and equipment such as the robotic welders and progression presses of the organization have PLC's which may be used to retrieve data from sensors of those machines and equipment in real time. Company XYZ can use this data to implement predictive maintenance, by charting the data and monitoring. Tools such as Statistical process control (SPC) can be utilized to identify variations in the data, which could alert maintenance team members to investigate. It is recommended that Company XYZ get a quotation from a control systems specialist consultant to extract data from the machine or equipment sensors and compare this quotation to the cost of hours lost for repairs done on control systems. If the cost of the repairs and the manhours lost (Maintenance and Production) is substantially higher, then it is suggested that the organization proceed with the quotation from the control systems specialist.

ABSTRACT

The importance of cybersecurity has become an indisputable reality in an increasingly digitised world; the escalating frequency, severity, and public visibility of cyberattacks underscore the increased demand for robust, holistic cybersecurity measures. This systematic literature review (SLR) proposes to conduct a thorough review of the role of the human element in cybersecurity and subsequent relationships with both organisations and management. Multiple elements inform cybersecurity behaviour, including personality dimensions, risk-taking tendencies, decision-making styles, demographic factors, protection motivation, and environmental stressors. The manner in which individuals interact with systems, their understanding of cybersecurity, and their actions are critical components in protecting against cybersecurity incidents. This review demonstrates that organisations need to invest in cybersecurity training and awareness programmes.

Keywords: cybersecurity, human factor, cybersecurity behaviours, cybersecurity management

1 INTRODUCTION

Cybersecurity has become a critical component of operational resilience in today's digitised and interconnected systems. As industrial systems grow increasingly complex, so does integrating IT, operational technology, and human interaction; as such, the need for robust, system-wide cybersecurity measures is more urgent than ever. The World Economic Forum reports a staggering 358% rise in malware attacks and a 435% increase in ransomware incidents since 2020, underscoring the expanding risk landscape [1].

While technological defences continue to advance, the human element remains a key vulnerability. Human behaviour directly impacts system integrity; a study by Stanford University and Tessian found that 88% of data breaches stem from human error [2]. In industrial systems, where downtime or security incidents can result in severe operational and financial losses, understanding and mitigating these human-related risks is essential.

Despite the prevalence of awareness training, current practices often fall short. Cognitive overload, fatigue, and behavioural inertia reduce the effectiveness of interventions [3]. Organisations frequently default to assigning blame, overlooking systemic and behavioural insights that could improve resilience [4], [5].

This systematic literature review (SLR) investigates how cybersecurity behaviours are assessed and what strategies are used to mitigate the human element in cyber risk. It also identifies the key attack vectors that target human vulnerabilities. By framing cybersecurity as a socio-technical challenge, this work aligns with industrial engineering's focus on optimising system performance, enhancing reliability, and integrating human factors into risk management frameworks. The findings aim to inform the design of more effective, human-centred cybersecurity strategies within complex organisational systems.

1.1 Research Question

This research aims to examine and synthesise the existing literature on the relationship between human elements and cybersecurity. The following research questions were developed to help determine which aspects would be explored within this work:

RQ1. What cybersecurity behaviours do employees exhibit within an organisational structure?

RQ2. How do these behaviours contribute to the cybersecurity posture of an organisation?

RQ3. How can businesses or employers manage the human element of cybersecurity risk successfully, across all organisational levels?

1.2 Related Work

Due to the importance of the interaction between the human element and cybersecurity systems, several literature reviews have been conducted.

Alsharida et al. [6] reviewed 93 studies on human cybersecurity behaviour, revealing a growing interest in the field and highlighting the dominance of certain theoretical models that require broader investigation. The article details that various cybersecurity behaviour theories require further study, as certain theories tend to be favoured in research. Jeong et al. [7], in a review of 27 articles, found a persistent technical bias in cybersecurity research, underlining the neglect of human factors. They identified personality traits, demographics, and cultural context as key influences and called for interdisciplinary, qualitative studies.

Rahman et al. [8] analysed 24 articles, framing cybersecurity as a sociotechnical issue. They noted cultural biases (particularly Western-centric perspectives) affect generalisability. They identified 17 human factors, with awareness, privacy, and trust perceptions as the most prominent. Kannelønning and Katsikas [9] reviewed 26 studies on how cybersecurity

behaviours are assessed, noting a reliance on subjective self-assessments and adapted measurement scales. They recommend developing more objective evaluation methods.

Our research questions (RQ1, RQ2, and RQ3) align with the practical concerns of businesses and employers, addressing not only the identification of these cybersecurity behaviours but also their direct implications on the overall cybersecurity posture of an organisation. By concentrating on organisational-level implications, this SLR aims to bridge the gap between theoretical constructs and actionable insights for decision-makers at an organisational level.

2 METHODOLOGY

This SLR adheres to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement [10]. Prior to conducting the SLR, a review of related work was performed to investigate whether similar reviews had been conducted. No reviews were identified that would diminish the significance of this review's contribution to the body of knowledge, pertaining to the research questions posed in this study.

2.1 Search and Selection

To ensure that all relevant literature has been identified and selected, a well-developed search strategy is crucial. The search strategy has been refined using two methods, both “building blocks" and “pearl growing”. The building block method required determining the correct vocabulary for each discrete fact or concept, which was then combined into a final search, as seen in Figure 1.

```
(TITLE-ABS-KEY ( “cybersecurity” OR “cyber security” ) AND TITLE-ABS-KEY ( human W/2 element ) OR TITLE-ABS-KEY ( human W/2 factor ) OR TITLE-ASB-KEY ( human W/2 behavio*r ) )
```

Figure 1 Example Search Strategy

In addition, to mitigate the risk of overlooking important articles, a combination of pearl-growing and building blocks search strategies was used. The pearl growing method relies on a “pearl” article, which is an authoritative article in a field of relevance to the topic of enquiry. This method has the result of identifying the right set of descriptors to find other relevant literature [11]. The “pearl” articles were identified (sources [12] and [13]) and related articles were explored using an online citation-based literature mapping tool, ResearchRabbit.

2.2 Eligibility Criteria

Relevant articles were selected for the SLR using defined inclusion and exclusion criteria. Studies were excluded if they did not address the human element of cybersecurity, were non-academic (e.g., news articles, editorials, presentations, or posters), were not in English, focused on physical or general information security, lacked full-text access, were published before 2010, or were duplicates.

2.3 Keywords and Data Sources

This SLR investigates the impact of human (employee) behaviour on cybersecurity. As outlined in the search strategy (Figure 1), relevant literature was sourced from Web of Science and Scopus, being two multidisciplinary, internationally recognised databases known for their extensive coverage of academic, indexed publications related to technology and other fields [14].

2.4 Screening and Selection

This SLR has been conducted according to the guidelines of Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) [10] guidelines. The flow diagram of the process followed is illustrated in Figure 2.

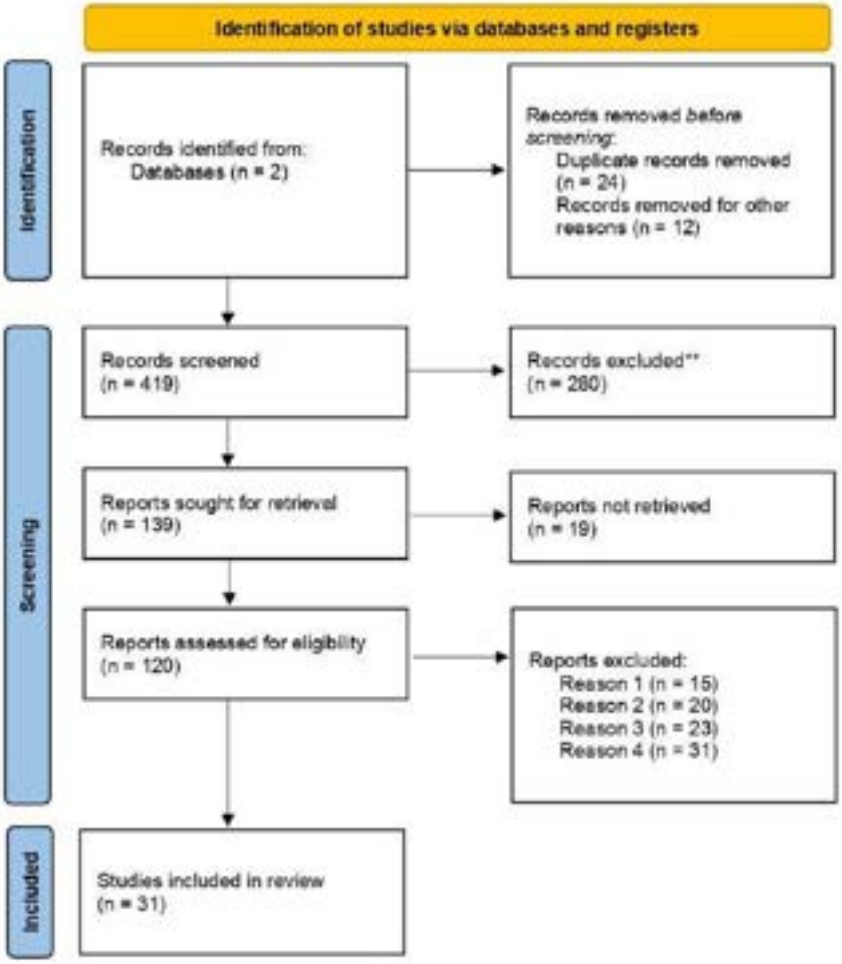

Figure 2 PRISMA Flow Diagram

The screening criteria discussed in Section 2.4 were used to exclude irrelevant retrieved reports, as seen in Figure 2. Titles and abstracts that were evidently irrelevant were removed during the first screening pass, which did not require justification. Thereafter, justification was required for all excluded reports. Four main reasons were considered, namely:

1. The article was a literature review, analysed separately in Section 1.2.
2. It did not sufficiently address the human element of cybersecurity.
3. Its focus was on technical systems or modelling, not behavioural aspects.
4. It examined behavioural topics outside the scope of this study (e.g., threat actor motivation).

2.5 Data Extraction and Quality Assessment (QA)

The screened data were imported into ATLAS.ti, and read in full, for qualitative content analysis, including coding and thematic categorisation [15]. QA is necessary for ensuring the reliability and validity of findings in a SLR [16]. While no single QA standard is universally applied, this study adopts criteria based on the PICOC framework:

- Population: Individuals or employees across various organisational contexts,
- Intervention: Cybersecurity behaviours, measures, or management strategies,
- Comparison: Between different practices or with studies lacking specific interventions,
- Outcome: Employee participation in cybersecurity, breach involvement, or mitigation effectiveness,

- Context: Organisations of any size, industry, or geographical location.

2.6 Method of Synthesis and Analysis

Employing ATLAS.ti in conjunction with the data extracted from the 31 studies, we performed an analysis of the data collected to support the review questions. We meticulously reviewed the selected research articles, examining them thoroughly and then coding the relevant qualitative and quantitative information based on the topics addressed in each study.

3 FINDINGS

Seen in Figure 2, a total of 419 records were extracted from Scopus and Web of Science. After removing duplicates, titles and abstracts were screened, resulting in the exclusion of 280 irrelevant records. Of the remaining 139 articles, 19 could not be retrieved. A second screening of introductions and conclusions reduced the final sample to 31 studies.

Figure 3 SLR Sources and Concepts

Figure 3 above describes the sources and corresponding concepts covered in the 31 analysed studies.

3.1 The Weakest Link

The notion that the human factor is the weakest link in cybersecurity is a recurrent theme in the reviewed literature, with various perspectives considered. Debb and McClellan [17] discuss a widespread assumption that the human is conceptualised as the weakest link in maintaining

cybersecurity across numerous sectors. Furthermore, Klimburg-Witjes and Wentland [18] state that while both technology and humans are considered risk vectors in cyberphysical systems, human susceptibility to errors is a common narrative. During their interviews with cybersecurity professionals, an overwhelming sentiment was prevalent: humans are categorically seen as the weakest link.

Our review found that this sentiment was echoed in seven studies [5], [12], [19], [20], [21], [22], [23] However, the perception that the human element of cybersecurity is only a "part of the problem" has changed to viewing humans as a possible "part of the solution" in three studies [18], [24], [25]. Ergen, Ünal and Saygili [25] interviewed a pool of eight cybersecurity professionals across different sectors; whilst most participants in the study agreed that humans are the weakest link in cybersecurity, there was disagreement. In particular, it was argued that a well-trained human may be able to enhance technical systems, and that "naming [a] human as the weakest link in the chain would affect their risk perceptions negatively". Klimburg-Witjes and Wentland [18] discuss the perception of a "deficient use", lacking the ability to comprehend the complexities of cyberphysical systems. This narrative can be reductive, overlooking the valuable contributions of laypeople, and minimising the possible benefits of continued education. Although human error can undoubtedly contribute to cybersecurity vulnerabilities, different points of view are emerging.

3.2 User-centric Threats

Cyber-attacks can be executed through two approaches: system-centric and user-centric. The former involves exploiting vulnerabilities in a system, computer, or network, while the latter leverages user negligence or errors as a potential avenue for an attack [26].

In this study, various user-centric threats are discussed. Figure 4 illustrates the density of codes related to threat types. The review found that the most discussed threats include social engineering, phishing (including spear-phishing), and insider threats.

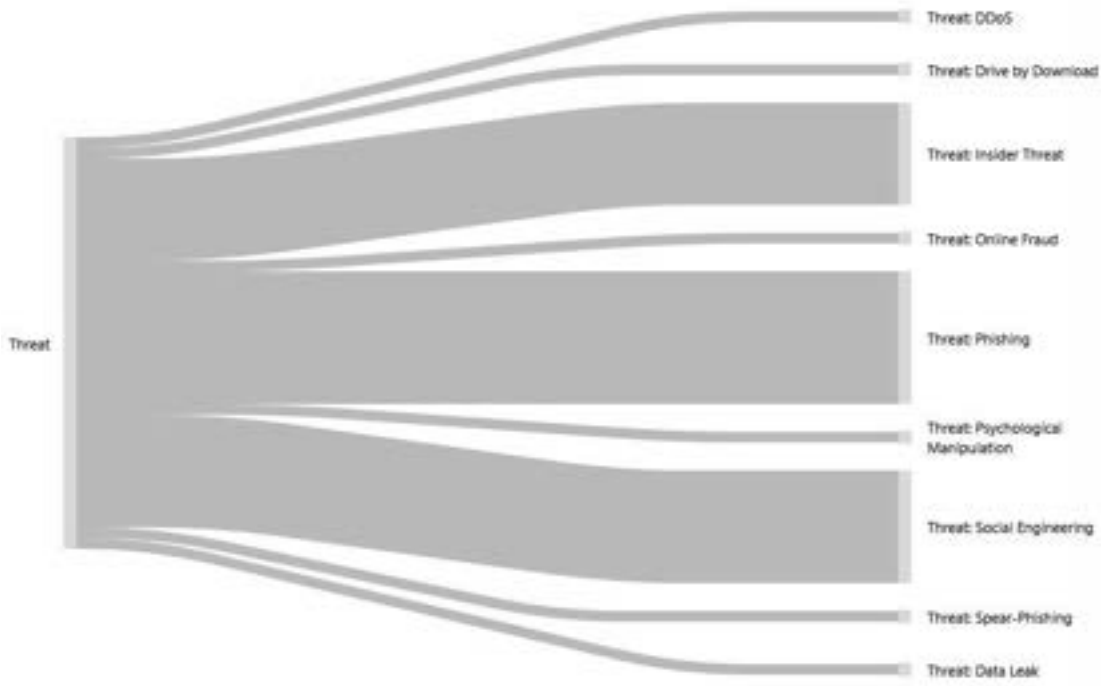

Figure 4 Threat Vectors

Social engineering encompasses techniques aimed at manipulating individuals into revealing confidential information, often through emotional or psychological tactics [27]. A common

form of social engineering is phishing, which involves deceptive websites, emails, or images designed to extract personal data from victims [28]. Insider threats, another significant risk, may be either malicious or unintentional. Malicious Insider Threats (MITs) involve individuals with authorised access who intentionally misuse sensitive information to harm the organisation. In contrast, Non-Malicious Insider Threats arise from carelessness or accidental actions that compromise security [5]. These user-focused threats exploit the human element of cybersecurity. The next sections explore the factors that influence vulnerability to such threats.

3.3 Research Questions 1-2

> *"What cybersecurity behaviours do employees exhibit within an organisational structure? How do these behaviours contribute to the cybersecurity posture of an organisation?"*

The balance between viewing employees as great assets to an organisation, while also being perceived as one of their biggest potential threats to cybersecurity, is precarious [19]. An individual's behaviour, attitude, and personality have been linked to their cybersecurity behaviours and intentions [12].

3.3.1 Personality Traits

The Big Five personality traits, or Five-Factor Model (FFM), are a widely used framework for describing individual differences in thoughts, emotions, and behaviours. The five dimensions include openness (intellectual curiosity), conscientiousness (organisation and dependability), extraversion (sociability and energy), agreeableness (cooperativeness), and neuroticism (emotional instability) [29], [30].

Six studies in this review explore the relationship between FFM traits and cybersecurity behaviours [12], [19], [20], [31], [32], [33]. Alotaibi, Furnell, and Clarke [19] used the Big Five Inventory to examine behaviours such as clicking email links, updating antivirus software, and deleting suspicious messages, concluding that personality traits influence cybersecurity risk. Gratian et al. [12] found strong links between neuroticism and phishing susceptibility, and noted associations between openness or extraversion and weaker privacy settings. Kalhoro et al. [20] reported positive cybersecurity behaviours among individuals high in conscientiousness and agreeableness.

López-Aguilar and Solanas [31] focused on neuroticism, noting mixed findings: while one study found high neuroticism increased phishing risk, another showed a decrease in online social network contexts. They also observed that men with high extraversion and neuroticism, and low agreeableness and conscientiousness, were more vulnerable to virtual offences.

Marin et al. [32] found conscientious individuals more likely to follow organisational security policies, whereas those low in conscientiousness and agreeableness were less compliant. Similarly, Upadhyay et al. [33] reported that extraversion and conscientiousness were linked to better device security, and extraversion and agreeableness to proactive cybersecurity awareness, supporting findings by Gratian et al. [12].

3.3.2 Risk-Taking Behaviour

Risk-taking behaviour is often listed as one of the root causes of cybersecurity threats. These behaviours affect numerous areas, such as phishing susceptibility, proactive cybersecurity behaviours, password management, and keeping software updated [34]. The review found that risk-taking behaviours are discussed in seven articles [12], [13], [20], [25], [34], [35], [36].

There are five dimensions of risk-taking: ethical, financial, health or safety, recreational and social [12]. Risk-taking is a measure of risk attitude that shapes decision-making in relation to risky behaviour, in any of the five dimensions; this can be measured using the Domain Specific

Risk-Taking (DOSPERT) inventory [37]. The instrument is presented as a 30-item assessment with five subscales. It uses a seven-point Likert scale ranging from “very unlikely” to “very likely” to determine risk-taking tendencies [12].

Both Gratian et al. [12] and Egelman, Harbach and Peer [36] indicate that risk-taking is a significant predictor of cybersecurity behaviours; willingness to take safety risks is inversely correlated with proactive cybersecurity behaviours. Furthermore, users who are averse to risk have a much lower incidence of phishing susceptibility [38]. These factors indicate a link between risk-taking behaviours and cybersecurity behaviours. Jadha, Haggag and Haggag [13], Ergen, Ünal and Saygili [25] and Abroshan et al. [35] agree with these points.

Kalhoro et al. [20] state that risk-based decision-making can be associated with optimism bias. Individuals often think that they are not in danger and that good things should occur; they may be optimistic that the probability of adverse effects happening to them will be very low. This can increase the incidence of risk-taking behaviours, subsequently influencing cybersecurity vulnerability.

3.3.3 Decision-making Styles

Decision-making is a cognitive process influenced by a person’s knowledge, experience, available information, and skills [5]. As individuals perceive and interpret data differently, their decisions also vary [39]. The General Decision-Making Style Inventory (GDMS), developed by Scott and Bruce in 1996 [40], categorises decision-making into five styles: avoidant (delaying decisions), intuitive (instinct-driven), spontaneous (quick decisions), dependent (seeking external input), and rational (logic-based). The GDMS consists of 25 Likert-scale questions across five subscales.

Six sources in this review explore how decision-making styles influence cybersecurity behaviour [5], [12], [13], [35], [39], [41]. Duzenci, Kitapci, and Gok [39], using Harren’s topology [42], found that rational decision-makers showed higher cybersecurity compliance, while intuitive and dependent decision-makers demonstrated lower awareness.

Abroshan et al. [35] used GDMS to study phishing susceptibility. While no significant link was found for early-stage phishing (e.g., opening an email), decision-making styles appeared more influential at later stages (e.g., clicking links). Limitations in the study may explain inconsistencies with other findings. Collier et al. [5] offer a broader view, examining how moral, ethical, and cultural factors shape security decisions. They question whether culture can be reliably measured or generalised in this context.

Gratian et al. [12] and Egelman, Harbach, and Peer [41] applied GDMS to analyse cybersecurity behaviour. Both noted a strong link between rational decision-making and secure device practices, though they differed on password generation: Gratian et al. found avoidant styles most correlated, while Egelman et al. identified both rational and avoidant styles. Jadhav, Haggag, and Haggag [13] used these findings to propose personalised training based on behavioural factors, including decision-making.

3.3.4 Demographic Factors

Differences in demographic factors such as education, gender, and age can directly or indirectly affect cybersecurity behaviour.

3.3.4.1 Age

Seven studies discuss the correlation between age and cybersecurity behaviours [12], [13], [22], [25], [33], [35], [43]. Ergen, Ünal and Saygili [25] indicate that people aged 30-65 tend to have greater awareness of cybersecurity compared to people aged 18-29. The 18-29 age group is correlated with higher phishing susceptibility; this is echoed by Gratian et al. [12] and Ergen, Ünal and Saygili [25]. Jadhav, Haggag and Haggag [13] and Upadhyay, Singh and Singh

[33] indicate that this age range is rather 18-25. Jadhav, Haggag and Haggag [13] attribute the vulnerability of younger age groups to the larger online footprint that younger people tend to have on social media; the frequency of interaction with cyber systems also increases the likelihood of being targeted by a certain threat. However, Upadhyay, Singh and Singh [33] further state that older age groups tend to be less efficient in Internet security than their younger counterparts.

Neigel et al. [22] suggested that as people get older, their knowledge of cyber hygiene increases. They found that older individuals had a more positive attitude toward cyber hygiene and were more likely to participate in activities related to it. Xu, Singh and Rajivan [43] investigated personalised persuasion in spear-phishing attacks, but did not find that age had a significant impact on spear-phishing performance. Furthermore, Abroshan et al. [35] indicates that age did not have any direct association with clicking on a phishing link.

3.3.4.2 Gender

Twelve sources examine the relationship between gender and cybersecurity behaviours [12], [13], [17], [19], [20], [22], [25], [28], [31], [33], [35], [43].

Abroshan et al. [35] found that gender may indirectly influence susceptibility to phishing due to disparities in technical knowledge and training, which can vary culturally. Alotaibi, Furnell and Clarke [19] reported that most insider incidents involved male employees. Alsharif, Mishra and AlShehri [28] identified gender-based differences in the adoption of cybersecurity measures such as two-factor authentication, anti-spam tools, and phishing awareness.

Several studies indicate that women tend to score lower than men in areas such as password generation, proactive awareness, and overall cybersecurity self-efficacy [12], [13], [17], [20], [25]. Jadhav, Haggag and Haggag [13] found significant gender differences in self-efficacy, experience, and computer skills, suggesting the need for gender-specific interventions. López-Aguilar and Solanas [31] linked higher neuroticism scores (more correlated to women) to increased phishing susceptibility.

Conversely, Neigel et al. [22] found that women exhibited greater knowledge and engagement with cyber hygiene practices than men. Similarly, Xu, Singh and Rajivan [43] and Upadhyay, Singh and Singh [33] reported no significant gender-based differences in spear-phishing susceptibility or intentions toward secure online behaviour.

3.3.4.3 Socio-Economic Factors

Bolpagni [44] argues that the human development index, the GDP, and the level of democracy and peace play a role in the prevalence of cyber risk. The results of the analysis suggest that human development is a major factor in reducing cyber risk. It is likely that a stronger economy will lead to the adoption of more advanced technologies, thus reducing the chances of exploiting vulnerabilities. Furthermore, a good education system can be expected to promote skill development and better policies. According to Alotaibi, Furnell and Clarke [19], organisational culture and regional or national culture should be considered when studying insider threats, as these can significantly influence the effectiveness of information security and behaviour. Jadhav, Haggag and Haggag [13] recommend specific cyber-awareness required, informed by cultural background, depending on regions such as America, Europe, Asia or Africa.

3.3.5 Perceived Threat, Self-Efficacy and Protection Motivation Theory (PMT)

Seven sources in this review discuss Protection Motivation Theory (PMT) and the role of self-efficacy in response to perceived cybersecurity threats [17], [21], [23], [25], [32], [39], [45].

PMT is a widely used framework for explaining why individuals engage in protective behaviours [46]. It posits that behavioural intentions are shaped by two key components: threat appraisal

(how severe and likely a threat is perceived to be) and coping appraisal (how confident individuals feel in managing the threat, or self-efficacy) and what costs are associated with doing so. Prior experience and knowledge also influence these appraisals [47]. Security self-efficacy refers to one's belief in their ability to safeguard personal information against cyber threats [48]. PMT has been applied to understand risky cybersecurity behaviours, even when users are aware of potential consequences [39].

Duzenci, Kitapci, and Gok [39] argue that PMT is applicable in cybersecurity contexts, especially given the growing digital exposure through personal devices and smart technologies. They found that perceived vulnerability, severity, and self-efficacy varied with decision-making styles and influenced cybersecurity compliance.

Debb and McClellan [17] identified correlations between self-efficacy, past experiences, perceived threat, peer behaviour, and vulnerability to cyber risks. Ergen, Ünal, and Saygili [25] found that nearly all PMT factors influenced employees' willingness to follow cybersecurity policies. Klein and Zwilling [21] showed that awareness of cyber threats increased users' motivation to learn protective behaviours.

Marin et al. [32] found a strong link between self-efficacy and phishing reporting intentions, which greatly benefits organisational defence. Torten, Reaiche, and Boyle [23] showed that all five PMT components (perceived severity, vulnerability, self-efficacy, response efficacy, and response cost) except perceived vulnerability, significantly predicted secure desktop behaviours. Williams, Hinds, and Joinson [45] suggest enhancing self-efficacy in online security through features like warnings, peer verification, and expert feedback. These could help users identify phishing attempts, build confidence, and reduce reliance on technical systems alone.

3.3.6 Environmental Stressors

Stress-inducing stimuli, or stressors, can be classified as short-term (acute) or long-term (chronic) [49]. Five sources have discussed the impact of these stressors on cybersecurity behaviour in this review [20], [34], [49], [50], [51].

Abroshan et al. [34] state that stress and anxiety are correlated with increased susceptibility to phishing. They recommend psychological methods to address these feelings, such as Cognitive Behaviour Therapy (CBT). This therapeutic approach can be used to treat stress and anxiety, to address the root cause of certain cybersecurity behaviours. Baluta et al. [50] state that stress is a highly variable factor, which can change over time according to circumstances. Kalhoro et al. [20] state that people who experience emotional distress may be more likely to act recklessly when it comes to cybersecurity. Furthermore, they state that a high neuroticism score implies that a person is more likely to have irrational thoughts, lack control over their impulses, and struggle to manage stress, linking back to the FFM. Maalem Lahcen et al. [51] indicate that insider threats were strongly correlated with stressful events, while Trang and Nastjuk [49] indicate that stress induced by time constraints negatively affected non-compliance with policies significantly.

3.4 Research Question 3

> *"How can businesses or employers manage the human element of cybersecurity risk successfully, at all organisational levels?"*

Given that the human element of cybersecurity is multifaceted, another question remains: How can businesses or employers manage the human element of cybersecurity risk successfully, at all organisational levels? Within this paper, the evidence indicates that holistic, sociotechnical solutions must be investigated, as well as tailored awareness training.

3.4.1 Policy

Organisational Cybersecurity Policy is a formally defined document that specifies user behaviour deemed acceptable and unacceptable, which acts as a baseline statement on which cybersecurity tasks should be carried out by employees [19]. In this review, authors Bolpagni [44], Ghafir et al. [52] and Klein and Zwilling [21] stress the importance of robust and easily understood cybersecurity policies.

In addition, Alotaibi, Furnell and Clarke [19] report a positive correlation between organisational security and employees' understanding of security policies. They highlight a general lack of awareness among end users regarding the importance of information security and associated organisational requirements. Non-compliance is categorised into three behaviours: malicious (intentional harm), negligent (intentional policy violation without intent to harm), and unaware (lack of knowledge or understanding). Many organisations fail to regularly review and update their security policies, and designing effective policies that align with strategic goals can be resource-intensive. Regular awareness training and education are essential for policy effectiveness; without them, such policies are likely to fail.

Collier et al. [5] point out that certain issues can lead to policy noncompliance. If the policies are too complicated or too strict, people will try to find a way to bypass them, while appearing to be compliant. Additionally, when people do not have a robust justification for the rules and regulations they are expected to follow, they are less likely to adhere to them or may not follow them at all.

Klimburg-Witjes and Wentland [18] indicate that experts from various fields and policy areas define and evaluate what constitutes the correct knowledge and practice of IT security. Consequently, their objective is to identify, "diagnose," and "solve" problematic cases at an organisational level. Furthermore, the employee is not only seen as a problem, but is also prevented from having any control over security practices, thus limiting their work life. They argue that it appears that large organisations are increasingly consolidating their decision-making processes while transferring the repercussions to their employees. They suggest that companies and policymakers create and nurture a culture of cybersecurity and accountability to try to address these problems.

Both Zimmermann and Renaud [4] and Pollini et al. [24] argue that cybersecurity approaches have taken a holistic sociotechnical system perspective, which includes governance and policy-making considerations, user-centred issues that focus on customers and hackers, and external conditions such as physical, technological, and economic factors. The concept of sociotechnical approaches and holism in addressing the human factor of cybersecurity is discussed in more detail in Section **Error! Reference source not found.**.

3.4.2 Awareness Training

Awareness training is widely recommended to counter human-targeted threats in sociotechnical systems, yet its implementation faces challenges. Common issues include one-size-fits-all approaches, information overload, poor organisation, lack of follow-up, and insufficient context [17], [24], [52], [54]. While awareness programmes are known to improve knowledge and behaviour, poorly designed training can lead to disengagement or a false sense of competence.

Effective training should be interactive, creative, and scenario-based, incorporating tools like gamification or AR/VR to boost engagement and retention [24]. Overly frequent training can result in employee resistance; hence, personalised approaches using risk scores, based on human factors such as risk tolerance, gender, age, and emotion, are more effective [11], [33].

Long-term success also depends on integrating awareness into daily routines and adjusting content for hybrid or remote work environments [20], [52]. Incentive programmes can

reinforce good cybersecurity behaviour by rewarding diligence and encouraging peer learning [31].

Additional support tools, such as decision aids (e.g., email banners), emotional feedback mechanisms [55], and threat-based message filtering [56] can enhance training effectiveness by drawing immediate attention to potential risks. A tailored, engaging, and integrated awareness training strategy, which is supported by technical tools and organisational culture, offers the best chance to improve cybersecurity behaviour.

3.4.3 Holism and Sociotechnical Systems

Our review identified seven sources that emphasise the importance of a holistic, sociotechnical approach to cybersecurity [5], [24], [25], [44], [51], [53], [54]. Pollini et al. [24] highlight the overreliance on technical solutions (e.g., firewalls, antivirus) and argue that combating cyberattacks requires addressing both technical and human factors.

Zimmermann and Renaud [4] propose "Cybersecurity, Differently," an approach that views humans as integral to the solution rather than the problem. Instead of assigning blame to individuals for breaches (e.g., phishing attacks), they advocate for designing secure sociotechnical systems (STS) that are user-friendly and resilient. This includes investing in awareness and training initiatives.

Mcevoy and Kowalski [54] critique the narrow focus on compliance and training, proposing a more integrated method using sociotechnical and human factor analyses to identify weaknesses in organisational practices. Bolpagni [44] supports this, noting that a sociotechnical framework best captures the complex interplay between human, technical, and organisational elements, which they used to develop a composite index. Collier et al. [5] and Ghafir et al. [52] also underscore the need to embed human factors into training and everyday practice to foster a strong cybersecurity mindset and create more resilient systems.

4 DISCUSSION

A common cliché in cybersecurity is the notion that the human is the "weakest link" in the chain [17], [55]. Specific cyber-attacks target human behaviours, while inattention, naïveté, and lack of awareness can provide a foothold for various threats. User-centric threats, such as phishing, social engineering, and insider threats, pose financial and reputational damage for organisations [26]. The increasing frequency, severity, and public visibility of cyberattacks contribute to the demand for robust, holistic cybersecurity strategy. The purpose of this literature review was threefold. First, it aimed to determine the cybersecurity behaviours employees exhibit, as well as the underlying motivations. Second, it aimed to investigate the effects these behaviours have on an organisation's cybersecurity posture. The connection between specific behaviours and damaging cybersecurity practises was investigated. Thirdly, organisational approaches to mitigate potential negative impacts of the human element of cybersecurity were explored.

The first two review questions can be discussed in tandem. Cybersecurity behaviours are shaped by individual traits and contextual factors. Many sources link behaviours to personality, particularly the Big Five traits, risk-taking tendencies, and decision-making styles [12], [13], [20], [25], [34], [35], [36]. These are often measured through subjective tools like DOSPERT and GDMS, though such methods risk bias due to convenience [9].

Demographics also matter. Individuals aged 30–65 tend to show greater cyber awareness than their younger counterparts [12], [13], [25], while gender effects remain inconsistent. Some studies found that women score higher in hygiene awareness and participation [22], but lower in password creation and self-education [12], [20]. Self-efficacy gaps between genders suggest that tailored training may be beneficial [13], [17], [31], though not all studies agree on gender

significance [33], [43]. Socioeconomic background also influences training needs [13], [19], [44].

Protection Motivation Theory (PMT) and self-efficacy correlate strongly with secure behaviour [17], [21], [23], [25], [32], [39], [45]. Key factors include perceived severity, vulnerability, skills, and peer influence. High stress and workload negatively impact compliance and decision-making [20], [34], [49], [50], [51], with mindfulness and CBT recommended to reduce risk [35], [55].

Our second review question aims to determine actionable interventions that organisations can use to manage the complex human element. As we have established, these behaviours are multifaceted; personality dimensions, risk-taking tendencies, decision-making styles, demographic factors, perceived threat and protection motivation, and environmental stressors all contribute to cybersecurity behaviours. Addressing human risk requires multilayered strategies. Clear, understandable cybersecurity policies are foundational [19], [21], [44], [52], but overly strict or poorly justified policies can drive non-compliance [5]. Involving employees in policy formation may enhance accountability and adherence [18].

Awareness training, though widely used, often suffers from a generic design and low engagement [19], [52]. More effective approaches include interactive, scenario-based modules [25], routine integration [52], and personalised training based on risk profiling [35]. Training should consider demographic, cultural, and emotional factors [13], and may be supported by incentive schemes that reward good practices [32]. Technical augmentations like emotional feedback and automated threat recognition can further enhance training impact [56], [57]. Ultimately, cybersecurity demands a sociotechnical, holistic approach [5], [24], [25], [44], [51], [52], [54]. Technical defences alone are insufficient; successful strategies integrate human behaviour, culture, and system design. Several studies advocate moving beyond blaming human error to addressing system-level factors that shape user decisions [4], [5].

4.1 Limitations of this Review

Our review presents a structured and comprehensive analysis of the literature, guided by defined inclusion and exclusion criteria to minimise bias and ensure balanced coverage. However, several limitations should be acknowledged.

Quantifying human behaviour remains challenging. Many studies on risk behaviour, decision-making styles, personality traits, demographic factors, and Protection Motivation Theory (PMT) rely on self-reported data, which may introduce bias. Nonresponse in surveys further threatens external validity. Additionally, while some sources consider cultural factors, regional biases, such as those in Abroshan et al. [35] and Jadhav, Haggag and Haggag [13] , may affect generalisability. Cultural perceptions of cybersecurity vary widely, and broader representation is needed to account for these differences. Lastly, although individual-level factors are well explored, organisational culture, leadership, and systemic influences receive comparatively less attention.

5 CONCLUSION AND FUTURE WORK

As cybersecurity becomes an increasing threat, organisations grapple with navigating human behaviour and its intersection with cybersecurity. Employee behaviour can greatly affect policy compliance, influencing an organisation's cybersecurity posture. Despite considerable investments in technical solutions, the human element remains an essential, yet nebulous, part of cybersecurity. This review highlights that user behaviour is undeniably critical to effective cyber defence.

The *way* in which people interact with cybersecurity systems is informed by multiple elements: personality dimensions, risk-taking tendencies, decision-making styles, demographic factors,

perceived threat and protection motivation, and environmental stressors. Attempting to create policies that disregard these aspects leads to eventual noncompliance and weakens the organisation's cybersecurity posture. A socio-technical approach is the best way to address the human element. This approach considers cybersecurity as a system made up of interconnected hardware, software, people, and communities. It also recognises that the human element is not the weakest link in cybersecurity, but rather a part of the solution. To address the human element of cybersecurity, organisations must invest in cybersecurity training and awareness programmes. They also need to design systems that are easier for humans to use and harder for attackers to exploit.

The existing literature on the relationship between personality traits, demographics, and cybersecurity behaviours is fragmented, with inconsistent findings and limited practical application. While this review found relative consensus on the influence of decision-making styles and the quantification of risk-taking behaviours, greater variability exists in studies examining demographic factors and personality traits. Notably, gender-related findings show the most divergence. Future research should aim to use larger, more representative samples to improve the reliability and generalisability of conclusions regarding the impact of personality traits on cybersecurity behaviour. Second, the synthesised findings provide a strong foundation for developing integrated conceptual frameworks that model the interactions between personality dimensions, risk-taking tendencies, decision-making styles, and environmental factors in shaping cybersecurity behaviours. Third, these theoretical developments should be empirically tested within specific Industrial Engineering contexts, such as manufacturing control systems, supply chain cybersecurity, and operational technology environments, where human-system interactions are critical to both productivity and security outcomes.

ASSESSMENT OF ORGANISATIONAL READINESS FOR ADOPTING PREDICTIVE MAINTENANCE PRACTICES: A CASE STUDY IN THE SOUTH AFRICAN PLATINUM PROCESSING INDUSTRY

G.M. Mafiri[1] and R.H. Peach[2*]

[1,2]Department of Engineering and Technology Management,
University of Pretoria, South Africa
[1]mafirigt@gmail.com, [2]rina.peach@up.ac.za

ABSTRACT

This study evaluates the readiness of the South African platinum processing industry to adopt predictive maintenance strategies. It compares current capabilities against the architectural components and functionalities necessary for successful implementation. The maturity levels of Operational Planning, Work Management, Cyber-Physical Systems, Internet of Things, Internet of Service, and Data Management measure adoption readiness. Data from 34 participants representing two platinum group elements concentrator plants reveal that, although architectural components exist, overall readiness is medium, and functionality is low due to the inadequate integration of predictive maintenance into legacy systems. Significant gaps include resourcing and planning within Work Management systems and substandard use of data for prognostics in Data Management and the Internet of Service. These findings underscore the industry's need to improve legacy systems integration and data utilisation to adopt predictive maintenance effectively, offering critical insights for advancing South Africa's platinum processing sector.

Keywords: Cyber-Physical Systems, Internet of Things, Internet of Service, Operational Planning, Work Management

1 INTRODUCTION

The South African Platinum Group Elements (PGE) processing industry is a key player in the global market, with organisations controlling the entire mine-to-market process value chain [1]. The substantial presence of engineering assets and equipment in the PGE processing value chain highlights the critical importance of asset reliability and availability for South Africa's long-term PGE production. Under the current hypercompetitive business environment, processing companies need to continuously increase the utilisation and efficiency of their production processes [2]. The business environment has highlighted maintenance and made its role even more crucial for business success [3]. making maintenance management strategies critical to business strategy. Preventive maintenance strategies are the preferred approaches to processing equipment and assets in the PGE industry. However, equipment failure frequently occurs between the predetermined maintenance intervals, posing a significant challenge to the industry. Critical equipment failure creates unstable production systems, reducing throughputs and product quality [4].

Industry 4.0 modernisation offers industrial operations unique capabilities made possible by Cyber-Physical Systems, Internet of Services, Data Management and the Internet of Things components [5]. Predictive maintenance systems require modularity to integrate into existing infrastructure and operational business models [6]. In the context of Mining 4.0, the components are collaboratively used to create a system that collects, exchanges, stores and analyses real-time equipment data into information used to make maintenance decisions. The primary objective of adopting predictive maintenance is to provide equipment owners with critical real-time information on the equipment's health and performance. Equipment owners can make statistical data-based decisions with readily available historical, real-time and prognostic data and information. Predictive maintenance offers the opportunity to monitor the health of operating equipment, progressively predicting the optimal service time before failure. The real-time health monitoring and the remaining useful life predictions allow maintenance to be planned in time to resource and execute work with minimum impact on productivity and process efficiency.

Mining process operations in the South African platinum industry continue to rely heavily on preventative maintenance strategies, typically executed through costly scheduled plant shutdowns. Although such shutdowns are designed to prevent unplanned breakdowns, equipment failures frequently occur between these predetermined intervals. As a result, organisations still depend extensively on corrective maintenance to restore equipment functionality, creating inefficiencies and production losses. This approach has been entrenched for many years, often without a systematic evaluation of the underlying drivers of shutdown maintenance. The persistence of these limitations highlights a pressing need to move beyond traditional maintenance practices towards predictive maintenance strategies. By leveraging real-time data and remaining useful life estimations, predictive maintenance has the potential to address the shortcomings of current approaches and improve asset availability, reliability, and overall operational performance.

This study evaluates the readiness of the South African platinum processing industry to adopt and exploit predictive maintenance, a need that is becoming increasingly urgent. The study compares current capabilities against the architectural components and functionalities necessary for successful implementation.

2 LITERATURE REVIEW

2.1 Background of the Platinum Group Elements industry

Platinum group elements (PGEs) are a valuable resource for various applications, including automotive catalytic converters, hydrogen fuel cells, jewellery, food and medical technology.

PGEs include platinum, palladium, rhodium, ruthenium, iridium, and osmium. The mineral-bearing ore is mined underground and in open-pit mining operations. The world PGE reserves estimate approximately 14kt in relatively few areas, with South Africa accounting 86% of the world's reserves [7]. PGE-bearing ores in South Africa are found in the Bushveld Complex, containing gold, considered a by-product with the six PGEs [8]. The primary production of South Africa contributes over 58% of the world's newly mined PGEs and over 80% of Platinum [1]. The mined ore is concentrated in metallurgical processing plants, including concentrators, smelters and refineries. Processing the volume of mined ore to the final refined PGE product requires considerable engineering assets and equipment capacity.

2.2 Business Operating Models

Until now, growing business and scientific interest have focused on the technical implications of predictive maintenance. However, the managerial implications have received little attention, even though they are significant barriers to adopting predictive maintenance solutions [9]. Extracting business insights and knowledge from the vast amounts of data from the intense employment of IoT technology and cyber-physical systems across the industrial value chain is arguably a significant technical challenge for predictive maintenance. Other technical implications are listed below [10].

- There is a lack of widely accepted standard solutions and the inability of current cybersecurity technologies to guarantee complete effectiveness in corporate data protection.
- The availability of sufficient and appropriate data, both real-time and historical.
- The integration of predictive maintenance solutions into legacy systems and expert knowledge modelling.

2.2.1 Operational Planning

Operational planning plays a significant role in implementing business strategies by translating strategic plans into functional activities [11]. Operational planning is required to specify the confidence of meeting business expectations by translating strategic plans into functional activities. It ties data and specifications from operations directly to business strategies at an organisational level.

Mateljak & Mihanović [12] measure the operational planning maturity level by planning raw materials, work, tools, equipment capacities and drafting and releasing various records and performance terms. Efficient operational planning focuses on preparatory tasks that lead to effective production processes capable of reaching the set operational key performance indicators (KPIs).

2.2.2 Business Performance

To achieve world-class performance, more and more companies are replacing their reactive firefighting maintenance strategies with proactive ones [13]. This includes all financial considerations for execution within the budgetary limits. The full potential of predictive maintenance practices can be measured using the multi-dimensional performance measurement model, the Balanced Scorecard (BSC), developed by Kaplan and Norton [14]. Van Looy and Shafagatova [15] express the need for organisations and scholars to measure the performance of business processes more holistically, considering the implications for different target groups. The BSC takes a four-dimensional approach to organisational performance: Financial performance, Customer performance, Internal business process performance and learning and growth performance. The BSC translates the organisational business strategy into operational performance indicators and objectives targeted at each dimension of performance.

Depending on use cases, predictive maintenance shows significant benefits, such as increased machine uptime, reduced maintenance hours and material used, more stable machine outputs, reduced lead times, and forced outages [16].

2.3 Predictive Maintenance

Sang et al. [17] categorise the maintenance management approaches into run-to-failure, preventive maintenance, condition-based maintenance and predictive maintenance. The complexity and efficiency increase with predictive maintenance, ranking as the most efficient yet complex.

Predictive maintenance practices improve production by optimising condition-based maintenance practices. When maintenance is predictive, it ensures that each part is checked and examined when it is most likely to need attention, rather than adhering to an arbitrary schedule that allocates equal time to every part. Predictive maintenance is carried out by continuously measuring equipment parameters that assist in monitoring the health of operating equipment, progressively predicting the optimal service time before failure.

The real-time health monitoring and the remaining useful life predictions allow maintenance to be planned in time to resource and execute work within the smallest amount of planned equipment downtime. Failure prediction also protects equipment from further damage, reducing the cost of auxiliary spares. In summary, the advantages of predictive maintenance include;

- High equipment utilisation and process production - equipment that requires maintenance remains in service and only shuts down for service before imminent failure [18].
- Reduction in high maintenance costs related to catastrophic failure damage to equipment. Including auxiliary equipment [19].
- Increasing equipment availability and reliability, increasing production operating time, and extending equipment life [20].
- Safe operation of equipment [21].

2.4 Maintenance Management Effectiveness

By implementing Predictive Maintenance strategies and technologies, processing companies gain a significant competitive advantage [20]. Kumar Mishra and Mahapatra [19] summarise the industry-observed distinctions between corrective, preventative and predictive maintenance strategies by the maintenance nature, basic philosophy, applications, advantages and disadvantages. The key takeaway is the distinct similarity between preventative and predictive maintenance strategies. They are both based on a common goal of repairing or replacing equipment before failure. The critical difference is the nature and basic philosophy of achieving this goal; preventative maintenance is time-based as opposed to condition-based predictive maintenance, yielding an estimated 8-12% cost savings.

2.4.1 Operational Maintenance Work Management

The primary goal of the maintenance work management process is to establish a clear link between maintenance activities and their outcomes to assist the company in meeting its strategic objectives [3]. There is frequently sufficient discretion within these parameters to effectively manage work scope and timing to deliver all performance targets (effectiveness, sustainability, and efficiency).

The maintenance work management process consists of task identification, work order requests, maintenance planning, scheduling and execution management (assigning and completing the work order task), and analysis and improvement [22]. Work orders are

generated to assist maintenance managers in organising, assigning, prioritising, tracking, and completing critical maintenance tasks. Work orders are essential to an organisation's maintenance operations, and each maintenance work order has a lifecycle that includes three major phases: creation, completion, and recording.

Maintenance work management enables operations to plan, manage and execute work efficiently. By predicting the failure of a specific equipment component, adequate work resourcing can take place before a failure occurs, allowing for shorter downtimes on equipment. Mining organisations with complex maintenance systems use a computerised maintenance management system (CMMS). CMMS systems automate most logistical functions performed by maintenance staff and management. Typical CMMS functions may include work order generation and tracking by equipment/component, tracking of scheduled and unscheduled maintenance activities, and complete parts and materials inventory control with automated reorder capabilities. One of the most significant advantages of the CMMS is eliminating paperwork and manual tracking activities. It should be noted that a CMMS's functionality is defined by its ability to collect and store information in an easily accessible format.

2.5 Predictive Maintenance Framework

Wang [6] defines Industry 4.0 as a collective term for technologies and concepts of value chain organisations based on the technological concepts of Cyber-Physical Systems (CPS), the Internet of Things (IoT), the Internet of Service (IoS), and Data management. To have a Smart Mine in the context of Industry 4.0, CPS monitor physical objects and processes to create a virtual copy of the physical world and make decentralised controls and decisions. The Internet of Things and cyber-physical systems communicate and cooperate with humans in real-time. In Data Management and the Internet of Services, internal and cross-organisational services are offered and utilised by participants of the value chain [6].

The modularity and integration of each component are crucial to realising predictive maintenance systems. Processing based on Cyber-Physical Systems and service innovations is two unavoidable trends and challenges for the processing industry. Modular design is a practical approach to reducing production costs and increasing mass customisation and personalisation in industries. Implementing modularisation requires the support of the entire technical system and a comprehensive understanding of modularity in product, service and supply chains [23]. Organisations should be able to transfer data across organisational borders needed to perform business functions, maximising production capacity through collaborative partner interactions.

2.5.1 Cyber-physical systems

Cyber-physical systems are equipped with network-capable sensors, actuators, and intelligent analytics for machine health monitoring and degradation predictions. By incorporating CPS into current industrial practices, today's operations would be transformed into Industry 4.0 facilities with significant economic potential. Lee et al. [24] further proposed a Five-level CPS structure; the architecture provides a step-by-step guideline for developing and deploying a CPS for processing applications, characterised by;

- Identification technologies like RFID tags, which allow unique identification of equipment.
- The physical equipment in the operation is transferred into the virtual environment.
- Storage and analytics have to be provided as a centralised service.

From the perspective of predictive maintenance, the second-generation Data-to-Information Conversions Level attributes are sufficient for a self-aware and self-maintained machine

system, considered a system that can self-assess its health and degradation, and further utilise similar information from other peers for informed maintenance decisions to avoid potential faults [25].

2.5.2 Internet of Things

The task of this module is to select a suitable sensor and optimal data collection strategy to extend the physical world using a variety of sensing, detection, and identification techniques and connect the objects or enable them to interact with each other [26]. Sensors collect raw data from equipment; temperature, humidity, pressure, current, vibration, air quality, and weight are just a few of the popular industrial IoT-enabled sensors used to monitor and collect data in real-time [27].

The data acquisition process transforms the sensor signals into domains that contain the most information on the condition of the equipment. Wireless Data collection networks allow continuous data acquisition, real-time condition-based monitoring, and machine health status. IoT also allows for sensors and equipment to interact and communicate. Practical challenges remain in several areas, such as security and privacy protection, network protocols, standardisation, identity management and trusted architecture [26].

2.5.3 Data Management

The generated digital data stream is saved as a database file on an organisation's local intranet or a secure centralised or remote cloud location. Data from IoT sensors is sent via Wi-Fi to a centralised cloud server or via Cellular networks or Bluetooth Low Energy (BLE) technology to remote locations [28]. Generally, there are two steps to deal with the signals from sensors. The first is signal processing, which enhances the signal characteristics and quality through filtering, amplification, data compression, data validation, and de-noising. The other is feature extraction, which extracts features from processed signals characteristic of an incipient failure or fault. Generally, the features can be extracted from three domains: time domain, frequency domain, and time-frequency domain [6].

Techniques for maintenance decision-making can be divided into diagnostics and prognostics classes. Processed signals are transformed into relevant information about the equipment, and the relationship between the collected data and the actual condition is identified, enabling the equipment's failure period to be model-predicted [5]. The most used prognostic tool is determining the equipment's remaining useful life (RUL). Predictive maintenance continuously monitors and predicts the RUL using data-driven models to find the relations between the RUL and the condition of the machine or component [6].

2.5.4 Internet of Services

Although IoT has taken centre stage, the real innovation in processing systems is in the Internet of Services. Operations must consider their business model and integrate how a product becomes a service with a long-term revenue stream. IoS addresses the business standpoint; it represents a set of services that improve the company's ability to do business with customers and suppliers. It is a project philosophy characterised by modularity, separation of concerns, service re-use, and composition from a technological standpoint [28].

An IoS platform is typically used as a front end or a dashboard to present and process equipment health. It depends on communication protocols and standardisation levels, critical to developing a prosperous and resilient solution, whether an organisation builds its IoS system in-house or hires a vendor [27]. The Internet of Services comprises business models, a service infrastructure, services, and participants. Various vendors provide integrated services that provide value-added services that are communicated to end-users and accessed through multiple methods for decision making [6].

2.5.5 Analyse and Improve

Relevant data assists managers with making proficient maintenance decisions. The models for decision support may be partitioned into four categorical models: physical, statistical model, data-driven and hybrid. Given that historical data and information can be easily retrieved, data-driven techniques are exceptionally great for distinguishing the cause of failure and assessing the condition of the equipment. The hybrid methods that combine the data-driven and model-based techniques can effectively evaluate the machine's condition if historical data is not fully available [17].

The critical asset performance measures in the PGE processing industry typically include equipment availability, uptime, and efficiency for the process and equipment.

2.6 Predictive Maintenance Architectural Layers

This section provides an architectural overview of predictive maintenance, including its fundamental components, principles, and significant benefits that drive maintenance effectiveness. According to Jagatheesaperumal et al. [29], intelligent machines and devices in the Industry 4.0 ecosystem fall under five architectural layers of operations;

- The device layer includes the machines, robots, PLC and controllers.
- The edge layer stores the data acquired from the industrial machines through communication protocols, such as Wi-Fi and Bluetooth, loaded onto cloud servers.
- The cyber layer manages the supply chain and handles information from web services. It also engages the networking of machines with trusted services and solutions.
- The data analytics layer runs specific machine learning algorithms and performs cloud analytics on the IoT data.
- The application layer can be enabled with several components, such as a dashboard, user visualisation resources, augmented reality, and chatbots; modularity is critical.

The device layer involves the real-time acquisition of raw sensor data in different domains and ultimately stores data and information from multiple sources in the edge layer. Resourcing, supply chain, peer-to-peer machine monitoring, and information from different IoT or web services are managed in the cyber layer. Data is commonly stored in historian servers and is available for extraction and analysis by in-house or external personnel in the data analytics layer. The data is translated and presented as KPI information in the application layer, ultimately used to monitor and support maintenance decisions.

3 CONCEPTUAL METHOD FRAMEWORK

To fully exploit the potential of predictive maintenance in the context of Industry 4.0, companies need a higher level of maturity in process monitoring, data management, performance measurement and inter-organisational capabilities. Predictive maintenance allows operations to identify potential equipment failures in time to allow maintenance planning to be executed when necessary before failure. The notifications for maintenance planning are generated automatically in the CMMS for oversight and approval from the responsible maintenance manager, with the necessary accountability for decision-making. To achieve optimal maintenance decision-making, a new approach should be in place to integrate multiple data sources from different domains. Production data, machine operational data, and sensor data are all required to analyse and build frameworks for predicting machine failure, reducing downtimes, costs, poor product quality and process inefficiencies [17].

3.1 Framework Introduction

The framework directly links predictive maintenance practices to delivering on business expectations, measured using performance drivers. Internal business processes, learning and growth processes are measured as leading indicators, to best predict outcomes regarding financial, customer, supplier and environmental performance, classified as lagging indicators. The current industry practice characteristics are used to assess predictive maintenance architecture and functionality readiness for adoption.

3.1.1 Capability Matrix and Indicators

Figure 1 overviews the proposed conceptual predictive maintenance framework, which ties the maintenance strategy to business objectives. This is done through tracking and making decisions using the available leading indicators. There are several prerequisites: focusing on the right equipment, gathering a sufficient amount of data, building, testing, validating, and continuously improving a predictive framework [16].

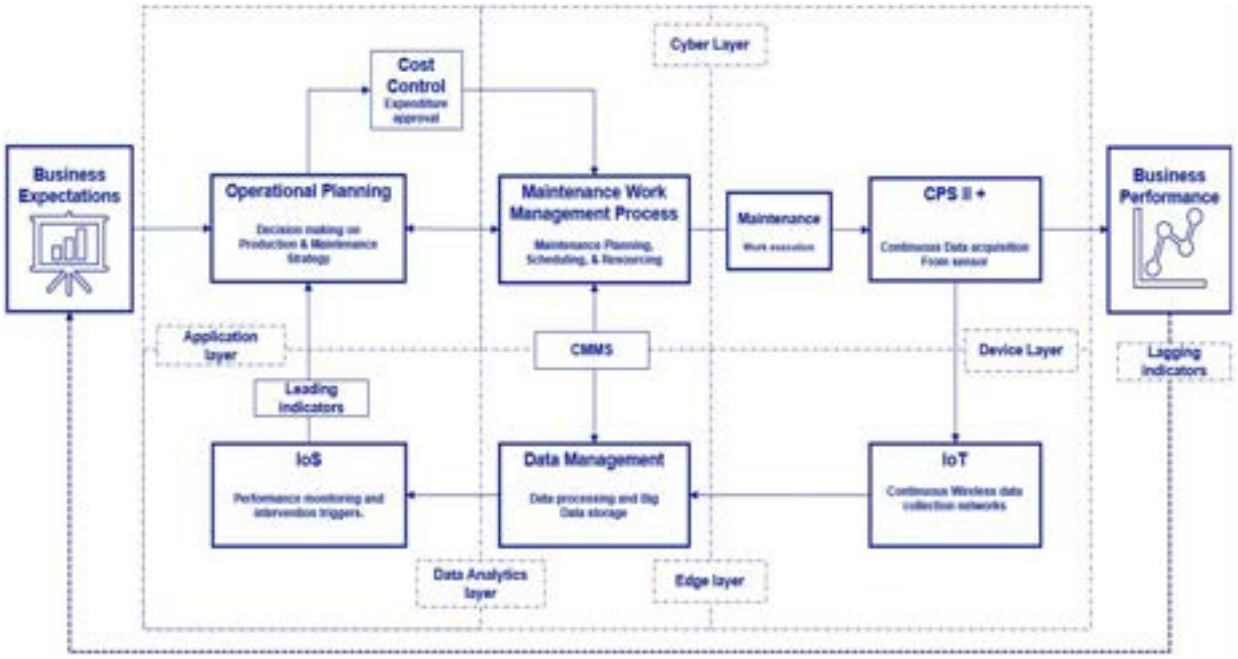

Figure 1: Proposed predictive maintenance management framework.

The architectural layers of predictive maintenance are adopted from the layers of operations in smart industries with the Industry 4.0 framework by Jagatheesaperumal et al. [29]. The architectural layer components were determined using the intelligent predictive maintenance framework by Wang [6]. The two frameworks were used in conjunction to highlight the integration of the operating framework into the intelligent predictive maintenance framework. The architectural layers have been summarised as:

- Device layer: integrating 2nd-level Cyber-physical systems and IoT smart sensors. This layer features error correction actions (optimisation and maintenance work).
- Edge layer: integrating IoT and data management with particular attention to data storage.
- Cyber layer: integrating 2nd-level Cyber-physical systems and work management, including supply chains
- Data Analytics layer: integrating IoS, algorithms, and analytics on the acquired IoT data.

- Application layer: integrating IoS performance dashboards and operational planning decision-making.

The effectiveness of predictive maintenance in Industry 4.0 is highly dependent on integrating predictive maintenance into legacy operational planning and maintenance work management process structures. The organisation's business operating models is used in conjunction with the intelligent predictive Maintenance framework by Wang [6]. The Matrix assesses the current maintenance capability in the South African platinum processing industry. Additionally, the matrix provides an assessment of the readiness of each component. The readiness is measured according to the architectural components' maturity.

To have a Smart Mine in the context of Industry 4.0, CPS monitor physical objects and processes to create a virtual copy of the physical world and make decentralised controls and decisions [6]. This is broken down into the following functional requirements;

- Physical equipment is transferred into the virtual environment
- Retrieve real-time equipment data wirelessly.
- Remaining useful life predictions on equipment.
- A dashboard view of equipment health and performance
- Analyse and improve initiatives.

The functional capabilities are a function of the maturity of the associated architectural components.

4 RESEARCH METHODOLOGY

A case study design is used to explore the maturity of the architectural components for predictive maintenance. A survey questionnaire is used as a data collection method to acquire the necessary data for analysis. The survey is used to gain structured information and data, with the questions aimed at assessing the operations' maturity according to the conceptual framework discussed in Section 3. The adoption readiness is measured using a 5-point Likert ordinal scale. Frequency analysis and a one-sample Wilcoxon signed-rank test were used to make deductions and interpretations of the results.

Two platinum processing concentrator plants were selected due to the more extensive equipment footprint of the concentrators compared to downstream operations. According to operational roles, a clustered approach is adopted for the employees involved in maintenance management. The research has scientific relevance in the research body of Mining 4.0. The descriptive teleological objective is used to gain new insight into how reactive and proactive maintenance practices can be successfully transformed into effectively proactive, predictive maintenance practices. The research is categorised under applied research as it tries to solve existing maintenance challenges experienced in the platinum industry with theoretical application techniques in predictive maintenance and Industry 4.0.

5 RESULTS AND FINDINGS

5.1 Individual Profiles

The survey respondents perform roles interacting with the operational equipment, production, and maintenance management. The information gathered is grouped according to the level of work complexity, giving insights into the availability of tools and systems at each level of work associated with maintenance. Operational management accounts for 41% of the respondents' distribution. The front-line managers in maintenance planning and execution are well represented with a cumulative 47% distribution. The remaining 12% is attributed to the maintenance engineers managing the front-line managers.

5.2 Industry Maintenance Strategies

Predictive maintenance evaluates the adopted maintenance practices by the operations. Most respondents rank preventative maintenance as the most common strategy used in the operation, representing 29% of the total distribution. Breakdown and corrective maintenance represent 26%, Condition-based maintenance 18%, and predictive maintenance represents 1% of the total maintenance strategy distribution.

100% of the respondents agree to practice preventative maintenance in the operations. A one-sample Wilcoxon signed-rank test indicated that the median of 5.00 was significantly different from 3, $Z = 5.09$, $p < .05$. This is consistent with our proposition that the operation conducts periodic cycle maintenance, which is the basic philosophy of preventative maintenance, according to Kumar Mishra and Mahapatra [19].

The data indicates that 47% of respondents perceive a monthly shutdown cycle and 50% on a six-weekly basis. 3% of the respondents cited a 2-monthly shutdown maintenance. The split in responses on the maintenance cycles entered by respondents highlights that the drivers of shutdown maintenance are currently time-based; the results are that shutdowns are conducted on a predetermined schedule without considering the condition of the asset/equipment. This is consistent with Muganyi and Mbohwa [31], highlighting the disconnect between organisational business strategies and the need to conduct shutdowns.

5.3 Descriptive Statistics of Results

5.3.1 Architectural Components

The data indicates that 91% of the respondents agree that the architectural components required for adopting predictive maintenance are present in their operations. A one-sample Wilcoxon signed-rank test showed that the median of 4.00 was significantly different from 3.00, $Z = 18.50$, $p < 0.05$. The results support the presence of the architectural layer framework components defined by [29] and the Intelligent Predictive Maintenance system framework by Wang [6].

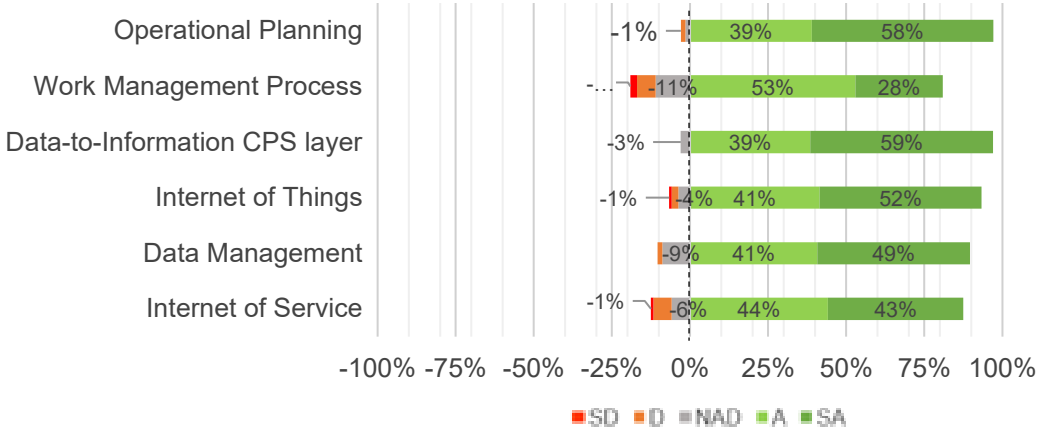

Figure 2: Summary of conceptual predictive maintenance architectural model components in operations

Of the respondents, 97% agreed to conduct operational planning activities, and 98% agreed to the presence of CPS capabilities in the operations. Additionally, 93% agreed to the presence of IoT capabilities. There is an evident variation in respondents' experience with work management, data management and IoS. Although most respondents confirm the capabilities, many remain undecided or disagree relative to other framework components.

5.3.2 Functional Components

The functional requirements of predictive maintenance are highly dependent on the maturity level of the architectural components. The functional requirements integrate predictive maintenance into the operational business framework. Figure 3 shows that 88% of the respondents agree that the functional components required for adopting predictive maintenance are present in their operations. A one-sample Wilcoxon signed-rank test indicated that the median of 4 was significantly different from 3, $Z = 12.69$, $p < 0.05$.

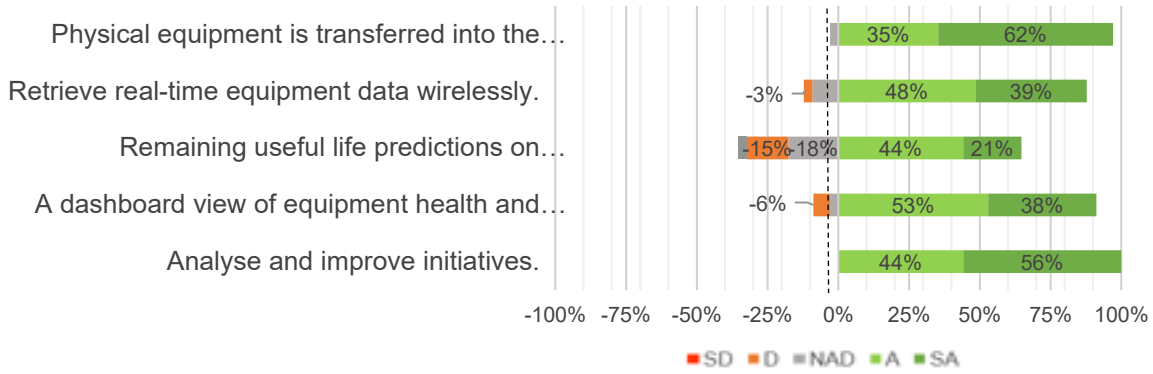

Figure 3: Contributing Factors to the Functional Framework Requirements

The operations indicated a high capability of transferring equipment into the virtual environment and analysing and improving initiatives. Only 65% of respondents agree with the performance of remaining useful life predictions on equipment. There is an evident variation in respondents' experience with equipment RUL predictions; this can be investigated further to probe whether the projections were statistical or based on expert knowledge. Interestingly, 91% of the respondents indicated the usage of dashboards for equipment health and performance; the low performance of RUL predictions indicates that the dashboards and maintenance information does not include prognostics.

5.4 Adoption Readiness Assessment

Table 1 indicates the operation's architectural and functional maturity for adopting predictive maintenance. The data analysis shows the capability of the operations in the conceptual framework.

Table 1: Predictive Maintenance Adoption Readiness of Architectural and Functional Components

Architectural Component	Readiness	Median	Mode	Q1	Q2	Q3	IQR
Operational Planning	High	5.00	5	4.00	5.00	5.00	1.00
Work Management Process	Low	4.00	4	4.00	4.00	5.00	1.00
Data-to-Information CPS layer	High	5.00	5	4.00	5.00	5.00	1.00
Internet of Things	High	5.00	5	4.00	5.00	5.00	1.00
Data Management	Medium	4.00	5	4.00	4.00	5.00	1.00
Internet of Service	Low	4.00	4	4.00	4.00	5.00	1.00

Overall	Medium	4.00	5.00	4.00	4.50	5.00	1.00
Functional Component	Functionality						
Physical equipment is transferred into the virtual environment	High	5.00	5	4.00	5.00	5.00	1.00
Retrieve real-time equipment data wirelessly.	Low	4.00	4	4.00	4.00	5.00	1.00
Remaining useful life predictions on equipment.	Low	4.00	4	3.00	4.00	4.00	1.00
A dashboard view of equipment health and performance	Low	4.00	4	4.00	4.00	5.00	1.00
Analyse and improve initiatives.	High	5.00	5	4.00	5.00	5.00	1.00
Overall	Low	4.00	4	4.00	4.00	5.00	1.00

5.4.1 Architectural component readiness

The existing operating business framework is represented by operational planning and work management. CPS, IoT, IoS and data management represent the predictive maintenance framework. The operations scored a medium overall architectural adoption readiness level.

Operational Planning: The results indicate a high adoption readiness level for operational planning. However, there needs to be more visibility of production and maintenance review actions at the lower managerial levels. Empowering all levels with a view of the strategic outlook can further improve decision-making in the lower levels of management.

Work Management: The results indicate a low adoption readiness level for work management, influenced by the supply chain misalignment with applied maintenance strategies on a tactical level, as defined by Crespo and Gupta [32]. Consistent with the need to comprehensively understand the modularity in product, service and supply chains [26].

Cyber-Physical Systems: CPS data-to-information conversion level from Lee et al. [24] ranks as the ideal architectural level, as it supplies decision-makers with information from the collected data. The results indicate a high adoption readiness level in the operations. Further improvements in the level of maturity will include using similar information from other peers for smart maintenance decisions to avoid potential faults [24]

Internet of Things: The results indicate a high adoption readiness level for the Internet of Things in operations, mainly due to their established wireless data collection networks, which allow for continuous data acquisition on sensors and transmitters.

Data Management: The results indicate a medium adoption readiness for data management. The operations indicate a strong capability for collecting and storing data. However, the use of data for diagnostics and prognostics is generally lower, highlighting the opportunity to decentralise decision-making by converting data to information using data analytics.

Internet of Service: The results indicate a low adoption readiness level of IoS in the operation. It is a valid concern as IoS addresses the business standpoint; it represents a set of services that improve the company's ability to do business with customers and suppliers. Since multiple service suppliers are required in the IoS component, modularity, separation of concerns, service re-use, and composition play a vital role from a technological standpoint [28]. The

common feature in predictive maintenance is the need for a comprehensive understanding of modularity in product, service and supply chains [33].

5.4.2 Architectural Layers and Functionality

The maturity of the architectural layers is expected to enable the functional requirements of practising predictive maintenance.

Device layer: Transferring physical equipment into a virtual environment is a functional capability of the device layer. The functionality is high owing to a high adoption readiness of CPS and IoT device layer components within the operations.

Edge layer: Wireless retrieval of equipment data is a functional capability from the edge layer, integrating IoT and data management. The functionality is low, and although IoT adoption readiness is high, the data management component is measured as a medium adoption readiness. Further investigation is required, possibly on organisational data access restrictions and cybersecurity protocols.

Cyber layer: The cyber layer integrates the 2nd-level Cyber-physical systems and work management, including supply chains enabling maintenance error corrections. Although CPS has a high adoption readiness level, a work management component is low, negatively affected by the gap in operational maintenance planning and supply chain activities. As a result, the respondents were not entirely confident about the effectiveness of maintenance work planning.

Data Analytics layer: RUL predictions and equipment health and performance dashboards are functional capabilities of the data analytics layer, integrating IoS, algorithms, and processed data in the data management component. The RUL prediction and performance dashboard view page functionality is low, consistent with the low adoption readiness of IoS and medium adoption of data management components. The operations indicated a high availability of real-time and historical data. However, the data utilisation remains low.

Application layer: Analysing and improving initiatives indicates the application layer, which integrates IoS performance dashboards and operational planning decision-making. The functionality is high, suggesting strong support for initiatives by decision-makers in operational planning, with or without IoS. The prognostics' low functionality on remaining useful life predictions of equipment and the lower predominance of dashboard views of equipment health and performance negatively affect the Internet of Service adoption readiness.

6 CONCLUSIONS AND RECOMMENDATIONS

6.1 Conclusion

This study assessed the organisational readiness of the South African platinum processing industry to adopt predictive maintenance. The findings show that, while the architectural components required for predictive maintenance are generally present, the overall readiness is only medium, and the functional capability remains low. The gap is most evident in work management processes, data utilisation, and the Internet of Service, where integration with existing legacy systems is insufficient.

The results highlight that predictive maintenance cannot be effectively adopted without strengthening these weak components. Although operational planning, cyber-physical systems, and the Internet of Things demonstrate high maturity, their benefits are undermined by poor alignment with work management and limited use of data for prognostics. This imbalance constrains the industry's ability to move beyond preventative maintenance and achieve the benefits of condition-driven strategies. This is visually shown in Figure 4.

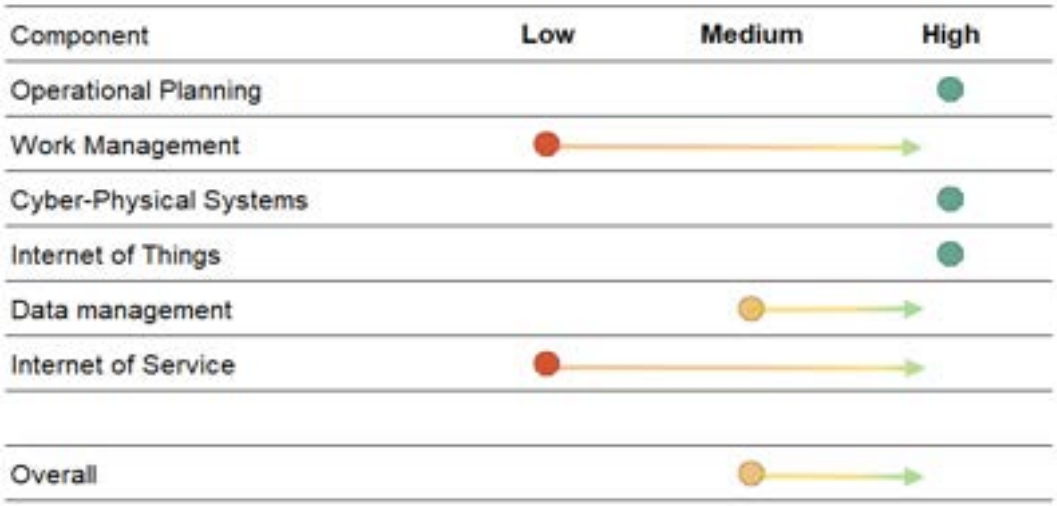

Figure 4: Summary of predictive maintenance architectural journey model.

Addressing these gaps requires focused investment in data analytics capability, integration of predictive functions into existing maintenance systems, and the development of Internet of Service platforms that support resourcing, spares planning, and decision-making. Improvements in these areas will position operations to exploit predictive maintenance more effectively, reducing unplanned downtime and improving asset reliability.

Overall, the research shows that the South African platinum processing industry stands at a transitional stage. By systematically strengthening functional capabilities and aligning them with existing architectural maturity, organisations can move towards predictive maintenance as a core business strategy. Doing so will not only enhance equipment availability and reliability but also provide a sustainable competitive advantage in an increasingly demanding global market.

6.2 Recommendations

The study findings point to specific areas that require attention if predictive maintenance is to be effectively adopted in the South African platinum processing industry. Work management processes should be prioritised, particularly the alignment of maintenance planning with supply chain resourcing, to reduce the deferral of critical tasks due to unavailable spares. Data management also needs strengthening, with greater emphasis on analytics and prognostics to convert the industry's extensive real-time and historical data into actionable insights.

In addition, developing Internet of Service capabilities will be crucial to support decision-making dashboards, resource planning, and equipment health monitoring. Organisations can begin with a staged integration approach, embedding predictive functions into existing legacy systems while progressively building modular IoS platforms. Investment in analytics capability and machine learning expertise will further enhance Remaining Useful Life predictions, which remain below the standard required for predictive maintenance practice.

ASSESSING THE READINESS FOR INDUSTRY 4.0 IN THE SOUTH AFRICAN MINING INDUSTRY: A CASE STUDY OF A MINING COMPANY'S UNDERGROUND MACHINERY MAINTENANCE STRATEGY

K. Ncube[1] and R.H. Peach[2]*

[1,2]Department of Engineering and Technology Management,
University of Pretoria, South Africa
[1]ncubekmt@hotmail.com, [2]rina.peach@up.ac.za

ABSTRACT

Industry 4.0 is poised to revolutionise industries globally, and the South African mining sector stands to benefit significantly. This study assesses the readiness of a South African mining company to adopt Industry 4.0 technologies in its maintenance strategy. A conceptual readiness assessment model, integrating elements from the IMPULS, PwC, and Industry 4.0 Maturity models, was developed to evaluate critical dimensions. The research employed a mixed-methods approach. Findings reveal that while there is strong leadership commitment to Industry 4.0 at a strategic level, gaps exist in key areas such as real-time data integration, predictive maintenance capabilities, and workforce readiness. The study emphasises the critical importance of change management and employee training for the successful implementation of Industry 4.0 technologies. The study outlines a clear roadmap for overcoming barriers to Industry 4.0 adoption, paving the way for improved competitiveness and sustainability in the mining sector.

Keywords: Industry 4.0, Underground Mining, Predictive Maintenance, Readiness Assessment, South Africa

1 INTRODUCTION

1.1 Background

The South African mining industry is a cornerstone of the national economy and employment, but faces volatile commodity prices, ageing infrastructure and persistent safety risks [1]. Harsh underground conditions accelerate equipment wear, driving costly unplanned downtime. Industry 4.0 technologies such as Internet of Things (IoT) sensors, big-data analytics and Artificial Intelligence (AI) enabled automation promise safer, more efficient operations by supporting real-time condition monitoring and predictive maintenance [2].

Traditionally, the mining industry has been slower to adopt new technologies compared to sectors such as manufacturing and logistics. Companies that adopt the modern concept benefit from maximum flexibility and a major competitive advantage [3]. Predicting equipment failures and optimising maintenance schedules are particularly important, as downtime can result in significant financial losses and operational disruptions. Additionally adopting Industry 4.0 technologies is essential for the mining industry to maintain competitiveness, efficiency, and sustainability.

Despite clear benefits, the mining industry faces challenges in adopting these technologies. Harsh underground conditions, high temperatures, dust, and vibrations can hinder the deployment of sensitive IoT devices. Additionally, the workforce may lack the skills to manage and maintain advanced technologies, necessitating significant investment in training and education [2]. The initial costs of implementing Industry 4.0 technologies can also be prohibitive, especially for small and medium-sized mining companies. Furthermore, implementing new technologies without properly assessing the organisation’s readiness can lead to suboptimal outcomes such as increased costs, decreased productivity, and compromised safety.

1.2 Objectives

This study aimed to assess one South African mining company’s readiness to embed Industry 4.0 in its underground maintenance strategy. The particular mining company operates several underground coal mines for the largest petrochemical company in South Africa, making it ideal for a case study.

In order to achieve the study's objective, the following research questions were asked.

- What factors determine the level of readiness for Industry 4.0 adoption in this sector?
- What is the current level of readiness for Industry 4.0 adoption in this sector?

2 LITERATURE REVIEW

2.1 The Concept of Industry 4.0

Industry 4.0 represents the fourth industrial revolution, characterised by the integration of digital technologies such as IoT, AI, big data analytics, and cyber-physical systems into industrial processes. These technologies enable real-time data exchange, automation, and enhanced decision-making, which are crucial for improving operational efficiency, reducing costs, and increasing productivity [4].

A key feature of Industry 4.0 is the creation of "smart factories", where machines and systems communicate to optimise performance and autonomously adapt to changing conditions [5]. In maintenance, this revolution allows for predictive analytics and real-time monitoring, facilitating the shift from reactive maintenance strategies to more efficient, data-driven approaches [6].

The mining industry, heavily reliant on continuous machinery operation, stands to benefit significantly from Industry 4.0 adoption. Integrating IoT and AI can enhance machinery

monitoring and maintenance, leading to improved equipment uptime, safer working conditions, and reduced maintenance costs. However, successful implementation requires overcoming barriers such as the harsh and uncertain operating environments of remote mines, the complexity of integrating new systems into existing processes, and the need for skilled personnel and cross-disciplinary collaboration to manage advanced technologies effectively [7].

2.2 Challenges to Industry 4.0 Adoption in Mining

Several challenges hinder Industry 4.0 adoption in mining. A short discussion on some of these follows.

- **IT Infrastructure Limitations**: Underground connectivity issues can impede reliable data transmission from IoT devices [7, 8].
- **Workforce Resistance**: Employees accustomed to traditional methods may resist new technologies involving automation or data-driven decision-making [2].
- **High Implementation Costs**: Significant financial investment is required for new systems and training, which can be challenging for smaller companies [9].

Effective change management strategies are essential to address these challenges, ensuring employee engagement and successful technology integration. Organisations must prioritise communication, training, and involvement of the workforce to reduce resistance and build a culture that embraces technological change.

2.3 Readiness Assessment Models for Industry 4.0

Readiness assessment models provide a structured framework for evaluating an organisation's preparedness to implement advanced technologies associated with Industry 4.0. These models are crucial for identifying gaps in capabilities and guiding organisations through the transformation process. Models such as the IMPULS readiness model, PwC's Industry 4.0 self-assessment and the Industry 4.0 Maturity Model are designed to evaluate readiness across multiple dimensions, including strategic alignment, technological adoption, workforce competencies, and organisational culture [10].

The IMPULS readiness model assesses Industry 4.0 maturity by focusing on the extent of digital technology integration within core operations. It consists of 6 measurement dimensions: people (employees), strategy and organisation, smart factories, smart operations, smart products, and data-driven services [11]. It emphasises critical components such as IT infrastructure, employee skills, and leadership commitment, which are essential for enabling successful technology adoption. A key strength of this model lies in its comprehensive approach to evaluating how effectively digital technologies are embedded into the organisation's operational fabric. It not only measures technical capabilities but also the organisation's ability to leverage these capabilities to achieve operational excellence [12].

PwC's self-assessment model takes a broader view, evaluating not only technological readiness but also the organisation's strategic capacity to leverage new technologies for long-term, sustainable transformation. This model emphasises the importance of integrating IoT, AI, and data analytics into business processes to foster innovation and resilience. Additionally, it evaluates whether the organisational culture supports continuous learning and adaptation, which is crucial for maintaining a competitive edge in an evolving technological landscape [13].

Figure 1: IMPULS Industrie 4.0 Readiness [12]

	1 Digital novice	2 Vertical Integrator	3 Horizontal collaborator	4 Digital champion
Digital business models and customer access	First digital solutions and isolated applications	Digital product and service portfolio with software, network (M2M) and data as key differentiator	Integrated customer solutions across supply chain boundaries, collaboration with external partners	Development of new disruptive business models with innovative product and service portfolio, lot size 1
Digitisation of product and service offerings	Online presence is separated from offline channels, product focus instead of customer focus	Multi-channel distribution with integrated use of online and offline channels; data analytics deployed, e. g. for personalisation	Individualised customer approach and interaction together with value-chain partners. Shared, integrated interfaces.	Integrated Customer Journey Management across all digital marketing and sales channels with customer empathy and CRM
Digitisation and integration of vertical and horizontal value chains	Digitised and automated sub processes. Partial integration including production or with internal and external partners. Standard processes for collaboration partly in place	Vertical digitisation and standardised and harmonised internal processes and data flows within the company; limited integration with external partners	Horizontal integration of processes and data flows with customers and external partners, intensive data use through full integration across the network.	Fully digitised, integrated partner ecosystem with self-optimised, virtualised processes, focus on core competency; decentralised autonomy. Near real-time access to extended set of operative information
Data & Analytics as core capability	Analytical capabilities mainly based on semi-manual data extracts. Selected monitoring and data processing, no event management	Analytical capabilities supported by central business intelligence (BI) system isolated, not standardised decision support systems	Central BI system consolidating all relevant internal and external information sources, some predictive analytics Specific decision support and event management systems	Central use of predictive analytics for real-time optimisation and automated event handling with intelligent database and self-learning algorithm enabling impact analysis and decision support
Agile IT environment	Fragmented IT architecture in-house.	Homogeneous IT architecture in-house. Connection between different data cubes developing.	Common IT architectures in partner network. Interconnected single data lake with high-performance architecture	Single data lake with external data integration functionalities and flexible organisation. Partner service bus, secure data exchange
Compliance, security, legal & tax	Traditional structures, digitisation not in focus	Digital challenges recognised but not comprehensively addressed	Legal risk consistently addressed with collaboration partners.	Optimising the value-chain network for compliance, security, legal and tax
Organisation, employees and digital culture	Functional focus in "silos"	Cross-functional collaboration but not structured and consistently performed	Collaboration across company boundaries, culture and encouragement of sharing	Collaboration as a key value driver

Figure 2: PwC maturity model - Industry 4.0 capabilities develop across seven dimensions and four stages [13]

The Industry 4.0 Maturity Model provides a structured framework to assess an organisation's readiness and progression in adopting Industry 4.0 concepts. It was developed to integrate both technological and organisational perspectives and comprises nine dimensions: Strategy, Leadership, Customers, Products, Operations, Culture, People, Governance, and Technology. Each dimension contains specific maturity items (62 in total) that capture critical enablers such as digitalisation of products and services, leadership commitment, ICT competence, and regulatory alignment [10]. An extract of this can be seen in Table 1.

These models offer a holistic view of an organisation's maturity concerning Industry 4.0 adoption. The IMPULS Readiness Model places significant emphasis on the digital integration within the organisation, assessing the robustness of the IT infrastructure and the readiness of the workforce to engage with these technologies. It also underscores the role of leadership in driving digital transformation initiatives, ensuring that strategic goals align with technological capabilities [12]. In contrast, PwC's self-assessment model provides a more comprehensive evaluation framework that encompasses both technological adoption and the strategic capabilities needed to leverage these technologies for long-term, sustainable business transformation.

Table 1: Dimensions and maturity items of Industry 4.0 Maturity Model [10]

Dimension	Exemplary maturity item
Strategy	Implementation I40 roadmap, Available resources for realisation, adaptation of business models, …
Leadership	Willingness of leaders, Management competences and methods, Existence of central coordination for I40, …
Customers	Utilisation of customer data, Digitalisation of sales/services, Customer's Digital media competence, …
Products	Individualisation of products, Digitalisation of products, Product integration into other systems, …
Operations	Decentralisation of processes, Modelling and simulation, Interdisciplinary, interdepartmental collaboration, …
Culture	Knowledge sharing, Open-innovation and cross-company collaboration, Value of ICT in the company, …
People	ICT competences of employees, openness of employees to new technology, autonomy of employees, …
Governance	Labour regulations for I40, Suitability of technological standards, Protection of intellectual property, …
Technology	Existence of modern ICT, Utilisation of mobile devices, Utilisation of machine-to-machine communication, …

3 MAINTENANCE MANAGEMENT IN THE MINING INDUSTRY

Maintenance management is critical for ensuring efficiency, safety, and longevity in mining operations. Traditionally, maintenance has followed reactive or preventive models. Reactive maintenance addresses issues post-failure, while preventive maintenance schedules regular checks based on time intervals or equipment usage [14]. Both approaches have limitations, especially in the complex underground mining environment, where unplanned equipment failure can lead to safety risks and costly delays [15].

Industry 4.0 introduces predictive maintenance, leveraging real-time data from IoT-enabled sensors to predict equipment failures, allowing maintenance teams to act before breakdowns occur [6]. Predictive maintenance reduces downtime and optimises resource use, as maintenance tasks are performed based on actual equipment condition rather than fixed schedules [16]. Additionally, condition-based maintenance is becoming more prevalent in the mining sector. Condition-based maintenance uses data from machine sensors to determine the actual state of equipment, allowing for maintenance to be performed precisely when needed [17]. This approach minimises unnecessary maintenance, maximises equipment uptime, and reduces overall costs.

3.1 Maintenance Practices

The effectiveness of maintenance practices directly impacts the production output of the mining company. These practices can be broken down into three main approaches: corrective maintenance, predictive maintenance, and condition-based maintenance, each of which serves a distinct purpose and is applied depending on the criticality of the machinery and the consequences of potential failures.

- **Corrective maintenance**: This is one of the oldest forms of maintenance, characterised by a reactive approach. It is performed after a system or equipment has failed, often resulting in considerable downtime and high repair costs. Corrective maintenance typically involves a highly skilled maintenance team ready to respond to equipment breakdowns. This method is suitable for non-critical equipment where the failure has minimal impact on safety and production. However, it is not ideal for high-capital assets or critical equipment, as unplanned downtime can significantly affect production targets and incur high costs. The approach lacks any form of advanced planning or budgeting, which contributes to its inefficiencies.
- **Predictive maintenance**: Predictive maintenance is a more advanced, data-driven approach that relies on continuous monitoring of machinery using installed sensors and data analytics. The aim is to predict failures before they occur, thereby avoiding unplanned downtimes. Technologies such as machine learning algorithms and real-time monitoring tools are used to identify abnormal patterns in parameters like vibrations, temperature, and lubrication oils, which serve as indicators of potential faults. For instance, in Industry 4.0, predictive maintenance leverages smart data analysis, AI, and IoT sensors to continuously monitor asset conditions. When abnormalities are detected, maintenance activities can be scheduled accordingly. This proactive maintenance strategy reduces the likelihood of unexpected breakdowns and extends the lifespan of equipment, making it an essential practice in the mining industry where reliability and efficiency are crucial.
- **Condition-based monitoring**: Condition-based monitoring is another proactive maintenance strategy that focuses on detecting signs of wear or defects before they evolve into major failures. Condition-based monitoring utilises various sensors and diagnostic tools to monitor the health of machinery components continuously. The P-F curve, a key concept in Condition-based monitoring, represents the progression from the point where a defect is detectable (P) to the point of failure (F). Effective maintenance during this interval helps avoid total system failure and ensures the reliability of the equipment. Techniques such as lubricant analysis, vibration analysis, and motor current analysis are common in condition-based monitoring. Lubricant analysis identifies contaminants or wear particles, which may indicate component degradation, while vibration analysis and motor current analysis help detect early signs of mechanical issues. By maintaining equipment based on actual conditions rather than fixed schedules, organisations can optimise maintenance resources, extend asset life, and minimise unplanned downtime.

3.2 Critical Maintenance Elements in the Mining Company

In the context of the mining company, critical maintenance elements have been identified to ensure systematic and efficient maintenance practices. These elements include the work management process, defect elimination, and defining maintenance tactics. Each of these elements plays a crucial role in ensuring high equipment reliability and availability, which is essential for the smooth functioning of mining operations.

3.2.1 Work Management Process

The mining company employs a detailed work management process to effectively manage maintenance activities. This process is central to improving asset reliability and is supported through weekly meetings, including maintenance and cost meetings. The work management process includes seven steps:

1. **Identify Work**: This step involves logging defects detected during inspections, ensuring that issues are documented for future maintenance.
2. **Prioritise Work**: After identifying the issues, they are prioritised based on their criticality. This helps in focusing on defects that, if left unaddressed, could lead to severe consequences.
3. **Plan Work**: In this step, the required tools, spares, and resources are determined to ensure readiness for execution.
4. **Schedule Work**: Establishing a timeline for maintenance activities ensures that work is carried out efficiently without interfering with production schedules.
5. **Execute Work**: The planned work is executed by the maintenance team, ensuring adherence to the schedule.
6. **Work Order Feedback**: Feedback is essential to capture details such as the time taken, spares used, and any delays experienced during execution.
7. **Work Order Status Control**: Finally, the work order is logged and closed in the system once the maintenance task has been completed. This structured approach ensures all maintenance activities are carried out systematically, thereby enhancing asset reliability.

3.2.2 Defect Elimination

Defect elimination is a critical process focused on improving asset reliability by addressing the root causes of defects. Using the "5 Why's" root cause analysis tool, defects are investigated until the fundamental reason is identified. Once identified, corrective actions are taken to prevent reoccurrences. This continuous process of identifying and addressing root causes contributes to the reduction of unplanned downtimes and ensures higher equipment reliability and performance.

3.2.3 Defining Tactics

The mining company employs Reliability-Centred Maintenance (RCM) to define maintenance tactics. RCM is used to determine failure modes, maintenance activities, and schedules, considering Original Equipment Manufacturer (OEM) recommendations. This approach ensures that maintenance tasks are aligned with the specific needs of each piece of equipment, enhancing operational reliability. The RCM process involves reviewing and updating maintenance schedules regularly, particularly when equipment is replaced or modified, to ensure the relevance of maintenance tasks.

4 CONCEPTUAL MODEL

This research proposes a conceptual model for assessing the Mining Company's readiness in terms of its maintenance strategy. The conceptual model combines the strengths of the IMPULS readiness model and the PwC self-assessment model, providing a comprehensive and tailored

approach to address the unique challenges and opportunities in the mining industry. This conceptual model, illustrated in Figure 3, is employed to evaluate the company's readiness across seven key dimensions, offering a nuanced and comprehensive understanding of both technical and organisational capabilities required for Industry 4.0 adoption. Each dimension is critical in facilitating a successful transition towards advanced, data-driven mining operations, particularly within the realm of underground machinery maintenance.

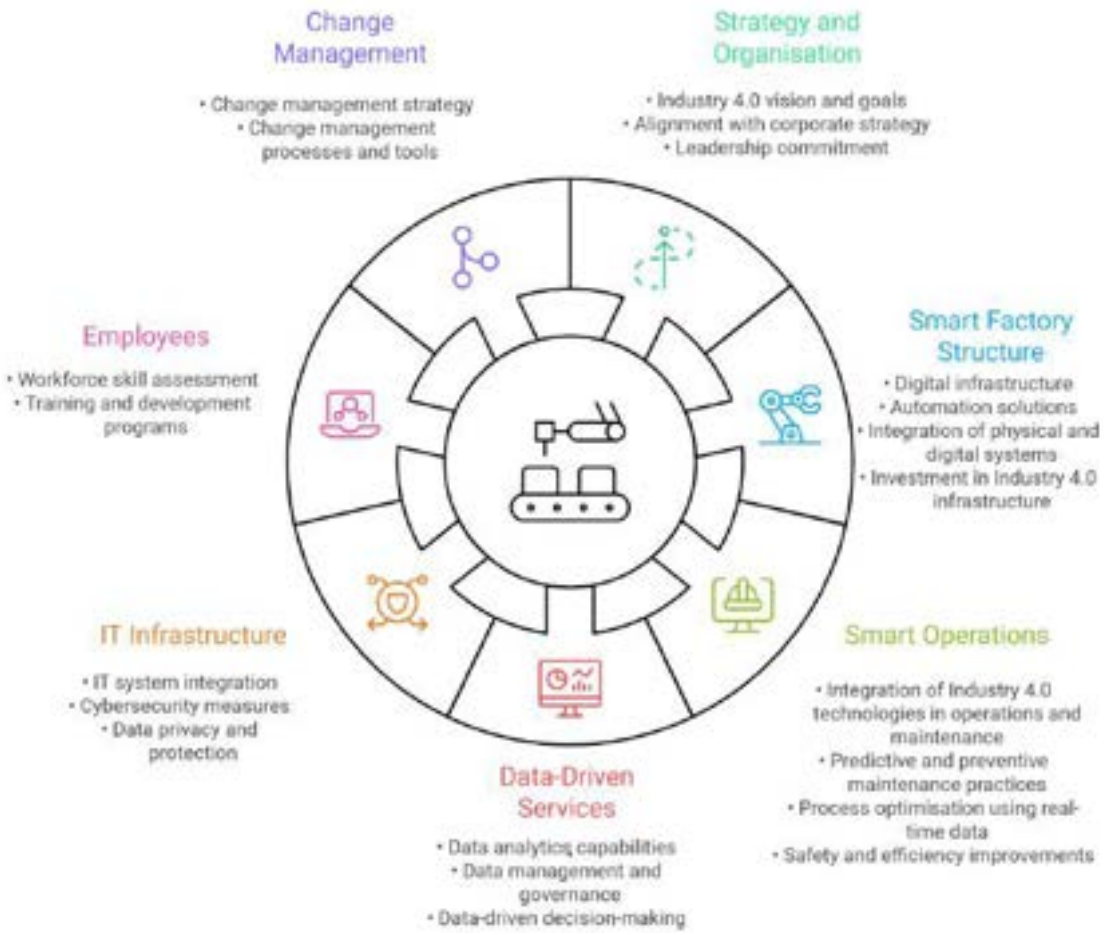

Figure 3: Conceptual model

4.1 Strategy and Organisation (IMPULS & PwC)

This dimension focuses on the strategic aspects of Industry 4.0 implementation, including defining the vision and goals for Industry 4.0 in the mining sector, evaluating the alignment of Industry 4.0 strategies with overall corporate strategy, and assessing leadership commitment and support for Industry 4.0 initiatives.

4.2 Smart Factory Structure (IMPULS)

Smart factory structure addresses the physical and digital infrastructure required for Industry 4.0 implementation. It involves assessing the current state of mining infrastructure, identifying areas for improvement in digitalisation and automation, and determining the necessary investments for upgrading mining infrastructure to support Industry 4.0 technologies.

4.3 Smart Operations (IMPULS & Industry 4.0 Maturity Model)

Smart operations focus on the integration (horizontally and vertically) of Industry 4.0 technologies in mining operations, particularly in maintenance processes. It includes evaluating the current level of integration, analysing the impact of these technologies on productivity, safety, and efficiency, and identifying best practices in predictive and preventive maintenance using Industry 4.0 technologies.

4.4 Data-Driven Services (IMPULS & PwC)

This dimension addresses the role of data in Industry 4.0 implementation. It involves assessing the current state of data analytics and management in the mining sector, identifying opportunities for improvement in data-driven decision-making, and evaluating the potential for new business models based on data-driven services.

4.5 IT Infrastructure (IMPULS & PwC)

The IT infrastructure requirements for implementing Industry 4.0 technologies in the mining sector are discussed in this dimension. It includes assessing the current state of IT infrastructure, identifying potential challenges and solutions for IT integration in the maintenance space, and evaluating the cybersecurity measures needed to protect data and systems.

4.6 Employees (IMPULS & Industry 4.0 Maturity Model)

This dimension addresses the workforce's readiness for Industry 4.0 implementation. It involves determining the skill sets required for employees to effectively utilise Industry 4.0 technologies, assessing the current state of workforce readiness, and developing training and development programs to upskill employees for Industry 4.0 implementation.

4.7 Change Management (PwC & Industry 4.0 Maturity Model)

This dimension focuses on the organisation's capacity to manage change during Industry 4.0 implementation. It includes evaluating the organisation's change management capabilities, developing a change management strategy tailored to the specific needs of the mining sector, and ensuring that the transition to Industry 4.0 technologies is smooth and well-managed.

By integrating elements from these established readiness assessment models, the conceptual model delivers a comprehensive analysis of both technical and organisational readiness for Industry 4.0 adoption. It pinpoints areas that require further enhancement and provides actionable insights to support the development of targeted strategies aimed at improving readiness in underground machinery maintenance. The conceptual model not only assesses the company’s current capabilities but also facilitates the creation of a structured roadmap for ongoing improvements.

5 RESEARCH METHODOLOGY

This study adopts a mixed-methods approach, integrating both quantitative and qualitative techniques to rigorously evaluate the company’s readiness for Industry 4.0 adoption, particularly in the context of underground machinery maintenance. The quantitative component involved the use of structured questionnaires distributed to key personnel, designed to measure critical dimensions such as leadership commitment, technological adoption, Information Technology (IT) infrastructure, employee competencies, and change management. The IMPULS readiness questionnaire was adapted to incorporate the additional elements from the conceptual model. After making the necessary adjustments, the questionnaire instrument comprised 23 quantitative questions. An extract of the questionnaire can be seen in Table 2. A Likert scale (1 = Strongly disagree, 5 = Strongly agree) was used as the appropriate scale for the questionnaires. The initial section of the questionnaire requests

respondents to provide details on the organisational framework of their businesses. Primarily, this information is employed to reinforce projections and ensure the survey's representativeness. Subsequently, the core of the survey comprises the fields that constitute the 7 dimensions of the conceptual readiness model, which assess the degree to which each field is present.

The target population included employees involved in the maintenance of underground machinery within the mining company, but at least at the middle management level. A stratified sampling method was employed to ensure representation across different departments, positions, and experience levels (Mouton, 2001).

Table 2: Extract from survey questionnaire

Dimension	Questions
Strategy and Leadership	• To what extent does your organisation have a clear vision and strategy for Industry 4.0 implementation in the maintenance of underground equipment? • How committed are the top leaders in your organisation towards Industry 4.0 implementation in maintenance operations?
Technologies and Solutions	• How effectively does your organisation identify and evaluate Industry 4.0 technologies relevant to the maintenance of underground equipment? • To what extent does your organisation have a technology implementation roadmap for Industry 4.0 in maintenance operations?
Smart Operations	• How well are Industry 4.0 technologies integrated into your maintenance operations for underground equipment? • To what extent does your organisation utilise predictive and preventive maintenance practices for underground equipment?
Data-Driven Services	• How well-developed are your organisation's data analytics capabilities for maintenance operations? • How effective is your organisation's data management and governance in the context of maintenance operations?
IT Infrastructure	• How well are your IT systems integrated to support Industry 4.0 implementation in maintenance operations? • How scalable is your IT infrastructure to accommodate Industry 4.0 technologies in maintenance operations?
Employees	• How well do your employees' current skills align with the requirements of Industry 4.0 technologies in maintenance operations? • How effective are your organisation's training programs for upskilling employees in Industry 4.0 technologies related to maintenance operations?
Change Management	• To what extent does your organisation have a well-defined change management strategy for the implementation of Industry 4.0 technologies in maintenance operations? • How effectively does your organisation communicate and engage stakeholders during the implementation of Industry 4.0 technologies in maintenance operations?

Quantitative data collection was conducted via an online survey administered through Qualtrics, which facilitated convenience for respondents and ensured efficient data capture. The response rate achieved was 76%, with 16 valid responses used in the subsequent analysis. Data preparation entailed a rigorous cleaning process, including the removal of extraneous

metadata, conversion of Likert scale responses to numerical values for analysis, and imputation of missing values to prevent bias. Column names were standardised to maintain consistency, thereby enhancing the quality and reliability of the dataset for analysis.

Ethical standards were strictly observed throughout the research process. Informed consent was obtained from all participants, ensuring that confidentiality and anonymity were maintained in accordance with the guidelines set forth by the University of Pretoria's Research Ethics Committee. Participants were fully informed about the objectives of the study and assured of their right to withdraw at any stage. Data security protocols were implemented to protect the collected information, ensuring compliance with relevant data protection regulations. This research methodology provides a robust and systematic framework for assessing Industry 4.0 readiness, ensuring the reliability and validity of the findings through rigorous data collection methods and adherence to ethical standards.

6 RESULTS

6.1 Data Gathering Process

The study utilised a structured questionnaire to collect data on the company's readiness for Industry 4.0 implementation in its underground machinery maintenance strategy. The questionnaire focused on key areas such as technological integration, workforce skills, and strategic alignment.

6.2 Readiness Assessment

Responses were categorised into key dimensions, and median scores were calculated to assess readiness levels and are shown in Figure 1

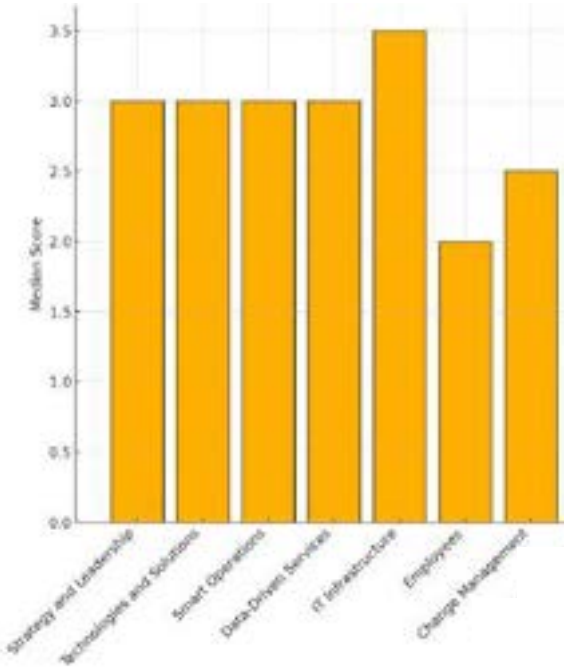

Figure 4: Median Score by Dimension

The results indicate moderate readiness in areas such as Strategy and Leadership and IT Infrastructure, but significant challenges in Employees and Change Management, suggesting workforce preparedness and organisational change are critical areas needing improvement [18].

6.3 Statistical Analysis

Various statistical tests were conducted to ensure the validity of the data and the robustness of the findings. **Normality Tests**: Shapiro-Wilk tests, Table 3, indicated that some variables deviated from normality, necessitating the use of non-parametric tests for those variables.

Table 3: Shapiro-Wilk Test

Variable	Shapiro-Wilk Statistic	p-value
Strategy and Leadership	0.927	0.222
Technologies and Solutions	0.932	0.262
Smart Operations	0.878	0.036
Change Management	0.892	0.061
Vendor Collaboration	0.921	0.175
Maintenance Technology Integration	0.927	0.218
Sustainability and Environmental Impact	0.922	0.185
Performance Measurement and KPIs	0.862	0.021

Linearity: Pearson correlation coefficients, Table 4, showed that most key variables exhibited linear relationships with the dependent variable.

Table 4: Pearson Correlation Coefficients

Variable	Pearson Correlation	p-value
Strategy and Leadership	0.66	0.003
Technologies and Solutions	0.74	0.002
Smart Operations	0.57	0.012
Data-Driven Services	0.64	0.004
IT Infrastructure	0.69	0.004
Employees	0.60	0.009
Change Management	0.60	0.009

Homogeneity of Variances: Levene's test and Brown-Forsythe test, Table 5, results indicated that while most variables met the assumption, some variables, such as Change Management, did not, suggesting heteroscedasticity.

Table 5: Levene's Test and Brown-Forsythe Test Results

Variable	Levene's Test Statistic	Levene's Test P-value	Brown-Forsythe Test p-value
Strategy and Leadership	1.23	0.276	0.291
Technologies and Solutions	1.67	0.206	0.217
Smart Operations	2.02	0.158	0.164
Data-Driven Services	1.89	0.174	0.181
IT Infrastructure	2.45	0.130	0.139
Employees	2.31	0.137	0.142
Change Management	4.58	0.041	0.045

Multicollinearity: Variance Inflation Factors (VIF), Table 6, were all below 10, indicating that multicollinearity was not a concern.

Table 6: Variance Inflation Factors (VIF)

Variable	VIF
Technologies and Solutions	2.45
Process Optimisation using Real-Time Data	1.85
Strategy and Leadership	2.31
Maintenance Technology Integration	2.05
Change Management	1.40

6.4 Regression Analysis

A multiple linear regression model was developed, with the dependent variable being Readiness for Industry 4.0 Implementation. Independent variables can be seen in Table 7.

Table 7: Multiple linear regression coefficients

Variable	Coefficient (β)	Standard Error	t-value	p-value
Intercept	2.15	0.58	3.71	0.003
Leadership and Management	0.141	0.045	3.13	0.011
Technology Readiness	0.139	0.047	2.96	0.015
Smart Operations	0.064	0.039	1.64	0.110
Data-Driven Services	0.075	0.042	1.79	0.088
Employees	0.052	0.038	1.37	0.195

The model explains nearly 100% of the variance in Industry 4.0 readiness, indicating a strong fit. Leadership and Management and Technology Readiness emerged as significant predictors.

7 FINDINGS

Through the conceptual model, 7 dimensions were identified that influence the level of readiness for Industry 4.0 adoption, which was used to determine a readiness assessment. The readiness assessment conducted that the Mining Company is at an intermediate level of readiness for Industry 4.0 adoption. This intermediate stage suggests that while the company has begun integrating digital technologies, several key areas need improvement before full-scale implementation can occur. The company scored well in the *Strategy and Leadership* dimension (mean = 3.8), indicating a strong commitment to Industry 4.0 from the leadership team. However, the lower score in the *IT Infrastructure* dimension (mean = 2.6) highlights a significant barrier to progress.

One of the major findings is the misalignment between the company's strategic goals and its operational capabilities. While leadership supports the adoption of Industry 4.0 technologies, the current infrastructure is insufficient to support these technologies at scale. This is consistent with the findings of Schumacher, et al. [10], who argue that organisational readiness must extend beyond leadership intent to include robust IT systems and workforce development.

The readiness assessment also revealed challenges in the workforce dimension. Employees expressed concerns about their ability to manage new technologies, as reflected in the relatively low score in the *Employees* dimension (mean = 2.8). The lack of skilled personnel presents a significant challenge to the company's digital transformation efforts. As Sony and Naik [18] noted, workforce readiness is a critical component of Industry 4.0 adoption. Without adequate training programs and continuous upskilling, the company risks falling behind in its digital transformation journey.

The company's readiness is further impeded by the complexity of integrating legacy systems with new digital technologies. The Mining Company relies heavily on older machinery that is not easily compatible with IoT systems or real-time analytics platforms. This finding is supported by Zambetti, et al. [19], who note that one of the main barriers to Industry 4.0 adoption in heavy industries is the challenge of upgrading or replacing legacy equipment.

8 CONCLUSIONS AND RECOMMENDATIONS

This study set out to evaluate the readiness of a South African mining company to integrate Industry 4.0 technologies into its underground machinery maintenance strategy, using a conceptual model that combined elements from the IMPULS, PwC, and Industry 4.0 Maturity Models. The findings indicate that the mining company has demonstrated an intermediate level of readiness. While leadership commitment and strategic intent are evident, significant gaps exist in IT infrastructure, workforce readiness, and change management capabilities. These gaps represent critical barriers to scaling up digital transformation efforts.

From a practical perspective, the company should prioritise investment in scalable, secure IT infrastructure capable of supporting real-time data acquisition, processing, and analytics. Concurrently, a structured workforce development programme should be implemented, focusing on continuous upskilling in digital competencies and change management to foster an organisational culture that embraces technological innovation. The gradual retrofitting of legacy machinery, coupled with the adoption of interoperable IoT platforms, would enable a smoother integration of new technologies without necessitating wholesale equipment replacement. Establishing cross-functional teams to drive pilot projects can further support knowledge transfer and reduce resistance to change.

It is important to acknowledge that this study was based on data from a relatively small sample within a single organisation. While this approach enabled an in-depth examination of context-specific factors, it limits the generalisability of the findings across the broader mining sector. Future research should expand the sample size and include multiple organisations across different commodities and operational environments to enhance the robustness and applicability of the readiness model.

ABSTRACT

The mining industry is the backbone of the South African economy, serving as the country's most significant primary economic sector. The South African mining industry is plagued with rising operational costs, declining commodity prices, deteriorating rail infrastructure and increased pressure to operate sustainably. Maintenance is a significant driver of operational expenses, accounting for as much as 70% of total asset lifecycle costs. This study explored the maturity of the South African mining industry in adopting Maintenance 4.0 technologies, focusing on the digitalisation of maintenance data. Despite the global push towards digital transformation, this study's findings indicate that South African mining organisations depend on reactive maintenance philosophies. Utilising interviews and a semi-structured survey, professionals working within the technology, mining and maintenance domains were engaged on their experiences around Maintenance 4.0. Lack of training programs, cultural resistance and financial constraints are among the top barriers to ushering in digital transformation. Remediation includes leadership support, digitalisation strategies, and improved change management to curb the gap.

Keywords: Maintenance 4.0, Mining, Predictive Maintenance, Data Digitalisation

1 INTRODUCTION

1.1 Background

The world is experiencing a paradigm shift towards increased automation, connectivity, and the demand for data-driven decision-making. Industries must adapt their operational frameworks to enhance their competitive advantage and generate value sustainably. Several factors are driving the increased generation of data that can be used to improve the execution of maintenance activities, including the emergence of cloud computing, the increased availability of mobile and electronic communications, and the decreased costs associated with advanced data computation [1].

Maintenance, a traditionally reactive and routine function, has evolved into a critical operational strategy. Maintenance is described as all the activities necessary to restore equipment to an operational condition [2]. Additionally, the Global Forum on Maintenance & Asset Management (GFMAM) describes maintenance management as the decision-making process that aligns maintenance delivery activities with corporate objectives and strategies [3]. Maintenance decisions span across long-term (strategic), medium-term (tactical) and short-term (operational) horizons [2]. The strategic aspect entails supporting the production function to ensure the organisation achieves a competitive advantage. The Tactical element refers to the effective utilisation of resources and finding the optimal interventions to ensure asset availability. The Operational aspect refers to the day-to-day operational and scheduling decisions regarding the sequence in which the work will be performed and the best personnel to execute the tasks.

The increased implementation of maintenance management information systems (MMIS) enhances data processing reliability and efficiency. According to a report by PwC, organisations that have implemented Predictive Maintenance (PdM) have achieved, on average, 9% more uptime from their assets, therefore capacitating them to generate increased financial value [4]. Maintenance and diagnostics play an important role in promoting equipment uptime, given that equipment maintenance can exceed as much as 30% of the total operating costs and between 60% and 75% of equipment lifecycle costs [1].

Apart from reducing costs, the benefits of maintenance include extending the physical asset lifecycle, improving product quality yield, reducing the volume of components that need to be replaced, increasing organisational profitability, and increasing process efficiency, which has an overall positive impact on the organisation’s production performance [5].

Despite the clear benefits of digitalising the maintenance function, a preliminary scoping review has shown that there needs to be more literature discussing guidelines for digitalising maintenance within the South African mining context. Some authors have covered ground on this topic in cross-border industries like manufacturing from an international perspective; however, there is still a gap in understanding whether these frameworks can be applicable within the South African mining context.

This study aims to develop a maintenance data digitalisation framework that can be adapted for the South African mining industry.

2 LITERATURE REVIEW

2.1 The South African Mining Industry

In partnership with the World Economic Forum, Accenture, a global professional IT services company, highlighted that the South African mining industry has the potential to unlock up to R213 Billion by 2026 through deploying a combination of initiatives aimed at bridging the digital gap, including smart sensor technology, advanced analytics, integrated platforms and remote operations centres [6]. A combination of these enabling technologies will empower

frontline operators to carry out operational activities with a greater degree of accuracy, increased safety, and a more proactive approach to diagnosing asset performance faults, enabling strategic, tactical, and operational decision-making backed by data.

The mining industry is the cornerstone of the South African economy and remains its most significant primary economic sector [7]. In 2023, the South African mining sector employed over 477,000 workers and contributed R426 billion to the Gross Domestic Product, as well as over R90 Billion to the South African government in profit taxes [8]. Benefits from this sector include foreign investment, economic activity driven by commodity exports, national revenue from government taxes, and job creation for the local population [9]. Despite the numerous benefits of a thriving mining industry, the sector faces critical challenges, including declining ore grades, falling commodity prices, ambitious production targets, and logistical challenges, all of which impact its overall contribution to the economy [10]. In light of these challenges, mining companies in South Africa must adopt technological innovations to enhance production efficiency, lower operational costs, and maintain a competitive edge in these turbulent markets. Maintenance cost is a significant driver of operational expenditure for mining organisations [7]. Effective maintenance management is a strategic lever that can be used to achieve substantial cost savings and operational efficiency.

The mining industry lags behind the manufacturing industry when levied in terms of digital transformation of the maintenance function. This lag is driven by minimal investment in Information Technology/Information Communications Technology infrastructure, the disparity between the business strategy and the digital strategy (the inability to link business objectives with information data, effective change management, and the practical application of technology) [11]. Some South African mining companies have begun adopting the fourth industrial revolution technologies; however, many digital technology implementations still need to realise better success [11]. It is essential to note that retrofitting innovative processes across the mining value chain will necessitate supporting technology platforms to ensure reliability in data collection, processing, analytics, and coordination. The introduction of digital transformation will result in the creation of big data, which will require flexibility in the mining organisation's IT infrastructure; furthermore, human resources with computer and data analytics skills will also be needed to complement the roll-out of digital technologies.

2.2 Maintenance Management

A maintenance strategy can be defined as a planned approach to preserve and conserve equipment in an acceptable functional state, comprising actions that include identifying, researching, and executing decisions to inspect, repair, and replace equipment [12]. The maintenance strategy requires executable and tactical plans, in the form of policies and actions, to preserve and conserve equipment, along with a decision-making support system for maintenance events.

The delivery of effective maintenance depends on three main factors, namely Technical, Human, and Economic [13]. The Technical aspects refer to maintenance products and services, as well as the methods, strategies, resources and materials used to deliver these services. The Human aspects refer to the internal relations between the maintenance department and other departments (both internal and external to the organisation), such as production, finance, labour bodies or government. The Economic aspects involve the financial considerations that influence maintenance decisions, including budget constraints, cost-benefit analyses, return on investment, and the long-term economic impact of maintenance strategies on operational performance. Leaders of organisations should strive to integrate management skills, personnel, policies, equipment, and practices in order for organisations to achieve the objectives of maintenance [2].

2.3 Maintenance Digitalisation

The world is currently experiencing the information age, where several industries, technologies and applications are adopting and implementing a digital approach to their ways of work; this is synonymous with the increased usage of smart devices, reliance on big data, advancement in the computational capacity of computers and the maturity of Artificial intelligence and Machine Learning [14]. Digital transformation can empower maintenance tasks by facilitating a shift from reactive and corrective practices towards a more data-driven approach that enhances operational efficiency and reliability. This is driven by the provision of real-time visibility into equipment health, thereby supporting evidence-based decision making instead of reliance on delayed reporting or operator intuition. Furthermore, digital transformation of maintenance data is ultimately the foundation for automating repetitive processes such as work order generation, data entry and overall reporting [15].

The adoption of advanced technologies, such as machine learning, AI, data analytics, big data, and cloud computing, has transformed traditional maintenance into a more innovative and efficient framework that enhances service delivery and asset performance. The core of this transformation is underpinned by Cyber-Physical Systems (CPS), which integrate physical assets such as heavy mining equipment with computational components capable of autonomous decision-making, data exchange and process control. These systems are enabled by retrofitting legacy equipment with Internet of Things (IoT) sensors, thereby converting conventional machines into intelligent, connected environments. In an industrial context, such as mining, this is referred to as the Industrial Internet of Things (IIoT). IIoT is particularly valuable for the mining industry as it facilitates the real-time condition monitoring of assets, enabling early anomaly detection and the conversion of physical and mechanical signals into digital data streams that form the foundation for predictive maintenance [16].

Despite the pronounced benefits of adopting digital practices to enhance maintenance frameworks, numerous challenges exist in achieving this prospect. The limited availability of good quality data inhibits the effective use of maintenance optimisation models [2]. Big data analysis will be a key driver in the next wave of economic innovation; however, the shortage of personnel with the skills needed to derive insights from big data will serve as a stumbling block [1]. Assets used in the mining industry are often sourced from various Original Equipment Manufacturers (OEM). This diversity introduces challenges to maintenance data digitalisation such as legacy system integration, limited cross network communication, vendor lock-in, lack of a strategic vision and overall scalability issues [1]. It is often challenging to justify the business case for ripping and replacing legacy technology, especially when assets are still functional. In addition, differences in system architectures and communication protocols across vendors lead to cross platform integration difficulties.

2.4 Benefits of Digitalisation in Maintenance

Maintenance personnel spend approximately 45% of their time obtaining instructions from documents; as such, digitalisation in maintenance can relieve their workload by simplifying processes and shortening the time it takes to diagnose and repair issues [16].

Combining digital tools (along with data) and remote facilities will allow maintenance teams to detect and prevent failures in advance, resulting in more reliable assets with high production volumes and reduced service delivery costs [17]. Utilising updated data and optimised equipment processes will assist with monitoring, diagnosing, troubleshooting, predicting and optimising maintenance activities [18].

The systematic implementation of targeted measures to reduce asset downtime will enable organisations to optimise the functionality of their assets, enabling them to perform at their

peak, consistently. This will fortify the organisation's ability to meet and exceed performance objectives [19].

3 CONCEPTUAL METHOD

3.1 Introduction

The foundation for deriving the conceptual model for the research stems from the work of Umair et al [16], who detailed a range of critical factors that are known to hinder the effective implementation phasing of technology within maintenance, particularly in the manufacturing industry. This work was adapted and applied within the South African mining industry and served as the guidance for this study.

3.2 Conceptual Framework

The conceptual framework used in this study is illustrated in Figure 1: Conceptual framework. According to the framework, organisations should only pursue digitalisation efforts for maintenance data after addressing the critical factors and key enablers highlighted.

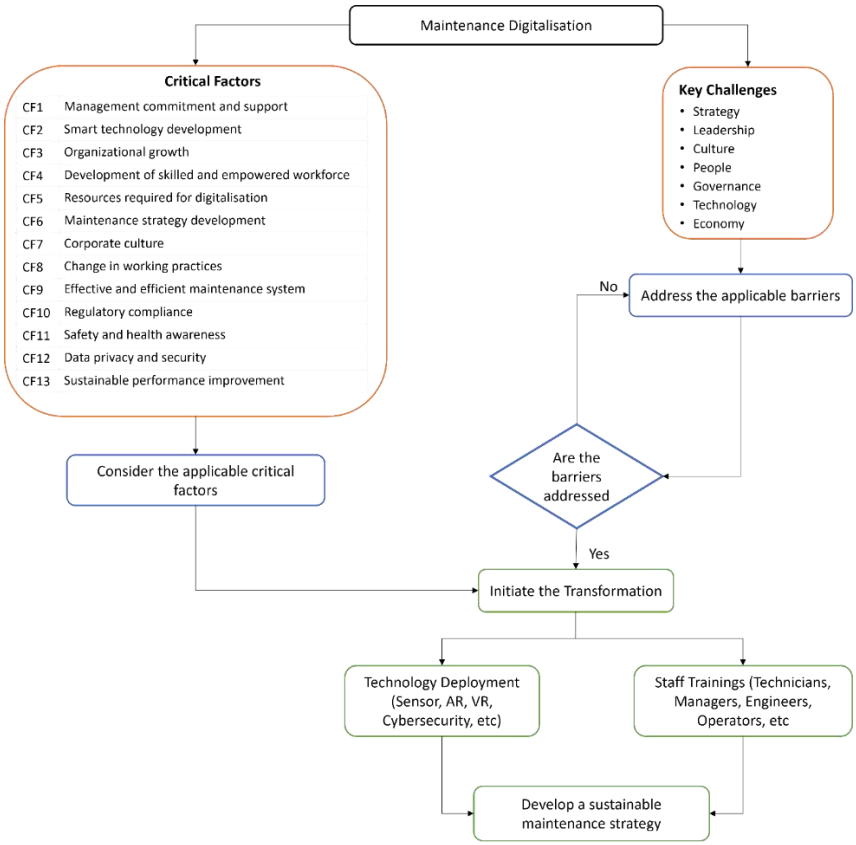

Figure 1: Conceptual framework

3.3 Propositions

The following propositions were tested within this study.

Proposition 1: The adoption of maintenance digitalisation tools will improve the effectiveness of maintenance execution within South African mining companies:

- Improved information management (the degree of ease to find maintenance data)
- Integration of maintenance systems (cross functional communication among systems)
- Increased ability to identify issues and devise remediation strategies

Proposition 2: Organisational culture moderates the relationship between digitalised maintenance data and maintenance performance.

- Support for learning and development
- Openness to change
- Innovation drive
- Policy, norms and values around digitalisation

Proposition 3: Organisations that use digitised maintenance data experience superior maintenance performance than organisations that rely on traditional maintenance data collection practices.

- Higher Overall Equipment Effectiveness
- Optimised maintenance scheduling
- Reduction in unplanned downtime

4 RESEARCH APPROACH

4.1 Introduction

The research design was based on mixed methods, allowing the researcher to harness the benefits of both qualitative and quantitative approaches. Data was collected from qualifying candidates through a combination of semi-structured interviews and online surveys.

The following criteria were used to identify eligible individuals for consultation, in line with the research study's objectives.

- Works for a South African mining company
- Works with the Engineering/Maintenance department
- Has over five years of experience in maintenance or digitalisation

4.2 Data Collection Methods and Tools

Literature reviews, surveys, and semi-structured interviews were used to gather information for the study. Scopus and Google Scholar were used to facilitate the scoping review and chart existing literature about the subject matter. A survey with sections comprising of company background, current maintenance practices and human factors was created in Qualtrics and shared with the qualifying participants. To ensure data validity and reliability, the researcher acted as the sole distributor of the surveys and the only interviewer, thereby maintaining consistency in the interpretation of the results. The questions for the survey were pre-tested with fellow scholars and mentors in the field (i.e., peers and study supervisor) to ensure its logical consistency before release. Interviews conducted in person and online were based on the same line of questioning to simplify data aggregation. No data was collected in contravention of the Protection of Personal Information (POPI) Act. The objectives of the study were explained to the respondents prior to the commencement of the survey, allowing them to provide written informed consent to either participate in the study or decline entirely of their own free will.

5 RESULTS

5.1 Introduction

The survey was shared with 36 companies that operate within the South African mining industry. The range of companies included traditional mining companies and technology services companies that provide maintenance digitalisation services (i.e., Internet of Things, systems integrators and digital asset management consulting services). As shown in Table 1: Survey Responses, 86% of the survey responses were valid, allowing for a comprehensive analysis of the data.

Table 1: Survey Responses

Description	Frequency	%
Test Responses	5	7%
Incomplete	6	6%
Valid Responses	54	86%
Total Survey Responses	81	100%

The following sections outline the information that was extracted from the various participants and the analysis thereof.

5.2 Descriptive Statistics

This section provides insight into respondents' roles, experience, organisational type and perspectives on their current maintenance practices. This information was gathered to contextualise the participants' responses by understanding their experiences.

5.2.1 Respondent Profiles

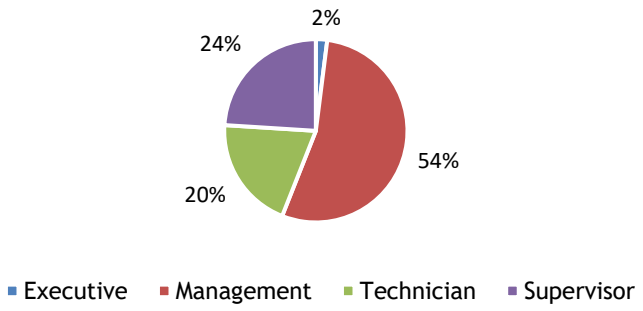

Figure 2: Respondents by Title

The majority of respondents were early to mid-career professionals with up to a decade of work experience, reflecting a strong hands-on practical experience. It should be noted that engagement from executive leadership was minimal, highlighting a potential gap in perspectives related to strategic and long-term organisational objectives.

5.2.2 *Mean, Median, Mode and Interquartile Range*

Respondents were asked to rate the level of satisfaction they had with their organisation's current maintenance practices on a scale of 0 to 10, with 10 signifying extreme satisfaction. The mean, median, mode, and Interquartile range were used to measure satisfaction with current maintenance practices and to derive the overall respondent sentiment. Upon analysis, the mean score for overall satisfaction was 6, as expressed by 30% of the respondents. The

modal value was also 6. Based on the interquartile range, 50% of the scores were clustered between a score of 5 and 7. These results indicate that the current maintenance practices are perceived to be functional but not yet optimised, highlighting room for improvement.

5.2.3 Maintenance Philosophies

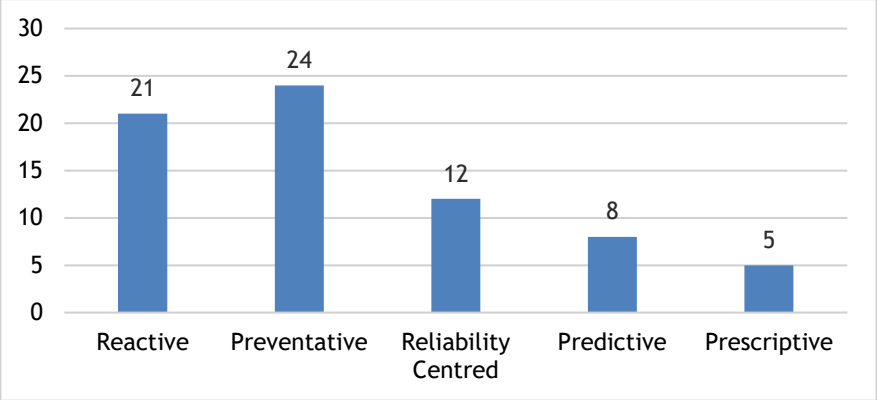

Figure 3: Maintenance Philosophies

64% of respondents indicated that they follow both reactive and preventive maintenance strategies as highlighted by Figure 3: Maintenance Philosophies.

5.2.4 Data Collection Methods

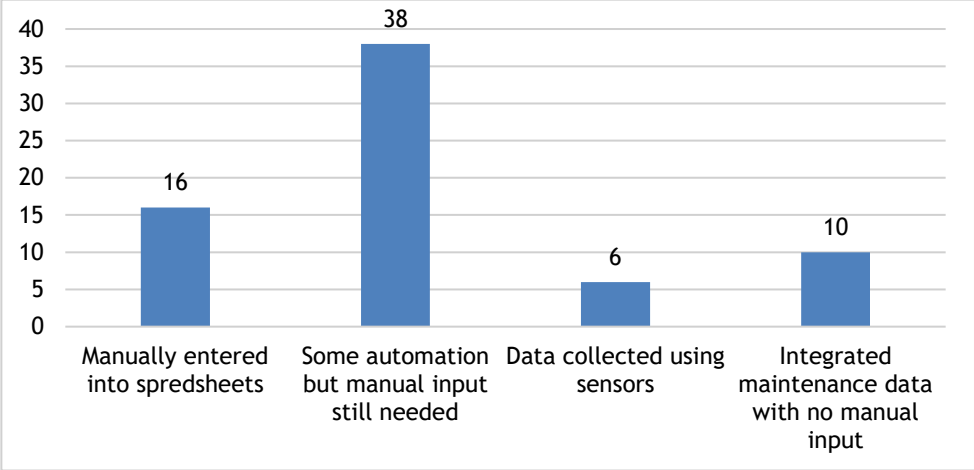

Figure 4: Data Collection Methods

An overwhelming 77% of respondents indicated that they use a combination of manual data capturing methods and have an immature level of automated data capturing. Furthermore, 55% of these respondents added that their organisations do not augment maintenance practices with digital technologies. These findings highlight the risk of computational errors which may compromise the analysis, leading to misinterpretations of the data. Manual data management also means that technicians and supervisors spend a significant amount of time collecting, cleaning, and synthesising the data. This data management approach leads to isolated data sources that may present contradictions, therefore undermining the reliability of the data. Delays in data interpretation limit timely decision-making, leading to missed opportunities for implementing effective maintenance.

5.3 Qualitative Analysis

Respondents were asked to respond to an open-ended question regarding their perceived barriers, benefits and support needed for the successful digitalisation of maintenance data. The survey tool's built-in semantic analyser was used to apply data codification to the different responses, preparing the data for thematic analysis.

5.3.1 Barriers to Maintenance Data Digitisation

Based on the thematic analysis performed, Figure 5: Barriers to maintenance data digitalisation outlines the identified barriers. The most recurring theme was the lack of skills enrichment programs tailored to the vast demographics of the maintenance workforce.

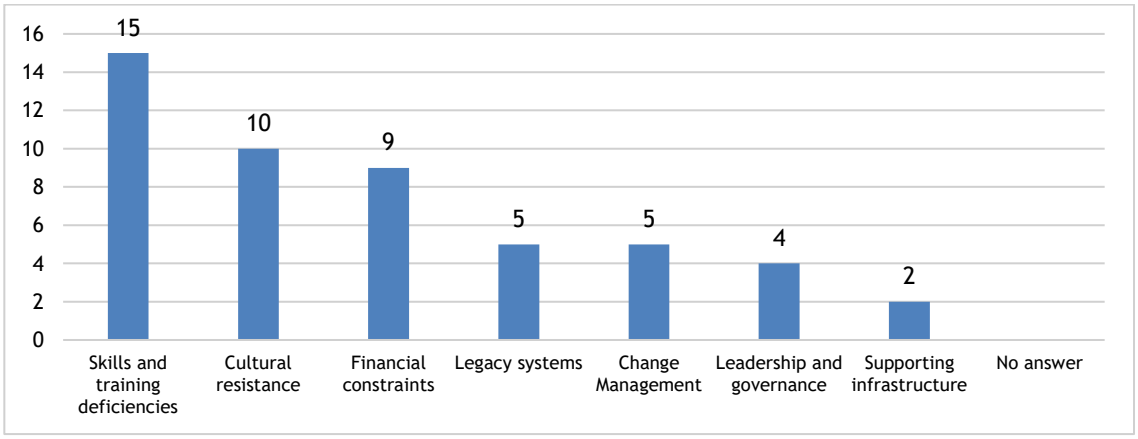

Figure 5: Barriers to maintenance data digitalisation

5.4 Maintenance Data Digitalisation benefits

Organisations that had made strides towards implementing digital technologies to collect and process their maintenance data were asked to comment on some of the key benefits that they had experienced. Based on a thematic analysis conducted, the results are summarised in Figure 6: Maintenance Data Digitalisation Benefits

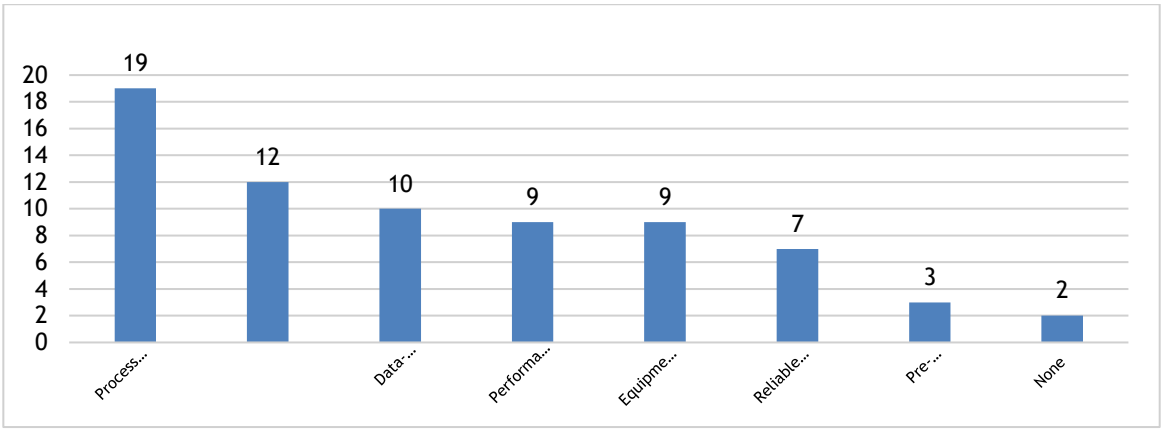

Figure 6: Maintenance Data Digitalisation Benefits

Augmenting technology with optimised workflows enables personnel to spend less time conducting repetitive data management tasks and more time analysing it and drawing conclusions to support equipment uptime. Using technology for data collection allows the data to be centralised, ensuring a single version of the truth about the current state of equipment. Data centralisation simplifies the prospect of information management (e.g., data retrieval, data sharing and processing), creating opportunities for the data to be used for various use

cases. Additionally, the availability of data enables personas such as the reliability engineer and the maintainer to proactively identify issues with equipment, paving the way for predictive maintenance.

5.5 Additional Support Required

Respondents were asked to provide open-ended responses on what they perceive as the support required to empower them in their functions. The findings are presented in Figure 7: Digitalisation Support Required.

Notably, 50% of the responses focus on the need to raise awareness regarding emerging technologies and invest in training programs to upskill the workforce in effectively utilising these technologies.

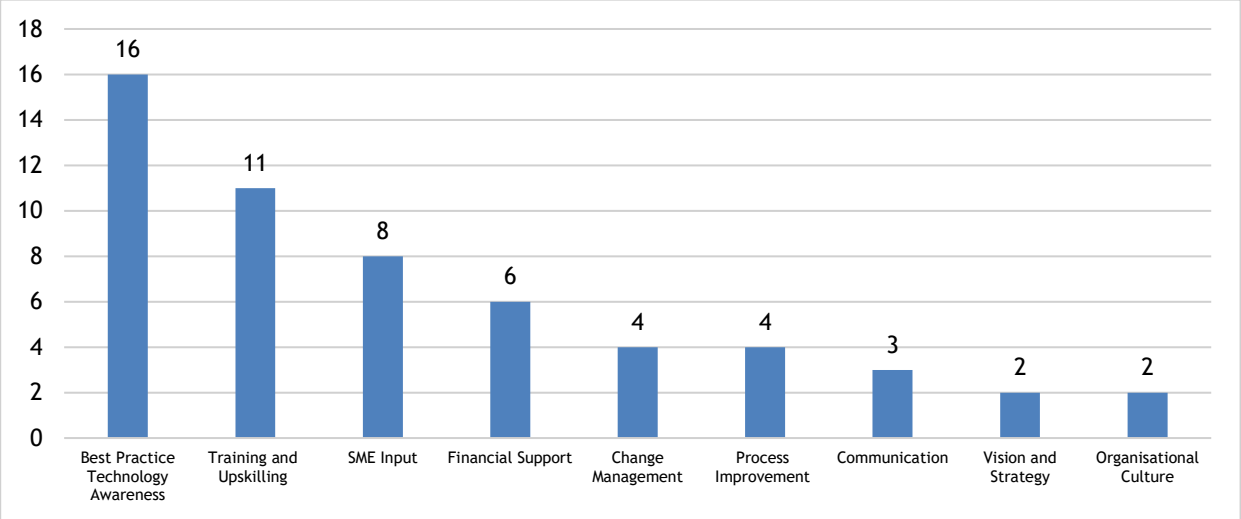

Figure 7: Digitalisation Support Required

6 CONCLUSION AND RECOMMENDATION

6.1 Summary of key findings

The South African mining industry is undergoing a transitional phase in adopting digital maintenance data. The dominant use of reactive and preventive maintenance, alongside manual data capturing through spreadsheets, suggests that while maintenance systems are in place, they often lack the intelligence and agility that digital technologies can offer. This presents a significant risk of data fragmentation, potential human error, and latency in decision-making, thereby hindering the adoption of predictive and performance-oriented maintenance strategies.

The study also highlighted critical barriers to broader digitalisation efforts. The lack of skills and training, cultural resistance to change, and financial constraints were some of the most frequently cited challenges. These factors suggest that the limitations to widespread maintenance digital transformation are not merely technical but also organisational and behavioural. The lack of clearly defined digital strategies that complement the business strategies also adds to some of the top barriers. Mining organisations understand the need for such a strategy; however, due to pressures to perform and deliver in the near term, there is little focus on the mid-term (tactical) and long-term (strategic) aspects of maintenance management. Organisations that have defined their digitalisation implementation plans are still in the infancy stages of realising value, suggesting that the South African mining industry is still warming up to Maintenance 4.0.

Despite these limitations, organisations that have adopted digital maintenance technologies have experienced notable benefits. The most common benefits are enhanced process efficiency, advanced information management and data-driven decision-making. These benefits demonstrate a clear correlation between digital adoption and improved operational and strategic outcomes, particularly in areas such as equipment performance, data reliability, and predictive maintenance. The conceptual model for this study has been revised to provide guidance on how South African mining organisation can phase their maintenance data digitalisation efforts as presented in Figure 8: Adapted Maintenance Data Digitalisation Framework.

6.2 Conclusion

6.2.1 Theoretical Framework Factors

The following factors were identified and validated through the study in comparison to the work of [16] carried out in the manufacturing industry. These factors were raised in the survey responses and interviews.

- Management commitment and support
- Smart technology development
- Organisational growth
- Development of a skilled and empowered workforce
- Resources required for digitalisation
- Maintenance strategy development
- Corporate culture
- Change in working practices
- Safety and health awareness
- Data privacy and security

6.2.2 Prepositions

Preposition 1: The adoption of digitalisation tools for maintenance will improve the effectiveness of Maintenance within South African mining companies.

The first proposition was validated based on the cited benefits realised by organisations implementing maintenance practices. Organisations that had successfully adopted digital tools experienced improved access to their data, enhanced remote monitoring of equipment, and improved process efficiency, allowing the workforce more time to conduct other value-added activities.

Proposition 2: Organisational culture moderates the relationship between digitalised maintenance data and maintenance performance.

The second proposition was also validated. The data indicates that having the tools at one's disposal is not enough. Social factors, such as change management and willingness to learn, contribute to the successful implementation of digital maintenance data. Organisations must develop comprehensive change management programs that address this aspect.

Proposition 3: Organisations that use digitised maintenance data experience superior maintenance performance than organisations that rely on traditional maintenance data collection practices.

The third and final proposition could not be validated statistically due to the lack of access to formal maintenance performance reports and metrics (e.g., OEE data, downtime logs). The proposition was however validated through perception-based measures captured in the survey responses. Analysis of the responses indicates that organisations reporting higher adoption of digitised maintenance practices also consistently perceived superior outcomes across these performance dimensions when compared to organisations relying on traditional, manual data collection. This validation is consistent with the literature study.

6.3 Revised Framework for Maintenance Data Digitalisation

Based on the findings of this study, the following guidelines have been developed to guide organisations in adopting maintenance data digitalisation efforts.

Step 1: Perform a structured organisational diagnosis

Establish a clear understanding of the organisation's operating environment, maintenance practices and digital maturity to align technology integration with business needs and priorities.

I. Stakeholder Engagement

- Conduct structured interviews/workshops with stakeholders including maintenance managers, reliability engineers, IT personnel, technicians, digital value chain leads and executive leadership to capture current maintenance challenges, digital priorities and readiness for transformation

II. Current State Assessment

- Map existing maintenance processes, workflows, tools and reporting structures
- Document how maintenance data is captured, stored and processed

III. Digital Maturity Analysis

- Use a verified digital capability maturity framework to benchmark the organisation in terms of data management, automation and decision making
- Identify gaps across people, processes and technology between current capabilities and desired future state

IV. Business Context Analysis

- Align findings with operational, tactical and strategic organisational goals (e.g., productivity improvement, cost reduction, improved safety or sustainability)

Artefacts to be produced:

- AS-IS report detailing business processes, tools in use, current challenges and an understanding of current maintenance ecosystem, digital readiness and identification of critical areas where maintenance digitalisation can add value
- Stakeholder map showing roles and responsibilities, reporting line and hierarchies
- Context alignment matrix showing relating maintenance needs and organisation objectives

Step 2: Assess Barriers

Assess the prevalent barriers to digital transformation across the critical factors (i.e., strategy, leadership, culture, people, governance, technology, and economy)

I. **Barrier Identification Workshops**

- Facilitate workshops with cross-functional teams to identify barriers from the wider workforce

II. **Categorisation of Barriers**

- Group the identified barriers under Strategy, Leadership, Culture, People, Governance, Technology and Economic/Financial

III. **Conduct a Barrier Intensity Assessment**

- Apply a scoring framework (High, Medium or Low) across the following criteria:
    - **Impact:** Degree to which the barrier hinders digitalisation efforts
    - **Likelihood:** Probability of the barrier persisting if there is no intervention

IV. **Root Cause Analysis**

- Conduct root cause analysis for high priority barriers using lean tools such as the 5-Whys and/or Fishbone diagrams

Artefacts

- Barrier Inventory Register across the seven themes
- Barrier Heat Map visual based on intensity (impact and likelihood)
- Root cause analysis report detailing structural and systemic causes

Step 3: Develop Mitigation Actions

Develop tailored actions to address the prevalent barriers across the various themes. These actions must be measurable in terms of both time and performance.

I. **Barrier-to-Action Mapping**

- Translate each high/medium priority barrier into one or more mitigation actions, ensuring that each action is linked to a barrier root cause

II. **Define Action Framework**

- Define SMART (Specific, Measurable, Achievable, Relevant, Time-bound) actions
- Group actions into short-term (0-6 months), medium-term (6 – 18 months) and long-term (18+ months) interventions, based on effort and impact
- Use a RACI (Responsible, Accountable, Consulted and Informed) matrix to assign the actions to owners

III. **Establish Monitoring and Evaluation Mechanisms**

- Define KPIs and success measures for each action
- Establish a cadence (monthly/quarterly) to review progress of KPIs

Artefacts

- Mitigation Actions for each barrier and root cause
- Action Roadmap detailing time horizon for each mitigation action
- RACI Chart (roles and responsibilities per action)
- KPI score card to track action, progress and impact

Step 4: Develop a Maintenance Data Digitalisation Strategy

Formalise and implement a digitalisation strategy that outlines measurable key goals and objectives of maintenance data digitalisation.

I. **Set Scope and Boundaries**

- Use steps 1-3 to define the data digitalisation sequence (e.g., critical assets first, high-maintenance equipment second, etc)
- Determine integration requirements required to support future state business processes (i.e., which systems must communicate in order to achieve desired goals)

II. **Roadmap and Milestones**

- Create a phased technology roadmap (short-term, medium-term and long-term) and align it with mitigation actions

III. **Establish Governance and Control Mechanisms**

- Define data governance policies (data ownership, quality standards, etc)
- Establish cadence for reviews and audits

IV. **Change Management and Communication**

- Launch a Change Management Program to communicate the upcoming change, impact and benefits to frontline workers

Artefacts:

- Digital Strategy document
- Implementation roadmap with milestones
- KPI framework and dashboard
- Change Management plan

Step 5: Deploy Relevant Digital Technologies

Identify, select and deploy digital technologies that enable the effective capturing, processing and utilisation of maintenance data

I. **Technology Selection and prioritisation**

- Evaluate technology options based on identified needs and objectives
- Conduct a cost benefit analysis of the technology options on hand considering scalability, vendor maturity and integration capabilities
- Select technologies for phased deployment, starting with high-impact and low-cost initiatives (i.e., quick wins)

II. **Pilot Projects**

- Run controlled pilots of selected technology on sampled assets and processes
- Capture lessons learned, and use lessons to refine full deployment

III. **Change Enablement and Training**

- Provide hands-on training to impacted stakeholders on using new tools

- Identify digital champions among frontline workers to drive peer learning
- Establish support structures to maintain and sustain the transformation

Artefacts to be produced:

- Technology deployment plan
- Vendor evaluation matrix
- Training material and user guides

Figure 8: Adapted Maintenance Data Digitalisation Framework highlights the refined conceptual model.

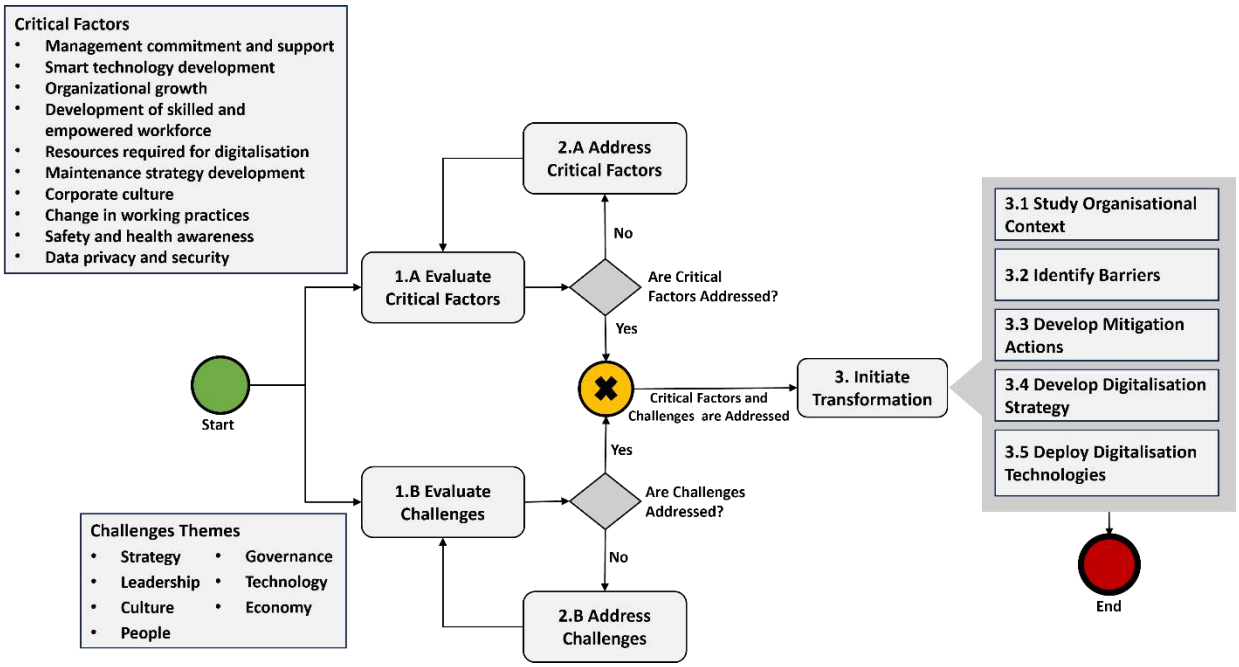

Figure 8: Adapted Maintenance Data Digitalisation Framework

6.4 Contributions of the study

The conceptual framework for this study was originally developed for the manufacturing industry but was adapted for this study on the premise that both manufacturing and mining industries rely fundamentally on the optimal functioning of engineering assets to generate economic value. The results of the study demonstrate that the linkage of these sectors is not only conceptual but also operational, as confirmed through the responses of maintenance personnel in the South African mining industry. By validating the applicability of the theoretical model within this new context, the study provides evidence of its transferability and robustness beyond its initial domain of conception.

Furthermore, the study makes a significant contribution by identifying barriers that hinder the adoption of digital maintenance practices in the South African mining context. In doing so, it offers decision-makers a structured approach to anticipate, prioritise, and address the critical organisational, technological, and human factors that could otherwise undermine maintenance data digitalisation efforts. This enables organisations to mitigate risks before undertaking full-scale digitalisation implementation, thereby improving the likelihood of successful transformation.

Due to the constraints of the study, the framework was only validated within the mining context, it does however exhibit strong potential for generalisability to other asset-intensive

industries, including energy, transportation, and utilities, which share comparable dependencies of asset reliability and face similar digitalisation challenges.

ABSTRACT

Systems Engineering (SE) must confront increasing complexity with innovative methods and tools to enhance its processes and decision-making. Integrating Artificial Intelligence (AI) into SE tools has the potential to assist in handling all sorts of complexities. In this study, we apply Cognitive Work Analysis (CWA), a framework for modelling complex sociotechnical systems, to analyse SE processes' fundamental structures and constraints. Through CWA, the research identifies potential areas where the integration of AI could serve as an enabling element to upgrade SE practices. With AI embedded into the CWA model, this study aims to evaluate how AI can assist in further decision-making, adaptability, and task performance within SE domains. Initial findings reveal that AI could help conduct complex analyses more easily while allowing for efficiency and support in dynamic responses to system constraints. The results offer valuable insights to researchers and practitioners who seek ways to improve SE capabilities in an ever more interconnected and complex world.

1 INTRODUCTION

Increased system complexity has forced Systems Engineering (SE) to play a vast and crucial role in grappling with multi-faceted technical and organisational problems. SE must consider complicated technical specifications, stakeholder interest, the fast pace of technological change, and operating environment dangers [1]. As SE develops in such sociotechnical contexts, the view is gaining support among SE researchers that human cognition plays a vital role in system design and integration [2]. This requires different tools to analyse how SE is practised and where modern technologies, most conspicuously Artificial Intelligence (AI), can help manage complexity.

AI technologies, especially those at the forefront, such as the Large Language Models (LLMs), can assist the cognitive work of systems engineers by automating, enhancing, or transforming a taxonomy of tasks traditionally dependent on human judgment. Injecting AI into SE is not merely the next technical refresh; it is about the reconfiguration of workflows, redefinition of decision points, and re-examining human-machine interaction within a sociotechnical framework [3, 4]. To make sense of and govern such an integration, it is imperative to have a framework that encapsulates the intricacies of SE both as a technical and cognitive activity.

When it comes to applying AI in SE, the framework must identify the impacts of this “new” technology on the SE process and indicate its contribution to managing complexity. The framework needs to distil the cognitive processes in SE before inserting the AI capabilities to make the differences explicit. The prominence of the term Sociotechnical System (STS) is increasing in SE literature [5]. While definitions may differ, the common understanding is that STSs are about both social (people) and technical components [6].

This recognition is essential since systems engineers strive to solve technical challenges and societal considerations, which aligns with a vision such as the International Council on Systems Engineering (INCOSE) Vision 2035 [7]. By its very nature, SE is concerned with integrating heterogeneous elements such as people, processes, tools, and technologies to develop and manage complex systems. This fits with the STS concept, which accentuates the interdependence of social and technical elements within organisational settings. Viewing SE as an STS helps underline social and technical concerns as important considerations in engineering approaches.

For that reason, Cognitive Work Analysis (CWA) will be used to develop the AI integration framework for this paper. CWA is a well-established method for modelling complex STSs, emphasising constraints, goals, tasks, strategies, social interactions, and competencies involved in real-world work [8, 9]. Applying CWA to the SE process will systematically expose cognition and structural dimensions of SE, including mapping how AI can embed to support or disrupt those dimensions.

CWA provides a systematic methodology to analyse the complex interactions between your system's social and technical elements, leading to more effective and adaptable system designs. Therefore, applying CWA to the SE process should expose the cognitive aspects of SE. AI also has cognitive-like characteristics, making CWA lend itself well to considering its potential impact as a new tool in the SE process in the modern complex world. The analysis in this paper focuses primarily on the Work Domain Analysis (WDA) phase of CWA, using it to construct an Abstraction Hierarchy (AH) model that captures SE’s functional purposes, processes, and tools across system life cycle stages [10, 11].

The research approach follows a qualitative, design-science methodology. It begins with a generic SE process model based on international standards and the INCOSE SE Handbook [1], which is then deconstructed through the WDA to identify where and how AI tools can contribute. The resulting models serve as analytical artefacts and practical guides for

identifying high-value opportunities for AI integration. Future work will extend this analysis across additional CWA phases to further explore control task analysis, task strategies, organisational factors, and human competencies [5, 6, 7].

A scoping study has established the state of the art regarding the use of Artificial Intelligence for for Systems Engineering (AI4SE). AI features such as Machine Learning (ML), automated design exploration, generative design, Natural Language Processing (NLP), Large Language Models (LLM) were identified as some of the key AI approaches that can be used in the broader SE domain [12].

2 METHOD

Performing a CWA on the SE process requires a carefully planned research approach, drawing on qualitative research methods and systems modelling methods. Existing literature on applying CWA in organisational and design settings suggests using a case study or field study approach enriched with expert input to gather the necessary data for each analysis phase [9, 13]. The CWA is iterative and integrative. Insights from one phase may lead to refinements in another. The whole CWA process provides an in-depth, iterative analysis of the work domain, environmental constraints, and users' tasks and knowledge requirements (in this case, the practitioners of the SE process). The end result is a set of models/diagrams and structured information that collectively describe the SE process in sociotechnical terms.

Therefore, the first step is to analyse and delineate the scope of the SE process in the form of a generic SE workflow model derived from standards. The goal is to gather sufficient information to populate all CWA modelling levels from high-level objectives down to individual decision-making processes. The WDA provides a blueprint of the SE work domain –a map of what needs to be achieved and what means are available. It can illuminate how different technologies or methods contribute to SE goals, helping foresee how changes, such as adopting a new modelling tool, might ripple through the process [10].

Performing the WDA will first identify the core purpose of the SE process, its values and priorities (e.g. deliver a safe, effective system; meet stakeholder needs; adhere to cost/schedule), the functions and processes that make up SE (requirements analysis, trade studies, integration, verification, etc.), and the physical or informational resources used (tools, models, documents, teams). These are often captured in an Abstraction (and Decomposition) Hierarchy model, which links the high-level purposes to the functional activities and the physical elements that support them. For example, an AH might reveal that a value like “minimise project risk” is supported by risk analysis and design review, which rely on concrete resources like simulation software, review meetings, and expert knowledge [11].

From a research design standpoint, performing CWA on the SE process can be framed within the design science research paradigm or a qualitative SE research method. Design science research is appropriate because it focuses on creating and evaluating artefacts (here, the CWA models and possibly improved process designs) to solve identified problems. It emphasises a rigorous process of problem identification, artefact development (the models), demonstration, and evaluation, which aligns well with how a CWA study would proceed [3].

3 BACKGROUND

3.1 Systems Engineering

Over the past decades, SE has matured and established itself as a suite of robust interdisciplinary methodologies that facilitate the successful development of complex systems. It integrates various engineering domains and technical specialisations into a coherent and structured process, spanning the entire system lifecycle—from initial concept development through to production, deployment, and sustained operation [14]. Importantly, SE practice is domain-agnostic with standards like ISO/IEC/IEEE 15288 that define generic life

cycle processes for any system created by humans [15]. These methodologies systematically address technical and organisational challenges across various sectors, including aerospace, defence, automotive, energy, healthcare, and manufacturing [14], [15].

SE is fundamentally concerned with systems' design, integration, and management throughout their entire lifecycle. Its practices aim to enhance system efficiency, quality, and performance while managing cost and mitigating risk. At its core, SE strongly emphasises understanding stakeholder needs and defining system functionality at the project's outset. This includes maintaining a holistic, system-wide perspective while eliciting and documenting requirements, system design and performance validation [16]. A critical contribution of SE lies in its ability to manage the inherent complexity of modern systems. Therefore, key and fundamental focus areas in SE include [16]:

- **Requirements Engineering**: Identifying, analysing, and documenting stakeholder needs to derive system requirements.
- **System Design**: Developing a system architecture and design specifications that address the system requirements.
- **Integration and Testing**: Implementing and combining system components and verifying their correct interaction and performance.
- **Verification and Validation**: Ensuring the system meets its requirements through verification and fulfils its intended purpose in its operational environment with validation.

Traditionally, SE focused more on the technical integration of system components, but modern thinking recognises that the SE process is embedded in an STS context. Therefore, performing SE is not just a technical endeavour because it involves people, tools, procedures, and organisational structures interacting as a unified system to manage complex problems.

3.2 Socio-technical Systems

An STS encompasses social and technical elements, emphasising the interaction and interdependence between people, technology, and the organisational environment in achieving system goals. This concept recognises that technical systems (e.g., software, hardware, tools) and social systems (e.g., human roles, culture, communication) must be designed and managed to optimise overall performance and effectiveness [4, 17]. An STS is typically defined as a combination of humans applying technology to perform work through processes within a social structure to achieve a particular objective [3]. The SE process fits this definition: it comprises human teams (social), engineering methods and tools (technical), and defined workflows within an organisation, all aimed at delivering a system that meets stakeholders' needs. System engineers and other stakeholders use SE processes and tools to perform the system engineering function. It is a complex interaction between people and technical systems.

Complex engineering projects often exhibit emergent behaviour and unanticipated social and technical interactions, especially when introducing new technologies or processes. A traditional reductionist approach (breaking a problem into isolated components) can miss these emergent properties. Simply decomposing a system and designing components in isolation may overlook changes needed in information flows, roles, or procedures when a new technology is integrated into a socio-technical environment. If such social-technical interactions or newly "emerging requirements" are ignored, the result can be misaligned systems or outright failures in practice. In short, the success of a complex system depends not only on its technical soundness but also on how well the engineering process accounts for human and organisational factors [4].

The STS theory itself underlines the inseparability of social and technical elements. At the core of this theory is the notion that the performance of a complex system "can only work satisfactorily if the 'social' and the 'technical' are considered together". Optimising purely technical subsystems while neglecting human/workplace aspects leads to sub-optimal outcomes. SE practices must be coupled with understanding team dynamics, user needs, and organisational context. Baxter and Sommerville [2] argue for a socio-technical SE framework that bridges traditional engineering with considerations of work design, human-computer interaction, and organisational factors. Embracing the SE process as an STS applicable across domains and over the whole life cycle ensures that critical human factors (communication, decision-making, teamwork) and technical factors (methods, tools, technologies) are addressed in tandem at every stage [18].

Treating the SE process as an STS provides a broader, more realistic model of executing complex projects. It acknowledges that SE involves a complex interaction between social humans and technical systems [3]. By adopting an STS perspective, we can better manage emergent behaviour, align system development with organisational needs, and ultimately deliver robust and well-integrated systems into their operational context [19]. This sets the stage for implementing AI tools to improve the SE process.

3.3 Artificial Intelligence

AI is, in essence, computer programs created to engage in activities requiring human intelligence if done by humans, such as learning, reasoning, problem-solving, perception, and understanding natural language [20]. This recent surge in AI development has enhanced its use in healthcare, finance, transport, and education industries. In healthcare activities, AI exhibits assistance in diagnosis and personalised treatments [21]. It is a powerful financial fraud detection tool and implements advanced trading techniques. AI can smooth the way for intelligent automobiles and smart city infrastructures, thus enhancing safety and efficiency. Education is another industry where AI-based personalised learning models promote better accessibility and efficacy. This is where a widely accepted AI begins industrial revolutions, hence innovations and disruptions of computer-human interface. However, the question that perhaps arises is: How can AI be used within and for SE tools in the SE process?

Public awareness regarding LLMs has increased since ChatGPT launched at the end of 2022. Increasingly, these models are used for writing various forms of formal creative and technical content, triggered only through the natural language prompt, enabling the user to specify the information and style they want. SE activities involve considerable language use, including gathering, documenting, and validating system requirements from stakeholders. The explicit nature of this language makes these tasks suitable for AI support [22, 23].

This study analysed how AI could be incorporated into the SE development process to tackle the rising complexity of systems and assist in better decision-making. AI technologies can automate operations, improve efficiency, and foster innovation by generating adaptive and resilient systems that react to real-time data and varying conditions. Hence, integrating AI with SE systems may lead to significant benefits like cost savings, efficient resource allocation, and superior user experiences. AI-powered systems give companies competitive advantages because they provide new capabilities and functionalities, which are much needed in today's and tomorrow's technological market.

3.4 Cognitive Work Analysis

CWA enables the assessment and design of complex STSs, especially in dynamic environments where human operators interact with technology. It was developed mainly to understand how people cope with unforeseen situations and adapt to evolving environments [24]. The use of CWA applied to SE offers several advantages [25, 26, 27]:

- **Understanding Work Constraints**: CWA looks at the constraints imposed by the work environment and helps analyse how systems can support different work practices, but it does not prescribe particular procedures. This is especially useful in SE, where flexibility and adaptability are required.
- **Modelling Complex Interactions**: With the help of tools like the AH, CWA allows the representation of interactions at different levels of systems, from goals at the highest level down to physical components. This holistic view helps us understand how various aspects of the SE process interact and affect each other.
- **Enhancing System Design**: Cognitive-dependent systems will probably be more resilient and susceptible to alignment with human thoughts. For instance, studies demonstrated that CWA is conducive to system design when considering the complex interactions that characterise human-machine relations in different domains.
- **Supporting Decision-Making**: Using CWA allows one to analyse decision-making methods in SE, with possible improvement and optimisation areas emerging due to the capabilities of a new technology.

The key phases of CWA are discussed below.

3.4.1 Work Domain Analysis

The first phase of CWA focuses on understanding the system and the operating domain's structure and constraints without considering the operator's specific tasks or goals. It represents the system's operation under all normal and abnormal conditions [28]. The WDA uses the AH tool, representing the system at multiple levels, from physical components to high-level system purposes. The AH is a method for modelling complex socio-technical systems, representing the functional relationships at different levels of abstraction, from the system's purpose to its physical form [10]. In addressing the research questions, the AH provides a framework to identify the impacts at the different levels. This will enable a focus on the relevant areas that are affected. Below is a template for creating an AH, typically organised into five levels [11].

Table 1: Abstraction Hierarchy Description

Level	Description
Functional Purpose	The overall purpose or goal of the system
Abstract Function	The high-level principles or concepts that fulfil the system's purpose
Generalised Function	The processes or tasks that need to be performed to achieve abstract functions
Physical Function	The physical actions or operations required to carry out the tasks
Physical Form	The hardware, software, or physical entities involved in the system

By identifying these levels, it becomes possible to investigate the impact of AI on this world in a structured manner and provide meaning and context to the different types of functions. This categorisation then helps define the effects at the various levels.

3.4.2 Control Task Analysis (ConTA)

This phase identifies the tasks or functions required for operating within the system. It focuses on what needs to be done rather than who does it or how it is done. The goal is to understand the functional requirements that must be satisfied under various operating conditions. Understanding functional requirements is fundamental within SE. Applying this principle to SE

by investigating what has to be done will lead to some clarity on research questions aimed at finding where the most potential benefit of AI for SE is [29].

3.4.3 Strategies Analysis

This level explores different strategies or methods that can be used to perform the identified tasks. It identifies various ways operators can achieve the system's goals, given the flexibility and constraints of the system. By investigating how specific tasks can be done from a strategic perspective, guidance is given towards answering the research questions of how AI can best benefit SE [10, 28].

3.4.4 Social and Organisational Analysis

This phase addresses the interactions between people, teams, and the organisation. It focuses on communication, coordination, and allocating roles and responsibilities. It helps in understanding how social factors and organisational structures influence system performance. Social factors are essential when introducing change into an established discipline. Issues like trust in the technical systems, such as AI tools being added to SE, are paramount. All relevant communication, roles and the like have a strong bearing on factors that affect the questions of crucial factors that contribute to the successful adoption of AI in SE [10, 28, 30].

3.4.5 Worker Competency Analysis

The final phase deals with individual competencies, such as knowledge, skills, and abilities needed to perform tasks. It links the design of functions and systems to the cognitive capabilities of the operator. The required competencies of system engineers lead to a specific type of skill profile found in System Engineering. Understanding what factors in this typical profile may aid or deter the successful use of AI in SE will guide answering the research questions regarding the critical factors for successful adoption [28, 29].

3.4.6 Summary of CWA Phases and Methods

The diagram below is a graphical summary of the CWA phases and methods. Each phase uses particular methods and may influence the other phases. This research focuses on the WDA, focusing on the purpose, abstraction and decomposition of SE. The other phases will be conducted in future research.

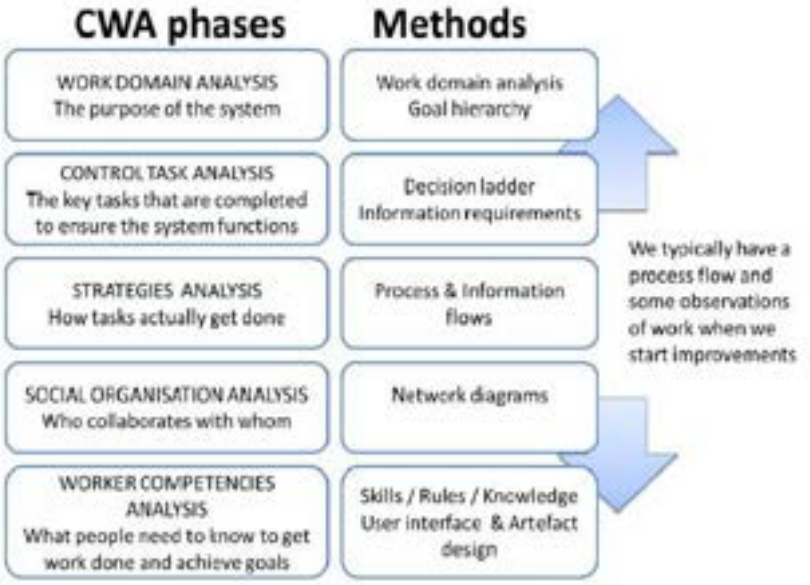

Fig. 1 Graphical Summary of CWA phases and methods [31]**.**

3.5 Modelling the Systems Engineering Process with Cognitive Work Analysis

A CWA offers a powerful model and analysis framework because the SE process is an STS with inherent complexity. As a conceptual framework, it was initially developed to model complex STSs that focus on understanding work constraints (instead of prescribing specific task procedures) [32]. In essence, CWA provides a multi-dimensional, formative analysis of an activity or process, helping to uncover the deep structure of work – the goals, constraints, decisions, strategies, and interactions that shape how the work gets done [28]. Therefore, CWA is useful for examining the SE process:

- **Holistic, Constraint-Based Modelling**: CWA enables analysts to construct a structured model of the work domain of SE, capturing its purposes, functions, values, and resources in an AH. This helps make explicit the goals and constraints under which systems engineers operate. By focusing on fundamental constraints (e.g. safety, budget, stakeholder goals) rather than just sequences of tasks, CWA reveals why certain engineering activities are necessary and how technical and organisational limits bound them. Such insight is invaluable for SE and often reconciles conflicting constraints (performance vs. cost, technical requirements vs. human capabilities). Modelling the SE process via a WDA can, for example, link the functions provided by different engineering tools or methods to the higher-level objectives and requirements of the project. This ensures that any analysis or improvement of the SE process keeps the overall system purpose in view [3].
- **Handling Complexity and Emergence**: Because CWA is a formative analysis (it explores the space of possible activities under varying conditions), it is well-suited to dealing with unanticipated events and emergent behaviours. SE processes must often adapt to changes, such as new stakeholder needs, technology insertion, or unexpected problems. A CWA model of the SE process is "event independent", meaning it is not tied to one specific scenario; instead, it characterises the constraints and affordances that apply across many situations. Analysts can ask "what if" questions and foresee how the engineering process might respond to novel challenges or failures. During requirements, analysis helped uncover potential emergent requirements and design implications when introducing new technology. Traditional methods might overlook such emergent interactions, but the CWA model exposes them, thus helping to mitigate undesirable outcomes early. In general, by capturing the invariant structure of the work (the underlying rationale and relationships), CWA supports more resilient process designs that remain effective even as conditions change [4].
- **Integration of Social and Cognitive Factors**: The SE process is carried out by people (systems engineers, designers, testers, managers, etc.) who's decision-making and collaboration significantly impact success. CWA explicitly accounts for the cognitive and cooperative aspects of work. Beyond mapping the domain's physical and functional structure, later phases of CWA examine tasks/activities, the strategies people use, how work is shared among roles, and the competencies needed. This is crucial for SE as it highlights how information is propagated, how decisions are made under pressure, and where there may be bottlenecks or mismatches between human capabilities and process demands [25,33]. Applying this to SE, CWA treats the engineering team and tools as a joint system, thereby identifying opportunities to support better human cognitive work through improved decision support tools or process adjustments [34].
- **Proven Utility in Abstract Domains**: While CWA originated in analysing operational environments like nuclear power plants or aviation, its utility has extended to more abstract, process-oriented domains. It can be applied to analyse and design engineering processes and methodologies. CWA is not limited to examining how humans interact with a finished system; it can also discuss how humans work to create a system. This makes it an appropriate choice for studying the SE process, which involves

abstract activities like requirement negotiation, trade-off analysis, and collaborative design. Modelling the SE process with CWA provides a rigorous, human-centred analytic view, helping improve the process and ensuring that engineered systems are developed with full awareness of social and technical constraints [4, 35].

SE promotes a holistic framework wherein diverse elements such as user experience, cognitive ergonomics, and operational constraints are interwoven [2]. It is precisely in this space that conceptual frameworks like CWA significantly overlap with SE. Both disciplines strive to optimise complex systems by understanding and leveraging the intricate interplay between human cognition and physical tools [10]. Applying CWA to a system aligns naturally with the layered structure of SE. Both frameworks have a fundamental separation between abstract and physical dimensions. In SE, abstract user needs are progressively transformed into user requirements, system requirements, system architecture, detailed design, and physical implementation [1]. CWA's AH provides a rigorous method for modelling this separation, allowing systematic tracing of how decisions and constraints at one level impact other levels [11]. Performing CWA on SE is analogous to performing SE on the SE process itself [34]. As the cognitive aspects of SE are examined, the analyst must ask: What cognitive functions are system engineers performing? How do these cognitive functions relate to the physical tools and actions involved in SE? [35].

Physical artefacts in SE (software, documents, models) do not themselves exhibit cognition—they are manipulated and interpreted by human engineers [29]. However, modern computer systems augment human cognition by enabling data storage, management, transport, and transformation, allowing the human mind to focus on higher-level cognitive tasks [32]. AI technologies now introduce a further shift. While not truly cognitive, AI employs statistical and algorithmic techniques to perform functions traditionally attributed to human cognition [20, 21]. Recent advances, particularly in Large Language Models (LLMs), have made this capability highly visible [22, 23].

This raises an important question when applying CWA to AI-enabled SE tools: At what level in the AH does an AI tool reside? Physically, it is hardware and software. Yet, the tasks it performs may be classified, at least from the observer's perspective, as cognitive [28]. This challenges traditional views of role allocation in SE and necessitates careful modelling of AI's impact on the human-machine division of labour [34, 36]. With AI capabilities, cognitive functions that were once the sole domain of humans are increasingly being offloaded onto physical systems [32, 33]. The traditional view that only predictable, repetitive tasks should be automated is no longer valid [18, 37].

When seeking areas where AI can offload human cognitive functions in SE, the most promising opportunities are those deemed tedious, error-prone, or cognitively fatiguing [22, 36]. Many engineers would welcome AI tools that remove such tedium and improve consistency, provided trust and transparency are adequately addressed [36, 37]. By applying CWA in this context, we can systematically identify which SE tasks are suitable for cognitive offloading, where AI integration may yield the most value, and how to preserve human oversight and accountability in AI-augmented workflows [10, 18].

Therefore, CWA offers a means to systematically analyse the SE process as a complex sociotechnical work system. It clarifies the purposes and constraints governing SE activities, accommodates the unpredictability of real-world projects, and keeps human and organisational factors at the forefront of analysis. By doing so, CWA can support the design of better SE processes. Indeed, a structured CWA of the SE process can become a tool for process improvement, for instance, identifying where new methods or tools are needed, where communication breakdowns might occur, or how to structure teams for maximum effectiveness. This aligns with the broader goal of the INCOSE SE Vision 2035: to expand SE's

capability to address social and human elements in system development. CWA provides the analytical framework to realise that vision in practice [7, 17].

3.6 Requirements Engineering

Requirements Engineering (RE) software tools are explicitly intended for authoring, eliciting, capturing, analysing, classifying, valuing, validating, specifying, communicating, measuring the quality of, verifying, and managing requirements [16]. These capabilities are foundational to ensuring that the engineered system ultimately satisfies stakeholder needs and system objectives [1]. Within the broader scope of SE, the verification and validation processes also serve as critical pillars that bridge the conceptual realm of user needs with the tangible outcomes of system implementation. These steps ensure that what is built aligns with what was envisioned, maintaining accountability and coherence across all layers of system development [15]. At the heart of this is the iterative refinement of requirements, from high-level user needs to detailed technical specifications [2].

Toolchains designed for RE play a pivotal role in enabling this iterative refinement. By employing advanced software capable of modelling, simulating, and visualising complex systems, engineers can anticipate downstream challenges and address them early in the design phase [3, 27]. This proactive approach is particularly critical in layered systems where interactions between abstract and physical elements can introduce emergent complexities that are otherwise difficult to manage [18]. The traditional RE methods and techniques are not entirely suitable for meeting the needs of Industry 4.0 systems. Many opportunities remain to improve RE [38]. AI-enabled systems are strong candidates for enhancing the current shortcomings present in RE.

4 WORK DOMAIN ANALYSIS APPLIED TO SYSTEM ENGINEERING

The abstraction hierarchy in Table 2 offers a clear and systematic way to understand and manage the SE process as an STS by organizing it across multiple layers of abstraction, each serving a distinct role in the SE process. An abstraction hierarchy provides an activity-independent representation of a work domain's intentional and physical capabilities and constraints. It is structured as a two-dimensional matrix. The vertical axis represents an AH comprising five levels: system purpose, domain values, domain functions, technical functions, and physical objects. The horizontal axis captures a decomposition hierarchy, reflecting the levels identified during analysis as necessary for understanding the functional structure of the work system. We can view the physical form as a tool at the lowest level of the hierarchy.

At the highest level, the Functional Purpose defines the fundamental reason for the system's existence. This purpose is not technical in itself but speaks to the mission or business goal that the system must achieve. In the context of an STS, which integrates human, organizational, and technological elements, this purpose typically addresses broad societal needs, organizational objectives, or market demands. Considering the abstraction hierarchy categories, deriving an abstraction hierarchy of the SE process begins with identifying the following functional purpose of SE:

"The purpose of SE is to conceive, develop, produce, utilise, support and retire the right product or service within budget and schedule constraints." [1]

As seen in the top level in Table 2, the SE process is about application within each life cycle phase, focusing on the right product or service with explicit budget and schedule constraints. This provided the top layer of the abstraction hierarchy. This can be decomposed into the main life cycle phases, which can be listed as follows [1]:

- Conceive
- Develop

- Utilise
- Support
- Retire

Each life cycle phase has specific pertinent aspects from conception through to retirement. Table 2 maps the relationship between the high-level purpose life cycle phases and the abstract function technical processes. The Abstract Function layer translates this purpose into a set of conceptual processes required to realize it. Each SE Technical Process is considered part of an SE process over the project's life cycle [1]. They provide guidelines on executing the SE process in various contexts. These processes encompass both the technical and non-technical aspects of system development — from business or mission analysis to stakeholder requirements, system architecture definition, and beyond to operation and disposal processes. This level ensures that all critical dimensions of system development are accounted for by addressing human and organizational factors inherent in STSs and ensuring that the system is technically sound but also sustainable, acceptable, and usable within its intended operational context.

Table 2 Abstraction Hierarchy Description

Level	**Description**
Functional Purpose	SE aims to conceive, develop, produce, utilise, support and retire the right product or service within budget and schedule constraints.
Abstract Function	• Business or Mission analysis • Stakeholder Needs and Requirements Definition • System Requirements Definition Process • System Architecture Definition Process • Design Definition Process • System Analysis Process • Implementation Process • Integration Process • Verification Process • Validation Process • Operation Process • Disposal Process All of the above is in the list of technical processes in [1].
Generalised Function	The processes or tasks that need to be performed to achieve abstract functions. The activities typically required for each process are defined in Input Process Output (IPO) diagrams [1].
Physical Function	The physical actions or operations required to carry out the tasks.
Physical Form	The hardware, software, or physical entities involved in the system are often software tools running on computer hardware.

The next layer, the Generalised Function, further decomposes abstract functions into specific tasks and processes that systems engineers perform. The generalised function typically consists of activities required per SE process over the system lifecycle. It bridges the conceptual and the executable functions, which are typically described through structured Input-Process-Output (IPO) models. These models facilitate understanding how data and resources flow through the system, how processes transform inputs into outputs, and where

human or machine interventions are required. When mapping down to the generalised function level, the diagrams fan out significantly.

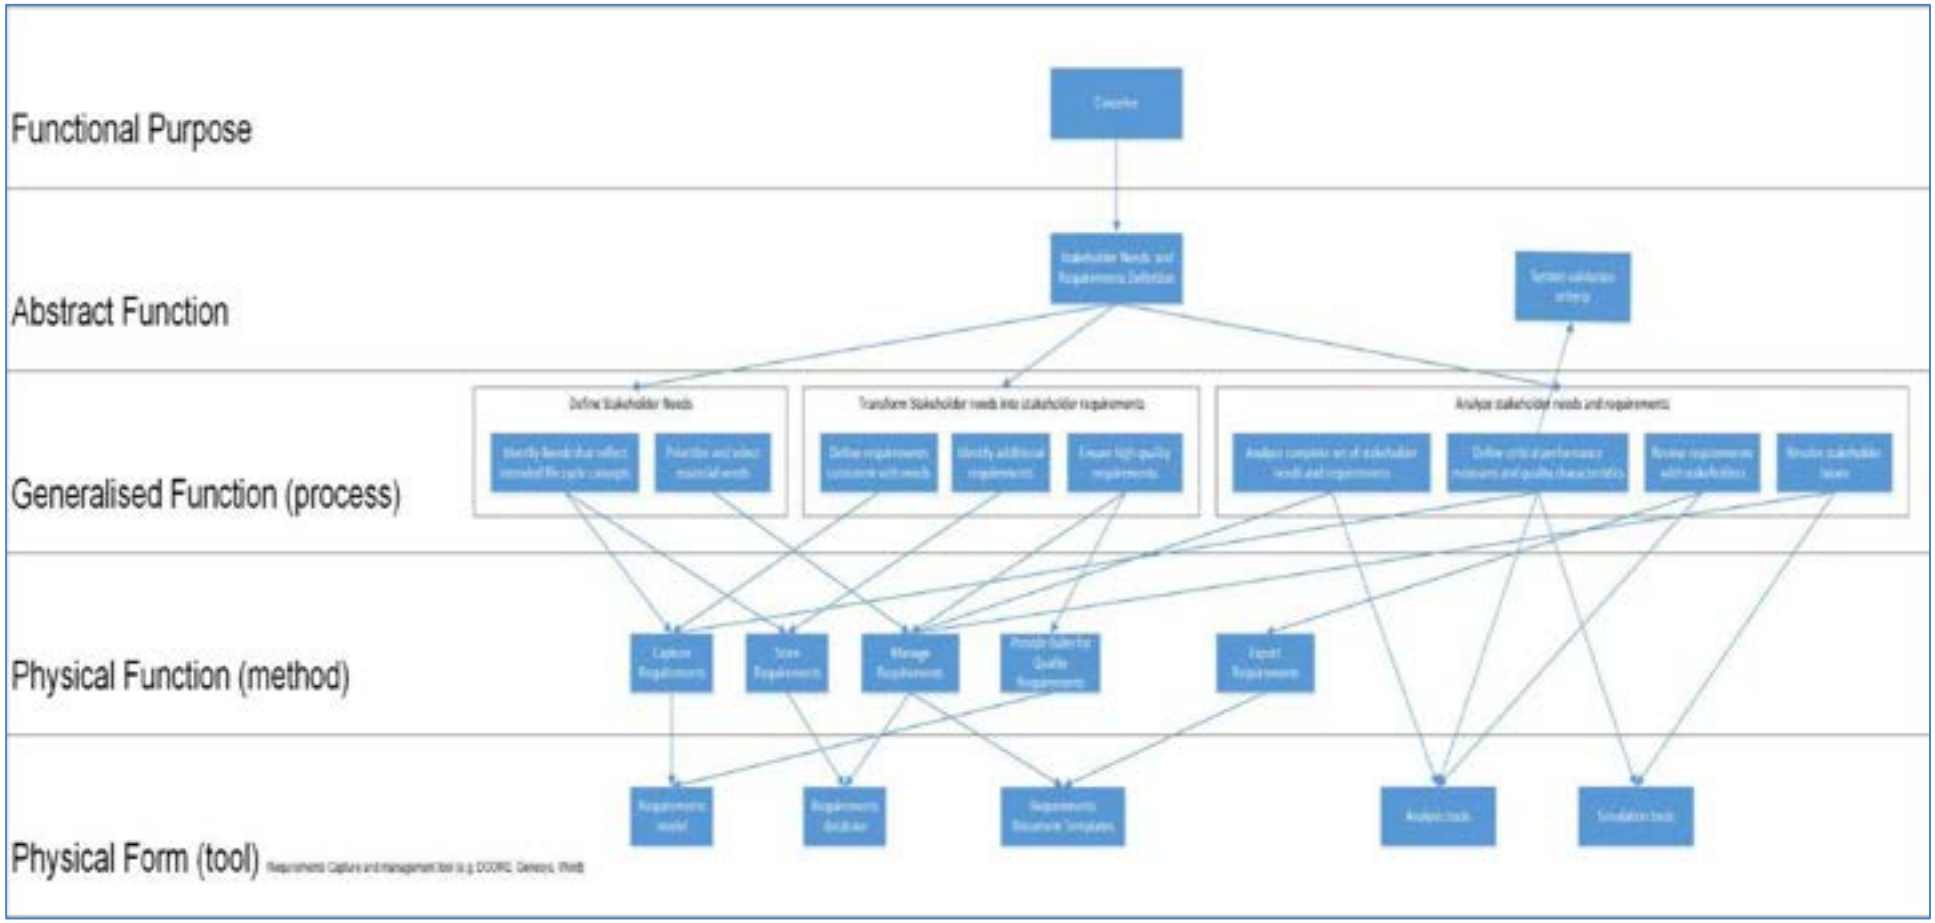

Fig. 5 Work Domain Analysis for Systems Engineering Process for the First Phase [30]**.**

Taking a slice down from “conceive” to the generalised function of Stakeholder Needs and Requirements Definition to the lower level of the abstraction hierarchy gives the view in Figure 5. For STSs, these functions are critical for explicitly modelling interactions between technologies, people, and organizational processes and supporting human-technology integration [1]. At the generalised function level, processes such as “Define Stakeholder Needs” can be grouped as separate, related aspects of “Identify needs that reflect the life cycle concepts” and “Prioritise and select essential needs”.

Skipping to the Physical Form layer represents the tangible elements, the actual software, hardware, and physical entities that realise the system and embody the system’s capabilities, and design choices that affect usability, safety, and organizational performance. For sociotechnical systems, this often includes technological artefacts, tools, work environments, and physical infrastructure that support human work. The lowest level, the physical form, typically manifests as software tools running on computer hardware. These provide the physical actions and operations required in the Generalised Function layer. These include manual operations, automated actions, physical manipulations, and interactions between various system components.

The physical function layer can also be the physical actions or operations in their simple form. In order to carry out such generalised functions, physical functions such as “Capture Requirements”, “Store Requirements”, and “Manage Requirements” are performed. Such physical functions also apply to other aspects of the generalised function, as indicated in the diagram. At the physical form level, the software tools typically required are tools that can be classed as “Requirements Model”, “Requirements database”, and “Requirements Document Templates.”

In summary, the abstraction hierarchy provides a framework for managing the inherent complexity of SE as an STS. It enables engineers to maintain clear traceability from high-level societal or organizational goals to the implemented system components, ensuring that the final system is technically effective and well-aligned with its broader human and organizational context. By systematically addressing each layer, SE practitioners can create systems that are functional, adaptable, resilient, and supportive of human and organizational well-being. In STS contexts, this layer highlights the importance of ergonomics, human-machine interfaces, and workflow design, ensuring that the physical realization of the system supports its intended human use. The high-level ADS view in Table 2 enables analysis per life cycle and abstract function to identify phases and levels to determine the possible high-level grouping of AI application areas.

Table 3 provides a more detailed model of the SE processes in an abstraction hierarchy. In this model, the horizontal axis is the life cycle phase that measures decomposition. This macro-level view across the life cycle phases and abstraction levels guides the focus areas of potential AI application areas. At lower levels, the details can provide more specific guidance. Considering the abstraction hierarchy, one typically can add a new tool, method or process into the current system and analyse its impact on neighbouring layers. Adding an AI tool into the SE process STS is somewhat different.

The type of functionality AI can provide is associated more with what is typically associated with higher abstraction levels. This is due to the cognitive type nature of AI functionality. The impact is not adding a tool but of a physical or general function being performed by a tool or assisting the SE in carrying out the function. When viewing the function that is impacted by using AI, the result could be that the function performed by humans may change. For example, if AI is used to “capture requirements” and even at the generalised functional level to “Identify stakeholder needs”, the cognitive human function could change from “Capture Requirements” to “Review AI captured requirements” Alternatively, AI could be used in a

reviewer type role so that a human could capture requirements and AI can be used to review the quality of requirements with suggested improvements. Transforming Stakeholder needs into Stakeholder Requirements is also something that AI can perform.

Table 3 Abstraction Hierarchy Description

Level	System Lifecycle Phases					
Functional Purpose	Conceive	Develop	Implement	Utilise	Support	Retire
Abstract Function	Determine needs and constraints	Develop architecture and design	Manifest the design into physical deliverables	Derive functional utility of the system in situ	Sustain and support the system use in situ	Remove the system from use
Generalised Function (process)	Define needs and requirements	Define structure and interfaces	Manage physical implementation	Manage the operation of the system	Manage the sustainment of the system	Dispose or transform the system
Physical Function (method)	Capture, store, and manage requirements	Manage system architecture and design	Build, integrate and test the physical system	Operate and monitor the system	Monitor, maintain, and service the system	Transform, remove system
Physical Form (tool)	Requirements model, database, templates	Architecture and design model, database, artefacts	Manufacturing and testing devices	Operational mechanisms	Maintenance and support tools	Disposal tools and mechanisms

AI's transformation is in the tools themselves, carrying out generalised or physical cognitive functions. Some of these functions may be split, where the AI tool performs the function, and the person then has more of a supervisory or accountability role in managing the AI tool and ensuring that the tools are used correctly and that the quality of the outputs is in line with the abstract function and the functional purpose.

5 CONCLUSION

The AH has highlighted that AI applications are quite different from what is commonly perceived as software tools. AI adds direct value to physical and generalised functions, which are typically performed by humans using software tools to frame, model and capture the requirements when defining stakeholder needs and requirements. The impact is mainly on the SEs themselves and how they need to adapt to this new paradigm. Trusting a tool to perform a function that has been the domain of the human mind may not be an easy transition for many. Initially, this will likely manifest mainly in AI performing an assistant role, where suggestions from AI give input to the SE. As the technology matures and improves, and SEs start to appreciate the advantages and improvements in efficiency and quality that such AI assistants may provide, more reliance on AI performing more SE functions may manifest.

ABSTRACT

Additive Manufacturing (AM) in the South African automotive industry can enhance production efficiency, reduce material waste, and promote innovation. However, its integration is constrained by technological, organisational, and industry-specific challenges. This study proposes a conceptual model to examine determinants of AM adoption, including relative advantage, complexity, compatibility, cost, management support, human factors, external factors, organisational culture (readiness and capacity for change), and intention to adopt. A quantitative approach was employed, utilising survey data from 30 automotive industry professionals. The measurement instrument, developed from literature-derived constructs, was evaluated for internal consistency using Cronbach's Alpha. In addition to the reliability assessment, descriptive analysis was conducted to provide preliminary insights into their perceptions of AM adoption across the measured constructs. The pilot results yielded coefficients ranging from acceptable to excellent across all constructs, indicating satisfactory reliability of the instrument. These findings provide an empirically validated basis for subsequent, more extensive empirical analysis of AM adoption determinants in this context. The study contributes to research on AM adoption by providing a validated measurement instrument and a structured model for analysing the relationships between technological, organisational, and environmental factors in the automotive manufacturing context.

1 INTRODUCTION

The global automotive industry is undergoing a significant transformation driven by the rise of Additive Manufacturing (AM), also known as 3D printing. AM introduces a fundamentally different way of designing and producing vehicle components, enabling manufacturers to shift away from rigid, traditional processes toward more flexible and innovative approaches. With capabilities such as rapid prototyping, complex geometrical design, weight reduction, and on-demand production, AM is becoming a powerful tool for improving product performance, enhancing customisation, and streamlining supply chains [12; 10]. In automotive applications, AM extends beyond prototyping to include the manufacture of end-use parts, custom tooling, and low-volume production runs. These benefits contribute to greater agility in product development and improved fuel efficiency through lightweight design. The potential for AM to minimize material waste and reduce time-to-market also offers substantial value in a highly competitive manufacturing landscape [17].

However, despite its potential, AM adoption is not without challenges. Companies must evaluate a range of internal and external factors, including technological maturity, organizational capacity, supply chain integration, regulatory compliance, and economic justification [14;12]. Adoption frameworks that address these dimensions are critical to guiding a successful transition toward AM-enabled production models, particularly in emerging economies such as South Africa, where local constraints and opportunities must be carefully considered.

While South Africa has made strides in AM research and investment through institutions such as the Council for Scientific and Industrial Research (CSIR) and national initiatives like the South African Additive Manufacturing Strategy, adoption within the automotive sector remains limited. Barriers such as insufficient technical expertise, high initial investment costs, and a general lack of awareness among key stakeholders continue to hinder widespread implementation [7;8]. To address these challenges and bridge the existing knowledge gap, this study aims to explore the factors influencing AM adoption in the South African automotive industry. By developing and testing a conceptual model grounded in the Technology–Organization–Environment (TOE) framework, the research seeks to provide insights into the technological, organizational, and environmental determinants of AM adoption. This study therefore aims to explore the key factors influencing the adoption of AM technologies in the South African automotive industry through the development and testing of a context-specific conceptual model. The research addresses the following objectives:

- To identify and analyse the perceived benefits and barriers to adopting AM technologies in the South African automotive sector.
- To develop a conceptual model that integrates technological, organisational, and environmental factors influencing AM adoption.
- To assess the reliability of the proposed model and its constructs through a pilot study involving industry professionals.

2 LITERATURE REVIEW

Several scholars have investigated the factors influencing the adoption of AM within the automotive industry, presenting diverse perspectives based on empirical evidence, theoretical models, and sector-specific studies. Their findings consistently reveal that AM adoption is a multi-dimensional phenomenon, shaped by a confluence of technological attributes, organisational readiness, supply chain integration, and the broader environmental context. These factors not only determine whether AM is adopted but also influence the rate and maturity of its implementation.

Technological factors have been widely acknowledged as foundational to AM adoption. Studies by Delic, Eyers and Mikulic [6] emphasise the significance of perceived relative advantage, compatibility with existing systems, complexity, and cost as key technological drivers or barriers. In their study of 124 automotive firms in Europe, they found that AM improves supply chain integration and firm performance, but only when firms perceive the technology as offering clear strategic value and when integration costs are manageable. The perceived complexity of AM technologies, especially in relation to design tools and materials can also negatively influence intention to adopt, particularly among small to medium manufacturers with limited technical capacity.

Organisational readiness is another dominant theme in the literature. Weller, Kleer and Piller [21], through a structured literature review, identified the availability of skilled human resources, leadership support, and alignment with internal strategies as essential enablers of AM implementation. This view is echoed in the work by Mona and Nkosi [15], who argue that AM adoption is strongly influenced by internal organisational dynamics such as knowledge management, training, and innovation culture. Firms that exhibit a strong learning orientation and encourage experimentation are more likely to embrace AM, particularly in environments where incremental innovation is necessary to remain competitive.

Environmental and market-related factors also play a critical role. Steenhuis and Pretorius [19], conceptualise AM adoption as a phased process influenced by external stimuli, categorising AM maturity into four phases: equilibrium, supply chain evolution, product evolution, and business model transformation. Their model suggests that automotive firms initially adopt AM to improve supply logistics or prototyping before evolving toward full-scale integration that transforms business models. Similarly, Cotteleer and Joyce [5], emphasise how market dynamics, regulatory frameworks, and technological uncertainty shape strategic decisions related to AM. These external pressures are particularly salient in emerging economies such as South Africa, where industry ecosystems and institutional support structures are still evolving

In addition to these factor-based insights, various scholars have developed conceptual models to better explain the adoption pathways of AM in automotive contexts. Table 1 below summarises a few notable models:

Table 1: Conceptual Models of AM Adoption in Automotive Contexts

Author(s)	Model Type	Key Constructs	Sector Focus
Delic et al. (2019)	SEM-based empirical model	Technological fit, supply chain integration, firm performance (RBV framework)	EU automotive firms
Steenhuis & Pretorius (2017)	Stage-based adoption model	Equilibrium → SC evolution → Product evolution → Business model transformation	Global, incl. SA
Weller et al. (2020)	Organizational factors framework	Innovation culture, management support, economies of scale, technical complexity	Manufacturing
Ahmad et al. (2023)	AHP decision model	Cost, tech maturity, resources, design for AM capabilities	Malaysian automotive

In the South African context, several scholars have highlighted the importance of a more integrated approach to understanding AM adoption, especially within the automotive manufacturing industry. Booysen, Blankley and Moses [3], argue that while technological capacity is an essential enabler, it is insufficient on its own to ensure successful adoption. Organisational innovation capabilities, such as absorptive capacity and learning orientation, play a crucial mediating role. Likewise, Mudzingwa and Chinomona [16] emphasise that government policy, institutional support, and local infrastructure significantly influence technology diffusion across South African manufacturing sectors. Similarly, Steenhuis and

Pretorius [19] suggest that AM adoption is hindered by a fragmented value chain, lack of standardised regulations, and insufficient awareness of AM's strategic benefits among industry stakeholders. These findings collectively suggest that a localised, context-sensitive framework is necessary to fully understand and address the multi-dimensional barriers to AM adoption in the South African automotive sector.

3 CONCEPTUAL MODEL

3.1 Theoretical Foundations

This study uses the Technology–Organisation–Environment (TOE) framework and the Innovation Diffusion Theory (IDT) to develop the conceptual model for understanding the adoption of AM in the South African automotive industry [20;18]. These two frameworks offer a structured way to examine the different factors that influence the adoption of new technologies in organisations. The TOE framework identifies three main categories that affect technology adoption: the technological context, the organisational context, and the environmental context. The technological context refers to the characteristics of AM technologies, such as their benefits and complexity. The organisational context includes internal factors like leadership support, available skills, financial resources, and the organisation's openness to change. The environmental context considers external influences such as market conditions, competitors, suppliers, and government regulations. The IDT focuses on how innovations spread within and between organisations. It explains adoption based on how potential users perceive the innovation, especially in terms of its relative advantage, compatibility, complexity, trialability, and observability [18]. These perceptions influence whether organisations view AM as a useful and practical solution.

Recent studies have extended these theories to account for current trends in digital transformation and smart manufacturing. For example, Chong and Weng [4] highlight the importance of organisational readiness, including digital skills and leadership, in successful technology adoption. [13], point out that data capabilities and the ability to manage both exploration and exploitation (known as innovation ambidexterity) help organisations adapt to uncertain environments. Al-Okaily, Ameen and Al-Hattami confirm the usefulness of the TOE framework in emerging economies by showing how it explains the adoption of digital technologies in resource-constrained settings.

By combining TOE and IDT, this study can examine AM adoption from multiple perspectives. These include:

- Technological factors, such as the advantages of AM and its complexity.
- Organisational factors, such as internal support, infrastructure, and employee capabilities.
- Environmental factors, such as competition, customer demand, and regulatory requirements.

3.2 Constructs and Hypothesized Relationships

The conceptual framework is built around six key constructs:

- Technological Factors: Comprising relative advantage, compatibility, complexity, and cost—these affect the perceived value and ease of integrating AM into existing manufacturing processes.
- Organisational Factors: Include management support and human resources. These elements determine the organisation's internal readiness for adopting AM.
- Environmental Factors: External conditions such as market dynamics, regulatory frameworks, industry ecosystems, and technological uncertainty that shape the contextual landscape for adoption.

- Technology Readiness: Encompasses support for experimentation, openness to change, competitiveness, and learning culture—factors that mediate the ability to adopt new technologies.
- Organisational Culture and Capacity for Change: Highlights cultural drivers such as continuous learning, leadership, resource availability, and innovation orientation as key enablers.
- Intention to Adopt AM: Serves as the dependent variable and is influenced by all preceding factors, representing the organisation's commitment and preparedness to implement AM technologies.

Hypothesized Relationships:

Table 2: Summary of Hypotheses

Construct	Relationship Path	Hypotheses
Relative Advantage (RA)	RA → OC-Readiness RA → IA-AM RA → OC-Readiness → IA-AM	H1, H2, H3
Complexity (CX)	CX → OC-Readiness CX → IA-AM CX → OC-Readiness → IA-AM	H4, H5, H6
Compatibility (CO)	CO → OC-Readiness CO → IA-AM CO → OC-Readiness → IA-AM	H7, H8, H9
Cost (CT)	CT → OC-Readiness CT → IA-AM CT → OC-Readiness → IA-AM	H10, H11, H12
Management Support (MS)	MS → OC-Readiness MS → CC MS → IA-AM MS → OC-Readiness → IA-AM MS → CC → IA-AM	H13–H17
Human Factors (HF)	HF → OC-Readiness HF → CC HF → IA-AM HF → OC-Readiness → IA-AM HF → CC → IA-AM	H18–H22
External Factors (EF)	EF → OC-Readiness EF → CC EF → IA-AM EF → OC-Readiness → IA-AM EF → CC → IA-AM	H23–H27
Mediators	OC-Readiness → IA-AM CC → IA-AM	H28, H29

3.3 Conceptual Model for the adoption of Additive manufacturing in the automotive industry

Figure 1 illustrates the key factors influencing the adoption of AM in the South African automotive industry. The conceptual model is structured around three primary independent variables: technological factors, organisational factors, and environmental factors. These collectively influence the adoption process. Additionally, two mediating variables, technology readiness and capacity for change, shape the relationship between these factors and the intention to adopt AM, which serves as the dependent variable. The relationships within the model highlight the interconnected nature of these factors, demonstrating how organisational culture, external pressures, and technological attributes interact to drive AM adoption decisions.

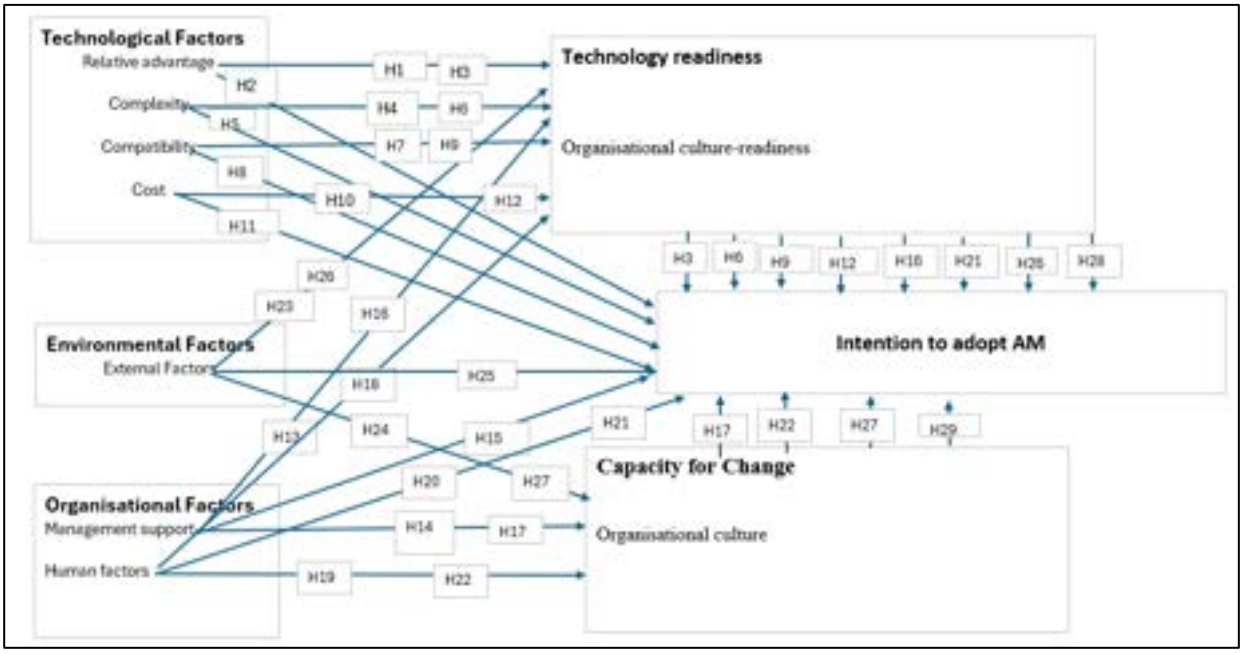

Figure 1: Conceptual model for Additive Manufacturing Adoption in the South African Automotive Industry

4 METHODOLOGY

This study employed a systematic research methodology aimed at investigating the factors influencing the adoption of AM technologies within the South African automotive industry. The methodology was structured into three primary stages: literature review, conceptual model development, and pilot survey administration.

4.1 Literature review

A comprehensive literature review was conducted to establish a solid theoretical foundation for the study and identify key factors affecting AM adoption. Relevant scholarly articles, industry reports, and policy documents were sourced from academic databases including ScienceDirect, Scopus, IEEE Xplore, and Google Scholar. The search process focused on publications from 2015 onward using targeted keywords such as “Additive Manufacturing,” “technology adoption,” “automotive industry,” and “South Africa.” Inclusion criteria ensured that selected literature was directly related to AM technology and its application within manufacturing or organisational contexts. Data extracted from the literature were thematically analysed to identify core constructs and inform the development of a conceptual model grounded in the Technology–Organisation–Environment (TOE) framework and the Innovation Diffusion Theory (IDT).

4.2 Conceptual Model

Based on the literature review, a conceptual model was developed to guide this investigation. The model integrates technological, organisational, and environmental factors as independent variables influencing the intention to adopt AM, with organisational culture—readiness and capacity for change included as mediating variables. Each construct was defined using established concepts from prior technology adoption research and adapted to reflect the context of the South African automotive industry. Hypotheses outlining the expected relationships among these constructs were formulated to provide a theoretical foundation for future empirical testing.

4.3 Pilot Design and Administration

To assess the reliability and validity of the measurement instrument, a pilot survey was conducted using a structured questionnaire. This questionnaire was developed based on the constructs identified in the conceptual model and comprised multiple items for each construct. Each item was measured using a five-point Likert scale, where respondents indicated their level of agreement with each statement (ranging from 1 = Strongly Disagree to 5 = Strongly Agree). This scale was chosen for its effectiveness in capturing the degree of respondent agreement and generating ordinal data suitable for reliability analysis. The pilot survey was distributed electronically to a purposive sample of 30 professionals working in or closely affiliated with the South African automotive sector. These individuals were selected for their industry expertise and practical knowledge, allowing them to provide informed feedback on the clarity, relevance, and comprehensiveness of the questionnaire items. The sample size of 30 was deliberately chosen as it aligns with standard practice for pilot studies, providing sufficient data to evaluate the reliability and validity of the instrument while maintaining feasibility for initial testing. For specialized environments like the automotive sector, this sample size is considered adequate to capture expert insights and assess the questionnaire's applicability within the industry context. This size enables preliminary assessment of the questionnaire's internal consistency and identification of potential issues before full-scale deployment. Responses from the pilot were analysed primarily to assess internal consistency, with Cronbach's Alpha coefficients calculated for each construct to ensure the reliability of the scales before the main data collection phase. The questionnaire consisted of carefully worded items grouped under key constructs drawn from the conceptual model. Table 3 below outlines the construct codes, summarised item statements, and the Likert scale used for measurement.

Table 3: Survey Instrument: Factors Influencing the Adoption of Additive Manufacturing in the Automotive Industry

Relative advantage	RA1	AM reduces waste and supports sustainability.
	RA2	AM improves efficiency and speeds up prototyping.
	RA3	AM saves costs, justifying the investment.
Complexity	CX1	AM is too technically complex to adopt.
	CX2	Material strength limits AM scalability.
	CX3	AM is too slow for mass production.
Compatibility	CO1	AM fits with future manufacturing.
	CO2	AM works with current supply chains.
	CO3	AM aligns with current practices.
	CO4	AM meets quality and manufacturing standards.
Cost	CT1	High initial costs are a major barrier.
	CT2	Ownership and maintenance costs are barriers.
	CT3	Training costs hinder AM adoption.
	CT4	AM costs still strain budgets.
Management Support	MS1	Management would provide needed resources.
	MS2	Management supports innovation and learning.
	MS3	Management sets goals and addresses AM challenges.
	MS4	Management clearly communicates AM plans.
Human Factor	HF1	Workers would adapt and see AM benefits.
	HF2	Industry would invest in AM training.

	HF3	Workforce is open to AM despite resistance.
	HF4	Staff would embrace upskilling for AM.
External Factors	EF1	Customer demand would influence AM adoption.
	EF2	Market trends would drive AM use.
	EF3	Regulations challenge AM adoption.
	EF4	Industry collaboration is key to AM adoption.
Organisational Culture - Readiness	OCR1	Our organisation supports trying new tech.
	OCR2	Our organisation is open to tech change.
	OCR3	We see AM as key to competitiveness.
	OCR4	We encourage learning and adapting to AM.
Organisational Culture - Capacity for Change	OC1	We promote continuous learning.
	OC2	We value new tech adoption.
	OC3	Leaders drive AM adoption.
	OC4	We have resources to adopt AM.
Intention to Adopt AM	IA1	We intend to use AM if available.
	IA2	We're likely to adopt AM soon.
	IA3	AM will be part of our production.
	IA4	We're willing to invest in AM.

5 PILOT STUDY RESULTS

5.1 Reliability analysis

To evaluate the internal consistency and reliability of the constructs used in this study, a pilot survey was conducted. The table below presents a summary of the pilot study results, reflecting the number of items per construct, their corresponding Cronbach's Alpha values, and the resulting reliability assessment. All constructs demonstrated acceptable to excellent internal consistency, indicating that the scales used are dependable and suitable for further analysis.

Table 4: Summary of Pilot Study Results- Construct Reliability and Internal Consistency

Construct	Number of Items	Cronbach's Alpha	Reliability Assessment
Relative Advantage (RA)	3	0.705	Good internal consistency; scale is reliable.
Complexity (CX)	3	0.636	Acceptable internal consistency; construct is considered reliable.
Compatibility (CO)	4	0.782	Good internal consistency; scale is reliable.
Cost (CT)	4	0.866	High internal consistency; construct is highly reliable.
Management Support (MS)	4	0.940	Excellent internal consistency; construct is highly reliable.
Human Factor (HF)	4	0.801	Good internal consistency; scale is highly reliable.
External Factors (EF)	4	0.843	Good internal consistency; scale is highly reliable.
Organisational Culture - Readiness (OCR)	4	0.937	Excellent internal consistency; construct is highly reliable.
Organisational Culture - Capacity for Change (OCC)	4	0.863	Good internal consistency; scale is highly reliable.
Intention to adopt (IA)	4	0.759	Good internal consistency; scale is reliable.

5.2 Descriptive analysis of pilot study responses

To further understand the pilot study responses, descriptive statistics (mean and standard deviation) were calculated for each survey item as illustrated in Table 5.

Table 5: Descriptive analysis of the pilot study responses

Construct	Items	Mean	Standard deviation
Relative advantage	RA1	4,4	0,545
	RA2	4,333	0,733
	RA3	4,6	0,482
	RA4	4,233	0,704
	RA5	4,266	0,715
Complexity	CX1	3	0,894
	CX2	4,033	0,912
	CX3	2,967	1,048
	CX4	3,533	0,805
	CX5	3,367	1,048
Compatibility	CO1	3,967	0,836
	CO2	3,9	0,831
	CO3	3,967	0,836
	CO4	3,833	1,003
Cost	CT1	3,833	1,213
	CT2	3,4	1,2
	CT3	2,867	1,118
	CT4	3,567	1,146
Management Support	MS1	3,5	1,024
	MS2	3,667	0,977
	MS3	3,567	0,989
	MS4	3,3	0,862
Human factor	HF1	3,833	0,819
	HF2	4,1	0,539
	HF3	3,933	0,814
	HF4	3,933	0,771
External factors	EF1	4,233	0,803
	EF2	4,133	0,884
	EF3	4,133	0,846
	EF4	3,9	1,136
	EF5	4,133	0,957
Organisational culture readiness	OCR1	3,7	1,005
	OCR2	3,533	1,024
	OCR3	3,767	0,989
	OCR4	3,733	0,928
Organisation culture capacity for change	OCC1	3,933	0,771
	OCC2	3,933	0,727

	OCC3	3,7	0,9
	OCC4	3,6	0,879
Intention to adopt AM technologies	IA1	4,2	0,748
	IA2	4,133	0,763
	IA3	4,167	7,734
	IA4	4,2	7,748

The mean reflects the general level of agreement with each statement, while the standard deviation indicates the degree of variation in responses.

Overall, participants expressed strong agreement with the perceived benefits of AM (Relative Advantage), particularly in terms of cost savings (RA3, M = 4.60, SD = 0.48) and sustainability (RA1, M = 4.40, SD = 0.55). Perceptions of complexity were mixed, with some agreement that material strength supports scalability (CX2, M = 4.03, SD = 0.91), but concerns that AM is too slow for mass production (CX3, M = 2.97, SD = 1.05). Compatibility ratings suggested that AM aligns with future manufacturing (CO1, M = 3.97, SD = 0.84) and meets quality standards (CO4, M = 3.83, SD = 1.00), though integration with current systems showed moderate variability.

Cost-related items reflected concerns about initial investment (CT1, M = 3.83, SD = 1.21) and ongoing expenses (CT2, M = 3.40, SD = 1.20), with higher standard deviations suggesting differing organisational capacities. Management Support and Human Factor scores were moderately high, indicating general confidence in leadership support and workforce adaptability. External Factors such as customer demand (EF1, M = 4.23, SD = 0.80) and market trends (EF2, M = 4.13, SD = 0.88) were seen as influential drivers of adoption.

Organisational culture scores revealed moderate readiness (OCR3, M = 3.77, SD = 0.99) and capacity for change (OCC1 & OCC2, M = 3.93, SD < 0.80). Finally, intention to adopt AM was rated highly (IA1, M = 4.20, SD = 0.75), although IA3 and IA4 showed unusually high standard deviations due to outlier responses, suggesting the need for review before the main study.

6 DISCUSSION

The results of the pilot study provide initial support for the usefulness of the proposed conceptual model in understanding the adoption of AM technologies in the South African automotive industry. A descriptive analysis of the pilot study responses indicated that most constructs recorded mean scores above the midpoint of the measurement scale, suggesting generally positive perceptions toward AM adoption across the sampled respondents. The standard deviation values for these constructs were relatively low to moderate, reflecting a reasonable level of agreement among participants. This consistency in responses supports the reliability findings and implies that the instrument was well understood by participants, with limited extreme variation in responses. The high reliability scores for most constructs, especially organisational readiness, management support, and capacity for change, show that internal organisational factors are likely to play an important role in influencing adoption. This suggests that successful AM adoption depends not only on the technology itself but also on the organisation's leadership, culture, and willingness to change. Technological factors such as relative advantage, compatibility, and cost also showed good internal consistency, indicating that they are important considerations when evaluating the value and practicality of AM. However, the construct of complexity showed slightly lower reliability, which may reflect differences in how complex AM is perceived by professionals, depending on their experience or exposure to the technology. Environmental factors, including regulatory conditions and market influences, also showed good reliability, suggesting that external conditions play a significant role in shaping the intention to adopt AM. The results further

confirm that the intention to adopt construct is reliable and appropriate for measuring future adoption behaviour.

7 CONCLUSIONS AND RECOMMENDATIONS FOR FUTURE WORK

This study set out to explore the key factors influencing the adoption of AM technologies in the South African automotive industry by developing and testing a conceptual model grounded in technological, organisational, and environmental dimensions. The pilot study confirmed that the model's constructs are reliable, with all Cronbach's Alpha values indicating acceptable to excellent internal consistency. A descriptive analysis of the pilot study results further provided preliminary insights into the sample's characteristics and adoption trends, helping to identify potential patterns and refine the survey instrument for future studies. The results indicate that while technological factors, such as relative advantage and cost, remain significant, organisational readiness, shaped by internal capabilities, management support, human capital, and a culture that embraces change, plays a central role in influencing adoption. In addition, environmental factors, including regulatory policies and market pressures, emerged as important contextual drivers. These findings highlight the importance of adopting a holistic perspective on technology adoption, particularly within industries characterised by high capital intensity and stringent regulatory oversight, such as automotive manufacturing. Looking ahead, future research should aim to validate the proposed conceptual model using a larger and more representative sample, with structural equation modelling (SEM) employed to examine the strength and direction of the hypothesised relationships. Longitudinal designs would allow for the examination of how adoption readiness develops over time, particularly in response to changes in policy, market conditions, and technological advancements. Incorporating qualitative approaches, such as interviews, focus groups, or case studies, could yield deeper insights into organisational behaviours and external influences that may not be fully captured through quantitative surveys.

University of Pretoria, South Africa
[1]suvengovender1@gmail.com, [2]krigevisser51@gmail.com

ABSTRACT

Over the past decade, South Africa faced frequent power outages due to problems with its electricity supply. One cause of these outages was the deteriorating condition of the aging coal fired power stations, resulting in breakdowns and failures.

A research study was performed to compare the maintenance management used at the auxiliary plant at five selected coal-fired power stations with five elements of the Global Forum on Maintenance and Asset Management (GFMAM) maintenance framework. An online survey questionnaire was used to gather data from personnel involved in engineering and maintenance activities at these power stations. The questionnaire included five elements of the subject groups mentioned in the Maintenance Framework.

Results indicated that most of the principles outlined in the five elements of the GFMAM framework have been implemented and applied at power stations to improve the effectiveness and efficiency of maintenance activities and management.

Keywords: Maintenance Management, Maintenance Management Framework, Maintenance Tactics, Maintenance Strategy

1 INTRODUCTION

1.1 Background

Eskom Holdings SOC, a state-owned utility in South Africa, generates 96.7% of the country's electricity and supplies 45% across Africa [1]. With three divisions i.e., Generation, Transmission, and Distribution, the utility operates 13 coal-fired power stations with a capacity of 46,47MW. Due to deferred maintenance, these aging plants experience frequent outages, leading to unreliable supply and load shedding to prevent blackouts. This disrupts the economy and deters investors. The executive team at Eskom introduced a strategy for operational recovery through improved maintenance management to enhance plant performance and eliminate load shedding [2]. An effective maintenance management system is crucial for achieving operational recovery of the power stations and improve plant performance, availability and reliability.

1.2 Objectives

The main objective of this research study was to investigates the application, performance, and effectiveness of the maintenance management system within Eskom (Generation Division) in comparison with the maintenance framework developed by the Global Forum on Maintenance and Asset Management (GFMAM) [3]. The following five propositions were formulated to guide the study.

1. Various maintenance tactics and associated tasks are used to effectively maintain the different plant systems at the power stations.
2. Asset maintenance strategies for plant systems are being developed and implemented.
3. Materials resource management principles are being implemented to effectively manage maintenance spare parts.
4. A maintenance work management process is adopted.
5. The maintenance data and information management system are used to manage all maintenance activities.

1.3 Limitations of the Study

The number of power stations that could be included in this research study was restricted. The scope of this study focused on five coal-fired power stations within Eskom's generation fleet namely Lethabo, Kendal, Matimba, Duvha, and the Tutuka.

Due to the geographical distribution of Eskom's power stations across the country, it was not practical to physically access all power stations. Therefore, data was collected through an online survey questionnaire. However, this method of data acquisition is bound by limitations such as low response rates from participants.

Due to the complexity of systems and infrastructures found within a coal-fired power station, the scope of the research study was restricted to the supporting auxiliary plant/systems. The maintenance management system for the entire power station was not considered. Additionally, the research study focused on assessing the application, performance, and effectiveness of five subject groups/elements from the GFMAM Maintenance Framework, out of the total nine. The selected subject groups were:

1. Maintenance Tactics and Task Types
2. Asset Maintenance Strategy Development
3. Material Resource Management
4. Maintenance Work Management
5. Maintenance Data and Information Management

2 LITERATURE

2.1 Maintenance Classification

The main objective of the study was mentioned in the introduction. The topics used for the literature survey and discussed in this paper are therefore related to maintenance management frameworks and maintenance management strategies and tactics.

Dzulkifli et al. [4] categorised maintenance activities into planned and unplanned maintenance as illustrated in Figure 1. Planned maintenance is organised, controlled, and adheres to predetermined procedures, aiming to maximise asset performance while avoiding operational failures. It requires an understanding of the asset's operational and performance levels to develop critical work cycles and activities [5].

Unplanned maintenance is conducted in response to unexpected asset breakdowns or failures that are not supported by predetermined maintenance plans and schedules [6]. Numerous research studies have demonstrated a relationship between planned maintenance and reduced maintenance costs. When maintenance activities are planned, it is easier and less expensive to execute than unplanned work. Planned and scheduled maintenance activities are both effective and efficient.

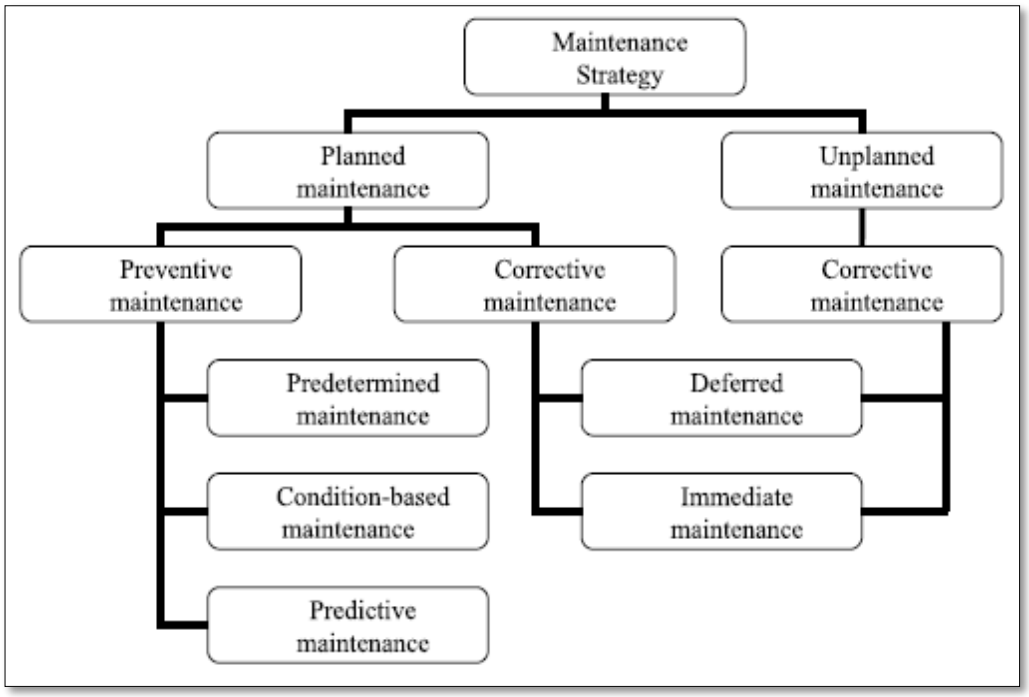

Figure 1: Maintenance classification [4]

2.2 Maintenance Types:

Two main maintenance categories or types are well-known and generally used by most companies, namely preventive maintenance and corrective maintenance. A third maintenance type could be added, namely failure finding maintenance. This type involves periodic checks to determine whether a hidden function is available when required. Further categorisation of maintenance types is illustrated in Figure 2. Preventive maintenance is “carried out at predetermined intervals to reduce the probability of failure or degradation of equipment's functioning”. Corrective maintenance is “carried out after fault recognition to restore the equipment's function”. Corrective maintenance is classified into two categories namely immediate and deferred. [7].

2.3 Maintenance Management Frameworks

Maintenance management frameworks are either prescriptive or descriptive. Prescriptive frameworks outline methodologies, while descriptive models explain maintenance management phenomena [8].

2.3.1 Maintenance framework of Márquez:

During the development phase of his maintenance framework, Márquez [9] noted that maintenance management must be aligned with the actions related to the three levels of business activities i.e., strategy, tactical, and operational levels). The proposed framework comprises three pillars namely the “IT pillar”, the “Maintenance engineering methods pillar” and the “Organisational (or behavioural) pillar”.

The “IT pillar” of the framework entails the implementation of a CMMS system within the company. This system allows employees to store, monitor, control plan, and analysis maintenance data related to all assets owned by the company. The “maintenance engineering methods pillar” comprises techniques associated with Reliability-centred Maintenance (RCM), Total Productive Maintenance (TPM), and optimisation models. The principles related to this pillar assist in designing and defining the maintenance plans to ensure equipment reliability and improve overall equipment effectiveness (OEE). The final pillar i.e., “organisational or behavioural”, involves the human aspect of maintenance management which can foster relationships among the various stakeholders.

2.3.2 Maintenance framework of Campbell & Reyes-Picknell

Campbell and Reyes-Picknell [10] developed the "Pyramid of Excellence" to enhance maintenance management principles and techniques. The pyramid consists of three levels i.e., leadership, essentials, and choosing excellence. Leadership focuses on strategy and human resources, essentials include work management, materials management, performance management, information system, and basic care. The “choosing excellence” level emphasises principles of RCM, continuous improvement, and evidence-based asset management (EBAM).

2.3.3 Maintenance framework by GFMAM

GFMAM [3]) developed a maintenance framework comprising nine subject groups, as illustrated in Figure 2. These nine groups aim to promote a common understanding of maintenance roles and values, assisting companies in achieving their goals. The framework is based on the “plan-do-check-act” (PDCA) cycle of an asset. The first group focuses on business requirements and organisational context, while the second group considers asset creation and acquisition. The third group focuses on maintenance tactics and task types, while the fourth group develops an asset maintenance strategy. The fifth group focuses on maintenance work management, while the sixth group focuses on asset performance and condition management. The seventh group focuses on maintenance data and information management, while the final group focuses on maintenance program management. The GFMAM framework aims to help companies achieve their goals by focusing on these key areas and implementing effective maintenance strategies across various industries and end-users. The three main deliverables (or value) of maintenance are **performance, risk, and cost**.

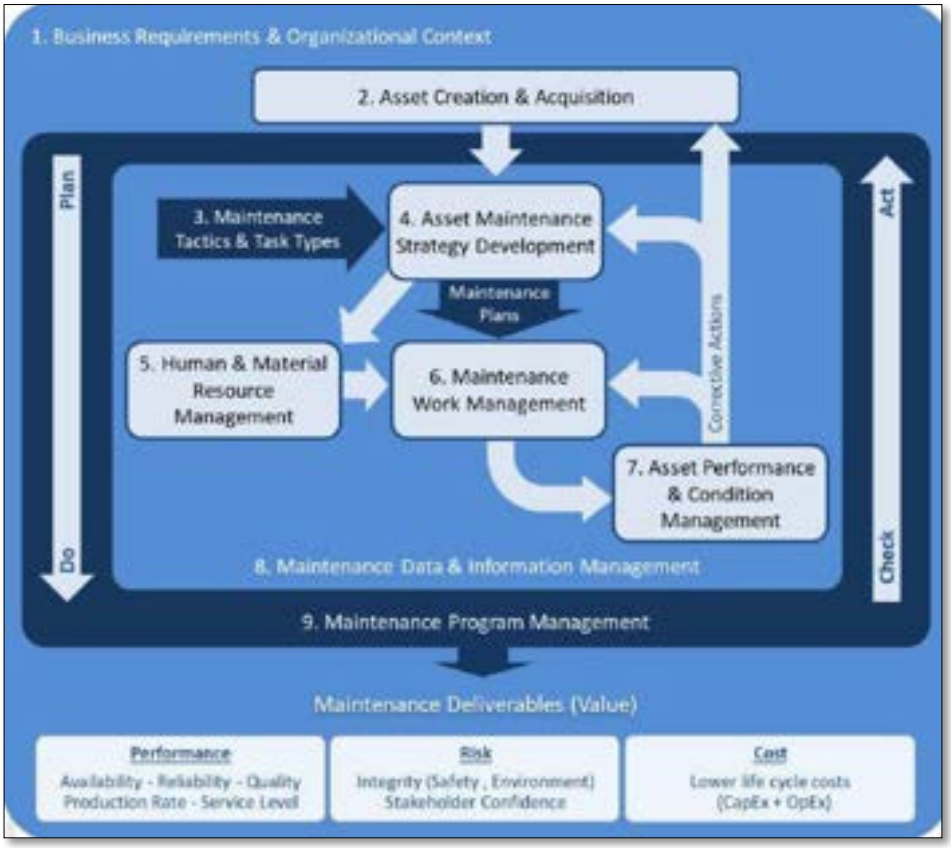

Figure 2: Maintenance framework according to GFMAM [3]

2.4 Maintenance Strategies or Approaches

A maintenance strategy is a long-term plan for a company's assets, considering asset features, resources needed, and service level. Fraser et al. [11] identified 37 maintenance management approaches across various industries. However, RCM, TPM, BCM appear repeatedly in literature and is discussed briefly.

2.4.1 Reliability Centred Maintenance (RCM):

RCM is a structured methodology that identifies maintenance activities and frequencies for physical assets in their operating context. It requires defining an asset's functions, identifying potential failures, and developing preventive maintenance tasks [12]. The success of this process relies on a detailed functional analysis by a review team, including employees from various functions within the company. The output of an RCM process is a life plan for each system component. The most important tool in RCM is Failure Mode and Effect Analysis (FMEA), which identifies failure modes, causes, frequencies, and potential effects of specific failures.

2.4.2 Total Productive Maintenance (TPM)

TPM is a structured approach developed based on productive maintenance concepts to maximise equipment effectiveness, eliminate breakdowns, and promote autonomous maintenance by operators [13]. It involves various company functions to improve asset availability, performance, quality, reliability, and safety. The goal of TPM is zero defects, accidents, and breakdowns.

2.4.3 Business-centred Maintenance (BCM)

Kelly [5] developed the Business-centred Maintenance (BCM) approach as a cost-effective maintenance model that prioritises safety and can be applied across various industries. It aligns maintenance functions with company objectives and involves a detailed analysis of system operations. A life plan is developed, outlining maintenance procedures, activities, and tactics (condition-based, fixed-time, or operate to failure) for each unit, ensuring a well-planned and efficient maintenance schedule.

3 METHODOLOGY

3.1 Data Collection

This research study used secondary data from Eskom's SAP system and Hyperwave knowledge management system to gather historical data on maintenance activities at the coal-fired power stations. The SAP system captures maintenance activities, while the Hyperwave system manages records, reports, and investigations.

Primary data was collected through self-administrated online survey questionnaires distributed to employees in the maintenance and engineering departments at the five power stations. The online survey questionnaire, structured into six sections, comprised 29 questions. The questionnaire includes sections on demographics, maintenance tactics and task types, asset maintenance strategy, material resource management, maintenance work management, and maintenance data and information management. The questionnaire also included questions about the implementation of maintenance strategies, the use of spare parts, inventory stocking methodology, and the five-step maintenance work management system.

A survey questionnaire was generated using Qualtrics software and distributed to 695 participants via email. The link was unique for each participant's email address, preventing duplication of responses. The response rate was monitored on Qualtrics XM, and participants received three reminders to complete the survey. Data was collected for four months, with the link suspended once the required number of responses were received.

This study focused on the engineering and maintenance departments of coal-fired power stations which act as baseload stations for meeting electricity demand. A population of 695 employees was studied from five coal-fired power stations. This population included 172 engineering personnel, 429 maintenance personnel, and 94 works management personnel. Eighty-nine (89) useful responses were received; therefore, the response rate was 12,8%.

3.2 Data Analysis

Pre-testing of the survey questionnaire was done to identify potential issues and improve reliability. The pre-testing involved 10 engineering colleagues and the study leader, who did not form the target population. The study leader revised questions to eliminate ambiguity and misinterpretation, and the time required to complete the questionnaire was determined. All participants supported the research and recommended adding "not sure" choices, a timeframe, and a consent condition.

A survey questionnaire collected quantitative data on maintenance management systems at coal-fired power stations. The results were presented in tables, graphs, and charts using Microsoft Excel, allowing for easy communication of recommendations and conclusions.

4 RESULTS AND DISCUSSION

4.1 Introduction

Statements and questions in the questionnaire were formulated for each of the five subject groups that were included in the study.

4.2 Maintenance Tactics and Task Types

4.2.1 Maintenance tactics

Various preventive and corrective maintenance tactics are employed in maintaining assets utilised in electricity generation. Participants were asked to indicate which of the six maintenance tactics, as defined by Duffuaa et al. [14], are implemented for maintaining the Auxiliary Plant Systems in a coal-fired power station. The results are illustrated in Figure 3.

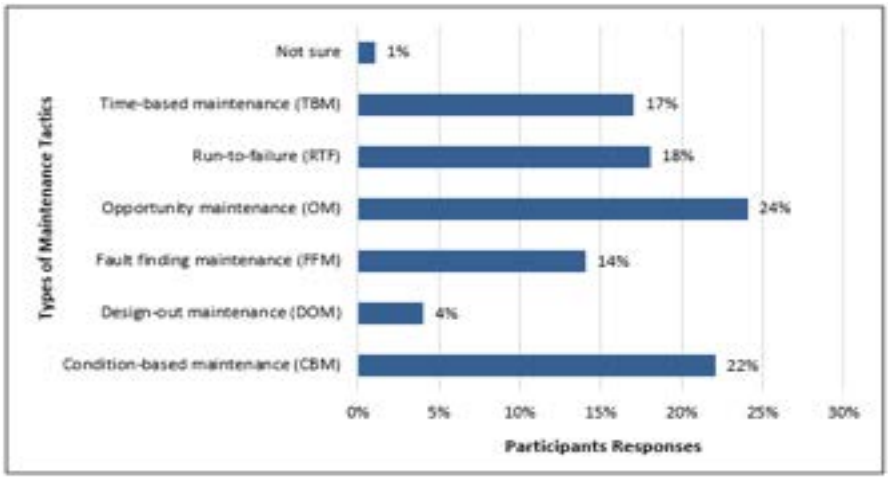

Figure 3: Maintenance tactics used for the auxiliary plant systems (APS)

Opportunity maintenance and condition-based maintenance is mostly used while the use of fault-finding maintenance (FFM) is quite low at 14%. This tactic could be increased since a power station has many protective systems and items e.g., high temperature trip, safety valve on pressure vessels, and high-speed cut-out on rotating equipment. More failure-finding tasks can decrease the hidden failures associated with backup and protective devices. Eskom's coal-fired power stations use a combination of preventive and corrective maintenance strategies. The power stations also conduct regular inspections, routine upkeep, and monitoring to mitigate plant degradation and failures.

4.2.2 Maintenance activities

Maintenance tactics comprise of a set of maintenance activities or tasks that can be employed by maintenance technicians. Participants were requested to indicate which of the five maintenance activities or tasks, as defined by Márquez [7], are used in maintaining the Auxiliary Plant System (APS).

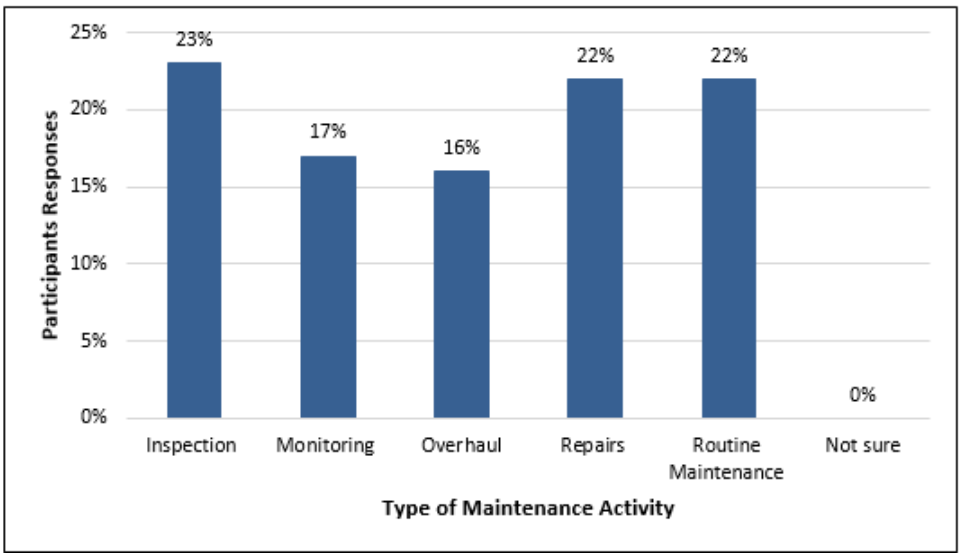

Figure 4: Maintenance activities or tasks used for the APS.

As shown in Figure 4, all five maintenance activities or tasks are employed with inspections the highest response of 23%. Effective maintenance departments use all these activities and tasks, but the ratios differ due to different equipment and skills available.

4.2.3 Condition monitoring

Condition monitoring methods are implemented to detect potential failures of an item or component before a functional failure occurs. Participants were asked to specify which of six condition monitoring methods are utilised at the APS. The results are shown in Figure 5.

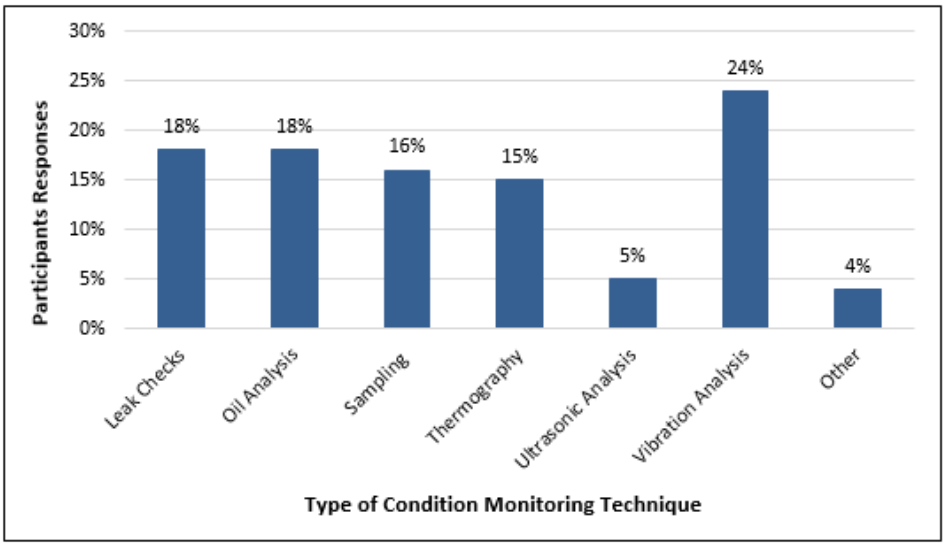

Figure 5: Condition monitoring methods used for the APS.

Vibration monitoring and analysis is the method that is mostly used. This is expected since many rotating equipment is used at a power station e.g., pumps, compressors, turbines, and motors. Ultrasonic measurement and analysis are only used for certain specialised equipment.

4.3 Asset Maintenance Strategy

4.3.1 The role of a maintenance strategy

The operational efficiency of a power station is dependent on the availability and reliability of its plant systems and equipment. Respondents were asked to indicate whether a maintenance strategy was in place. Most respondents (89%) said yes, thus, indicating that a maintenance strategy plays a crucial role in maximising the power station's life-cycle value. A second question asked the participants to indicate which of six benefits are achieved when implementing a maintenance strategy at the power station. The results are illustrated in Figure 6.

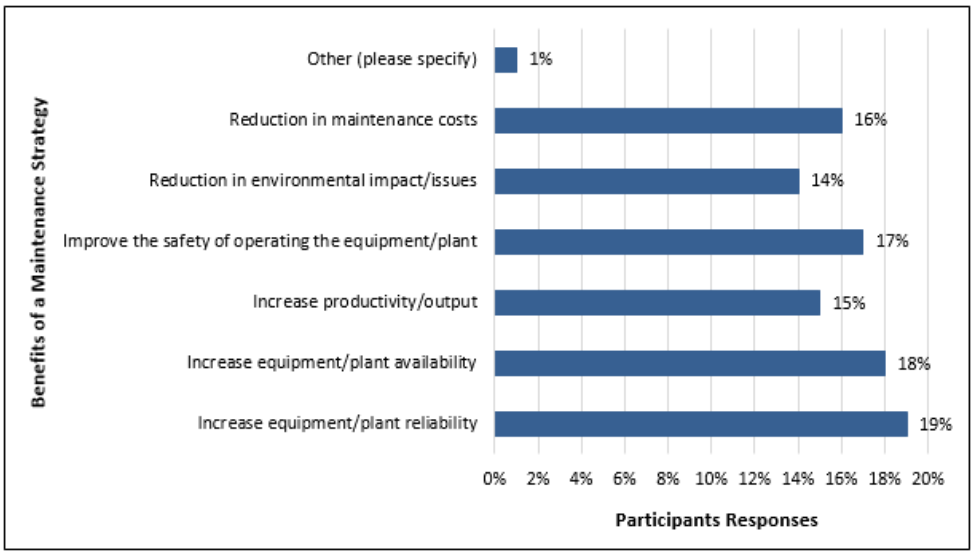

Figure 6: Benefits of a maintenance strategy

The findings indicate that a maintenance strategy significantly enhances plant reliability (19%) and availability (18%) and improve overall productivity (15%). Furthermore, the strategy improves plant safety (17%) and reduces maintenance costs (16%). However, a small percentage of respondents mentioned other benefits such as reduced failure incidents, increased plant life span, and optimized performance optimisation.

Secondary data obtained from the document management system revealed that Reliability Based Optimisation (RBO) [2] program is utilised as a maintenance strategy to determine and record the required maintenance activities on the plant systems and equipment. The process involves a step-by-step approach that considers plant-specific knowledge, maintenance history, health and safety, compliance with legislation, optimal operational costs, and environmental and corporate responsibilities. The primary objective is to establish an effective preventive and condition-based maintenance program to contribute to Eskom's generation goals of improved personnel safety, optimal equipment, plant availability and reliability, maximised plant life, and optimal operational costs.

4.3.2 Maintenance approaches

When developing a maintenance strategy, information about the asset's failure modes, operating context, and operational history is crucial. Participants were asked to indicate which of the five maintenance approaches (RCM, TPM, BCM, RBM, and RBI) were used at the power station. The results are shown in Figure 7.

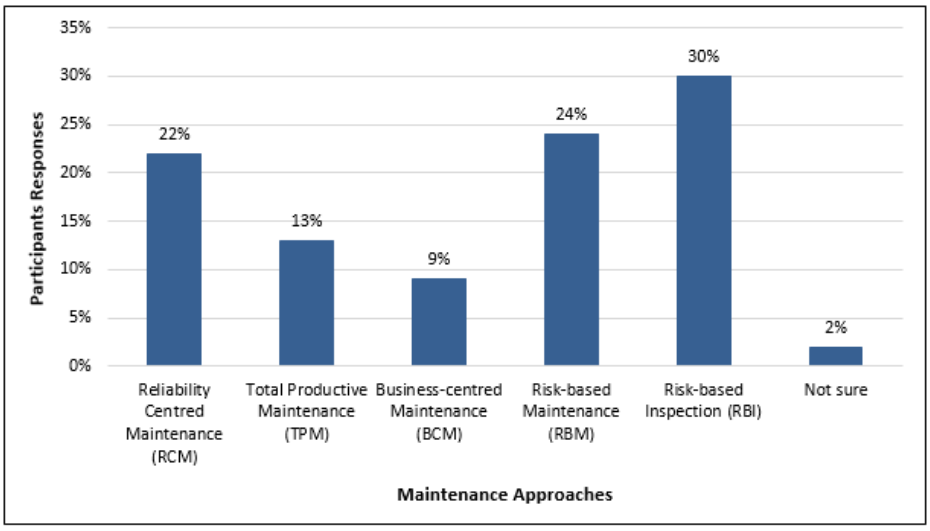

Figure 7: Maintenance approaches used for the APS.

The risk-based approaches, RCM, RBI and RBM, account for 76% of all five approaches. This finding indicates that asset managers and maintenance managers value safety and risk as particularly important.

4.4 Maintenance Resource Management

4.4.1 Management of spare parts

The process of identifying, cataloguing, and acquiring maintenance materials is critical for planning and conducting maintenance activities at the power station. Participants were asked to indicate which of five methodologies are used to identify maintenance spare parts at the power stations. The results are illustrated in Figure 8.

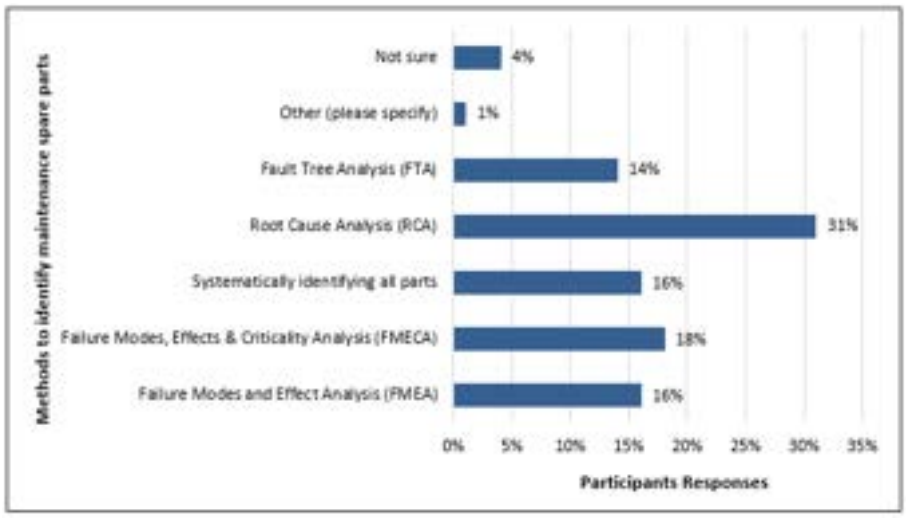

Figure 8: Analysis methods for identifying spares usage.

Root cause analysis (RCA) is mostly used to identify which spares and how many of each should be stocked and procured to deal with similar failures in the future. Other techniques like FTA, FMEA and FMECA are also used since such techniques are important in applying the RCM methodology.

The power stations utilise a materials management system to ensure the availability of spare parts and materials for maintenance activities. This system uses RCA and FMEA approaches to

identify and catalogue spares, with a bill of materials (BOM) being used for inventory control. Common criteria for stocking include asset criticality, projected usage, potential downtime, and material lead time.

4.4.2 Stocking inventory

It is important to have spare parts and materials readily available to prevent delays in maintenance activities. Participants were asked to indicate which of the four methodologies, as defined by GFMAM [1], are implemented when stocking maintenance spare parts for the power station. The results are shown in Figure 9.

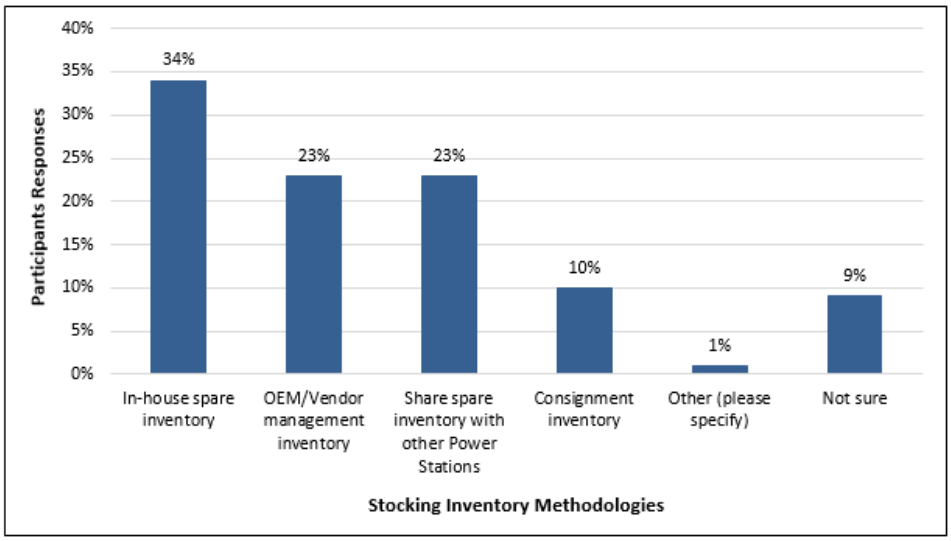

Figure 9: Methodologies adopted to stock spare parts.

The findings illustrated that coal-fired power stations use a combination of methodologies to stock maintenance spare parts and materials. In-house inventory (34%) is mostly used but OEM/Vendor management inventory and sharing spare inventory with other power stations is also used to improve availability and reduce plant downtime.

4.5 Maintenance Data and Information Management

4.5.1 Data management systems

An effective maintenance department collects, stores, and manages data and information relating to the company's equipment, operations, and maintenance. Participants were asked to indicate which of five data management systems are used at the power station. The results are shown in Figure 10.

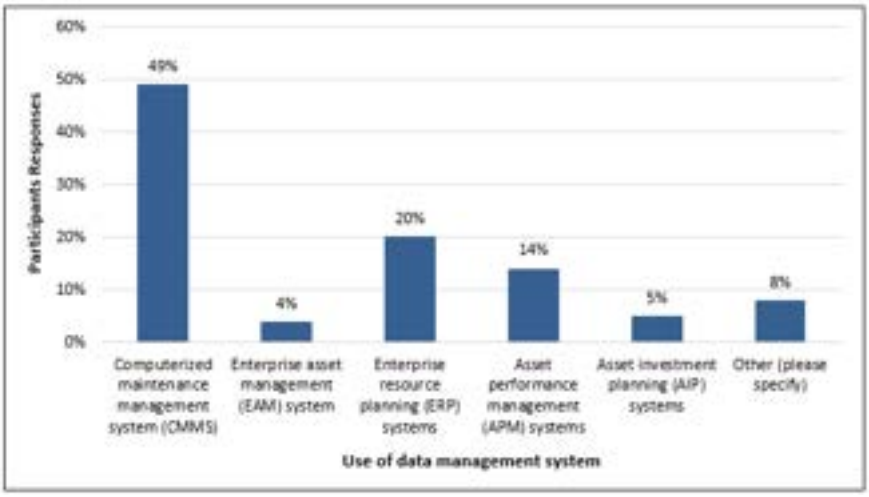

Figure 10: Data management systems used at the power station.

Eskom uses a CMMS (SAP system) and a Hyperwave system for efficient maintenance management in power stations. The CMMS allows employees to create, assign, and track work orders, materials, spare parts, and consumables. It also captures relevant asset data for informed maintenance decisions, ensuring efficient plant operation.

4.5.2 Data recorded

The asset data collected provides managers with valuable information for making informed decisions related to equipment replacement or refurbishment. Participants were asked to indicate the specific data recorded for all plant assets. The results are shown in Figure 11.

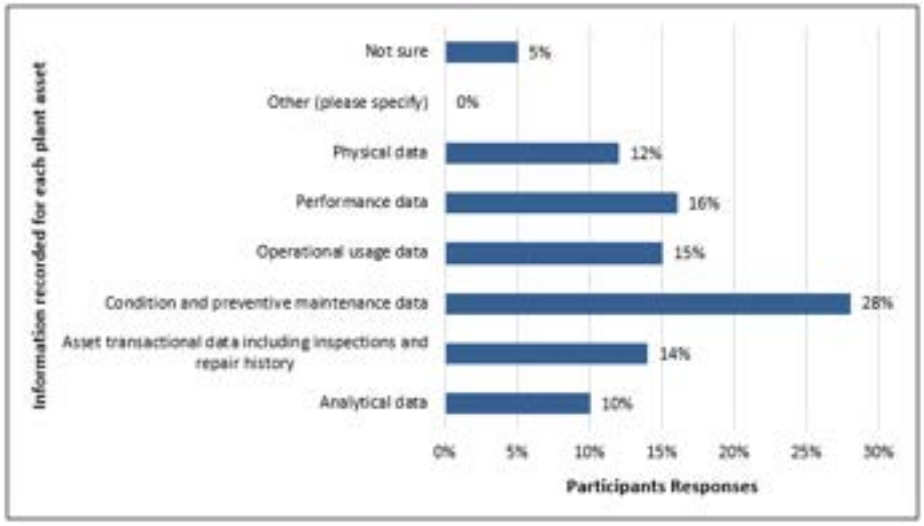

Figure. 11. Data recorded for plant assets

The findings indicate that various types of data are recorded for each plant asset at the power station. A notable number of respondents (28%) indicated that condition and preventive maintenance data is recorded for plant assets. A follow-up question requested participants to indicate the completeness of the information captured in the data management system to make informed decisions on the plant. The results reveal that there is a mixed perception regarding the completeness of information in the data management system. While most respondents (52%) agree that the data is sufficient for making informed decisions, a number disagreed (25%) or were uncertain. This suggests that 48% of the participants lack confidence in the data's accuracy and adequacy.

4.6 Summary of Results

The findings discussed in the previous sections were used to assess the acceptability of the five propositions mentioned earlier.

Proposition 1: *Various maintenance tactics and associated tasks are used to effectively maintain the different assets at the power stations.*

The results indicate that Eskom uses a combination of maintenance tactics to maintain its coal-fired power stations. Two commonly used tactics are opportunity maintenance (i.e. used during periods of reduced demand or brief shutdowns) and condition-based maintenance. The findings further indicate that a comprehensive maintenance approach is adopted, with condition-based inspections used to identify wear, deterioration, or abnormal behaviour in components. Condition monitoring techniques like sensors that measure temperature, pressure, vibrations, and oil conditions, are used to track and compare data trends to predefined thresholds or historical data. This aids in identifying early signs of potential equipment failures so that repairs can be done. These findings support the proposition.

Proposition 2: *Asset maintenance strategies for plant systems are being developed and implemented at the power stations.*

An authorised maintenance strategy is crucial for achieving the life-cycle value of a power station. Most respondents perceived the strategy's implementation positively, but a small percentage (11%) were "not sure" or "disagreed" with it. The benefits observed when implementing a maintenance strategy were well-maintained equipment operating at optimal efficiency levels and correct safety systems, reducing accident risks and complying with environmental regulations and safety standards. Risk-based and data-driven analytical approaches are adopted when developing a maintenance strategy for the plant systems. The results support the proposition.

Proposition 3: *Materials resource management principles are being implemented to effectively manage maintenance spare parts at the power stations.*

RCA and FMEA are key methods for identifying maintenance spare parts in coal-fired power stations. They help understand equipment failure and manage critical components. Combining these with FMECA optimises inventory by prioritising essential components, ensuring availability, and reducing excess costs. Strategies like in-house spares inventory, OEM/vendor management, and inventory sharing are common. Criteria such as asset criticality, projected usage, potential downtime, and lead-time are used for stocking spare parts.

Proposition 4: *A maintenance work management process is adopted at the power stations.*

All maintenance tasks at the power stations are managed using a six-step process (i.e. work order procedure) to ensure that completed work is done safely, effectively, and efficiently. Preventive maintenance work packages are developed according to approved maintenance strategies, containing all necessary planning information for successful maintenance work. This reduces rework and corrective maintenance, improving plant availability and reliability. The maintenance department employs various strategies to reduce work order backlogs, including improving the team's skills and capabilities, incorporating a 13-week look ahead, and assigning additional resources for urgent tasks. However, the practice of conducting reviews during maintenance work closeout is not commonly implemented, hindering the effectiveness of the maintenance department. The findings demonstrate that a work management system (i.e. a six-step process) is implemented at Eskom’s coal-fired power stations.

Proposition 5: *Maintenance data and information management system is used to manage all maintenance activities at the power station.*

Eskom's coal-fired power stations use a computerised maintenance management system (CMMS) to manage and track maintenance activities, resulting in improved equipment reliability and reduced downtime and maintenance costs. The CMMS is widely used in engineering and maintenance departments of Eskom. It includes features like condition and preventive maintenance, material management, and work order management, allowing employees to create and manage schedules based on time, usage, or condition-based triggers. Users can also create, assign, and track work orders for various maintenance activities, including materials, spare parts, and consumables. Employees have differing opinions on the accuracy and adequacy of the data captured. Based on the findings, the proposition is supported.

5 RECOMMENDATIONS

The unplanned maintenance ratio in power stations is below the world-class ratio of less than 15%. To improve this, managers should implement a rigorous maintenance plan, refurbish older equipment with modern technology, ensure well-trained personnel, and foster a culture of collaboration among maintenance teams. The power stations should prioritise capturing diverse data types for each plant asset to improve maintenance management and optimise performance. Analytical data collection will provide engineers and maintenance personnel with a comprehensive understanding of trends, enabling informed decisions to enhance operational efficiency, compliance, safety, and overall performance. Integrating data analysis tools into the maintenance management system can facilitate improved preventive maintenance.

6 CONTRIBUTIONS OF THE RESEARCH STUDY

The research study explores the maintenance management systems and practices used by coal-fired power stations in South Africa, focusing on improving plant reliability and performance. The study found that the principles and framework developed by the GFMAM can be applied to power stations to enhance efficiency and effectiveness. The study confirms that the principles and framework are being implemented to maximize plant efficiency and effectiveness. The study highlights the importance of maintenance strategies, tactics, data management, material management, and work management systems.

7 CONCLUSION

This research study investigated the current maintenance management system and practices at the auxiliary systems of five coal-fired power stations. The findings were obtained through primary and secondary data collection. A survey was conducted to determine to what extent five of the subject groups or elements of the Maintenance Framework of the GFMAM are applied and used at the power stations. It was found that the basic principles of the framework are used to a fair extent to improve the effectiveness and efficiency of maintenance activities, thereby improving the plant systems' reliability, availability, and performance.

It was determined that five of the major maintenance tactics i.e., time-based maintenance, run to failure, condition-based maintenance, opportunity maintenance and failure-finding maintenance are all used at the power stations. This indicates a balanced approach in maintenance and reliability management. Another important finding was that five condition monitoring techniques or methods i.e., oil analysis, vibration, thermography, leak checks and sampling (water, gas) are an integral part of preventive maintenance at the power stations that were investigating in this study.

8 ACKNOWLEDGEMENT

The authors thank the Graduate School of Technology Management (GSTM) at the University of Pretoria for supporting this study, and Eskom Holdings SOC, and the five power station managers for allowing data collection.

BALANCING ARTIFICIAL INTELLIGENCE WITH HUMAN JUDGEMENT WHEN MODELLING

N.S. Pillay[1*]
[1]Eskom Research Testing and Development, South Africa
Pillayna@eskom.co.za

ABSTRACT

Artificial Intelligence (AI) is rapidly transforming systems engineering by enhancing efficiency, accuracy, and reliability across various stages of the engineering lifecycle. This paper examines the integration of AI into modelling, balanced with human intelligence (HI). HI uses judgement to make decisions, which often relies on ambiguity, past experiences, and other intangible considerations. In the deployment of AI, possible gaps between the decision-making capabilities of artificial intelligence and those of human judgement in modelling is investigated. We explore the key difference and synergies for a human-centered and AI-based approaches for simulation and modelling, highlighting their potential to improve decision-making, automate complex tasks, and optimize system performance. A population model was used as a case study to understand the key similarities and differences between AI and HI generated population models. This research provides an analysis of the gaps and advantages of integrating both AI and HI.

Keywords: Artificial intelligence, systems engineering, human intelligence, population model

1 INTRODUCTION

The development and operation of modern systems are inherently complex, often requiring interdisciplinary collaboration to manage technical and organizational intricacies effectively [1]. Systems engineering was established as a discipline to coordinate diverse teams of experts in addressing such complexity by facilitating the structured integration of knowledge, tools, and processes throughout a system's life cycle. As systems become more intricate and interconnected, they demand an increasingly broad spectrum of technical expertise and adaptive thinking to resolve emerging challenges [2]. A defining strength of systems engineering lies in its capacity to enable collaborative innovation—where large, cross-functional teams can embed advanced concepts, including emerging technologies, directly into system architectures [3]. From the perspective of systems engineers, systems are not only technological artifacts but also socio-technical entities shaped by human interaction, cooperation, and expertise.

The individuals involved—and the tacit knowledge they bring—are fundamental to the success of complex systems projects. As digital transformation accelerates, systems engineering is increasingly influenced by advances in information and communication technologies, which are now more accessible, integrated, and dependable. Effective systems engineers require a blend of skills, including collaborative leadership, integrative problem-solving, and the agility to navigate and interconnect legacy and contemporary systems [4]. More recently, there has been growing momentum toward integrating artificial intelligence (AI) into systems engineering, particularly in the areas of modelling, simulation, and decision-support [5]. AI methods—such as machine learning, natural language processing, and predictive analytics—are increasingly employed to enhance system performance, reduce complexity, and improve operational readiness in dynamic environments [6].

In this paper, we explore the key differences and synergies between a population model generated using AI and one developed through human intelligence (HI), incorporating tacit knowledge and contextual judgment as a basis for comparison.

2 BACKGROUND

The advent of AI has brought great progress and convenience to the global society across multiple applications [7]. Predictions on AI surpassing human intelligence appear to approach reality, even though some argue the possible unintended consequences [8]. Real concerns rise in the future interplay between human and artificial intelligence. Studies reveal the unprecedented role of human-centric, adaptable, and continuously self-evolving intelligence in facing global challenges. If developed, excessive dependency on AI may limit adaptive decision-making in real time and the capability for managing natural, complex systems [9]. On the other hand, aggressiveness in maintaining system performance might stimulate humans' fear and distrust in ultimate consequences.

Contrary to the primary design of systems that mimic human intelligence, human intelligence (HI) provides great advantages in terms of adaptability, creativity, integrative thinking, interpersonal skills, and continuous self-learning [10]. Indeed, many tasks—from long-term strategy decision-making to real-time agility under uncertainty—are extremely difficult to learn and are hardly performed by a typical AI system [11]. It is well known that AI excels in tasks like number recognition, text translation, and medical diagnosis because these are rule-based and operate in well-defined problem spaces. More importantly, AI model development generally relies on large-scale pre-collected data for training. When the environment deviates significantly from this data distribution, it can lead to invalid or brittle decisions.

Furthermore, the integration of human and artificial intelligence into systems engineering has gradually become a top priority in engineering and digital transformation domains [12]. The

premise explored here is that, for many human-oriented engineering challenges, significant benefits can be derived from simulating systems to better blend HI and AI—and that niche of systems engineering is increasingly critical [13].

3 METHODOLOGY

The methodology followed included a literature review of AI, HI and systems model development. Using an AI platform, a population model was developed. Through group model building, variables were then identified that were not included in the AI generated population model. A gap and the synergies between the AI generated model and the human discussion-based model was then noted. The original AI model was then modified to include the HI identified factors.

4 SURVEY OF THE ENVIRONMENT

A scan of existing literature on AI, HI and systems simulation & modelling integration was conducted.

4.1 Artificial Intelligence

Artificial intelligence (AI) spans a wide array: from systems that interact with the world slowly and effortfully to those that handle sensory inputs in real time with ease [7]. But if an AI system encompasses a broader range of capacities, what fundamentally constitutes artificial intelligence? Artificial intelligence is the engineering and study of computational systems that perceive, reason, learn from data, communicate, and act in open-world, complex, uncertain, unbounded, and changing environments, towards perception- and cognition-related tasks that normally require human intelligence [14]. This includes foundations such as deep learning, Markov decision processes, and game theory and the study of systems with a wide array of capabilities, from rule-based systems to high-performance robotic manipulators [15]. At the core, however, are principles such as perception, reasoning, and learning that underlie any functioning AI system. From these first principles, systems can be situated on a spectrum by way of their complexity, and systems outside the field entirely can be evaluated by way of these first principles. Although tremendous leaps have transpired in AI systems in recent decades, advances that can think and feel and can design a scientifically robust model is still questionable [11]. Still, even the utilization of first-order narrow AI systems can produce extensive impacts [16]. Therefore, systems engineering and various mutual applications that relate to artificial thinking require in-depth consideration regarding the AI system being interactive with [17].

4.2 Human intelligence in systems engineering

Human beings have some characteristics and capabilities, including common sense, that distinguish them from artificial intelligence, and imitating this sort of knowledge may have a disconnect with the reasoning of an artificial system. Another facet of human intelligence that is hard to formalize is the flexibility of the mind. Appropriate thought is considered such, that distinguishes humans from artificial intelligence, operates despite the lack of clarity and uniformity, makes sense to logical minds but not to the rest, has multiple facets of reasoning and consequently does not admit an easy definition of intelligence. The fact that computers and robots have been created so as to work and learn rapidly but they do not use common sense. It is therefore important to understand when not to rely completely on AI and when HI may be required or even a hybrid when modelling and simulating.

4.3 Challenges and opportunities in integrating human and artificial intelligence

Human intelligence is a multi-faceted construct encompassing skills like problem-solving, abstract reasoning, memory, and learning [18]. It also comprises emotional intelligence (EI), interpersonal and intrapersonal capabilities that allow individuals to understand and manage

their emotions as well as perceive and influence the emotions of others. Emotional intelligence can involve reading unspoken messages, such as picking up on an excited tone when proposing a project in a meeting. Human intelligence is contextual, drawing on experience, feelings, and unconscious brain function, all of which are difficult to conceptualize with algorithms and mathematics [19]. Initially, integrating human and artificial intelligence may appear quite straightforward. AI has been developed to automate various activities that have conventionally depended on humans, and machine learning algorithms have been established to learn and replicate human decision-making and reasoning. The assumption then follows that systems engineering would easily make use of AI to carry out complex decision-making, processing, and recognition tasks.

However, the process demands considerable forethought and sensitivity. The introduction of AI in system engineering processes, especially the modelling step, can be considered as disruptive and may necessitate changes in the methods and processes applied by systems engineers. Nonetheless, methods that make intelligent use of data and algorithms can support, assist, and automate tasks for systems engineering in engineering projects. Systems artificial intelligence suggests that consequent changes will challenge systems engineering practices and thereby introduce implications that warrant consideration from a human systems integration standpoint. Human systems practitioners, researchers and domain experts adapting these practices to emerging methods and technologies are in a position to both identify new challenges and influence the nascent field of systems artificial intelligence. System engineering processes frequently put the ability to analyze extensive quantitative data and derive patterns from that data, as well as interpret the automated processes derived from the data to good use. Therefore, AI systems automating these tasks have strong potential to contribute to the efficiency of systems engineering processes, wherein the complex systems' view on data processing is required alongside a good understanding of both the theory and the topic. With the advancements in machine learning and the availability of big data, such AI systems and respective methods have become feasible and widespread.

There are several technical difficulties currently affecting the integration of human intelligence into AI techniques. First, many artificial intelligence algorithms are based upon the assumption of structured in-out data, with internal analysis often performed against normalized and statistically, ordered data. This is a significant limitation, as non-normalized data contains most of the complexity of the real-world situations and decisions fostered by AI technologies are better adopted, more acceptable, and more insightful when they carefully reflect the real-world situations and not just the data. Furthermore, while it is widely recognized the fundamental effect of personal traits and immediate emotions on every cognitive process, it is currently difficult that AI techniques carefully replicate the modelling and reflection of this data. In this framework, AI and its current experiments represent an under-estimate of the complexities that are linked to representing real life systems when modelling and simulating.

While AI streamlines the modelling process, human oversight remains essential, as domain experts refine AI-generated models to enhance accuracy and relevance. Additionally, human intervention ensures model interpretability and correctness, maintaining reliability and trust in the AI-driven process. In terms of societal aspects, productivity using AI may displace human resources and increase human redundancy. This study was comparative based on qualitative and quantitative approaches. Additionally, chances of social isolation may become rife. AI may be able to simulate empathy but would lack human connection.

Table 1 provides a summary of the difference between HI and AI modelling [20].

Table 1: Summary of Human-AI Collaboration in Simulation and Modelling [20]

Task	AI Role	Human Role
Model Development	Auto-generates models from data	Refines and validates models
Simulation Optimization	Uses AI to optimize scenarios	Adjusts objectives and constraints
Decision Support	Provides predictive analytics	Interprets insights and makes strategic decisions
Data Processing	Cleans and generates data	Ensures accuracy and removes bias
Continuous Learning	Adapts models with new data	Provides feedback for improvement
Visualization	AI-driven graphics and 3D models	Interprets and modifies outputs
Predictive Simulations	Runs probabilistic models	Integrates real-world judgment

4.3 Population models

Demands on policymakers to address social, economic, and environmental issues have given rise to an array of modelling methodologies that attempt to depict the multiple ways in which population structure is linked to transitions in these spheres [21]. Population models describe how populations change over time. They can give rise to political and strategic decisions by predicting how populations will develop. The basic model can build up from factors such as birth, death, and migration rates [22]. For a population, it is often of interest to measure how the population size changes with time. Many factors may affect these dynamics, but the four fundamental variables that affect how the population changes its size over time have been identified, referred to as birth rate, death rate, migration rate, and resources [23]. Birth rate is defined as the rate of births per unit time per individual, death rate is defined as the rate of deaths per unit time per individual, and migration rate is defined as the rate of individuals entering or leaving the population per unit time per individual, exerted at the border of the population [24].

Resources, in turn, can be conceptualized in two parts: the carrying capacity of the environment (denoted as H) and a density-dependent measure of how population pressure modifies vital rates [25]. When resources are scarce or overutilized due to high population density, they influence the birth rate negatively. In closed populations with a fixed resource utilization rate, these interactions can result in oscillatory dynamics in population size, driven by feedback loops between resource consumption and demographic processes [26]. Such models demonstrate how resource availability indirectly governs birth and survival rates, producing periodic cycles in population growth and decline.

In this study, AI generated variables will be identified to develop a population model and then human identified variables will be integrated in the model to create an integrated population model.

5 RESULTS

As a first step, an AI generated model was developed, the second step was to consider those variables that are identified through HI (through group model building). The last step was to take the HI generated variables to incorporate it back into the original AI model to develop an integrated model based on both AI and HI. Fictional numbers were used in order to create graphical illustrations of the system behaviours over time.

5.1 AI generated population model

ChatGPT [27]was used to identify all the critical variables impacting a population model. The fundamental equation governing population dynamics is the logistic growth equation with modifications to account for various influencing factors. The drivers that were considered

included biological, environmental, economic, and social factors that would affect population growth and decline. Equation 1 is the mathematical representation of the model.

$$\frac{dP}{dt} = (B - D + I - E)P - f(P, K, E_c, H) \quad (1)$$

Where:

P = Population size

t = Time

B = Birth rate (per capita per unit time)

D = Death rate (per capita per unit time)

I = Immigration rate

E = Emigration rate

K = Carrying capacity (limit imposed by resources)

E_c = Environmental conditions (climate, disasters)

H = Human impact (technology, healthcare, policies)

$f(P, K, E_c, H)$ = Feedback function accounting for carrying capacity, environmental factors, and human intervention.

The variables that influenced birth and death rates are explained as follows.

5.1.1 Birth Rate (B) Influences

Fertility Rate (F): Number of children per woman

Healthcare (H_m): Access to maternal and infant care

Cultural & Social Factors (C_s): Family planning, gender roles

Economic Conditions (E_c): Cost of raising children, employment

Education (E_d): Women's education and reproductive knowledge

Mathematically, birth rate can be modelled as shown in Equation 2:

$$B = F(H_m, C_s, E_c, E_d) \quad (2)$$

5.1.2 Death Rate (D) Influences

Age Distribution (A_d): Proportion of elderly and youth

Healthcare Quality (H_q): Availability of treatments and vaccines

Nutrition (N): Access to sufficient food and clean water

Environmental Hazards (E_h): Pollution, climate change, disasters

Conflict & Violence (C_v): Wars, crime, pandemics

Death rate can be modelled as shown in Equation 3:

$$D = D(A_d, H_q, N, E_h, C_v) \quad (3)$$

5.1.3 Immigration (I) and Emigration (E) Influences

Economic Opportunities (E_o): Job availability in destination country

Political Stability (P_s): Conflict, human rights in origin country

Climate Conditions (C_c): Natural disasters, desertification

Government Policies (G_p): Immigration laws, border control

Immigration is shown in Equation 4 and emigration by Equation 5.

$$I = I(E_o, P_s, C_c, G_p) \quad (4)$$

$$E = E(E_o, P_s, C_c, G_p) \quad (5)$$

5.1.4 Carrying Capacity (K)

Carrying capacity is determined by resource availability as shown in Equation 6.

$$K = K(R, A, T, P_o) \quad (6)$$

Where:

R = Available resources (food, water, energy)

A = Agricultural and industrial output

T = Technology improving resource efficiency

P_o = Pollution and environmental degradation

If population P exceeds K, growth slows down due to resource scarcity.

Figure 1 shows the AI generated results. Four scenarios were run which include:

- **Scenario 1: Exponential Growth** where births are greater than deaths and no resource constraints exist;
- **Scenario 2: Logistic Growth** where if population reaches carrying capacity and leads to stabilization;
- **Scenario 3: Decline** where if deaths are greater than births or emigration is high; and
- **Scenario 4: Boom and Bust** Cycles where rapid growth is followed by resource exhaustion and collapse.

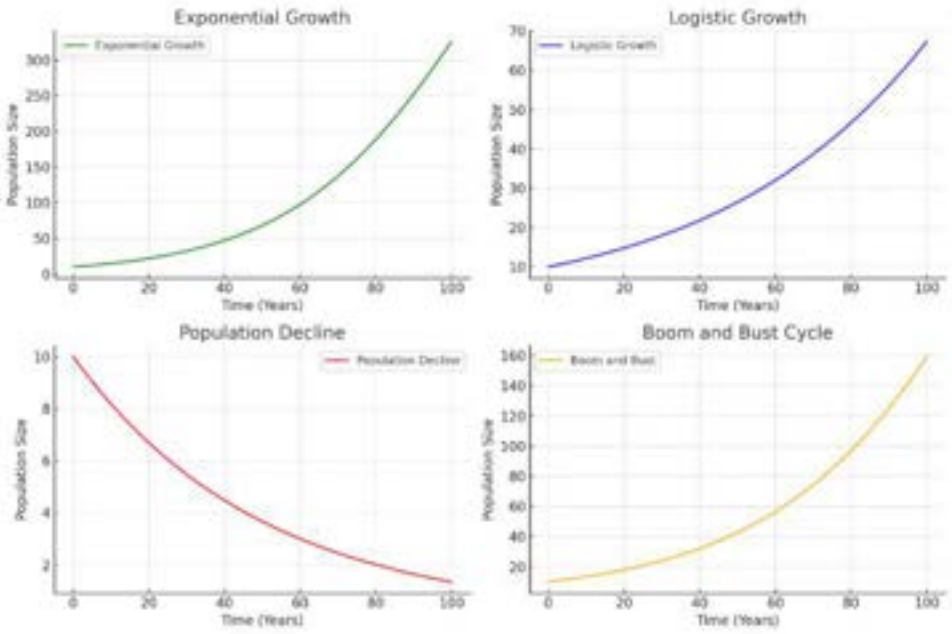

Figure 1: AI model results

With Scenario 1 (Exponential Growth), the population grows rapidly without constraints since births are greater than deaths and no resource limits exist. In Scenario 2 (Logistic Growth), growth starts fast but slows as the population approaches the carrying capacity. In Scenario 3 (Population Decline), the population continuously decreases because deaths are greater than births or high emigration has taken place. With Scenario 4 (Boom and Bust Cycle), the population grows rapidly but then collapses due to resource depletion over time.

5.2 HI generated population model

In a population system dynamics model, many variables can be measured quantitatively (e.g., birth rate, death rate, resource availability). However, certain variables require human intelligence to interpret, predict, or generate, as they involve subjective decision-making, cultural influences, or emergent social behaviours, as shown below:

5.2.1 Cultural and Social Norms

- **Family size preferences**: Varies by region and societal values.
- **Marriage patterns**: Age of marriage, arranged vs. love marriages.
- **Religious beliefs**: Influence on contraception, abortion, and gender roles.
- **Urbanization trends**: Driven by lifestyle aspirations, not just economic factors.
- **Work-life balance**: Social attitudes toward parenting and career.

These norms evolve dynamically and cannot be easily quantified without surveys or qualitative studies.

5.2.2 Political and Policy Decisions

- **Immigration policies**: Border control, refugee acceptance, labour migration laws.
- **Family planning policies**: e.g. pro-natalist policies (Hungary) [28].
- **Education reforms**: Investment in female education influences fertility rates [29] [29, 1].
- **Healthcare policies**: Impact on longevity and infant mortality.
- **Climate policies**: Regulations on pollution, conservation efforts affecting resources.

Policies are shaped by ideology, public sentiment, and leadership decisions, which are unpredictable and require human judgment.

5.2.3 Technological Innovations

- **Medical breakthroughs**: Cures for diseases, longevity treatments.
- **Agricultural advancements**: Vertical farming.
- **Energy production**: Shift from fossil fuels to renewables affecting sustainability.
- **AI and automation**: Impact on employment and economic migration.
- **Contraceptive technologies**: Birth control accessibility and effectiveness.

Innovations emerge unpredictably, driven by research, funding, and socio-political factors.

5.2.4 Economic Shifts and Crises

- **Job market trends**: AI replacing jobs, remote work changing urbanization.
- **Recession effects**: Economic downturns reducing birth rates.
- **Wealth distribution**: Inequality affecting access to healthcare and education.

- **Consumer behaviour**: Changing spending habits affecting family planning.
- **Financial policies**: Interest rates, social safety nets influencing migration.

Economic shifts depend on complex, human-driven financial systems and speculative behaviours.

5.2.5 Geopolitical Events

- **Wars and conflicts**: Affecting mortality, migration, and stability.
- **Refugee crises**: Humanitarian responses determine long-term population trends.
- **Diplomatic relations**: Trade agreements shaping economic migration.
- **Nationalism vs. globalization**: Shifting attitudes toward open borders.

Political tensions and alliances involve strategic human decision-making and are difficult to model.

5.2.6 Psychological and Behavioural Factors

- **Risk perception**: Will people have children during uncertain times?
- **Social movements**: Feminism, environmentalism influencing reproductive choices [30].
- **Aspirations and happiness**: Birth rates dropping as people prioritize lifestyle.
- **Crisis response**: Public reaction to pandemics, climate change, economic crashes.

These involve emotions, culture, and personal choices that AI struggles to predict accurately.

While biological and resource-based factors follow natural laws and can be modelled mathematically, variables driven by human intelligence, decision-making, and culture require interpretation, forecasting, and subjective judgment.

5.3 Integrating AI with HI factors with the population model

In this step, an advanced population system dynamics model was built that integrated both quantifiable variables (birth rates, death rates, resources) and human-intelligence-driven factors (culture, policy, psychology, and innovation).

5.3.1 Modified birth rate with human factors

$$B = B_o \times F\left(G_p, C_s, P_s, E_d, T\right) \quad (7)$$

B_o= Baseline birth rate

C_s = Cultural & social norms

G_p = Government policies

P_s = Political stability

E_d = Education levels

T = Technological impact

5.3.2 Death Rate (D) with human factors

$$D = D_0 \times \left(1 - H_q\right) + \left(C_v + E_h\right) \quad (8)$$

where:

D_0 = Baseline mortality rate

H_q = Healthcare quality

C_v = Conflict & violence.

E_h = Environmental hazards

5.3.3 Immigration and Emigration with Policy & Social Impact

Instead of static migration rates, we define:

$$I = I_o \times M(E_o, P_s, C_c, G_p, S_n) \quad (9)$$

$$E = E_o \times M'(E_o, P_s, C_c, G_p, S_n) \quad (10)$$

where:

I_o, E_o = Baseline immigration/emigration rates

M , M'= Migration response functions

E_o = Economic opportunity in destination country

P_s = Political stability

C_c = Climate change impact

G_p = Government policies (strict vs. open immigration laws)

S_n = Social norms

5.3.4 Carrying Capacity with Technology & Policy

Traditional models assume fixed carrying capacity. We modify it as:

$$K = K_o \times R(T, P_o, G_p) \quad (11)$$

where:

K_o = Natural carrying capacity (land, water, food supply)

$R(T, P_o, G_p)$= Resource function

T = Technological advancements (increases food production, medical care)

P_o = Pollution and environmental degradation (lowers carrying capacity)

G_p = Government sustainability policies

5.3.5 Psychological & Behavioural Factors

A new human-driven variable (B_h) influences all components:

$$B_h = f(R_p, S_m, C_c) \quad (12)$$

where:

R_p = Risk perception (do people feel safe to have kids?)

S_m = Social movements (feminism, environmentalism)

C_c = Crisis response (e.g., COVID-19 changed work & birth trends)

Scenarios were then simulated, shown in Figure 2 where:

Scenario 1: Technological Boom,

Scenario 2: Climate crisis, and

Scenario 3: Global war and Nationalism.

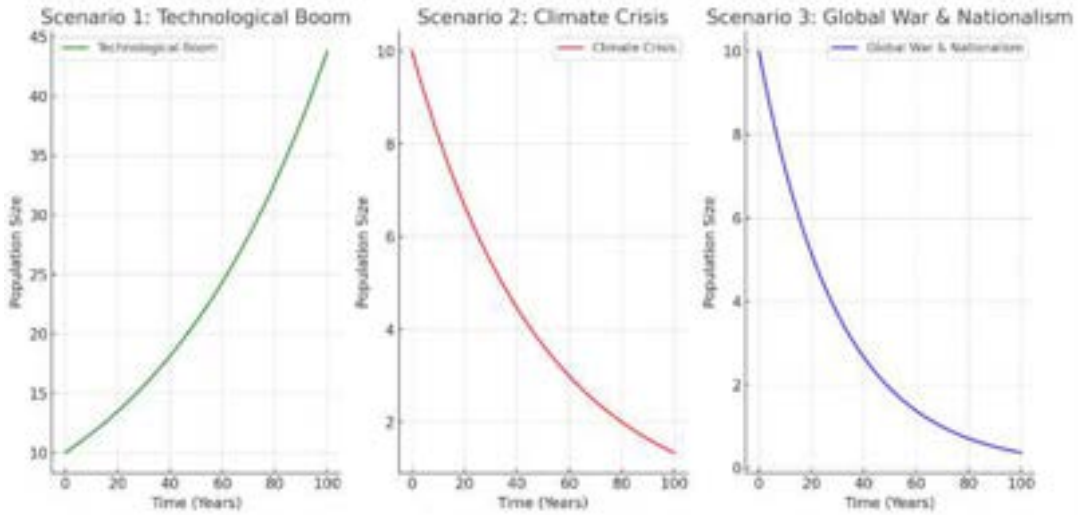

Figure 2: AI and HI combined model results

In Scenario 1, the population grows slowly but steadily due to improved healthcare, food, and tech. Migration helps sustain the population and growth stabilizes at a higher carrying capacity. In Scenario 2, the Population declines due to lower birth rates, high emigration, and disasters. The decline is gradual with fluctuations, representing regional instability while the Carrying capacity is lower, causing stagnation. In Scenario 3, there is a sharp population decline due to high death rates from war. Strict immigration policies prevent recovery and the low carrying capacity worsens the decline.

The main differences between the first set and the second set of graphical results lies in the underlying causes of population change, summarised in Table 2.

Table 2: Summary of core difference between the 2 models

Feature	First Set (Basic Growth Models)	Second Set (Human-Driven Scenarios)
Main Drivers	Birth rate, death rate, resources	Policy, war, technology, climate, migration
Carrying Capacity	Fixed	Dynamic (changes over time)
Migration	Not included	Included
Complexity	Simple growth/decline	Real-world geopolitical & environmental effects
Instability	Smooth trends	Fluctuations due to external shocks

Table 3 summarises the key differences between the AI generated population model and the model that integrated human intelligence.

Table 3: Summary of Human-AI Collaboration in Simulation and Modelling

Task	AI-Generated Models	Human-Driven Models
Predictability	High (Stable trends)	Lower (External shocks & uncertainty)
Complexity	Simple (Basic biology, resources)	Complex (War, tech, climate, policy)
Policy Impact	Limited (Fixed equations)	High (Governments can intervene)
Best Use Case	Long-term forecasting (growth limits)	Crisis response & policy design

6 CONCLUSION

With respect to AI models, these are excellent for predicting general population trends based on mathematical rules. They help understand biological constraints (birth, death, carrying capacity), however, the simple models miss external shocks like war, climate, and policy changes.

With respect to the models that integrate human intelligence, they factor in unpredictable events like technological advancements, war, climate disasters, and migration. They capture fluctuations caused by human choices and external pressures, but they are less deterministic, meaning policies and interventions can alter outcomes.

When using AI models, adjust them with real-world intelligence for policy planning and crisis management. The feedback loops between AI automation and human expertise ensure adaptability, reliability, and practical applicability of simulations.

AI can simulate "what-if" scenarios, but human intelligence must interpret and apply them to real-life policymaking.

Going forward, human and artificial intelligence (AI) are likely to be more integrated in model development than before. more complex rules and reasoning typology needed to integrate human and AI effectively. By making such AI systems aware of their human counterparts, not only the machine intelligence may be more effectively leveraged, but it may also lead to a revolutionary change in the way engineers engage in the model development.

AN INVESTIGATIVE ANALYSIS INTO THE INDUSTRY 4.0 READINESS OF A MULTINATIONAL SUBSIDIARY LOCATED IN A DEVELOPING COUNTRY

S. Ndwandwe[1] and T.P. Letaba[2*]

[1,2]Department of Engineering and Technology Management
University of Pretoria, South Africa

ABSTRACT

There has been an uptake of research focusing on the adoption level and the ability of developing countries to catch up in Industry 4.0 implementation. However, little information is available on the level of Industry 4.0 readiness for multinational firm subsidiaries. This study aimed to apply a readiness assessment model to international food manufacturing firms located in Eswatini to measure their level of readiness while establishing the causative relationship between Industry 4.0 readiness and location. Two research tools were utilised: quantitative and qualitative surveys. The results of this study revealed that subsidiaries of multinational firms in Eswatini are transitioning towards a state of maturity in Industry 4.0. The assessment also highlighted the impact of location on the readiness level, revealing that location is an umbrella factor for the barriers faced by companies located in developing countries.

Keywords: Industry 4.0 readiness, adoption level, multinational firm subsidiaries, developing countries

1 INTRODUCTION

The term Fourth Industrial Revolution, also called Industry 4.0, German “Industrie 4.0” or “IR 4.0”, refers to the cutting-edge technologies representing the core of change in industrial settings, which aim to deliver a significant transformational change either in the organisation or in the management of industrial processes [1]. We live in an era of this revolution, where competitiveness and relevance are largely dependent on a business’s ability to align its operations with the requirements of Industry 4.0.

Industry 4.0 is built on systems, structures, and processes that are capable of improvement [1], in speed and flexibility to production processes, and are integrated. This integration is not only limited to production systems but has also resulted in an intertwined supply chain system in the production industry. Different authors in the literature have recorded the underlying principles of the Fourth Industrial Revolution. For example, authors Rajnai and Kocsis [2] describe Industry 4.0 as the digital transformation of manufacturing processes based on intelligent machines and devices. The features of the revolution, as described by Maisiri and van Dyk [3], are technological evolution taking place at an exponential pace, in-depth advancement of technologies, which is a combination of multiple technologies, and finally, its impact across the entire system affecting industries, companies, and even countries. In simple terms, Industry 4.0 is an integration, adaptation, and optimisation of the technologies of all preceding revolutions. While the implementation of these main technologies, practices, and technologies is the basis and pillar of Industry 4.0 implementation, it does not necessarily mean all technologies must be implemented at once. The composition of technologies is dependent mainly on the needs and main functions of a business, industry, or organisation.

Despite several factors affecting the decision of manufacturing firms to adopt Industry 4.0, Kee, Khin and Ho [4] noted in their study that limited literature has addressed these. The authors highlighted a claim made in literature that companies and researchers have focused more on the barriers to Industry 4.0 implementation compared to the driving or facilitating forces due to their adverse effects. Market factors such as customer requirements and competitors, benefits such as cost reduction and turnaround time, as well as strategic, operational, environmental, business model innovation, and social opportunities are considered as positive drivers for Industry 4.0 [4]. In addition to driving forces are the facilitating factors, which indirectly influence Industry 4.0 implementation of Industry 4.0, such as governmental and financial support and skills given to employees of an organisation.

Industry 4.0 is becoming more popular and relevant, and is gaining attention from not only scholars but also leaders of countries who seek to adopt it to advance their manufacturing industries and position themselves to compete in the global space. Developing and least-developed countries are also in the same quest and currently have limited manufacturing bases and potential in Industry [5]. For developing countries, whose economies grow fast because they produce different products, Industry 4.0 is an important enabler of improved production [6]. Developed countries have seen greater success in this endeavour, while some countries are still lagging behind. Research in Industry 4.0 and internationalisation is also still a new phenomenon. Over the past decades, scholars have increasingly paid attention to changes in business management and firms’ international activities concerning Industry 4.0 [7]. An established relationship between the two phenomena is that ‘Industry 4.0 changes internationalisation strategies, transforming, for example, the structure of global value and supply chain’ [8], or the dynamics of competition [9]. It is also noted from the review that the international configuration of firms and countries' characteristics influence the choice of Industry 4.0, but what is lacking in the evidence on how and to what extent?

The objective of this study is to apply a readiness assessment model to international food manufacturing firms operating in Eswatini to measure the level of readiness while located in

a developing country, to establish the variance in performance to firms of the same business located in developed locations, and identify the dimensions of Industry 4.0 readiness that are impacted by location, and determine the causative relationship that leads to success in Industry 4.0 implementation. The study will focus on six dimensions, i.e., organisational strategy, people, infrastructure, operations, products, and data-driven decision-making. This article is presented in six sections, where section two will present a literature review on readiness assessment models that are available in the literature. Section three will highlight the methodology that this research followed, and the results in section four of this study. The last two sections will cover a discussion of the results and the conclusion thereof.

2 LITERATURE REVIEW

2.1 Industry 4.0 readiness

Preparedness for the implementation of Industry 4.0 is subjective and depends on a lot of factors. Thus, measuring preparedness level by organisations can be beneficial to the overall success in Industry 4.0. Readiness models are thus used by organisations, entities, and countries to evaluate their capacity for Industry 4.0, which facilitates change and actions to eliminate current shortcomings. Authors Genest and Gamache [10] highlighted, though, that the implementation of the Fourth Industrial Revolution requires the implementation of several technologies, which require large investments for companies. On the other hand, organisations must indeed realise and comprehend that industry 4.0 readiness is not only concerned with one level, which is the technology investments only. Preparedness is effectively measured from the top, at the organisational strategy level to the commitments made by management towards implementation [2], until the final product produced by an organisation.

2.2 Assessment models of Industry 4.0

Generally, the two terms, maturity and readiness, are described and utilised in different ways. According to Schumacher, Erol and Sihn [11], maturity is a state of completeness and implies some progress in the development of a system. Readiness refers to preparedness considering the conditions, attitudes, and resources, at all levels of a system, needed for achieving its goals [12]. The difference between the two assessment models, i.e., the maturity model and readiness model, is that readiness assessment must occur before the maturing process starts [13]. The aim of the readiness model or assessment, as described by the authors, is the initialisation of the transformation process for Industry 4.0, while a maturity model will diagnose the level of maturity a company is in. Company-specific assessments are referred to as self-assessments [14]. The practice is that surveys target general information on awareness, perception, attitudes, and more [2]. Some surveys, though, focus more on the enterprises, manufacturing, and branch-specific data. Both angles are important since they give a true picture of the company's position. Firms' management must be aware of the already existing trends and be self-aware of their current position for them to start on the digital transformation journey. Industry 4.0 assessment thus seeks to identify the phase of an organisation's digital transformation [3].

Maisiri & van Dyk [3] referenced a two-phased assessment model, comprising a macro-level and micro-level Industry 4.0 readiness index from the literature. The macro-level Industry 4.0 index classifies countries into four categories, presented in Table 1, considering the level of sophistication of production processes in a nation's industry, including the level of automation, how innovative the workforce is, and what their attitude towards innovation is like [15].

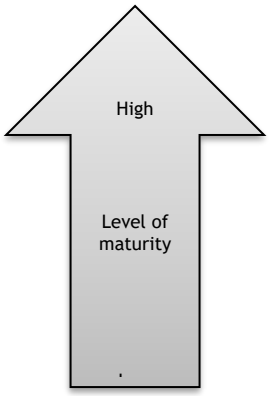
Table 1: Industry 4.0 readiness categories at the macro level [3]

Industry 4.0 readiness category	Description
Frontrunners	Manufacturing has a large share in GDP, is innovative, dictates technologies, and path leaders
Potentials	Manufacturing on a downward trend in previous years, innovative attitudes, and pathfinders
Traditionalists	Manufacturing has a noticeable share in the GDP, underdeveloped technologies, and production methods
Hesitators	Manufacturing and technology require development, and uncertainty in adopting digitalisation.

The micro-level industry 4.0 readiness index places manufacturing firms into four different development levels, based on their Industry 4.0 digital solutions application and adoption:

- Digital novices- entities with isolated digital applications and solutions, focusing on products and not customers, their operations in functional silos, and manual processes. Little IT (Information Technology) architecture is in place.
- Vertical integrators- emphasising digitalisation, have unstructured cross-functional collaborations and isolated analytical capabilities with limited integration with the external supply chain.
- Horizontal collaborators- here, digitalisation activities are observed across the whole value chain, internal and external supply chain, with thorough data use and comprehensive data analytics.
- Digital champions- at the top of the categories are the champions who have developed novel digital models, with collaborations extending beyond their value chain partnerships. These entities are completely digitalised and utilise predictive analytics in real-time optimisation.

The author, Nagy [15] noted that the criteria for each of the levels described above were getting more and more complex. Thus, it was difficult to classify a company or country as a digital champion using these models. Also, the two models assume some relationship between the financial performance of a country or company and Industry 4.0, which might not always be true. Forester's digital maturity model measures the complexity and maturity of enterprises in digital transformation in four dimensions, i.e., Culture, Technology, Organisation, and Insights [3]. Four maturity levels are utilised as seen in Figure 1:



Maturity segment	Characteristic behaviour	Strategy	Score range
Differentiators	Leverage data to drive customer obsession	Blend the digital and physical world	72-84
Collaborators	Breaking down traditional silos	Use digital to create a competitive advantage	53-71
Adopters	Investing in skills and infrastructure	Prioritise customer relationship over production.	34-52
Skeptics	Just beginning the digital journey	Prompt a willing attitude	0-33

Figure 1: Forrester's four levels of digital maturity readiness levels [16]

This model can grasp both the complexity and maturity of the digital transformation of enterprises. Its application uses a quantitative approach, which is often criticised in literature for its lack of clarity on the method of application.

Schumacher et al. [11] applied Becker's step-by-step process for the development of maturity models and followed a systematic literature review, expert interview, conceptual modelling, and validation approach to develop their model. The procedure applied included initially creating an understanding of Industry 4.0 among industry leaders, crafting a core structure of the model, and finally testing the model in an industry to verify its usability. From the numerous numbers of models available, the authors were able to consider a total of 72 maturity models, most of which had five levels and four to six dimensions to consider. The authors thus came up with a three-step procedure that can be used in the assessment of Industry 4.0 maturity.

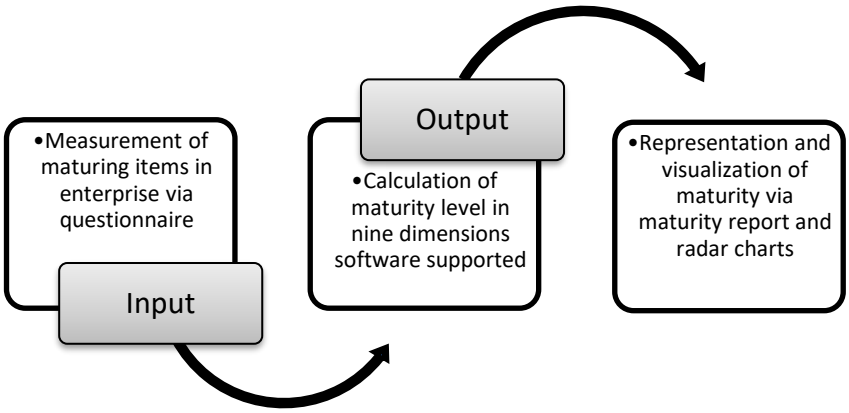


Figure 2: Three-step procedure to assess industry 4.0 maturity [11]

3 RESEARCH METHODOLOGY

This study adopted a mixed-methods research design, combining qualitative and quantitative approaches within a case study framework to assess Industry 4.0 readiness among international food-manufacturing firms in Eswatini. Given the small population of such firms in the region, a census-based non-probability sampling (quota sampling) strategy was employed, focusing on senior decision-makers, including CEOs, CTOs, and engineering

managers. Data collection was conducted via Qualtrics over a six-week period, utilising two key instruments: a quantitative survey adapted from the VDMA Industry 4.0 Readiness Model [17;3] and a qualitative survey with open-ended questions. The quantitative survey assessed maturity across six dimensions—Organisational Strategy, Smart Factory, Smart Operations, Smart Products, Data-Driven Services, and Employees—while the qualitative component explored contextual barriers and enablers of Industry 4.0 adoption.

For deeper insights, a focused analysis was conducted within a single firm (IFM0100), where 36 employees from IT, Engineering, and Quality departments completed the quantitative survey, yielding 19 usable responses. Additionally, 8 senior and middle managers participated in qualitative interviews, though time constraints led most to prefer written responses over live discussions. Data analysis followed a triangulation approach: the VDMA Impuls Industry 4.0 Readiness Online Check provided baseline maturity scores, supplemented by descriptive statistics and Pearson's correlation to examine relationships between Industry 3.0 technologies and production systems. Qualitative responses underwent thematic content analysis, with open coding used to identify recurring themes.

The mixed-methods design strengthened validity by cross-verifying findings across different data sources, while the VDMA framework ensured alignment with established Industry 4.0 assessment criteria. This methodology provided a comprehensive evaluation of technological readiness in a developing economy context, balancing scalability (through the quantitative survey) and depth (via qualitative insights).

4 RESULTS

This section presents and discusses the information collected as part of the research. Its first part provides a descriptive analysis of the profile of the sampled firms operating in Eswatini. The section progresses to discuss the analytical models that have been used in testing the hypotheses and propositions under analysis in this study.

4.1 Maturity determination

Results from the online survey are presented below, comparing the participating firms at the six dimensions the IMPULS model measures maturity at: Strategy and organisation, Smart factory, Smart operations, Smart products, Data-driven services and finally Employees.

4.1.1Descriptive statistics of the overall maturity levels

Below is a table of the maturity levels of the four different firms that participated in the survey. The table represents the maturity level, based on the maturity items under each dimension.

Table 2: Industry 4.0 overall readiness results

FIRM ID	Readiness level	Level description	Employee size
IFM0100	3	Experienced	100 to 249
IFM0200	4	Expert	500 or more
IFM0300	1	Beginner	20 to 99
IFM0400	1	Beginner	100 to 249

The mean readiness level of the sampled firms is 2.25, which is at the intermediate level. From the statistics above, the mode is 1 and 2 out of the 4 firms were found to be at level 1 of readiness. The highest level of readiness obtained from the gathered data was at level 4, representing the expert level. Table 3 summarises the readiness level for each of the firms in the different dimensions. All firms are not yet capable of data-driven services.

Table 3: Summary of dimension-specific readiness level

FIRM ID	Strategy and organisation	Employees	Smart factory	Smart operations	Smart products	Data-driven Services
IFM0100	4	4	1	2	5	0
IFM0200	4	5	3	4	5	0
IFM0300	0	1	1	2	0	0
IFM0400	2	2	0	2	0	0

4.1.2 Dimension-specific readiness

The Strategy and Organisation dimension is rated at 0.254, according to the IMPULS Industrie 4.0 readiness study. The results for this dimension revealed that most of the firms have already implemented the Industry 4.0 strategy. The rating of the model contains five levels, with level 5 being the highest level of maturity, and most firms are at level 4 of strategy implementation, with only one firm having no strategy in place. From the results of the employees' dimension, we can see that the participating firms have at least a minimum of the skills required for Industry 4.0 readiness, with more skills still requiring acquisition. Also, some of the firms have made investments in line with ensuring that employees acquire the required and missing skills.

The results of the smart factory dimension revealed that IFM0200 was a leading Smart factory, rated at the experienced level, with future functionalities satisfied and having upgradable technologies. From the VDMA assessment, it is shown that hurdles towards reaching beyond level 3 in this dimension are mainly due to machine and systems infrastructures that do not meet all future requirements. The collection of data is not consistently digitised [17]. It was determined from the results that the firms are somewhat engaged in Smart operations, with an average score of two for most of the firms. The highest-scoring firm obtained a score of 4, which represents a high level of information sharing, cloud usage, IT security and autonomous processes.

Two of the firms are rated level 5 for smart products, where their products feature comprehensive functionalities that are add-ons, and there is comprehensive use of data for various functionalities [17]. All the firms scored zero for data-driven services. It is apparent that there is none among the sample of firms that was rated anything above zero (outsider level). This can be interpreted as simply that firms have not met any of the requirements that determine readiness in this dimension. Lichtblau et al. [17] explained that this simply means firms are focusing on the traditional product, with no data-driven services offered.

4.2 Firm-specific survey

As highlighted in the data collection sub-section, the quantitative data collection was split into two phases. The first phase has been discussed above, where representatives from different firms were requested to fill in a quantitative survey to measure readiness in Industry 4.0. For the second phase, the quantitative survey was sent to a group of 36 associates within IFM0100, focusing on Industry 3.0 transition into the current revolution.

Table 4 presents the descriptive statistics for participating departments within IFM 0100. The majority of the participants are from the engineering department, with equal representation of 15.8% from three departments, i.e., Finance, Quality, Safety and Environment, and Operations.

Table 4: Participants' departments descriptive statistics

Department	Frequency	Percentage	Cumulative percentage
I.T.	3	15.8%	15.8%
Engineering	7	36.8%	52.6%
Finance	2	10.5%	63.2%
Quality, Safety and Environment	3	15.8%	78.9%
Operations	3	15.8%	94.7%
Operational Excellence	1	5.3%	100.0%
Total	**19**	**100.0%**	

Table 5 displays descriptive statistics for the participants' tenure. About 74% of the respondents have work experience of 0 and 9 years. Only 26.3% of the respondents have been with the company for more than 15 years.

Table 5: Participant's tenure descriptive statistics

Year range	Frequency	Percentage	Cumulative percentage
0-4	7	36.8%	36.8%
5-9	7	36.8%	73.7%
10-14	0	0.0%	73.7%
15 and more	5	26.3%	100.0%
Total	**19**	**100.0%**	

Industry 3.0 is characterised by specific technologies and a typical design of the production company. Therefore, the quantitative survey had one section focusing on interrogating the presence of these technologies and the typical design of the production system. These questions sought to understand the state of the firm's case towards Industry 3.0 implementation. The aim of these questions was to establish if the firm under study had fully transitioned to Industry 3.0 before the Industry 4.0 era. Also, the aim was to understand the relation between the Industry 3.0 implementation and the typical production system associated with the Industry 3.0, and finally, the technologies associated with it.

A. Descriptive summary data for Industry 3.0

From the results in Table 6, we can basically summarise that the firm had already transitioned fully into Industry 3.0 and had implemented most of the technologies that characterise Industry 3.0. Table 6: Descriptive summary on Industry 3.0

Question	Possible Response	Code	Frequency
Q3. Which of the following statements is true about your company concerning Industry 3.0?	A. The company had fully implemented the technologies of the preceding Industrial Revolution	1	6 (31.6%)
	B. The company had mostly implemented Industry 3.0 technologies	2	13 (68.4%)
	C. The company had only partially implemented Industry 3.0 technologies	3	0 (0%)
	D. No technologies from Industry 3.0 had been implemented	4	0 (0%)
Q4.1. Which of these technologies from Industry 3.0 had been fully implemented in your company before the Industry 4.0 era? – *Computers*	A. Yes	1	19 (100%)
	B. No	2	0 (0%)

Q4.2. Which of these technologies from Industry 3.0 had been fully implemented in your company before the Industry 4.0 era? - *Electronic systems*	A. YES B. NO	1 2	19 (100%) 0 (0%)
Q4.3. Which of these technologies from Industry 3.0 had been fully implemented in your company before the Industry 4.0 era? - *Information systems*	A. YES B. NO	1 2	18 (94.7%) 1 (5.3%)
Q4.4. Which of these technologies from Industry 3.0 had been fully implemented in your company before the Industry 4.0 era? - *Programmable logic controllers*	A. YES B. NO	1 2	17 (89.5%) 2 (10.5%)
Q5. Does your company layout follow the typical Industry 3.0 production system, which is made up of the mechanical workshop, the assembly workshop, and additional departments including planning, logistics, optimisation and so on? -	YES NO NOT ENTIRELY COMMENT	1 2 3 4	17 (89.5%) 0 (0%) 1 (5.3%) 1 (5.3%)

This is evident in that 68.4% of the participants believed that almost all the technologies had been implemented, while the rest (31.6%) submitted that the company had all the technologies in place. Computer and electronics were implemented fully, while 94.7% submitted that IT infrastructure had not been fully implemented. We explored the correlation of these results using data analytics.

B. Correlation analysis

Correlation analysis between Industry 3.0 implementation and the typical 3IR production system was conducted. The results revealed that there is a positive relationship between the two variables: Industry 3.0 implementation and having a typical production system, with a Pearson's correlation coefficient of 0.23. Although the strength of the correlation is weak, which means that as the score of one variable changed, the other changed an amount considered to be weak in magnitude. The 0.05 significance signifies that there is less likelihood that this could have been due to chance. Thus, the results show that although the correlation is positive, the relationship is statistically less significant, which means a firm could have implemented Industry 3.0, while it does not have the typical mechanical workshop, assembly workshop and additional departments layout as suggested by Zakoldaev, Shukalov & Zharinov [18]. It is important to note, though, that 89.5 % of the participants had submitted that the firm does have a typical Industry 3.0 production layout.

Table 7 presents the correlation between Industry 3.0 implementation and the implementation of the technologies, which, according to the literature, characterise the Third Industrial Revolution.

Table 7: Correlation between 3IR and its technologies

	3IR	**Computers**	**Electronic systems**	**Information systems**	**Programmable logic controllers**
3IR	1.00				
Computers	0.00	1.00			
Electronic systems	0.00	0.00	1.00		
Information systems	0.16	0.00	0.00	1.00	
Programmable logic controllers	0.23	0.00	0.00	-0.08	1.00

The results show a positive correlation between 3IR implementation and the presence of two technologies: Information systems and Programmable logic controllers, as much as the relationship is weak.

4.2 Qualitative Interviews Results

The interviews targeted senior and middle management (or their delegates) within IFM0100, with 15 individuals invited and 8 responses collected. The majority of respondents (50%) were from middle management, while 37.5% were senior management and 12.5% were other delegates. Participants came from various departments, including Operations, Quality, and Supply Chain, with tenures ranging from 5 to 20 years — 37.5% had 10-14 years of experience, and another 37.5% had 15-20 years.

Regarding Industry 4.0 adoption, nearly all participants agreed their firm was at an advanced stage, embedding technologies like robotics, automation, and cloud computing into operations. Respondents highlighted a steady progression toward maturity, supported by mindset shifts and digital transformation initiatives. Benchmarking against sister firms in developed countries revealed that the local firm was a "fast follower," though lagging in fully automated processes and advanced infrastructure.

Implemented technologies included automated data collection, digital dashboards, cobots (collaborative robots), and real-time monitoring systems, improving efficiency and proactive issue resolution. However, opportunities for further growth remained, particularly in end-to-end data integration, AI adoption, and cultural change toward automation. Barriers included capability gaps, slow learning curves, inadequate infrastructure, and geographical challenges (e.g., unreliable IT networks in the African region). Location was seen as a significant hindrance, though some believed commitment could overcome these limitations.

Incentives from Industry 4.0 included operational efficiency, faster decision-making through real-time data, and improved compliance. Key enablers for sustained progress were strong leadership, clear strategic roadmaps, and workforce agility. Finally, firm-specific opportunities centred on leveraging AI, reducing project waste, and maximising existing technologies. Overall, while the firm has made substantial progress, challenges in resourcing, change management, and infrastructure must be addressed to achieve full maturity.

5 CONCLUSION

Industry 4.0 is indeed ever evolving and introducing new technologies that enterprises need to keep abreast of, but it would be futile for enterprises to simply focus on technology while neglecting the foundational principles of Industry 4.0. The method of assessing readiness is meant to guide enterprises in a holistic transformation journey. Although developed countries have made such huge progress in Industry 4.0, the level of preparedness remains unclear. This research's findings are that subsidiaries of multinational food manufacturing firms located in developing countries are also transitioning towards Industry 4.0 maturity. A relationship between the identified gap and the location of the firms was established when it was gathered from data collected in this study that location is in fact the main driver of any barriers relating to Industry 4.0. For example, capabilities and capability building were identified as a limitation in this part of the world, which is taking longer to overcome due to the slow pace of learning.

As much as the findings of this study cannot be generalised to the whole population of firms that are in Eswatini, the study revealed that there are noticeable challenges relating to smart services, operations, and products, while the area of data-driven services still requires more focus since there was no indication these are available. It is recommended that firms, as much as they are linked to international subsidiaries, establish their roadmap to follow and implement when it comes to Industry 4.0. It was apparent during the duration of this study

that most of these subsidiaries mainly rely on already established road maps. It is also true that one strategy succeeding in one location does not mean it will be the same for another location. Thus, the importance of adopting and adapting Industry 4.0 in consideration of the location. There needs to be a huge focus on skills building or skills transfer from developed countries. This study has laid a foundation for many interesting issues that can benefit organisations tremendously in considering future strategies. Further, to increase the generalisability of this study type and address its limitations of a small sample size, it is recommended that the same research be carried out with the inclusion of the overall population of firms (including other industries) located in the study location.

EXPLORING COGNITIVE BIASES IN PROJECT MANAGEMENT DECISION-MAKING

ABSTRACT

This paper investigates the impact of cognitive biases on decision-making in Project Management, particularly in ambiguous versus straightforward scenarios. Cognitive bias can lead to suboptimal decisions and unforeseen project challenges. A mix of intuition and experience influences the decision-making process, shaping how information is processed. This research addresses real-world challenges by offering strategies to mitigate biases amid increasing project complexity and uncertainty. Using mixed methods, data were gathered through interviews with project managers and surveys and analysed quantitatively and qualitatively. Statistical analyses examined how bias awareness impacts project complexity and decision-making quality. The research establishes that biases are more prevalent in ambiguous situations than in straightforward ones. Managers aware of biases make better choices in straightforward scenarios, though no significant relationship was established in ambiguous situations. Cognitive biases negatively affected project outcomes. The findings contribute to understanding how cognitive biases influence project outcomes and suggest areas for further research.

Keywords: Cognitive Biases, Project Management, Decision-Making, Uncertainty, Mitigating biases.

1 INTRODUCTION

1.1 Background

In Project Management, understanding how cognitive biases influence decision-making is crucial. In civil engineering, these biases are particularly significant, as decisions often involve conflicting evaluation criteria and long-term consequences [1]. Research by Chadee, et al. [2] highlighted the impact of heuristics on time and cost in construction projects, affecting performance throughout various phases. The Engineering Council of South Africa identifies judgment and decision-making as core competencies for professional engineers. These competencies emphasise the importance of understanding cognitive factors that influence decisions in complex engineering activities [3]. Thus, exploring cognitive biases offers valuable insights for improving project outcomes and enhancing engineers' decision-making abilities. Recent research has explored various facets of cognitive biases, particularly in the context of decision-making in ambiguous versus straightforward scenarios [1], [4], [5], [6]. Despite the extensive research, gaps still need to be addressed. These gaps underscore the importance of the proposed research, which aims to clarify the nuances of cognitive biases in Project Management.

1.2 Objectives

In project management, understanding the intricacies of decision-making is paramount. This paper aims to present and discuss the following:

- Identify the most common cognitive biases affecting decisions and examine how these biases influence decision-making in different scenarios.
- Assess the impact of these biases on key project performance indicators, such as stakeholder satisfaction, productivity, and overall project success.

1.3 Research questions

This paper will also endeavour to uncover potential research gaps associated with cognitive biases in project management decision-making by answering the following questions:

1. How do cognitive biases influence project performance measures?
2. Are there instances where repeated cognitive biases have led to systemic issues or failures in project management?
3. Which cognitive biases have been extensively studied and documented in project management?

2 LITERATURE REVIEW

> *"The physician's hunch initiates a deliberate search for the ailment, and a musician's conscious and meticulous practice is the very basis from which those precious moments of flow emerge, where improvisation progresses without conscious guidance" [7].*

When making decisions in life situations or circumstances, people rely on intuition and factual information, which can be influenced by personal biases and past experiences that impact how choices are ultimately made. These biases can contribute positively to the decision-making process, but often, negative outcomes are derived from cognitive "guessing" when decisions are made [8]. Understanding the effect of cognitive biases on project management stems from the realisation that cognitive biases can profoundly influence the outcomes of projects, potentially leading to suboptimal decisions and unforeseen challenges. The following sections will delve into the identified main concepts: cognitive biases, how cognitive biases significantly affect decision-making in project management across straightforward and ambiguous scenarios, and the impact of biases on project outcomes.

2.1 Cognitive biases

In decision-making, heuristics can lead to cognitive biases, influencing our intuitive judgments and our observable behaviours (behavioural biases) [9]. While heuristics and intuition can help in efficient decision-making, especially under time pressure or complexity, they can be susceptible to errors due to cognitive biases. By being aware of the potential for cognitive biases to influence heuristics, intuition, and behaviour, steps can be taken to mitigate their impact. In summary, while heuristics, behavioural biases, and intuition are distinct concepts, they are all related to cognitive biases in the sense that cognitive biases can influence and often explain the mechanisms behind these other phenomena in human thought and behaviour [9]. Current literature often merges these concepts without clear distinctions despite their unique cognitive and psychological mechanisms. In this research, intuition, heuristics, and behavioural biases are considered subsets within the broader category of cognitive biases.

The cognitive biases identified to date include more than 200 items, according to Flyvbjerg [9]. External pressures affect some biases, such as strategic misrepresentation, while the project manager's internal factors cause others, like the uniqueness bias. This alludes to the fact that project management biases will differ and are scenario-specific. “Behavioural science tells project planners and managers, 'Your biggest risk is you. It is not scoping changes, complexity, and so forth in themselves that are the main problem; it is how human beings misconceive and underestimate these phenomena, through optimism bias, overconfidence bias, and strategic misrepresentation” [9]. Flyvbjerg [9] notes that these biases can be summed up into the ten most important biases and, if not identified and managed at the initiation stage and during execution, could negatively impact project outcomes.

Flyvbjerg [9] delves into several biases that commonly influence project decisions and outcomes, highlighting the importance of their recognition and mitigation. Optimism bias is a cognitive bias where individuals, including experts, are overtly confident about the consequences of planned actions [10]. This bias leads to decisions based on idealistic visions of the future, resulting in overestimating benefits and underestimating costs and risks. Kahneman, et al. [11] emphasise that when people feel optimistic about something, they often do not realise how positive their outlook is.

Fink and Pinchovski [12] use an empirical approach to investigate the time-saving bias and its effect on software development projects. Their research focuses on the plan-based and agile project management approaches. Implementing agile development approaches could result in better instinctive decision-making but may also be susceptible to cognitive biases. “To counteract this, managers should insist on using formal methods of time estimation even when heuristics are readily available” [12]. Their findings reveal that bias can be mitigated by providing reliable information but not eliminated. They provide only one mitigation specific to the project management approach, and their empirical studies are ongoing.

Flyvbjerg [9] argues that political bias stems from power dynamics, not cognitive factors, and involves deliberate distortions. In large projects with significant political and organisational influence, political bias plays a key role, particularly through strategic misrepresentation. However, this paper focuses only on cognitive biases, not behavioural biases. While cognitive biases like heuristics often provide the best solutions, especially when optimisation is challenging or inaccurate due to computational issues or estimation errors, Love, et al. [13] note that heuristics are used not only because of cognitive limitations but also due to environmental factors like complexity. In uncertain environments, good decision-making may involve ignoring some available information [13]. Okoli and Watt [14] emphasise that while intuition often precedes analytical thinking, both strategies can provide value when their application is clearly understood. This leads to the concept of scenario-specific cognitive

biases, which will be explored in relation to decision-making in straightforward and ambiguous situations.

2.2 Decision-making

A company's success is a result of good decision-making. Understanding project managers' decision-making processes can help identify why many projects fail. In their 2012 analysis, the Gartner Group identified that 61% of technology projects do not meet success criteria. Echoing this, McKinsey & Company, in collaboration with the University of Oxford in 2011, highlighted a troubling trend: a significant portion of projects fail to meet their objectives and pose existential risks to their companies. They found that projects typically exceed budgets, are often delayed, and fail to deliver expected value [15].

Nikolić [5] believes that simplifying the decision-making process using heuristics negatively affects the quality of decisions. However, Julmi [16] argues that previous research has focused on the negative effects and believes that there is a shift towards benefits of intuition, and it "…may be as good or even superior to analytical thinking". Intuition has its strengths and weaknesses, and should not be considered inferior to analytical decision-making when making practical decisions Julmi [16].

Tsiga and Emes [15] call for research into project decision-making processes to uncover the causes of high failure rates, particularly in complex projects. Cristofaro [17] notes studies linking cognitive biases to decision-making effectiveness, with psychological research exploring how personality types influence this Nikolić [5]. emphasises that decision-making is influenced by economic, psychological, and personal factors. While Nikolić examines the impact of cognitive traits on decision-making, Cristofaro focuses on the role of personality types. Project managers often fall victim to cognitive biases, as they are "very often victims of cognitive biases" [17].

Nikolić's concept of bounded rationality highlights cognitive limitations in decision-making. While aiming for rationality, decision-makers simplify complex problems using heuristics, leading to biases like overconfidence, framing effects, and confirmation bias [5]. Nikolić [5]suggests that though efficient in some contexts, this approach often leads to suboptimal decisions, particularly in complex situations with multiple variables and outcomes.

Decision-making in an ambiguous situation is difficult because it is often unclear what the problem or potential solutions may entail. In a straightforward situation, the situation or problem is clear; however, it is still challenging to predict the outcomes as a result of any decision due to a lack of information about events in the future. Julmi [16] introduces the organisation information processing theory, which considers that "it is equivocality and not uncertainty that determines intuition effectiveness". Julmi states that ambiguous situations are better suited for intuitive decision-making due to high equivocality. In contrast, in straightforward environments where information is available, decision-making is often centred around assessing risks and developing contingency plans. This concept is further reinforced by Mousavi and Gigerenzer [18], who state that in the face of fundamental uncertainty (ambiguity), the probability that is used to calculate risk may be irrelevant, whereas "fast and frugal heuristics can provide robust decisions under risk versus uncertainty strategies that can perform well under uncertainty".

2.3 Cognitive bias influence on project outcomes

Chadee, et al. [2] explore the causes of cost overruns in public-sector construction projects, emphasising the influence of cognitive biases, particularly the planning fallacy, a form of optimism bias [9]. Project planners often overlook historical data and past experiences, underestimating time and effort despite similar tasks requiring more time. Interestingly, the planning fallacy also leads to negativity when assessing others' tasks, often overestimating the

required time. Optimism bias is a key factor in project delays and budget overruns, with Chadee, et al. [2] proposing contingency time windows in contracts to mitigate its impact. Current methods lack safeguards like "plan reliability" to counteract optimism bias.

Forecasters rarely attribute their predictions to optimism bias, instead blaming misrepresentation and common challenges such as scope changes and weather [19]. Chadee, et al. [2] connect cognitive biases to key project performance measures like cost, schedule adherence, and quality. Mousavi and Gigerenzer stress the importance of identifying biases without suppressing beneficial cognitive functions, as both reason and intuition are essential for decision-making [7]. entrepreneurship often involves decision-making in uncertain (ambiguous) situations [19]. Wang [20] argues that recognising and addressing biases is crucial for decision-making integrity.

Cristofaro [17] highlights the need for a multi-faceted approach to mitigating biases, combining quality control tools, psychological instruments, and an understanding of decision-makers' cognitive and personality traits to promote rational and objective decisions.

In summary, cognitive biases like optimism bias, overconfidence, and planning fallacy significantly impact project outcomes, leading to cost overruns and delays. These biases were found to be more prevalent in straightforward scenarios but potentially more harmful in ambiguous ones. These insights inform the conceptual model developed in Section 3, providing a framework for further research.

3 PROPOSED MODEL OR CONCEPTUAL METHOD

A conceptual model is developed guided by the literature discussed in the previous section. The model aims to answer research questions and highlight the research's contribution to existing knowledge [21]. It focuses on the prevalence of cognitive biases in different scenarios and their impact on project performance. A conceptual framework is developed first, which then leads to the development of a conceptual model. Cognitive psychology, decision theory, project complexity and outcomes were determined as the focus areas for the conceptual framework.

3.1 Cognitive psychology and decision theory

Acknowledging the influence of biases on judgment and decision-making is crucial for improving decision quality. Systematic mistakes caused by biases can be mitigated through awareness and a critical decision-making approach [5]. To address the research questions, this research will only focus on some of the biases that Flyvbjerg identified: overconfidence, anchoring, optimism, and confirmation bias as well as planning fallacy, some of which Flyvbjerg did not list. The studies analysed in Section 2 revealed that these biases were the most prevalent in discussions about the effects of biases on decision-making by different authors. These biases were chosen largely due to their direct and blatant correlation with project outcomes, which seek to answer research question 1.

In a study by Abatecola, et al. [22], the authors give an example of a manager who realises they may have been overly favourable towards a subordinate due to empathy falling prey to the affect heuristic. They say the manager should consider how this bias might have led to other cognitive errors, such as a shallow evaluation. They conclude that recognising the complex interplay between various heuristics and biases allows decision-makers to control their judgments better.

Managers regularly encounter complex decision-making scenarios that are better suited for traditional analytical methods. In such cases, they tend to depend on simple heuristics or rely on their intuition for judgment [23]. The research by Stingl and Geraldi [23] reinforces the idea that using simple heuristics can benefit decision-makers.

Based on the above information, the following hypotheses were formulated:

H1a: Project managers aware of cognitive biases make better decisions in straightforward scenarios.

H1b: Project managers aware of cognitive biases will make better decisions in ambiguous scenarios.

3.2 Project complexity

Project complexity moderates the relationship between project managers' cognitive bias awareness and the quality of their decision-making. This means that the simplicity or complexity of a project characterised as straightforward or ambiguous affects how significantly cognitive bias awareness impacts decision quality. This section seeks to address research question 2 by exploring how cognitive biases manifest more prominently in ambiguous and complex project scenarios, potentially leading to systemic issues or failures. Ambiguous situations, characterised by multiple stakeholders, perspectives, interests, and uncertainties, necessitate using problem structuring methods and quality control tools designed to address cognitive distortions [17]. The discussion implies that the complexity and ambiguity inherent in these situations heighten the risk of biases.

Chadee, et al. [2] allude to the fact that individuals tend to overestimate their ability to identify and manage risks, and these biases are prevalent in ambiguous situations with unclear objectives. Osmani [24] acknowledges that ambiguity in information and the complexity of decisions can influence the prevalence of biases. Julmi [16] highlights the importance of understanding which contexts intuition is applied “before making strong claims about its performance", further strengthening the formulation of the hypothesis below.

Based on the above information, the following hypothesis was formulated:

H2: Cognitive bias is more prevalent in ambiguous than straightforward situations in project management.

3.3 Project outcomes

The literature explored in Section 2 of this research suggests that better decision-making, presumably resulting from effective cognitive bias management, leads to better project outcomes. This section addresses research question 3 by identifying specific biases such as optimism bias and overconfidence, which have been shown to adversely affect project outcomes. Flyvbjerg [9] explains that the core issue in project cost overruns and benefit shortfalls lies in bias rather than error, meaning attempts to correct these errors are misguided and ineffective. He notes that the focus should be on de-biasing estimates and decisions, which is different from merely eliminating errors. The root cause is the underestimation of costs and the overestimation of benefits, with overruns being a secondary effect that occurs downstream, often years after the initial miscalculations. Addressing these problems requires a shift in perspective from treating symptoms (cost overruns) to addressing the underlying biases [9]. Chadee, et al. [2] identify that optimism bias and its effects negatively impact project time and costs and, consequently, project outcomes.

Having considered literature that suggests that cognitive biases affect project outcomes negatively, it should still be understood that biases are part and parcel of humans, an inborn ability,” according to Dane and Pratt [25]. In some situations, decisions need to be made quickly.

Based on the above information, the following hypothesis was formulated:

H3: The presence of specific cognitive biases in decision-making processes negatively affects project outcomes.

Having discussed the conceptual framework, the proposed conceptual model was developed, as shown in **Error! Reference source not found.**Figure 1. It emphasises the pathway from cognitive bias awareness among project managers to high-quality decisions, ultimately contributing to successful project outcomes. Project complexity is highlighted as a key factor influencing this dynamic.

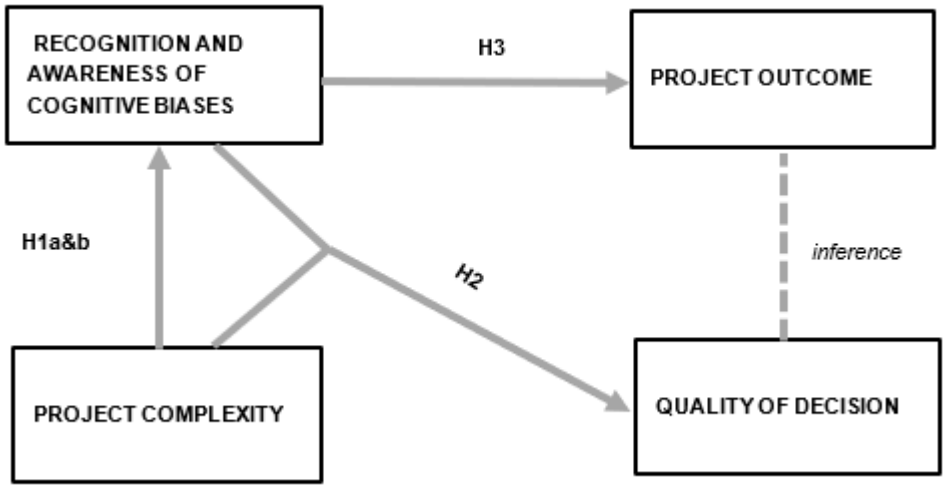

Figure 1: Proposed Conceptual Model

4 RESEARCH METHOD OR APPROACH

4.1 Research design

This research used mixed methods as the preferred research method. A convergent parallel mixed methods design was used, combining quantitative and qualitative research methods analysed separately with data collected in parallel, analysed separately, and then merged as described by Creswell and Plano Clark [26]. By using mixed methods, it will be possible to operationalise the key concepts identified in Section 3 in measurable terms, allowing for data supporting or refuting each hypothesis. Creswell likens it to how doctors often combine laboratory results (quantitative data) with a patient's personal history and symptoms (qualitative data) to make more accurate diagnoses and treatment plans.

4.2 Sampling strategy

The research took place at an international engineering consulting firm based in South Africa, which provides professional services across the lifecycle of infrastructure projects. The company prides itself on delivering solutions for complex challenges, making it the ideal environment for studying instances where repeated cognitive biases may have led to systemic issues or failures in project management.

The target population for the survey consisted of project practitioners, such as project managers, engineers, etc., engaged in project work. The research relied on a non-probability sampling method of snowballing that involved referrals. Respondents with vast project experience were selected and asked for referrals within the company; this is known as multiplicity (snowball) sampling [27].

4.3 Data collection

For qualitative research, a semi-structured interview was used to assist in acquiring insights regarding the expertise and cognitive strategies employed by experienced professionals to execute complex tasks [28]. Stingl and Geraldi [23] recommend this cognitive task analysis

approach for studying managerial decision-making, where the experts describe how they make decisions step by step.

Nisbett and Wilson [29] examine the reliability of verbal reports on cognitive processes, arguing that individuals often do not have direct access to their processes, a weakness associated with interviews in psychology research. However, they further give conditions under which individuals are correct in their verbal reports, such as the presence of influential stimuli and plausible causes of the response. The semi-structured interviews were structured so that some examples or scenarios helped make these stimuli more accessible, and questions were framed in a way that allowed interviewees to connect their actions or decisions with specific cognitive biases.

For quantitative research, a survey was conducted using Qualtrics. One significant limitation of surveys is their susceptibility to survey bias. Heeringa, et al. [30] define statistical bias as the "tendency of a statistical estimate to deviate systematically from the true value it is intended to estimate across replications of the survey process". Surveys are particularly prone to non-sampling biases arising primarily from measurement bias and survey nonresponse. While surveys are invaluable tools for statistical estimation, they are heavily dependent on the methodological diligence applied in their design and implementation. Therefore, the potential biases were addressed through rigorous survey methodology.

4.4 Data analysis

4.4.1 Qualitative data analysis

ATLAS.ti software was used for coding and thematic analysis of interview transcripts. "Data are coded and categorised until themes are identified or emerge" [31]. The interviews were held via Microsoft Teams to overcome geographical limitations.

4.4.2 Quantitative data analysis

Inferential statistics were used to test hypotheses stated in Section 3 and analyse outcomes derived from various statistical techniques [31]. IBM SPSS Statistics was used to compute all the chosen statistical techniques. Non-parametric techniques were chosen for their suitability to ordinal data and their ability to provide insights into relationships and group differences without assuming a normal distribution, as recommended by previous research [32]. This statistical approach will offer a rigorous analysis of cognitive biases in decision-making.

5 RESULTS

5.1 Data collection overview

Data was collected using a mixed-methods approach, combining qualitative and quantitative methods to explore the impact of cognitive biases on decision-making in project management. The paper involved semi-structured interviews with a sample of project managers and survey data collected from 150 participants across multiple industries, achieving an 87% completion rate. The data were analysed using statistical tools such as Spearman's correlation and Mann-Whitney U tests to assess the relationship between cognitive biases and project outcomes. The research explored how cognitive biases affected decision-making, particularly in straightforward versus ambiguous scenarios, and the resultant effects on key project performance indicators such as budget adherence and meeting deadlines.

5.2 Data gathering

For qualitative data, interviews were conducted to gain a deeper understanding of how cognitive biases affect decision-making in project management. These interviews aimed to uncover the perceptions and experiences of project managers regarding cognitive biases in both straightforward and ambiguous situations. For quantitative data, a questionnaire link was

distributed internally via email. The interviews and survey were conducted at a large global engineering consulting firm. The interview request was sent to 10 project managers, and the response rate was 80%. The response rate for the questionnaire was unknown due to the sampling strategy used; however, the completion rate for the 77 participants who attempted was 87% after screening the responses for missing data and incomplete responses. According to Pallant [33], errors in data can distort some analyses due to outliers, and as such, outliers were removed from the data set

5.3 Qualitative data analysis

The qualitative analysis was conducted using Atlas.ti, identified three key themes: awareness of cognitive biases, complexity in project management, and decision-making processes. Participants commonly described cognitive biases as "lenses through which people view the world," acknowledging their subconscious influence on decision-making outcomes. One respondent reflected, "Inevitably, you make decisions based on those filters, and if you are unaware of it, it can sometimes be fatal or detrimental." This highlights the often-unseen impact of biases in shaping project decisions. Complexity emerged as a significant factor, with many participants discussing the challenges posed by limited information and competing project outcomes, such as balancing risks with commercial and quality considerations. One interviewee noted the difficulty of navigating these complexities: "Project factors often have competing outcomes... it's about managing these trade-offs effectively". Finally, the theme of decision-making revealed a pattern of overconfidence, where participants admitted to overestimating their capabilities. One participant shared, "I overestimated myself in terms of what I am able to do... I assumed I could do it myself", illustrating how biases can lead to taking on unrealistic workloads and, subsequently, poor decision outcomes. Recognising biases during the decision-making process remains a challenge, as another respondent observed: "Sometimes you only see the bias when things become clearer to you... the difficult part is realising in the moment".

These insights underline the need for increased awareness and strategies to mitigate the influence of cognitive biases in complex project environments. The network diagram constructed using analysis results from Atlas.ti illustrated in Figure 2 shows how all the themes are interconnected and linked to the research questions.

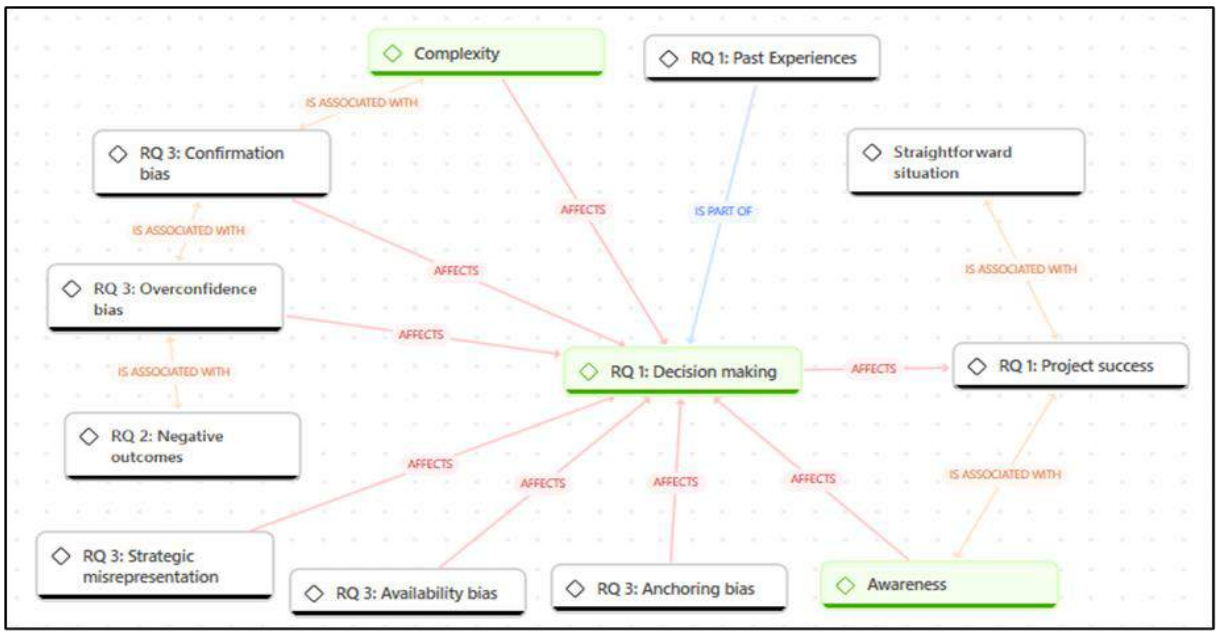

Figure 2: Network Diagram

In addressing RQ1, the diagram illustrates how decision-making in project management is shaped by awareness, complexity, and past experiences, with biases like confirmation, anchoring, and overconfidence often distorting decisions in complex projects, leading to delays and budget overruns. For RQ2, the diagram highlights that complexity exacerbates cognitive biases, negatively affecting outcomes, though awareness and experience can help mitigate these effects, particularly in straightforward scenarios. Addressing RQ3, participants acknowledged various biases, including power and political biases, but found them challenging to mitigate, underscoring the importance of active strategies to prevent these biases from impacting project outcomes.

5.4 Quantitative data analysis

Quantitative data analysis was done through IBM SPSS Statistics. The data was exported from Qualtrics and coded for input into SPSS. Each survey question was entered as a variable and classified according to data type, such as nominal, ordinal, or scale data. Descriptive statistics and hypothesis tests were carried out on some of the data and revealed key findings about cognitive biases in project management. Normality tests indicated a non-normal distribution, prompting the use of non-parametric tests for analysis.

5.4.1 Hypothesis testing

Table 1 summarises the results of various statistical tests concerning the three main hypotheses: Spearman's Rank Correlation, the Wilcoxon Signed-Rank Test, and the Mann-Whitney U Test. These hypotheses were designed to explore the relationship between cognitive bias awareness and decision-making quality in straightforward and ambiguous scenarios and the impact of cognitive biases on project outcomes. The corresponding test result accompanies each hypothesis, statistical significance (p-value), effect size or correlation coefficient (r/R^2), and a conclusion as to whether the hypothesis was supported or not. The table provides a clear and structured overview of the statistical findings and their implications for the research questions.

Table 1: Hypothesis testing

Hypothesis	Test Used	Result	p-value	Effect Size/Correlation (r/R^2)	Conclusion
H1a	Spearman's Rank Correlation	Positive correlation, but bias-aware managers made riskier decisions	< 0.001	R^2 = 18.8%	Not Supported
	Mann-Whitney U Test	Statistically significant difference between low and high-bias groups in straightforward scenarios	0.003	r = 0.367 (Moderate Effect)	Supported
	Spearman's Rank Correlation (Peer Review)	Negative correlation indicating peer reviews improve decision quality in straightforward scenarios	< 0.001	R^2 = 20.9%	Supported
H1b	Spearman's Rank Correlation	No significant correlation found	0.068	R^2 = 5.2%	Not Supported
	Mann-Whitney U Test	No significant difference between low and high-bias groups in ambiguous scenarios	0.607	r = 0.064 (Small Effect)	Not Supported
H2	Wilcoxon Signed-Rank Test	Significant difference in decision behaviour between ambiguous and straightforward situations	< 0.001	r = 0.427 (Moderate to Large Effect)	Supported
H3	Spearman's Rank Correlation	Significant correlations found between biases and negative project outcomes (budget adherence, deadlines)	< 0.001	R^2 = 24.5% - 31.6% (Moderate to Strong)	Supported
	Mann-Whitney U Test (Budget Adherence)	Significant difference between low and high-bias groups for budget adherence	0.002	r = 0.391 (Moderate to Large Effect)	Supported

6 DISCUSSION

6.1 Qualitative data

Using mixed methods to gather data improved validity through triangulation [34]. Participants understood how cognitive biases, such as anchoring, confirmation, and overconfidence, affect project performance, particularly in decisions about timelines and budgets. These biases align with those identified by Flyvbjerg [9] and Chadee, et al. [2] as having negative impacts on project outcomes. Many managers acknowledged being unaware of biases during decision-making despite reflecting on them afterwards. This supports the idea that bias awareness and structured decision-making processes help mitigate biases [5]. Participants also recognised how systemic issues, such as power dynamics and political pressures, distorted decisions even when better options were evident. This is consistent with Flyvbjerg [9] who asserts that political bias arises from power dynamics rather than cognitive factors. Decision-making, influenced by complexity, awareness, and past experiences, plays a crucial role in project success. As Cristofaro [17] notes that project managers often fall victim to cognitive biases. Complexity can exacerbate biases, though awareness can mitigate their effects, leading to better outcomes. Participants also found that decision-making in straightforward situations was less prone to biases, resulting in more successful outcomes, though some bias still occurred. This finding aligns with Tsiga and Emes [15], who call for further research into the causes of high failure rates in complex projects.

6.2 Quantitative data

Hypothesis 1a was tested using the Mann-Whitney U Test to examine the relationship between bias awareness and decision-making quality in straightforward scenarios. The results showed a moderate effect size, with high-bias participants making riskier decisions. The test supported Hypothesis 1a, indicating a significant difference in decision-making behaviour between low- and high-bias-aware participants. Hypothesis 1b, which tested the relationship in ambiguous scenarios, showed no statistically significant correlation, contrary to expectations and existing literature by Cristofaro [17], which suggests that bias awareness improves decision quality.

Hypothesis 2 was tested using the Wilcoxon Signed-Rank Test, which showed a statistically significant result with a moderate to large effect size. The findings indicated more cautious decision-making in straightforward scenarios and riskier decisions in ambiguous ones, supporting Hypothesis 2. This result suggests that cognitive biases are more prevalent in ambiguous situations, where decision-makers rely more on intuition, as highlighted by Julmi [16]. In uncertain scenarios, decision-makers often turn to heuristics due to the inability to apply traditional risk-based methods [18].

Hypothesis 3 explored the relationship between cognitive biases and negative project outcomes. Spearman's rank correlation revealed weak to strong correlations between biases (such as planning fallacy, overconfidence, and sunk cost fallacy) and missed deadlines. Similarly, confirmation and availability biases showed moderate to strong correlations with budget adherence. The Mann-Whitney U Test further supported Hypothesis 3, revealing a moderate effect size and statistically significant result, indicating that higher bias awareness significantly impacted budget adherence. These findings align with Chadee, et al. [2] and Strang and Vajjhala [35], who identified cognitive biases as major contributors to poor project performance.

The analysis demonstrated a clear relationship between the qualitative and quantitative results. Bias awareness improved decision-making in straightforward scenarios, supporting H1a, but had little effect in ambiguous scenarios, failing to support H1b. The prevalence of biases in ambiguous situations supported H2, while biases negatively impacted project outcomes like deadlines and budgets, supporting H3. These findings underline the importance of managing bias awareness and complexity to improve decision quality and project success.

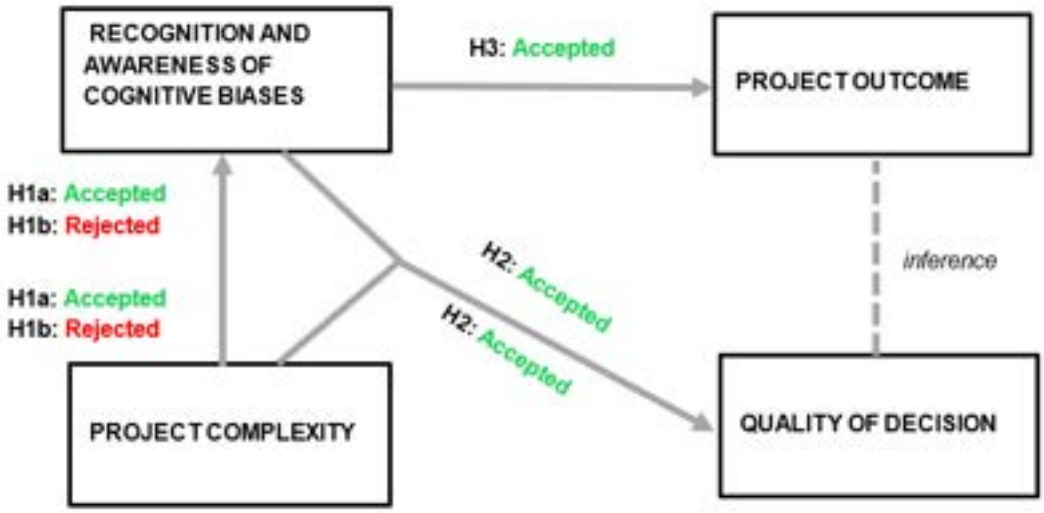

Figure 3: Research Model Results

Figure 3 illustrates the research model results, demonstrating the relationships between recognition and awareness of cognitive biases, project complexity, decision quality, and project outcomes. The model evaluates three hypotheses (H1a, H1b, H2, and H3) and their influence on decision-making and project performance. The hypotheses align with the findings and support the inference that bias awareness and project complexity directly affect decision-making quality and project success.

7 CONCLUSIONS AND RECOMMENDATIONS

This paper explored how awareness of cognitive biases, project complexity, and decision-making quality affect project outcomes. This research provides valuable insights and practical recommendations for project managers. Further research with more diverse samples is recommended to validate and expand upon these findings.

7.1 Summary of results

Cognitive biases such as planning fallacy, confirmation bias, and overconfidence were present in straightforward and ambiguous scenarios. However, their impact differed depending on the project's complexity. Bias awareness improved decision-making in straightforward situations, supporting the hypothesis that managers aware of cognitive biases make better decisions in these scenarios. However, in ambiguous situations, where uncertainty was higher, the impact of biases was more subtle and varied, indicating a more complex relationship. The data also revealed that cognitive biases were more common in ambiguous than straightforward ones, supporting the hypothesis regarding their increased frequency in such scenarios. Qualitative insights solidified these findings, showing that project managers often struggle to recognise and address biases in complex decision-making. The research supported the hypothesis that cognitive biases negatively impact project outcomes, particularly regarding budget adherence and meeting deadlines. Overall, the findings aligned with the research objectives and revealed important insights into how cognitive biases affect decision-making in project management.

7.2 Implications for theory and practice

Theoretical Contributions: The research reveals how biases like planning fallacy, overconfidence, and confirmation bias impact decision-making and project outcomes, especially in different scenarios. While bias awareness aids straightforward decisions, it has a limited impact in ambiguous situations. This challenges the assumption that awareness always improves decisions. The study also highlights the interaction between cognitive and political biases, suggesting that bias mitigation must consider power dynamics.

Practical Implications: Organisations should integrate bias awareness training with peer reviews, particularly for ambiguous projects. Scenario-based training can better prepare managers for uncertain conditions. Additionally, fostering a transparent, collaborative culture is crucial to reducing the impact of power dynamics on biases.

7.3 Recommendations

- Incorporate bias recognition tools (checklists, peer evaluations) into training.
- Use structured tools to manage biases in uncertain situations.
- Separate political biases to focus on cognitive biases.
- Combine qualitative and quantitative data in research for a complete view.

7.4 Future research

- Explore why bias awareness doesn’t always improve decisions using simulations.
- Study how bias awareness evolves and affects decision quality.
- Investigate the intersection of cognitive and political biases in high-stakes projects.
- Develop real-time decision support systems to alert managers to biases.

ABSTRACT

The usability of any tool or system must be assessed in relation to its context and appropriateness. This article assesses the perceived usability of a collaborative online tool, MURAL, when used in a specific context of Participative Modelling (PM). Additionally, we evaluate the perceived usability of a method, the EDU-BMI, when embedded within MURAL to support participants in the process of business model innovation (BMI). Our study therefore provides an academic usability evaluation within a specific context and advances knowledge about the intersection of tools, methods, and usability. Data collected from 30 respondents through the System Usability Scale (SUS) indicate that both MURAL and the EDU-BMI method are acceptable for our specific context (with average SUS scores of 77.25 and 74.42). User feedback and over 110 hours of recorded observations are used to deepen our understanding of usability in context and propose refinements to the EDU-BMI method.

Keywords: business engineering, business model development tools, business model innovation, engineering education, participative modelling, system usability scale

1 INTRODUCTION

According to Shah et al. [1], among the transformational forces shaping our world are two concurrent trends that continue to change how we look at and approach problems: (1) A surge in user-friendly and widely available technologies that cater to a digitally savvy generation and (2) A growing need for businesses to develop solutions for problems confronting society. The ability to generate novel ideas is becoming increasingly important to develop new solutions, with idea-generation skills proving valuable across disciplinary boundaries [2]. An example of a tool that offers straight-forward business language and an actionable process for innovation and change is the Business Model Canvas (BMC) [3]. The BMC is unique as it focuses on understanding what customers value while providing users with a single page to quickly outline and verify the "most salient and relevant information related to the business idea/innovation or initiative" [4].

In a study by Venter and De Vries [5], a group of participants used the virtual whiteboard software "MURAL" [6] for remote participative modelling (PM) of a BMC. Jackson et al. [7] have classified MURAL into the "Artifact management: virtual whiteboard software" technology type, along with tools such as Miro [8] and Google Jamboard [9]. The study by Venter and De Vries [5] found that MURAL is an acceptable system during participative enterprise modelling (PEM) when using the BMC, based on the System Usability Scale [10]. The study also found that the BMC templates within MURAL were insufficient for the systematic transformation of a traditional Business Model (BM) into a new iteration.

This is not surprising as, according to Szopinski et al. [11], the usefulness of a Business Model Development Tool (BMDT) depends on several factors such as a user's prior knowledge, the number of users, team location, and the user's workload. As an example, beginners need more guidance whereas experts may find this restricting/frustrating. Similarly, Pepin et al. [12] found that even though several tools have emerged to stimulate *sustainable* business modelling (SBM), these tools are often too complex for nonexperts in business modelling or sustainability, and thus insufficiently user-friendly for educational contexts. To address this limitation, Venter and de Vries [13] enhanced the BMC within the context of undergraduate engineering education. In their article, they propose a method, EDU-BMI, specifically designed to support students during PM sessions focused on Business Model Innovation (BMI) activities within the MURAL platform.

1.1 Background

While several websites offer comparisons of collaborative online tools like MURAL, e.g. Guinness [14] and Erdem [15], there appears to be a lack of academic studies that specifically compare these tools or examine their usability in the context of PM. Additionally, even though some researchers such as De Vries and Opperman [16] and Venter and De Vries [17] have already experimented within the knowledge area of Participative Enterprise Modelling (PEM) and online tools, there is no guidance available on which online tool should be used within a specific *context* of PEM to ensure that an appropriate and user-friendly modelling tool is selected.

1.2 Research objectives

The present study aims to understand the perceived usability when participants work together to develop a BMC using the EDU-BMI method embedded in MURAL. To achieve this objective, the following research questions (RQs) are posed:

RQ1: How user friendly is the *online tool* MURAL when innovating a business in the context of undergraduate engineering education during business modelling innovation?

RQ2: How user friendly is the EDU-BMI *method* itself when used in the context of undergraduate engineering education during BMI?

RQ3: What features contribute to this specific use-in-context, i.e. embedding the EDU-BMI method within MURAL within an undergraduate engineering education context?

Answers to RQ1 will further expand knowledge on the usability evaluation of MURAL, but within the context of a more prescriptive method when creating a BMC. This addresses a limitation identified in Venter and De Vries [5]. RQ2 will assess the EDU-BMI method, focusing on its ability to guide participants effectively through the process of BMI. RQ2 will inform areas for improvement for the method, which can be used to refine the EDU-BMI method for future iterations. RQ3 will be used to extract the features that contribute to this context of PEM, so that these features can be used to inform further studies about the development of a generic tool selection method.

2 LITERATURE REVIEW

2.1 Enterprise models and participative enterprise modelling

The term "model" is used in various ways as highlighted by Dietz and Mulder [18]. In their chapter on The MU Theory: Understanding Models and Modelling, it is stated that the only common denominator in the plethora of model notions is that a model is “a simplified representation of a thing, made for the purpose of studying those aspects of the thing that one is interested in” [18]. *Enterprise Modelling* (EM), which is an “integrated and multi-perspective way of capturing and analysing enterprise solutions” [19] is used to document the current or a desired future state of a company in a graphical and comprehensible way [20].

According to Smetschka and Gaube [21], participatory modelling (PM) is a method which uses models in three ways: (1) As a means to create knowledge, (2) To achieve knowledge integration and (3) To enable societal impact. By using this method, models can be used to obtain a better understanding of system dynamics, to reconstruct system dynamics, to develop future scenarios, and to structure communication processes around recommended actions [21]. For EM, innovative approaches such as *participative enterprise modelling* (PEM), a “fruitful method of eliciting information and creating enterprise models at the same time”, have been introduced with stakeholders actively taking part in the modelling sessions [20]. During PEM, participants are typically co-located and encouraged to collaborate to avoid conceptual misalignment. Today, people communicate more online than offline [22] which is leading to an embrace of online tools instead.

2.2 Business models and business model innovation

Schwarz and Legner [23] define a Business Model (BM) as “the blueprint of an organisation’s logic for value creation, delivery, and capture”. The BMC consists of nine basic building blocks that summarise the main areas of a business [3]. These blocks include key activities, key partners, key resources, cost structure, customer relationships, customer segments, value propositions, channels, and revenue streams [3]. By using the BMC, stakeholders have “a shared language for describing, visualising, assessing, and changing business models” [3]. According to Ladd [24], however, even though the BMC is appropriate for describing or visualising business models, it lacks guidance on the related innovation processes.

Business model innovation (BMI) takes place when BM elements and/or architecture is changed in a deliberate and observable way [25] and certain methods have been developed to address specific tasks during the BM design and implementation [23]. For example, an integrative conceptual framework for systematic BMI is proposed by Hoch and Brad [26] and a method that creates a visual roadmap of a business model’s evolution that assists in navigating the versions created, is proposed by Fritscher and Pigneur [27]. As mentioned in section **Error! Reference source not found.**, Venter and de Vries [13] proposed a method specifically designed to support students during PM sessions focused on BMI activities within the MURAL platform.

The EDU-BMI consists of seven main sections: (1) An introduction to MURAL and how the outline functionality [28] works, (2) An introduction to the participants (i.e. who the four team members are and what motivates them), (3) Background information on BMs and BMI, (4) Information on the initiation step, including examples and a fictitious use case, (5) Information on ideation, focusing on the business model pattern cards [29] and the similarity and confrontation principles [30] to innovate the use case, (6) Idea prioritisation, where the participants decide which idea is most relevant and how the idea impacts the current BM of the use case, and (7) Translating the use case's new business model onto the BMC.

The EDU-BMI method embedded in MURAL is shown in **Error! Reference source not found.**. T he left side includes the workspace, and the right side includes the outline and steps. Clicking on a step takes you to the relevant section, as shown in Figure 2. These figures are for illustration only, i.e. to demonstrate the core concepts and how they're applied in MURAL.

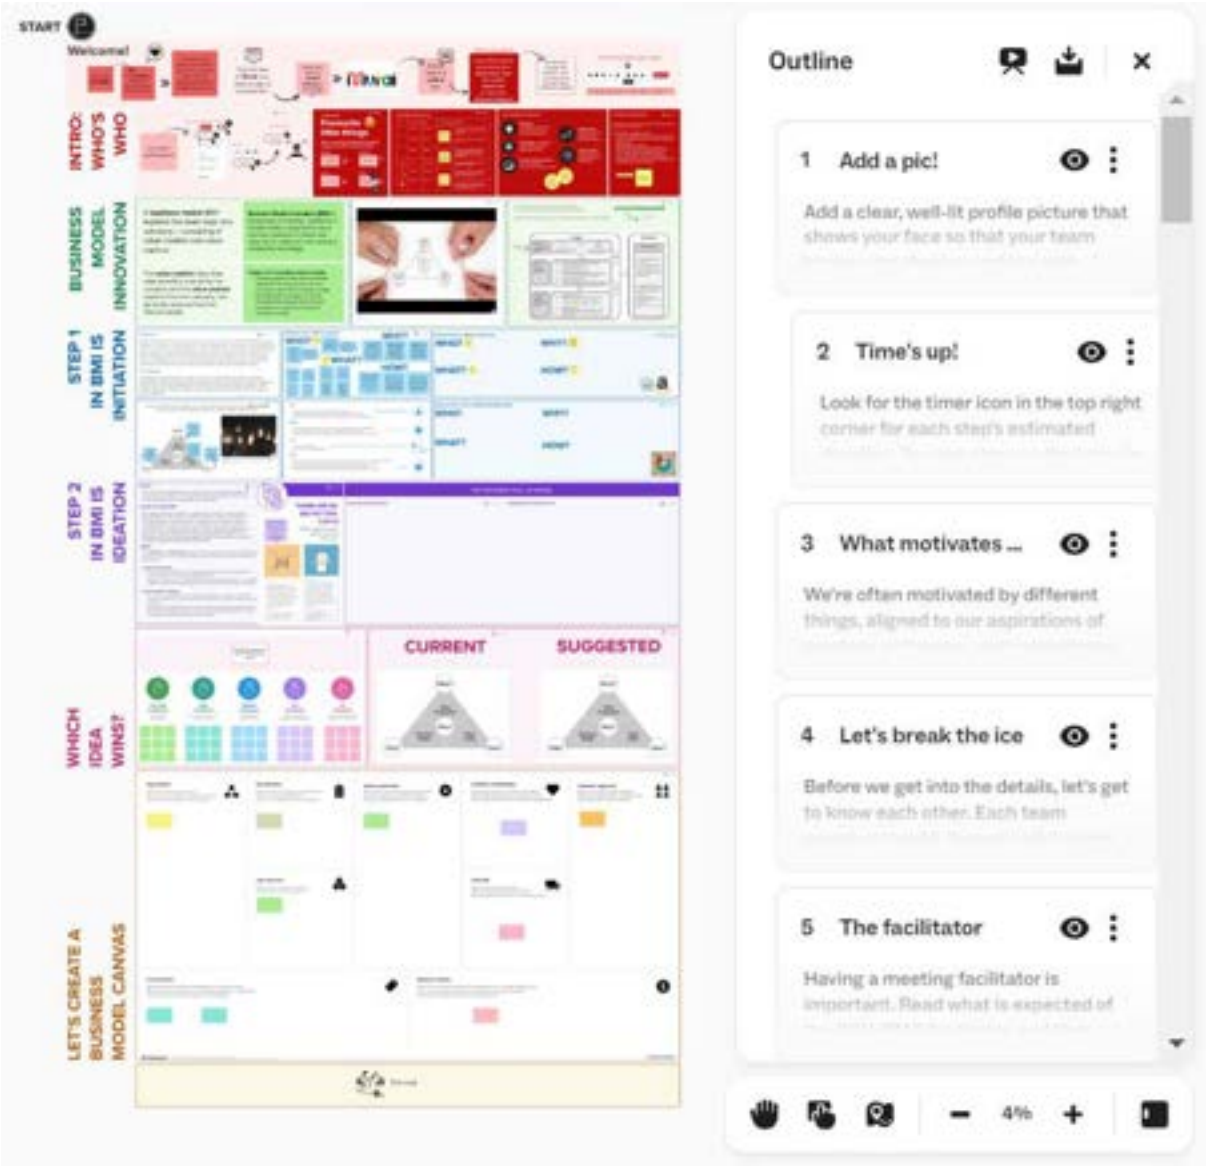

Figure 1: A visual overview of the EDU-BMI embedded in MURAL

Figure 2: Extract of Step 1 and how one is navigated to a specific section on the canvas

2.3 Usability evaluation methods (UEMs)

Techniques or methods are used to evaluate usability, defined by the International Organisation for Standardisation [31] as ''the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use''. In a Usability Evaluation Method (UEM) taxonomy created by Ivory and Hearst [32], method classes and method types per class are defined. As an example, in the inquiry method class, users provide feedback on an interface which could include methods such as interviews, surveys, or user feedback. Lu et al. [33] state that the UEM taxonomy remains highly relevant today, and found that most usability studies on educational technologies focus on e-learning in higher education, predominantly using *inquiry* methods such as questionnaires to assess technological usability. They also found that few studies address pedagogical or socio-cultural aspects, highlighting a gap in the broader evaluation of usability.

Standardised usability questionnaires, a type of questionnaire designed from metrics based on the responses obtained from participants, assess user satisfaction with perceived usability of a system [34]. The most widely used standardised usability questionnaires for the assessment of usability at the end of a study, according to Sauro and Lewis [35], include the Questionnaire for User Interface Satisfaction (QUIS), the Software Usability Measurement Inventory (SUMI), the Post-Study System Usability Questionnaire (PSSUQ), and the System Usability Scale (SUS).

2.4 The system usability scale (SUS)

The SUS is a "simple, ten-item scale giving a global view of subjective assessments of usability" [36] which is generally used after the respondent has had an opportunity to use the system being evaluated but before any form of discussion. When using the SUS, participants are asked to score the ten items, with one of five responses that range from Strongly Agree to Strongly disagree.

According to Lewis and Sauro [37], there are three primary goals with metrics like the SUS: (1) To estimate the SUS for a population from one sample, (2) To determine whether a SUS score exceeds a benchmark (such as 68, the average score), and (3) To compare SUS scores for comparable products or the same product over time. According to Sauro and Lewis [35], the more formative the focus of the test (e.g. focused on problem discovery) the less it is like a traditional experiment, whereas the more summative the focus (e.g. focused on measurement) the more it should resemble the mechanics of a traditional experiment.

According to Brooke [38], the individual statements aren't supposed to have diagnostic value in themselves or to relate to the specific features of a particular system. A single number representing a composite measure of the overall usability of the system being studied should

therefore be used [36]. To calculate the SUS score, the scale is first converted to a rating, e.g. 'strongly disagree' scores one point and 'strongly agree' scores five points. For odd-numbered items (i.e. positively worded), 1 is subtracted from the user's rating. For even-numbered items (i.e. negatively worded), the user's rating is subtracted from 5. The adjusted scores for the 10 items are then summed, and multiplied by 2.5 to scale it to a range of 0 to 100.

The SUS is suitable for small sample sizes as low as 12, as Tullis and Stetson [39] have shown that the same conclusion as a full dataset is reached at least 90% of the time with this sample size. However, larger sample sizes may provide a more precise estimate (i.e. narrower confidence intervals) [37]. According to Sauro [10], SUS scores can be interpreted using various frameworks, such as an acceptability scale (not acceptable, marginal, acceptable) or descriptive adjectives (worst imaginable, poor, OK, good, excellent, best imaginable).

3 MATERIALS AND METHODS

3.1 Research participants

The study included all students enrolled in a tertiary education module at National Qualifications Framework (NQF) Level 7 [40]. This resulted in an initial participant group of 111 students, all of whom were introduced to MURAL and the embedded EDU-BMI method by the primary researcher. The primary researcher then created 22 groups on the web-based learning management system 'Blackboard' [41]. Members could either join one of the 22 groups themselves, or be allocated to a random group if they had not joined a group by a specified date. Each group consisted of four members, with the exception of one group that consisted of five members.

3.2 Applying the EDU-BMI

The EDU-BMI was utilised in three online sessions (or deliverables), during which groups collaborated to complete the method's steps. These sessions were scheduled during dedicated tutorial time slots, providing students approximately two hours on three Wednesday mornings, totalling about six hours, to complete the EDU-BMI collaborative assignment. Groups were required to record their collaborative efforts throughout the process, as their teamwork was assessed alongside other criteria, such as adherence to the prescribed method.

3.3 Obtaining and evaluating the results

After conducting the three online sessions, the 111 members obtained access to a usability survey conducted via Blackboard. According to vom Brocke et al. [42], if knowledge is already available to solve a problem identified, this knowledge can be applied following routine design, which does not constitute Design Science Research (DSR). The surveys used in the previous studies [16, 43], as well as UEMs such as standardised usability questionnaires were already available. Questions were therefore reused in our study, and modified where necessary, to create a new survey that extracts both quantitative and qualitative data, i.e. *mixed methods research* [44]. The survey included 59 questions in total, of which 30 questions (about 51%) were free-text questions encouraging participants to motivate their answers.

Aligned with our approved ethical clearance application conditions, members were informed that participation in the survey is voluntary, that a participant could withdraw at any time without penalty, that their privacy would be protected throughout the survey, and that their participation would remain confidential. The first question was used to obtain consent, linked to the conditions for our approved application for ethical clearance and the second general question was used to obtain feedback on the participant's modelling experience, using MURAL as a modelling tool. After these initial questions, the survey included questions from the SUS by Brooke [36], as well as free-text fields in which motivations could be provided per question.

It should be noted that if a participant left a question unanswered, it was updated to "neither agree nor disagree".

The first ten SUS questions were focused on evaluating the usability of the *online tool* (i.e. MURAL). As students engaged with MURAL during group assignments in this module, the wording of the SUS statements was updated to reflect this specific context, e.g. "2. I found the system unnecessarily complex" was changed to "I found MURAL unnecessarily complex during group assignments". This ensured that participants' responses were framed within the scenario in which they had actually used the tool, thereby improving the accuracy and relevance of their feedback. The term "system" was also replaced with "MURAL" to minimise confusion, as Bangor, et al. [45] found that using terms such as "product," "application," or "website" instead of "system" does not change the results.

The second set of SUS questions focused on evaluating the usability of the *method* (i.e. EDU-BMI), e.g. "I found the EDU-BMI unnecessarily complex during the group assignments". While the objective of the SUS is to measure people's subjective perceptions of *system* usability in a short amount of time [39], the EDU-BMI, being embedded within a system, can still be evaluated by the SUS. Additional questions were also included to assess the method's effectiveness from an educational perspective (refer to section 4.2.1).

A few additional questions with supporting motivations were also included, such as whether the participant would recommend the tool MURAL, whether they preferred face-to-face modelling, and whether they experienced any tool and/or method frustrations.

Of the 111 members, 30 agreed to participate in our survey (about 27%). The primary researcher analysed the survey results, deriving a usability score from the standardised usability questionnaire used (see section **Error! Reference source not found.**). Supporting t ext feedback (or user feedback) was also obtained as the user could motivate their answers (see section 4.2). All groups' modelling sessions were observed as part of the group assessment, amounting to over 110 hours of recorded data. To manage the extensive viewing time, the recordings were occasionally reviewed at increased playback speeds. Key observations from these recordings are included in section 4.3.

4 RESULTS

4.1 System Usability Scale (SUS) results

As aforementioned, survey feedback was obtained from 30 participants. The margin of error of the SUS scores calculated at a 95% confidence level would therefore be approximately ±6.33 points. This is using a standard deviation of 17.7 based on an average calculated by Lewis and Sauro [37]. The SUS calculations for our study are available here.

4.1.1 MURAL online tool

The average SUS score for MURAL as an online tool, when combining all participants' scores, is 77,25. The SUS scores per participant are shown in Figure 3. Only two participants scored MURAL 50 or less (i.e. as "not acceptable").

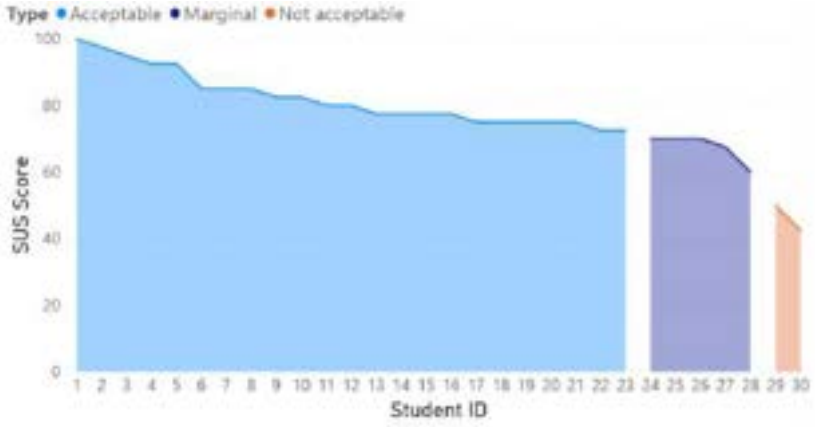

Figure 3: SUS score per participant for MURAL as an online tool

Responding to the ten SUS questions, participants provided feedback on how they felt regarding the statement by providing a ranking of strongly disagree, disagree, neither agree nor disagree, agree or strongly agree [36]. The odd-numbered SUS questions are positive-oriented. In these questions, agreement or strong agreement with the statements would indicate participant satisfaction with MURAL in the evaluation context. The positive-oriented SUS question feedback is summarised in Figure 4.

QuestionWithNumber	1. Strongly disagree	2. Disagree	3. Neither	4. Agree	5. Strongly agree
1) I think that I would like to use MURAL frequently to create a Business Model Canvas (BMC)/innovate a business with the EDU-BMI method.	0	2	3	14	11
3) I thought MURAL was easy to use during the group assignments.	0	1	1	18	9
5) I found the various functions in MURAL were well integrated for the purpose of the group assignments.	0	0	4	17	9
7) I would imagine that most people would learn to use MURAL very quickly.	0	3	2	15	10
9) I felt very confident using MURAL during the group assignments.	0	0	5	14	11

Figure 4: SUS positive-oriented question summary

Two participants expressed that they would not frequently use MURAL to create a BMC and/or innovate a business. One participant added that MURAL is "Not the best software" while another elaborated "If I have a template already, I think adding text boxes on it can be easier. Using MURAL requires internet access and sometimes you want to open something quickly see it. With MURAL it's a process to get onto the website whereas with Word, you can just open it". Participants who disagreed that people would learn how to use MURAL quickly mentioned "I think it depends how good you are with technology" noting that some people may struggle to adopt online tools. Another participant added that "Older people who have not used online collaboration tools might not be able to navigate with zooming in and out, using sticky notes as quickly".

The even-numbered SUS questions are negative-oriented. Figure 5 summarises the answers per negative-oriented SUS question.

QuestionWithNumber	1. Strongly disagree	2. Disagree	3. Neither	4. Agree	5. Strongly agree
2) I found MURAL unnecessarily complex during the group assignments.	5	21	3	1	0
4) I think that I would need the support of a technical person to be able to use MURAL.	11	16	3	0	0
6) I thought there was too much inconsistency in MURAL during the group assignments.	5	22	3	0	0
8) I found MURAL very frustrating to use when creating a BMC/innovating a business with the EDU-BMI method.	4	20	5	0	1
10) I needed to learn a lot of things before I could get going with MURAL.	7	16	5	2	0

Figure 5: SUS negative-oriented question summary

A participant that found MURAL unnecessarily complex during the group assignments added that learning "how to use the site and its functionality was a bit overwhelming, I still am not quick enough using it. It is a useful tool if given time to learn how to use". A participant that

agreed that they needed to learn a lot of things before they could get going with MURAL added that they "still don't know how to use some of the functions". Another participant that agreed clarified that "to a certain extent one does need to learn how to use MURAL and to get comfortable with the controls of MURAL. But I personally felt that it was intuitive, and then over time I was able to feel completely comfortable using MURAL".

4.1.2 EDU-BMI method

The average SUS score for EDU-BMI as a method embedded in MURAL, when combining all participants' scores, is 74,42. The SUS scores per participant are shown in Figure 6. Three participants scored the EDU-BMI 50 or less (i.e. as "not acceptable").

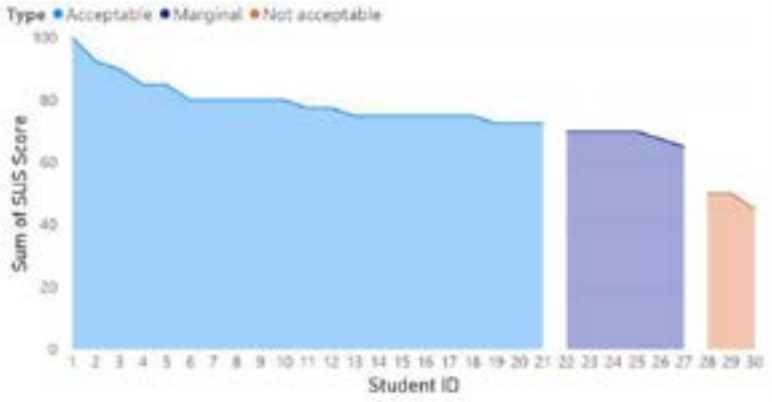

Figure 6: SUS score per participant for EDU-BMI as a method

As aforementioned, the odd-numbered SUS questions are positive-oriented. In these questions, agreement or strong agreement with the statements would indicate satisfaction with the EDU-BMI method. The positive-oriented SUS question feedback is summarised in Figure 7.

QuestionWithNumber	1. Strongly disagree	2. Disagree	3. Neither	4. Agree	5. Strongly agree
1) I think that I would like to use the EDU-BMI frequently to create a BMC/innovate a business.	0	0	6	19	5
3) I thought the EDU-BMI was easy to use during the group assignments.	0	0	3	20	7
5) I found the various functions in the EDU-BMI were well integrated for the purpose of the assignments.	0	0	4	20	6
7) I would imagine that most people would learn to use the EDU-BMI very quickly.	0	0	8	17	5
9) I felt very confident using the EDU-BMI during the group assignments.	0	2	2	18	8

Figure 7: SUS positive-oriented question summary

One student who did not feel confident using the EDU-BMI explained, "I feel like my peers know more, which frustrates me as I try to keep up." The other participant who disagreed with this statement did not provide a justification.

The even-numbered SUS questions are negative-oriented. Figure 8 summarises the answers per negative-oriented SUS question.

QuestionWithNumber	1. Strongly disagree	2. Disagree	3. Neither	4. Agree	5. Strongly agree
2) I found the EDU-BMI unnecessarily complex during the group assignments.	6	21	3	0	0
4) I think that I would need the support of a technical person to be able to use the EDU-BMI.	5	21	2	1	1
6) I thought there was too much inconsistency in the EDU-BMI during the group assignments.	4	20	5	1	0
8) I found the EDU-BMI very frustrating to use when creating a BMC/innovating a business.	6	19	3	2	0
10) I needed to learn a lot of things before I could get going with the EDU-BMI.	3	19	5	3	0

Figure 8: SUS negative-oriented question summary

A participant that agreed that there was too much inconsistency in the EDU-BMI during the group assignments added that "We had to do so many magic triangles it just felt very repetitive and almost like we were getting nowhere". Another participant that found the EDU-BMI very

frustrating to use commented that their group "had some struggles adapting to it and finishing it within the deadline". Another participant added that "It is quite a long process because you have to choose different business model cards and then do like 3 magic triangles". When asked whether they needed to learn a lot of things before they could get going with the EDU-BMI, one participant said "I first had to learn what business model innovation was, the different steps and components before the EDU-BMI started to make sense. Once I understood it, the EDU-BMI became really helpful".

4.2 User feedback results

4.2.1 EDU-BMI design requirements

In the specific context of teaching and training BM ideation, Schlimbach et al. [2] emphasise the importance of (and interplay between) educational, social, and motivational layers. Five design requirements were identified and incorporated into the EDU-BMI method [13]. The survey was therefore used as a means to evaluate whether the design requirements were met or not, as summarised in Figure 9.

Questions	1. Strongly disagree	2. Disagree	3. Neither	4. Agree	5. Strongly agree
The EDU-BMI provided a common base of knowledge on business model ideation.	0	0	2	23	4
The EDU-BMI prompted learners to connect and recombine ideas.	0	0	3	18	9
The EDU-BMI guided the learners through the ideation process and thinking modes.	0	0	2	26	8
The EDU-BMI enabled learners to interact and collaborate with real/digital entities.	0	1	5	19	5
The EDU-BMI considered different types of learners and their drivers for motivation.	0	1	8	17	4

Figure 9: Method design requirement feedback

Reporting on the high-scoring responses, about 93% of participants agreed or strongly agreed that the EDU-BMI *provided a common base of knowledge* on BMI and the same percentage agreed or strongly agreed that the method guided them through the *ideation process and thinking modes*. Additionally, about 90% agreed or strongly agreed that the EDU-BMI prompted them to *connect and recombine ideas*.

Reporting on less-optimistic responses, 80% of participants agreed that the method *enabled them to interact and collaborate with real/digital entities*. However, user feedback highlighted areas of improvement. One participant noted that they "feel like better examples could have been used during the MURAL assignment - we could not really innovate a lot with a 'university'". Another participant, who selected "neither agree nor disagree", admitted that they "don't understand what is meant by 'real/ digital entities'", which may explain the lower agreement.

Reporting on the least-optimistic responses, only about 70% participants agreed that different types of learners and their *drivers for motivation were considered*. Eight participants (about 27%) selected "neither agree nor disagree" indicating an area for improvement. The participant that *disagreed* simply commented "It just doesn't".

4.2.2 Preference of face-to-face communication

Participants were asked: "If I had to create a Business Model Canvas and/or innovate a business with the EDU-BMI in future, I would prefer to use face-to-face collaboration and drawing on a physical whiteboard, rather than using online modelling like MURAL". About 27% agreed or strongly agreed with the statement, while another 27% neither agreed nor disagreed with the statement. Some of the feedback provided by participants that either agreed or strongly agreed is included below:

- "You can engage more with someone in front of you"
- "I would agree, because in person it is easier to communicate during collaboration sessions. You can read facial expression better and I have experienced that it is easier

to talk 'over' someone when doing something online. I would love to rather have a face-to-face meeting but working on MURAL during that session with the Mural shown on a big screen"

- "Internet connection is not always reliable- some days the line is great and other days the connection is really bad, we can't control that. Also moving between MURAL and Blackboard was not nice - we can't see each other's faces on MURAL so when we are confused or don't understand it becomes harder (if) that person does not want to voice that they are confused"

About 47% disagreed with the statement, with none providing comments to support their response.

4.2.3 Frustrations identified

Participants were asked to share any frustrations they experienced with MURAL's functionality and the EDU-BMI method. The user feedback obtained is included in Appendix A. Some participants mentioned frustrations under the MURAL section that were also (or more) applicable to the EDU-BMI method, and vice versa. For example, one participant noted: "The first time, the outline disappeared and not all of us could click on it. I think only the facilitator could see it, but then it became hard to navigate through what needed to be completed." While this was categorised as a MURAL/online tool frustration by the participant, it could also be interpreted as a method-related issue. For instance, the EDU-BMI method could have clarified that only the facilitator would initially see the outline and provided guidance on updating permissions to ensure broader visibility.

Another example is a participant mentioning that "It took us a while to turn off everyone's cursors. It is distracting when everyone is moving across the page when trying to contribute". Although classified as an EDU-BMI frustration, another participant classified the same concern as a MURAL/tool frustration ("It took us a session and a half to realise you can remove the cursors on your screen individually so that it doesn't block what you're trying to see"). As a result, participants sometimes find it challenging to determine whether frustrations stem from MURAL or from the method itself.

Some participants mentioned other frustrations, like *issues communicating online* ("the only frustrating part was the online communication and the group work itself") and *team members being distracted* ("The only frustration I faced was that a group member who seemed to be distracted while working, i.e. not keeping up with where we were in the template and what we needed to do", "It's way too easy to go off topic and talk about your weekend").

Some participants *did not experience any frustrations*. One participant commented "With the assignments, the instructions were clear and quite straight-forward, making it easy to use MURAL. We also mostly used sticky notes and typed on it, which was really easy to do. The guideline on the right-hand side was also really helpful. Overall, my group and I did not experience any serious or frustrating issues with MURAL." Another participant said that "Once we got the basic idea of it down, it was easy to understand and complete".

4.3 Observation results

Not reading instructions. As mentioned in section 2.2, the EDU-BMI was utilised in three sessions (or deliverables). In the first deliverable, several challenges were observed. Many participants were uncertain about how to use the outline. Some groups forgot to utilise it, instead scrolling through the board without fully understanding the expectations. Additionally, some participants did not read the introduction section or watch the accompanying video, likely due to time constraints or oversight. This led to confusion about the outline's purpose and functionality.

Confusion on reusability of icons. In the first deliverable, participants were tasked with identifying their motivations using six predefined categories (e.g., socialiser, philanthropist). The instructions read: “Take a quick 5 minutes to reflect: what truly motivates you? Once you've identified your driver, drag the icon that best represents you to your sticky note in the 'Favourite Little Things' section and briefly discuss it within the group”. However, some groups mistakenly believed that once one person dragged a motivation icon, it could not be reused by others, seeing as the icon had been removed from the section. This led to confusion and incomplete discussions.

Effectiveness of the badge system. The badge system aimed to encourage collaboration and recognise contributions. The step in the EDU-BMI includes the following: “Throughout the modelling process, you can recognise contributions by awarding badges to your team members. Simply copy the badge and add it to the deserving player's name card”. Participants were also encouraged to create their own badges. Despite this, few participants added custom badges (e.g., a ‘lighten the mood’ badge was added by one group), and many forgot to assign badges altogether.

Instruction overload. While some instructions were simplified based on prior feedback [13], issues remained with the instructions and outline. Participants struggled with lengthy instructions and commented on the overwhelming number of details (e.g., “there are a million instructions”). As a result, critical information was often missed or misunderstood. For example, some groups were unclear whether they should discuss or simply choose cards and whether card choices needed to align with the business context or could be selected at random. Some participants also mistakenly researched the use case’s company online, found real-world results, and based their work on the actual company instead of the intended fictional context.

Confusion on using the outline. In the first deliverable, all participants had access to the outline. However, in subsequent deliverables, only the facilitator had access due to technical issues when recreating templates. This limited access caused confusion and frustration within groups, as participants were unsure why they could not find the ‘outline’ icon. Similarly, participants were unclear about the functionality of private mode, mistakenly believing all members needed to activate it. Participants expressed mixed feelings about the time allocation, with some finding it too short and others too long. Additionally, many were unclear about the timer’s purpose e.g. whether it applied to reading, modelling, or both in one step. One participant suggested adding a timer reminder and clarifying its intended use in the outline per step.

Facilitation skills. Some participants struggled with basic MURAL functions, such as adding or duplicating sticky notes. This information was available in the introductory video, but many participants missed it. Sometimes, a sticky note was also accidently added when a user double clicked on the Mural. Groups were also unsure whether they could use external tools like Google or AI for support. Clarifying this in future sessions is essential, as the EDU-BMI encourages leveraging external tools for ideation and problem-solving [13]. Lastly, team facilitation emerged as a critical factor in the success of the modelling process. While most facilitators performed well, some groups lacked effective guidance, such as the facilitator not reading instructions aloud or managing group discussions. Additionally, some participants watched videos without sound, not realising that audio was included, further impacting comprehension.

5 CONCLUSION, LIMITATIONS AND FUTURE WORK

Some participants indicated a preference for face-to-face collaboration over using an online tool like MURAL. Reasons included limited engagement when using an online tool, difficulty interpreting non-verbal cues, unreliable internet connections, and the complexity of

navigating between platforms. Despite these concerns, MURAL still obtained a SUS score of 77,25, making it an acceptable tool, according to the score interpretation guidelines provided by Sauro [10]. Taking into consideration that the mean SUS score could fall within ±6.33 points of the calculated score, the tool would still be considered acceptable.

When using the SUS to evaluate the usability of the EDU-BMI method embedded within MURAL, an average score of 74,42 is obtained. This score indicates that the EDU-BMI, as implemented in MURAL for business innovation, is generally perceived as an acceptable method within its context. Considering the confidence interval, the method's usability may range from marginal to acceptable. Several concerns and opportunities for improvement were identified. Appendix B summarises the suggested changes to the EDU-BMI method based on the concerns identified in sections 4.1.2, 4.2.1, 4.2.3, and 4.3. A 27% response rate may limit the representativeness of the findings. With less than a third of the members participating in the survey, the views of respondents may differ systematically from those who did not participate. This can reduce the generalisability of the conclusions to the broader group.

Features and functionality that impact the usability of MURAL within different contexts have been sourced and initial categorisation of the findings has been presented in Venter and De Vries [5]. In Figure 10, frustrations and features that were also mentioned in this study have been emphasised using **bold and underlined text**. 'Connection problems' were seen as a separate issue in our current study, as there was no mention of work lost due to the connection problems.

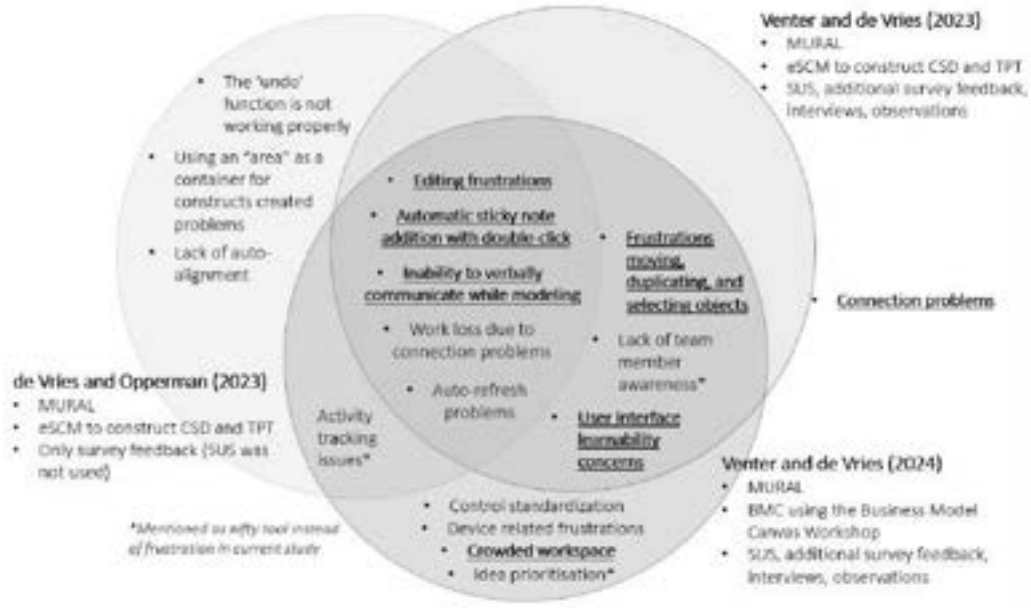

Figure 10. Venn diagram depicting frustrations identified in different studies

Using the identified frustrations and features, a more systematic classification of PEM requirements and evaluation of MURAL against these criteria is suggested. This approach is particularly necessary as the diagram in Figure 10 has become increasingly difficult to update. Future work could include the creation of a feature prioritisation tool (FePT) in which a more structured classification takes place. Additionally, conducting a systematic literature review (SLR) is proposed to explore decision-making methods that can leverage data from the FePT to guide users in selecting the most appropriate tool.

For future research, the usability of alternative modelling tools, such as FigJam or Miro should be assessed within the same context, so that different tools' usability can be compared to each other. As an example, undergraduate participants could use the EDU-BMI (method) to

create a BMC (model) in Figjam. Additional insights could then be obtained with regards to the features within these different tools, and how this impacts the perceived usability.

7 APPENDICES

7.1 Appendix A

Section comment was mentioned by participant	Participant quote	Potential relevance	
		Online tool (MURAL)	Online tool (MURAL)
MURAL	"Functionality was quite faulty as it would randomly disconnect saying that the network was bad when it wasn't"	X	
MURAL	"Had some frustrations w.r.t. the outline and the location it takes when you click on each step. Maybe it could have been a bit clearer as to where we need to go, but then again we should also figure out stuff on our own"		X
MURAL	"It kept freezing, the stickies disappeared, we didn't know how the timer thing worked and had to keep a backup timer"	X	
MURAL	"When someone selected a sticky at the same time as you did, it disappears or freezes or just malfunctions"	X	
MURAL	"The first time the outline disappeared and not all of us could click on it, I think only the facilitator could see it but then it became hard to navigate through what needed to be completed"	X	X
MURAL	"Didn't know where certain settings/functions were and there was not an intro when opening the app of where each button were and what it does etc."	X	X
MURAL	"The only problem we had was the G1 whereby we did not know where to make the outline appear again but after a few minutes, we discovered where to find it"	X	X
MURAL	"One thing that frustrated me was that you have to select every sticky that you want to move. There is no intuitive 'select a column/row' function"	X	
MURAL	"Difficulty with finding certain functions inside MURAL"	X	
MURAL	• "It sometimes happened that I still want to add to my sticky, but then someone else is typing there and I cannot access it. • It took us a session and a half to realise you can remove the cursors on your screen individually so that it doesn't block what you're trying to see. • If someone accidently click on the template and it wasn't locked they might move it which can be a bit disturbing or frustrating. • I sometimes found it frustrating that I couldn't make a sticky wider if I wanted to add more text, it can only make the text smaller"	X X X X	X
EDU-BMI	"I have mentioned them above, but the biggest issue was time and MURAL randomly freezing even if I had a good Wi-Fi connection"	X	
EDU-BMI	"We would have appreciated the time for the timer to be indicated on the 'Outline' for easier accessibility"		X
EDU-BMI	"Too long for the limited time set"		X
EDU-BMI	"Sometimes it would take you to a certain part of the template but then you are not sure what to do there and then only realise that it was just an intro for the next step where you add information"		X
EDU-BMI	"It took us a while to turn off everyone's cursors. It is distracting when everyone is moving across the page when trying to contribute"	X	X
EDU-BMI	"A link to a YouTube video would have been a bit more convenient than to download a video"		X

7.2 Appendix B

Concern/opportunity identified	Section	Suggested solution for next iteration of the EDU-BMI
Repetition of activities.	4.1.2	Instead of requiring participants to create multiple versions of the same deliverable for the example companies and the use case, we could incorporate different methods/visual aids. As an example, participants could watch a video demonstration of someone else performing the activity and then apply the learning to the use case.
Difficulty finishing within time frames.	4.1.2, 4.2.3, 4.3	Some instructions could be made more concise to improve clarity and efficiency. Additionally, addressing time-consuming issues, such as clearly explaining where to find the outline, could help optimise the modelling process and reduce concerns about time constraints.
Different use cases required ("we could not really innovate a lot with a 'university'").	4.2.1	A university was selected as we wanted an organisation/business that participants, as students, would understand. An alternative is using a business that is first discussed and explained in class in detail, to create shared context, and for that business to be used as the EDU-BMI use case.
Participants (as students) don't understand what 'real/ digital entities' are.	4.2.1	This is only relevant to future evaluation cycles. An explanation of what is meant by 'real/ digital entities' should be included in the survey.
Outline issues and confusion about outline navigation.	4.2.3, 4.3	Inform participants of the outline in-person before-hand, in addition to the video content that is provided.
Confusion that only the facilitator could see outline.	4.2.3, 4.3	Include more information in the outline.
Did not find/see the introduction; unsure how things work.	4.2.3, 4.3	Inform participants of the introduction section in-person before-hand, in addition to the video content that is provided.
Unsure how to find outline again after if disappears.	4.2.3	Inform participants of the introduction section in-person before-hand, in addition to the video/intro content that is provided.
Distracting cursors.	4.2.3	Include more information in the outline/introduction video.
Time limit is not always available in the outline as well.	4.2.3, 4.3	In addition to the time limit on the board, also include a time limit per step in the outline.
Unclear instructions (e.g. should something be done, or is it just information).	4.2.3, 4.3	Refine the instructions based on the feedback received. Simplify statements and shorten sentences.
Link to Youtube video instead of a video download.	4.2.3	Upload the video and provide a link in the Mural for easier access.
Confusion with 'what motivates you' section.	4.3	Refine the wording of instructions to enhance clarity and usability. For instance, replace "drag" with "copy" to better align with the tool's functionality, and explicitly inform participants that multiple individuals can share the same motivation.
Forgetting about badges.	4.3	Build reminders/tasks into the outline so that participants are reminded of badges and how they work, and encouraged to use it during the modelling.
Uncertainty about use case entity.	4.3	Explicitly state that it is a fictional entity which means that it is based on fabricated information.
Uncertainty about how 'private mode' works.	4.3	Include more information in the outline/introduction video and/or in the step itself.
Uncertainty about use of Google/AI	4.3	Include more information in the outline/introduction video.
Facilitation concerns.	4.3	Additional support could be offered to assist in selecting a facilitator. For example, a brief checklist outlining key qualities of an effective facilitator could guide the decision-making process. Alternatively, an anonymous vote could be implemented to assist in the selection.

Concern/opportunity identified	Section	Suggested solution for next iteration of the EDU-BMI
Some participants watched videos without the sound on.	4.3	Inform participants in the step that the video has sound and that they should ensure that they are able to see and hear the video.

EXPLORING CONTINUOUS IMPROVEMENT FRAMEWORKS IN THE FINANCIAL SERVICES INDUSTRY

T. Venter[1*] and L. Pretorius[2]

[1,2]Graduate School of Technology Management
University of Pretoria, South Africa
[1]ventertanz@gmail.com, [2]leon.pretorius@up.ac.za

ABSTRACT

Commercial banks are investigating new strategies to compete with innovative financial technology banks with a digital upper hand. Large financial service organisations can not merely pivot their digital strategy and change to another platform within a short period of time. Thus, another improvement strategy is required, while a digital transformation strategy focuses on large-scale initiatives. To address the objective of this paper, continuous improvement (CI) strategies were selected to identify if they can assist financial service organisations in improving their processes incrementally without disrupting large-scale initiatives. A conceptual CI model was designed by aggregating the generic elements of existing CI models. A questionnaire survey research methodology was selected to test the conceptual model of CI in the financial services industry. The survey results indicated traces of existing CI strategies in the financial services industry. However, it is not fully implemented. The survey results also indicated that the suggested CI model for the financial services industry might succeed.

Keywords: continuous improvement, continuous improvement model, financial services, service industry

1 INTRODUCTION

In a modern world with recent technology and disrupters being published every day, continuous improvement (CI) strategies are becoming increasingly critical for any organization [1]. While commercial banks or large financial services organizations spend time investigating digital solutions, startups are capitalizing on Financial Technology (FinTech) solutions to expedite their business development. Slowly, the traditional “brick and mortar” banking model is being replaced (or combined) with digital banking [2]. Financial services include organisations such as banks, as well as insurance, tax, and investment organisations.

It is noticeable that a lot of money is spent on large project initiatives that involve implementing information technology (IT) systems. Not all these projects are successful, and they take an exceptionally long time to be implemented. In 2013, a study was conducted on insurance policy replacement systems. It was found that large insurers took 20 months to complete initial system rollouts and 40 months to deploy the full solution [3]. Introducing incremental improvements that will not disrupt large-scale initiatives (like system rollouts) requires holistic design thinking. People are still unsure how to approach the paradigm shift in industries with existing frameworks [4]. Therefore, there is a need to establish if the existing CI frameworks can cater to CI in the financial services industry (FSI).

Based on the premise that the FSI is continuously changing and includes new products, service types, and industry branches, there is a need to be able to adapt to change and improve on a smaller scale during periods when an enterprise undergoes pivotal changes. Leaders and employees should be able to identify opportunities and implement improvement changes within their teams and environment to move forward, while the enterprise-level strategies are refined with each new disruption.

1.1 Research objective

The objective of this study is to establish a CI framework specifically for the FSI.

1. Establish if existing CI frameworks are relevant to the FSI.
2. Establish what elements of a CI framework will impact the development of an organization in the financial industry by testing a proposed CI model aggregated from existing models.

Given the objectives, the research questions are:

1. RQ1: Are the existing CI frameworks relevant to the FSI?
2. RQ2: What elements of a CI framework will make an impact to develop an organization in the FSI?

2 LITERATURE REVIEW

CI is an intentional, systematic approach introducing ongoing incremental improvement to an existing process [5]. CI can be described as “improvement initiatives that increase success and reduce failures” [6]. Bessant explains CI as “a company-wide process of focused and continuous incremental innovation” [7]. Scrutinizing existing literature, the definition of CIs has not changed, and most recent articles tend to quote Deming and Bessant’s definitions from the 90’s. Thus, CI can be summarised as continuous incremental changes to enhance and develop the existing processes. There is a need for studies to integrate CI strategies into other industries, especially since the Fourth Industrial Revolution [8].

2.1 Continuous improvement in the financial industry

The research was conducted to establish CI frameworks currently in the FSI to respond to RQ1.

2.1.1 CI levels of maturity

To establish the impact a CI framework has on a specific industry, the level of CI maturity needs to be understood within the organization being tested. Organization and process maturity models are research-based instruments to assess a specified area of an organization objectively [9]. The model is dependent on the area being measured. There are many organization capability and business process maturity models [9]. Since the coming of the Fourth Industrial Revolution, new models have also been developed, such as the digital transformation capability maturity model (DX-CMM) [10] , [11], and many other proposed Industry 4.0 maturity models, which focus on the manufacturing industry [12], [13].

The CI Maturity Model (CIMM) measures an organization's maturity level, especially in the CI capability. The model consists of structured CI (CI), managed CI, predictable CI, capable CI, and world-class CI [9]. There is another model called the Continual Improvement Maturity Model by Robert Falkowitz. The Robert Falkowitz continual improvement maturity model consists of five elements: Understanding, Value, Performance, Consistency, Method, and Intent. The skillset of CI can easily be planned or implemented in an organization, but the sustainability of the strategy is more complicated. Only 1.6% of the organizations that received recognition of the Shingo Prize or Best Manufacturing have sustained the CI journeys [14].

Currently, the most appropriate model to assess organization CI maturity is the Bessant and Caffyn Five Stages of Maturity in the CI. This CI Maturity Model describes the CI process in five stages, namely [9]:

1. Natural/background CI
2. Structured CI
3. Goal-oriented CI
4. Proactive CI
5. Strategic CI

2.1.2 Elements to measure CI framework maturity

The following criteria have been identified in successful CI initiatives [15], [16]:

1. Effectively utilizing communication systems.
2. Solving problems.
3. Measurements and feedback.
4. Knowledge sharing and training.
5. Cross-functional/departmental cooperation.
6. Policy deployment.
7. Strategic planning.
8. Incentives and pay.

To be able to establish an environment where employees are prone to continuously improve, encouragement, participation, and inclusivity are required [7]. The environment should also be conducive to support and ongoing change [17], [15].

Themes of CI failure have been narrowed down to the following by Antony and McLean [18]:

1. Expectations and motives.
2. Organizational environment and culture.
3. Management leadership.
4. Implementation approach.
5. Training.
6. Project management.
7. Levels of involvement from employees.
8. Results and feedback.

2.2 Continuous improvement frameworks

Further research was conducted on existing CI tools to address research question 2.

There are many CI methodologies that are adopted by different industries. The purpose of this section is to identify which methodology, or combination of methodologies, may work best in the financial industry. CI methodologies across industries include Six Sigma, Lean manufacturing, Kaizen, Agile software development, Quality management and Plan-Do-Check-Act (PDCA). In this section, the various methodologies will be addressed within industry types [19], [20].

2.2.1 CI in Six Sigma

Six Sigma is a methodology that utilizes statistics and process improvements to eliminate defects and improve quality [21], [22].

CI in Six Sigma refers to the incremental changes within the organization. The CI of Six Sigma is grounded in learning and improving based on experiences. This cycle has four stages, namely, planning, execution, assessment/progress tracking, and revision [23].

One of the tools used in Six Sigma to implement CI is the Deming Plan-Do-Check-Act cycle. The PDCA cycle promotes learning through iteration [24]. In the planning phase, the process is observed and analyzed, and a hypothesis for improvements is established. Each hypothesis has a criterion to be measured. In the Do phase, the plan is implemented. In the Check phase, the improvement is monitored, and learnings are documented. In the act phase, the new process is standardized, and the next target is set [25]. The purpose is for each iteration to create quality and get closer to a more efficient process [22].

Six Sigma tools and PDCA are mostly implemented in the manufacturing and construction environment, with some case studies in the healthcare industry [26]. Recent studies are starting to explore Six Sigma in the service industry [25], [27].

2.2.2 CI in lean manufacturing

Lean manufacturing is a waste reduction methodology that focuses on maximizing value by minimizing waste [28], [29]. Lean manufacturing focuses on waste and is driven by the 3Rs: reduce, reuse, and recycle [30]. Lean focuses on value and efficiency.

CI within the lean methodology is known as Kaizen. According to lean manufacturing research, CI requires employee training, engagement, and adaption, teamwork with leadership engagement, motivation, and initiative [28]. Kaizen combines 2 Japanese words, “Kai” and “zen”. Kai means change, and zen means for the better. Thus, the theory behind Kaizen is to change things for the better. Within the lean methodology, Kaizen consistently changes things for the better by reducing waste to be more efficient and get closer to the goal. Kaizen focuses on improving three areas such as Muda (waste), Mura (discrepancy), and Muri (strain). Kaizen is the methodology with various tools such as Total Quality Control, Automation Zero Defect, Total Productive Maintenance, Quality Control Circle, and Kanban [31], [32].

There are studies looking at the implementation of Kaizen in the healthcare industry, textile industry, manufacturing industry, and construction industry, but no clear case studies of Kaizen in the financial industry. Focusing on a study of Kaizen in small and medium enterprises (which may contribute to Fintech companies), successful factors to implement Kaizen include [31]:

1. Effective communication from top management downwards and from lower levels upwards.
2. Include Kaizen in the corporate strategy, goals, and policies.

3. Allocate a Kaizen champion as the link between lower levels and senior levels when sharing innovative ideas.
4. A horizontal and autonomous organizational structure allowing collaboration.
5. A “can do” mindset and attitude in the organization.
6. Compensation (and motivation).
7. Training.

The same paper has identified the following challenges:

1. Ability to implement the improvements identified.
2. Resistance to changes.
3. Lack of motivation.

2.2.3 Continuous Improvement in Agile software development

The finance industry is very reliant on the software industry, especially with FinTech starting to overtake the market [33]. This is because even though the products are financial, software supports most processes. Looking at Fintech organizations, of which the core is software, larger finance organizations that are not reliant on technology as much have a larger gap to fill when trying to improve quickly [34]. With this in mind, the Agile methodology is also unpacked. Studies have shown that the utilization of Agile methodologies increases the efficiency of software development processes in the FSI [35]. This could indicate that the same methodology would be useful for CI strategies in FSI.

The Agile methodology is based on an Agile manifesto developed with various principles to adhere to. The principles are guidelines for an organization to operate in, instead of a structured approach with fixed steps. Key values included in the manifesto are [36], [37]:

1. Individuals and interactions over processes and tools.
2. Working software over comprehensive documentation.
3. Customer collaboration over contract negotiation.
4. Responding to change over following a plan.

The agile methodology is based on iterative and incremental implementations.

In a study to unpack an overlap between lean and agile in software development, the following elements were identified as critical to ensure the successful implementation of CI and the reduction of waste [36], [37]:

1. Customer involvement.
2. Dedication to value-add improvements that are not lost in the day-to-day activities.
3. Metrics to create awareness of the impact.

Challenges identified in the same study as above include [36]:

1. There can be buckets of work not completed if Agile is not implemented correctly.
2. Extra enhancements are easily identified and create scope creep.
3. Relearning is required if there is no clear communication.
4. Agile does not support metrics for measurement of success, which was identified as critical in the above section.
5. Agile does not have CI methods and is expected to include improvement opportunities in daily tasks. Hence, dedication to value-added improvements is identified in the above section.

3 PROPOSED MODEL

The conceptual model has two phases to be able to address the research questions:

3.1 Phase 1: Maturity model

The Bessant model is selected to see which of the five stages of maturity the organizations tend to fall into in response to RQ1 [7], [15]. This model was selected under the guidance of the knowledge gathered in the literature review that Bessant is currently the most appropriate model to evaluate the CI maturity at a high level. Bessant was selected because the model allows for improvement evaluation on a general level [38]. This study focuses on the CI frameworks in the FSI and not the maturity model; hence, only a general classification is required.

3.2 Phase 2: Continuous improvement tools

The proposed CI model aggregates the generic elements of the existing CI frameworks. The model is designed to test the appropriateness of the elements in the FSI

The proposed model has four pillars illustrated in Figure 1: principles, people, process, and improvement. The pillars were established by identifying elements of the existing CI maturity models and CI frameworks, and associating the elements as responses to the challenges identified by Antony McLean and Dahlgaard [39].

- Principles are the guidelines within which the model needs to operate.
- People are the core of identifying and implementing the change.
- Process is the method, the how. The phases have been derived from the existing CI framework process steps.
- Improvement is the final output and metrics thereof. This would be organization and process-dependent.

3.2.1 The principles of the model

The suggested principles are derived from the existing models.

1. **Understand the environment:** Understand the current economy, organization, strategy, and people dynamics. This requires people to work together and operate outside of silos. This principle was selected from the Robert Falkowitz continual improvement maturity model [14]. This principle was selected as it is a common requirement across all the existing continuous improvement frameworks investigated in the literature review.
2. **Knowledge retention:** Ensure change is documented or communicated in such a way that the next person can continue. This principle was selected from Six Sigma, PDCA, Lean, and Kaizen [23] [25] [28] [31]. This principle was selected as it was a common challenge across all the existing continuous improvement frameworks in investigated in the literature review.
3. **Success management:** Ensure ideas are captured, implemented, and measured to provide the necessary and deserved incentives. This principle was selected from the Bessant and Caffyn CI maturity model, as well as Six Sigma [9] [23]. This principle was selected as it was a common challenge across two of the existing continuous improvement frameworks in investigated in the literature review.

3.2.2 The people of the model

The people pillar of the model includes the individuals conducting operations and leadership. Each element pertains to people in the organization who may typically be involved with the CI framework. The elements were selected from the existing model.

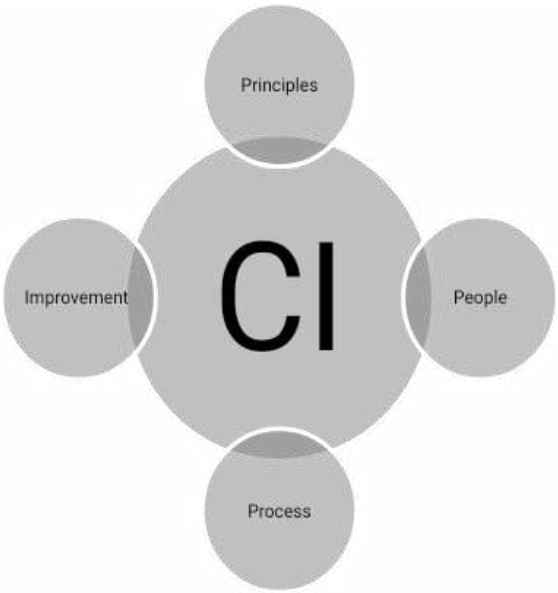

Figure 1: Conceptual model

1. **Motivation and buy-in:** All groups of people, high and low, should be aligned to the CI strategy. Incentives should be put in place for the individuals who participate. This element was selected from Agile, Lean, and Kaizen [36] [28] [31]. This element was selected as it was a common requirement across all the existing continuous improvement frameworks investigated in the literature review.
2. **Support:** Leaders are required to support the operations staff for implementation. Operations staff are required to support the leader with ideas and during implementation. Support functions are required to support the improvement culture and be able to act accordingly, e.g., IT. This element was selected from Agile, Lean, and Kaizen [36] [28] [31]. This element was selected as it was a common requirement across all the existing continuous improvement frameworks investigated in the literature review.
3. **Structure learning and training:** All groups of people must be trained accordingly using the relevant tools. This element was selected from Six Sigma, PDCA, Lean, and Kaizen [23] [25] [28] [31]. This element was selected as it was a common challenge across all the existing continuous improvement frameworks investigated in the literature review.
4. **Process:** Visibility of the process is required, as are ideas logged, processed, implemented, and succeeded. This element was selected from Theisens CI maturity model, Bessant and Caffyn CI maturity model, Robert Falkowitz continual improvement maturity model, Six Sigma, PDCA, Lean, and Kaizen [14] [23] [25] [28] [31]. This element was selected as it was a common requirement across all the existing continuous improvement frameworks investigated in the literature review.

3.2.3 Model process

CI requires iteration through the process to continuously improve the environment. The process in Table 1 requires an individual to revisit the first phase every time something has been completed, much like the PDCA cycle. The process steps in the table below were selected from the existing models. The process steps are aligned to the principles established in section 3.2.2.

Table 1: Conceptual Model Phases

	Iterative Phases	Element from existing Continuous Improvement model
Pre	Understanding the current landscape (Principle 1)	• Theisens CI maturity model [9] • Bessant and Caffyn CI maturity model [9] • Robert Falkowitz continual improvement maturity model [14]
	Conceptually introduce the change (Principle 1)	• Theisens CI maturity model [9] • Bessant and Caffyn CI maturity model [9] • Robert Falkowitz continual improvement maturity model [14]
Pre	Impact analysis (Principle 1 and 3)	• Theisens CI maturity model • Bessant and Caffyn CI [9] maturity model [9] • Robert Falkowitz continual improvement maturity model [14]
	Planning (Principle 1 and 3)	• Robert Falkowitz continual improvement maturity model [14]
During	Implementation (Principle 2 and 3)	• Theisens CI maturity model [9]
Post	Measure success (Principle 3)	• Theisens CI maturity model [9] • Bessant and Caffyn CI maturity model [9] • Robert Falkowitz continual improvement maturity model [14]
	Understand the new landscape (Principle 1)	• Theisens CI maturity model [9] • Bessant and Caffyn CI maturity model [9] • Robert Falkowitz continual improvement maturity model [14]
	Continuous monitoring (Principle 2 and 3)	• Bessant and Caffyn CI maturity model

4 RESEARCH METHOD

4.1 Research approach and strategy

Exploratory research is used to discover something new [40]. Exploratory research is required to answer RQ1 and RQ2 because there is little literature available on CI in the FSI, and the phenomenon is quite new.

A mixture of qualitative and quantitative research approaches has been selected for this study. Comparative research can be conducted using mixed methods, qualitative and/or quantitative methods. Charles Ragin designed qualitative comparative analysis to be between qualitative and quantitative research, resulting in a mixed-method approach [41].

The teleological research attribute type exploratory study is selected as there is not much research on the phenomena of CI in the financial industry, as seen in the literature review. There will be a deductive linkage to theory to test the research questions. The conceptual model is designed via experimental development, deduced from research.

4.2 Research design and methodology

A survey research methodology has been selected for this study. Survey research creates an opportunity to reach a wide audience, especially in an exploratory context like this study [42]. Qualitative surveys consist of open-ended questions, whereas quantitative surveys consist of close-ended questions [43]. This means a mixed survey is required for a mixed-method approach.

4.2.1 Data collection instrument

For this study, a questionnaire was used as an instrument to collect primary data to test the suggested model conceptually. Questionnaires are used for quantitative data research where individuals are asked a series of questions to gather an understanding of a specific topic [44].

A questionnaire survey is structured with questions purposefully asked to answer the identified research problem [45]. The questionnaire was distributed via a digital online form, distributed to friends, family, and colleagues, as well as published to social media platforms.

4.2.2 Sampling methodology

Convenience sampling (or accidental/haphazard sampling) is when a sample is selected from a population based on easy access and availability [46], [47], [48]. Convenience sampling can be used in qualitative and quantitative studies. It is also used to emphasize the generalization of the topic that is analyzed [46]. Convenience sampling relies on respondents being at the right place at the right time. This means that the type of respondents can include biases [49], [50]. A second consideration for convenience sampling is that the data can be skewed by outliers that do not belong in the data [46].

There are only two selection criteria for the questionnaire, namely, the FSI and the topic of improvement strategies. Incomplete questionnaires and responders not currently employed at a financial services organisation will be eliminated. The size of the organisation is not taken into consideration, and no personal identifying questions are asked. Refining the selection criteria too much would run a risk of excluding essential elements that should be considered for a CI strategy in the FSI.

4.2.3 Questionnaire design

The questionnaire was designed in five sections. All the sections were multiple-choice questions, and only requested free text when “other” was selected:

1. Section 1: Confidentiality and anonymity clauses.

Ensuring the scope is adhered to:

2. Section 2: Industry in which the respondent is employed, and in which capacity (i.e. self-employed or full-time employee).

Addressing RQ1:

3. Section 3: The opinion of the CI Maturity of the organization where the respondent finds themselves. Questions evaluated respondents’ knowledge on improvement strategies in their organisation, training, improvement projects, and improvement success reward systems. Questions gave options to select what improvement can look like, asking the responder to select what they know, how well improvement is managed, and how long improvement projects take.
4. Section 4: The opinion of the CI strategies in place in the respondent's organization. This section was a Likert Scale questionnaire with CI framework elements, requesting the responder to rate on a scale of Strong Disagree to Strongly Agree if the elements are present in their organisation. Questions about training, autonomy to improve, and execution of projects were included.

Addressing RQ2:

5. Section 5: Testing the concept of the new model elements with the respondent. This section was also a Likert Scale questionnaire with the suggested CI model elements, requesting the responder to rate on a scale of Strong Disagree to Strongly Agree if the elements would work in their organisation. All questions started with “I would like to be able to” and included the availability of talking to leadership about improvements, rewards for successful ideas, brainstorming culture, and formal improvement project processes.

The questionnaire was pilot-tested and adapted before distribution.

5 RESULTS

The questionnaire data was analyzed per section to create a picture of CI in the FSI. Fifty valid responses were analyzed. The remainder of the questionnaires were discarded because the respondents were in the incorrect industry.

The results were as follows:

1. **Section 1:** All questionnaires agreed to the relevant clauses.
2. **Section 2:** This section ensured that any responses unrelated to FSI were excluded from the analysis. Of the 50 questionnaires analyzed, all respondents participated in the FSI. The other questionnaires were discarded.

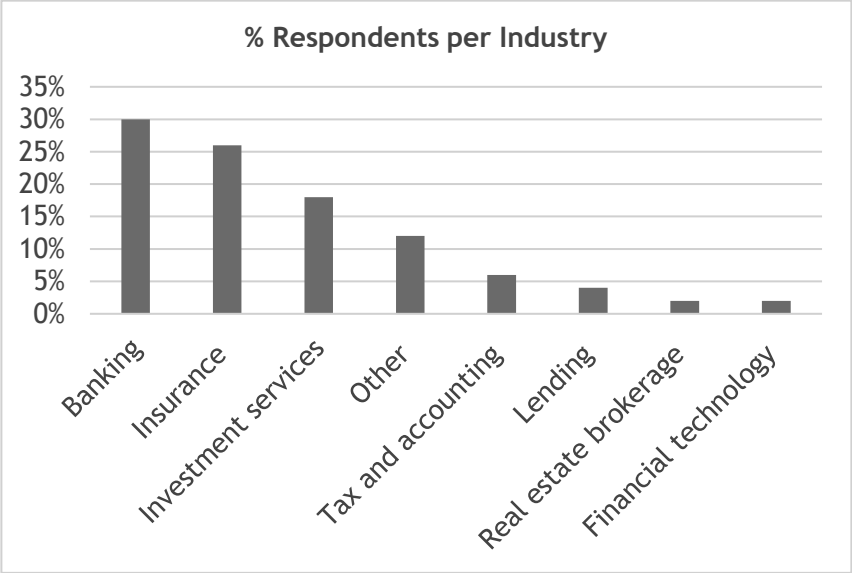

Figure 2: Number of respondents per financial services industry

3. **Section 3:** The Bessant Maturity Model was used to establish the general maturity of CI in the FSI. The Bessant Model has five maturity levels across six categories, and the final results for the FSI are listed below. The results indicate that the FSI does have knowledge of CI frameworks but does not necessarily reward participation in CI activities:
    a. Integration of CI into the organization - Level 4 indicates that there is a presence of a CI unit in the FSI.
    b. Extent of CI projects – Level 2 indicates that there is a presence of CI projects in the FSI.
    c. Management support – Level 2 indicates that there is a process for team members to communicate CI ideas with the relevant management teams.
    d. Strategic performance management – Level 3 indicates that there are processes to initiate the implementation of CI ideas in a financial services organization when the idea is aligned with the organization's strategic direction.
    e. CI training and learning – Level 4 indicates that employees of financial services organizations are trained in CI-related tools or are allowed to innovate and experiment.

f. Reward systems – Level 1 indicates that even if there are processes to submit CI ideas, these ideas are usually not rewarded or necessarily implemented.

Table 1: Continuous Improvement Maturity Analysis

Bessant Maturity Model Category	Level Scored in Financial Services Industry
• Reward systems	**1- Natural/background CI** Random CI and problem solving
• Extent of CI projects • Management support	**2 - Structured CI** Formal CI attempts
• Strategic performance management	**3 - Goal-oriented CI** Formal CI deployment and measurement
• Integration of CI into the organization • CI training and learning	**4- Proactive CI** CI assigned to problem solving units
• No category tested scored level 5	**5- Strategic CI** CI is a way of life

4. **Section 4:** The opinion of the CI strategies in place in the organization where the respondent works. This section tested the various existing models to establish whether the elements are present in financial services organizations.

   a. The study showed that 52% of the participants indicated that incremental improvements are present in their organization.

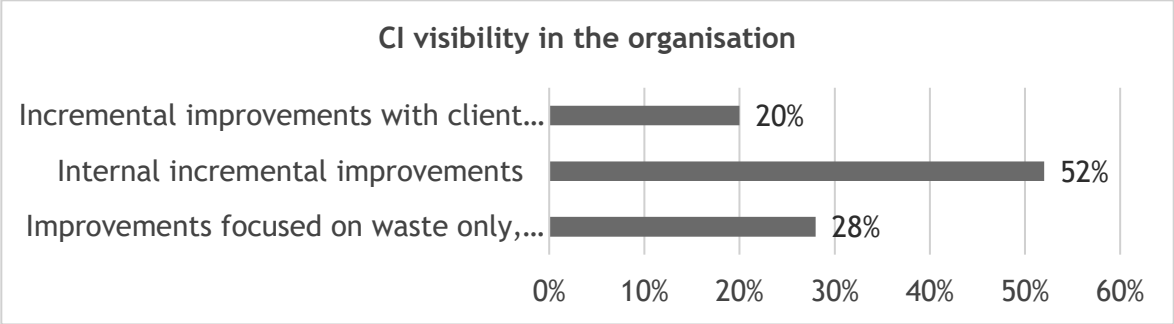

Figure 3: CI visibility

   b. The respondents agreed that existing CI elements (communication, CI strategy, customer involvement, documentation, CI champion, and autonomy) are present. However, the respondents did not agree that compensation for improvements, or success management, was present in their respective organizations.

Table 2: Likert Interpretation of existing CI elements in the financial services industry

Element	Mean	Likert Interpretation
Communication	76%	Positive agreement
CI strategy	71%	Positive agreement
Documentation	80%	Positive agreement
CI champions	77%	Positive agreement
Autonomy	72%	Positive agreement
Compensation/Reward	46%	Neutral, close to negative
Success measurement	60%	Neutral

   c. The respondents agreed that the existing challenges are present as per the existing CI frameworks in organizations, excluding the challenges of time and motivation for improvements. Organizations struggle with continuously improving over time. It is also clear that employees resist change, which impacts their adaptability to continuous change. However, the study indicated

that there is not a challenge with time and motivation for improvement in organisations.

Table 3: Existing CI challenges in the financial services industry

Challenge	Mean	Likert Interpretation
Continuous implementation	64%	Positive agreement that CI is not continuous
Resistance to change	71%	Positive agreement that there is resistance
Lack of motivation or time	46%	Very negative agreement

5. **Section 5:** Testing the concept of the new model elements with the respondent. This section tested the various sections of the suggested model to establish if it would benefit individuals in the FSI.
    a. 86% of the respondents agreed, and strongly agreed, with the proposed principles for a CI strategy in the FSI. With a mean of 84% results show very positive agreement according to the Likert scale.
    b. 79% of the respondents agreed, and strongly agreed, with the proposed elements for a CI strategy in the FSI. With a mean of 82% results show a positive agreement according to the Likert scale.
    c. 88% of the respondents agreed, and strongly agreed, with the proposed process steps for a CI strategy in the FSI. With a mean of 85% results show very positive agreement according to the Likert scale.

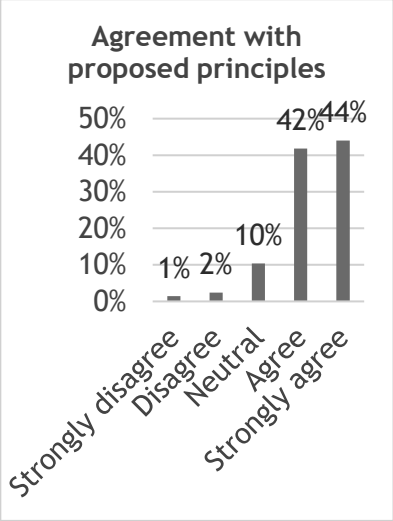

Figure 4: Principles

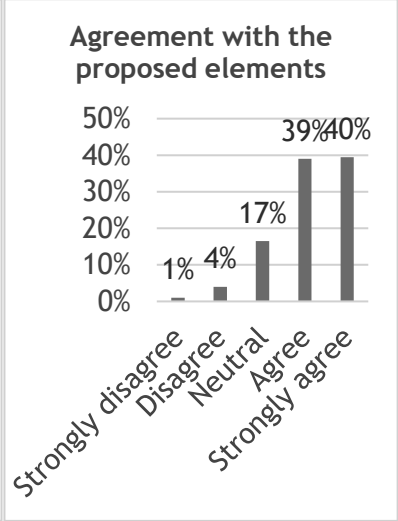

Figure 5: Elements

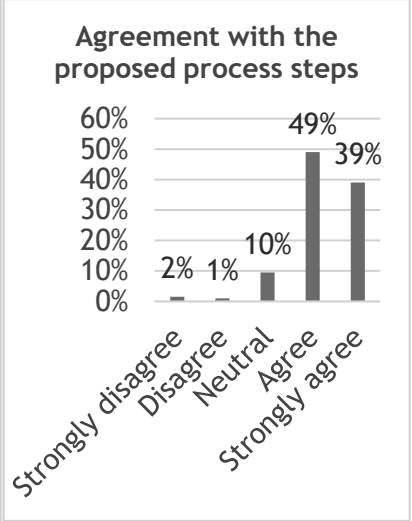

Figure 6: Process steps

Two research questions are posed to establish a CI framework in the FSI. The purpose of the questionnaire was to gather information that would answer the research questions posed.

RQ1: Are the existing CI frameworks relevant to the FSI?

RQ2: What elements of a CI framework will make an impact to develop an organization in the financial industry?

The following objectives were stated in the beginning:

1. Establish if existing CI frameworks are relevant to the FSI.
2. Establish what elements of a CI framework will impact the development of an organization in the financial industry by testing a proposed CI model aggregated from existing models.

The data gathered shows that the existing CI frameworks are present in the FSI. However, there seems to be a lack of application of CI ideas. This is based on the CI Maturity Level tested in the questionnaire. Research does not test the success rate of implementing CI projects.

Based on the data, existing CI frameworks can be used in the FSI, as there is currently a footprint of these frameworks. The correlation was positive agreement of all CI framework elements tested, excluding the rewards system, and success management, which was neutral. However, because it does not seem like the implementation of CI initiatives is successful, there is space for a new CI framework that emphasizes the implementation and measurement of the initiatives identified for CI. To test which existing elements of CI frameworks would work in the FSI, a new model was proposed with a combination of elements and tested with the same audience. The proposal suggests that a CI framework could bring all the elements currently working in the industry together to form a powerful framework that would impact the industry and prove the first proposition to be correct.

To respond to research question one, “Are the existing CI frameworks relevant to the FSI?”, it is clear that the frameworks are present and that improvement projects are initiated. However, there is a lack of execution, and tracking of successful CI projects. This was proven by the positive agreement result of the study.

To respond to research question two, “What elements of a CI framework will make an impact to develop an organization in the financial industry?”, by testing the suggested CI framework for the FSI, it has been found that the respondents are in positive agreement that the suggested framework with existing CI framework elements would be a success in the FSI.

In conclusion, the questionnaire sections supported the following:

Section 2: The questionnaire was completed by financial services related respondents.

Section 3: According to the Bessant CI Maturity Model analysis, the FSI fluctuates between Level 2 and Level 4 of CI maturity in the organization.

Section 4: Based on the responses, there is knowledge of CI methodologies in the FSI. However, there is a lack of execution, rewards systems and success management.

Section 5: The respondents are in positive agreement with the suggested new CI model principles, elements, and process steps.

Thus, the proposition that existing CI frameworks can be used in FSI is accepted. It has also been established that there is space for a new CI framework.

6 CONCLUSIONS AND RECOMMENDATIONS

In conclusion, it was established that even if there is limited literature on CI frameworks in the financial service industry, the existing frameworks have been present in this specific industry. However, the data also suggested that implementing improvement initiatives is not as successful as the existing frameworks require. The analysis also revealed that the participants agreed with the new suggested CI framework.

6.1 Results

Table 2 summarizes the results relating to the research questions posed for this study.

Table 2: Summary of the results

Research Question	Test	Results	Conclusion
RQ1: Are the existing CI frameworks relevant to the financial services industry?	Section 2: Industry in which the respondent works.	The questionnaire was completed by financial services respondents.	Yes, existing CI frameworks are present in the financial services industry; however, they are not fully implemented
	Section 3: The opinion of the CI Maturity of the organization where the respondent finds themselves.	According to an analysis of the Bessant CI Maturity Model, the FSI fluctuates between Level 2 and Level 4.	
	Section 4: The opinion of the CI strategies in place in the organization where the respondent works.	There is proof that there is knowledge of CI methodologies in the FSI (very positive agreement). However, there tends to be a lack of execution (neutral), and reward systems (neutral).	
RQ2: What elements of a CI framework will make an impact to develop an organization in the financial industry?	Section 5: Testing the concept of the new model elements with the respondent.	The respondents are in positive agreement with the suggested new CI model principles, elements, and process steps.	The suggested CI framework aggregated from existing CI frameworks proved that it will potentially impact the financial services industry

6.2 Recommendations for future research

This study was conducted on the general FSI with a small sample size to establish the presence of CI strategies in the industry and a general view of a potential new model.

Future research in terms of scope would be required on the sub-sections of financial services such as insurance, banking, investment etc. It would also be required to establish the knowledge and investment in CI on the various levels of the organizational structure.

Future research in terms of the new model would be required to test the new model practically on a small scale and then test the model on a scaled approach in larger communities. This would prove that the principles, elements, and process steps are practical. The analysis shows that the CI model theory is available in the FSI. Thus, a practical test of the new model is required to establish whether it would fill the current application gap in the industry.

A practical test would also be required to establish if the application and implementation of CI ideas are indeed lacking or if there is another reason the respondents seem unaware of the implementation of improvement ideas.

6.3 Conclusion

There is a footprint of CI in the financial service industry, but there is a large gap in implementing CI initiatives in this market. Most CI frameworks cater to the manufacturing industry, and some adaptation has occurred for the financial industry. However, more study is required. Combining the current CI frameworks into a new model seems appropriate, but thorough practical testing is required.

In conclusion, this study has proven that a new continuous improvement framework is not required for financial services as a specific industry, even though most models and frameworks are created with the manufacturing industry at their core. However, this study has also proven that there is a lot of work required for the adoption of continuous improvement strategies in the FSI.

ABSTRACT

Additive Manufacturing (AM) has the potential to support the South African automotive industry in achieving the objectives of the South African Automotive Master Plan 2035 (SAAM 2035), including increasing local content to 60 percent, expanding employment in the value chain, and raising South Africa's share of global vehicle production to 1 percent. This qualitative study was conducted in two phases. The first phase involved a comprehensive review of academic literature, industry reports, and policy documents to identify global best practices in AM adoption. The second phase analysed a set of secondary case studies, selected for their relevance to advanced manufacturing capabilities and policy frameworks, from Germany, the United States, China, and Italy. Thematic analysis, guided by a coding framework, identified key themes including cost reduction, skills development, standards and regulation, supply chain localisation, and technology infrastructure. Findings indicate that AM can enhance production efficiency, reduce material waste, and support the development of domestic manufacturing capabilities, but its adoption is constrained by high capital costs, skills shortages, and regulatory gaps. The study contributes to the literature by synthesising international lessons to inform South Africa-specific AM strategies and by providing a thematic framework applicable to future research on AM adoption in the automotive sector.

Keywords: Additive Manufacturing, SAAM 2035, Technology Adoption, Industrial Policy, Local Content, Employment, Automotive Manufacturing

1 INTRODUCTION

The automotive industry remains a key pillar of South Africa's industrialisation and economic development strategy, representing one of the largest manufacturing sectors in the country. In 2020, the sector contributed approximately 4% to national GDP and accounted for nearly 28% of manufacturing output [25]. The industry is dominated by multinational corporations and is deeply integrated into global value chains, consistently producing vehicles that meet international standards. Recent data indicate that vehicle exports were around 300,000 units in 2020, with significant contributions from automotive components, reflecting the sector's ongoing role in trade and industrial integration [24]. Direct employment in vehicle manufacturing is estimated at over 110,000, supporting several hundred thousand indirect jobs across the wider economy, highlighting the sector's importance for quality employment and skills development [5, 12].

Despite these achievements, the South African automotive industry continues to face challenges, including a relatively stagnant domestic market, increased import competition, and limited progress in raising local content and employment. Structural constraints such as technological gaps, reliance on imported components, and a fragile supplier base have constrained industrial expansion [7, 8]. Government interventions, including the Motor Industry Development Programme (MIDP) and the Automotive Production and Development Programme (APDP), have provided critical support, yet systemic barriers persist. Strengthening domestic manufacturing, fostering supplier development, and increasing local value addition remain central national priorities [7].

The South African Automotive Industry Master Plan 2035 (SAAM 2035) articulates a long-term vision to enhance competitiveness, industrial sustainability, and technological capacity in the local automotive sector. Achieving these objectives requires comprehensive understanding and innovation across the automotive value chain, from raw material sourcing to component manufacturing, vehicle assembly, and end-of-life recycling [7]. Technological innovation, particularly in advanced manufacturing, is essential to improving production efficiency, supply chain resilience, and environmental performance [12].

Additive Manufacturing (AM), also known as 3D printing, has emerged as a transformative technology capable of reshaping the automotive value chain. By enabling layer-by-layer fabrication of components from digital designs, AM is reported offers benefits such as reduced material waste, increased design flexibility, faster prototyping, and production of complex parts with minimal tooling [14]. These capabilities support localisation, reduce dependency on imports, and create opportunities for high-skilled employment while contributing to resource efficiency and environmental sustainability [9, 3]. As global automotive markets increasingly adopt AM, South Africa's integration of this technology will be crucial for sustaining industrial competitiveness [12].

This study examines the potential contributions of AM to the South African automotive sector, focusing on advancing the objectives of SAAM 2035. The research addresses the following questions:

- What is the role of Additive Manufacturing in improving local content across the automotive value chain?
- To what extent can Additive Manufacturing contribute to increasing vehicle production output in South Africa?
- How can Additive Manufacturing influence job creation in South Africa's automotive sector?

2 METHODOLOGY

This study adopts a qualitative research methodology to explore the potential contributions and challenges of AM technologies in supporting the objectives of SAAM 2035. The research design focuses on a comprehensive literature review, including secondary case-based examples drawn from existing academic and industry sources. The methodology followed a structured process as outlined below:

- Formulation of Research Objectives: The study began with the formulation of clear research objectives aimed at examining how AM technologies can influence key goals of the SAAM 2035, including increased local content, higher vehicle production levels, and expanded employment in the automotive sector. These objectives guided the entire research process.
- Literature Review and Data Collection: A detailed literature review was conducted to gather relevant information from academic journals, policy documents, industry reports, and published case studies. The following databases were comprehensively searched: ScienceDirect, Scopus, IEEE Xplore, and Google Scholar were used to access reliable and up-to-date sources. Key search terms included: “Additive Manufacturing in Automotive,” “3D printing and employment,” “SAAM 2035,” “local content South Africa,” and “automotive innovation.”
- To ensure the relevance and quality of the literature, specific inclusion and exclusion criteria were applied. Inclusion criteria focused on peer-reviewed articles and industry publications from 2010 onward, chosen because this period marks a significant acceleration in the development and adoption of AM technologies in the automotive sector globally. Selecting 2010 as the base year allows the review to capture contemporary advancements and policy developments relevant to current industry practices. Studies that lacked a clear focus on AM or were not applicable to the automotive sector were excluded.
- Screening and Selection: The identified literature was screened in two stages. First, titles and abstracts were reviewed to assess relevance. Then, the full texts of the selected articles were examined to confirm their suitability for in-depth analysis. Only sources that provided valuable insights into AM adoption, benefits, challenges, and policy implications were retained.
- Data Extraction and Synthesis: From the selected literature, data were extracted on AM applications, success factors, limitations, and their implications for the automotive industry. Some of the selected literature included international case-based examples from countries such as Germany, the United States, China, and Italy, which provided context on how AM has been implemented in advanced manufacturing environments.
- Data Analysis and Thematic Categorisation: The extracted information was analysed using a thematic approach. Patterns and themes were identified based on recurring issues such as production efficiency, skills development, employment creation, and local content. These themes were then aligned with the strategic pillars of SAAM 2035 to assess how global AM practices could inform South Africa’s approach.
- Contextualisation for South Africa: Finally, the global insights from the literature were interpreted within the context of South Africa’s automotive industry. Factors such as local policy frameworks, technological readiness, infrastructure, and skills availability were considered to evaluate the feasibility and potential impact of AM adoption in the country.

This structured and systematic approach allowed the study to build a strong theoretical and contextual foundation. The findings aim to guide policymakers, researchers, and industry stakeholders in understanding the role AM could play in advancing South Africa’s automotive industrial development goals.

3 LITERATURE REVIEW

3.1 South African Automotive Master Plan 2035 (SAAM 2035)

3.1.1 Overview of the South African Automotive Industry Master Plan 2035

SAAM 2035 is a long-term strategy aimed at strengthening the local automotive industry. Its main goals include increasing local content in vehicle production, creating more jobs, and improving the industry's position in global markets [9]. However, the industry still faces challenges such as a weak supplier base, limited technology, and heavy reliance on imported parts [5]. To overcome these challenges, SAAM 2035 highlights the need to adopt new manufacturing technologies. AM is one such technology that can help by enabling local production of parts directly from digital designs. This reduces the need for expensive tooling and can increase the local content of automotive components, supporting the plan's goal to raise local content from about 39% to 60% by 2035 [10;14]. AM is also reported to offer flexibility, allowing manufacturers to quickly adjust production to meet changing demands or supply chain disruptions [3]. This is important given the unpredictable global economy and rising quality and environmental standards [16]. In addition, AM encourages innovation by allowing the creation of complex and custom parts, which can help South African companies compete internationally. The use of AM is also expected to create new jobs in areas such as design, engineering, and digital manufacturing. This fits with SAAM 2035's goal to grow employment, especially in skilled roles [9]. Furthermore, AM is more environmentally friendly than traditional manufacturing methods, as it produces less waste and uses energy more efficiently, which supports national sustainability targets [3]. Thus, the success of SAAM 2035 depends partly on adopting technologies like Additive Manufacturing. These technologies can help increase local production, improve efficiency, encourage innovation, and support job creation in South Africa's automotive sector.

3.1.2 Current State of the Industry

The South African automotive industry remains a vital component of the national economy, contributing approximately 5.3% to the country's GDP and playing a significant role in the manufacturing export sector [25]. Despite its importance, the industry faces several persistent challenges that hinder its growth and competitiveness. High production costs intensified global competition, fluctuating demand, and inadequate infrastructure continue to restrict domestic expansion [5;8]. A significant issue is the decline in local content within vehicle production, primarily due to a heavy reliance on imported components. This dependence weakens the development of a robust local supplier network and limits value addition within the country [24]. Consequently, the industry struggles to capture greater economic benefits and maintain sustainable growth.

3.1.3 Strategic Importance of Additive Manufacturing in the Automotive Industry

AM presents significant opportunities for advancing the strategic objectives of SAAM 2035. These technologies are particularly valuable in enhancing production efficiency and enabling the localised manufacturing of complex, customised components. Both of these capabilities are essential for meeting the Master Plan's targets related to increased local content and employment generation [12]. AM allows for the creation of intricate geometries that are difficult or impossible to achieve through conventional methods. This enables the production of structural and functional components such as drive shafts, brake systems, and lightweight assemblies that are commonly used in high-end or low-volume vehicles [15; 26]. The ability to customise and adapt designs supports local component manufacturing, reduces reliance on imports, and strengthens the domestic supply chain [27]. In addition, the rapid prototyping capabilities of AM significantly reduce the design-to-production timeline. This accelerates innovation in product development and supports a more responsive and competitive

automotive sector [2; 17]. AM is also highly material-efficient, minimising waste and allowing for the use of lightweight materials, which supports broader sustainability goals [3]. The widespread adoption of AM has the potential to generate high-skilled employment opportunities in areas such as digital design, process engineering, and advanced manufacturing. This aligns directly with SAAM 2035's aim to double direct employment in the automotive value chain by 2035 [12; 29]. Therefore, the strategic integration of AM technologies provides a compelling opportunity to transform the South African automotive industry and position it for long-term, globally competitive growth.

Despite these advantages, a clear research gap remains. While several studies have explored the potential of AM in global automotive manufacturing [14; 26], limited literature has examined how AM adoption specifically aligns with the strategic objectives of South Africa's Automotive Masterplan 2035 [5; 11]. Existing South African studies focus largely on high-level technology policy or general manufacturing challenges, without a comprehensive assessment of AM's feasibility, scalability, and integration into local supply chains [23; 7]. Current adoption in the country is still limited, with use cases primarily limited to research institutions, specialised tooling, and niche aftermarket parts [23; 7]. This knowledge gap creates uncertainty for policymakers and industry stakeholders seeking to leverage AM to achieve SAAM 2035's goals of increasing local content, job creation, and competitiveness. Addressing this gap requires situating AM's technological capabilities within South Africa's specific industrial, infrastructural, and policy context, supported by evidence from early local implementations.

3.2 International Experiences with Additive Manufacturing in the Automotive Sector

To demonstrate the potential of AM in supporting SAAM 2035, this section presents a comparative analysis of how selected countries have successfully integrated AM into their automotive sectors. These international examples illustrate the varied benefits of AM adoption, from localising supply chains and accelerating product development to stimulating high-tech employment and supporting small-scale, customised production. By examining these cases, South Africa can better understand the strategic pathways available for leveraging AM to achieve SAAM 2035 targets related to local content, industrial competitiveness, innovation, and job creation.

3.2.1 German: Enhancing Local Content and Supply Chain Resilience

Germany's automotive sector is a global benchmark for manufacturing excellence and innovation. Major Original Equipment Manufacturers (OEMs) like BMW, Audi, and Volkswagen have made significant strides in embedding AM within their production and R&D frameworks. BMW, for example, employs AM extensively to produce customised tooling, assembly jigs, and lightweight structural components for both its electric and combustion-engine vehicles [19]. By shifting tooling production in-house through AM, BMW has not only accelerated product development cycles but also reduced supplier dependency and logistics complexities. This internalisation has led to a more resilient and flexible supply chain, crucial in times of global disruptions such as those seen during the COVID-19 pandemic [34]. Moreover, BMW's approach integrates AM within its Industry 4.0 initiatives, combining digital twins, sensor networks, and machine learning to optimise production workflows and predictive maintenance [29]. Audi, meanwhile, utilises AM for lightweight parts made from advanced polymers and metal alloys, improving vehicle fuel efficiency and performance. The capacity to rapidly prototype and test complex geometries without tooling constraints has allowed Audi to accelerate innovation in electric powertrains and autonomous vehicle components [19]. The German government supports these industry efforts through policies promoting Industry 4.0 adoption and funding for AM research hubs, fostering a robust ecosystem for innovation. Additionally, vocational

training programmes have adapted curricula to upskill workers in AM technologies, addressing skills shortages in advanced manufacturing [21].

Implications for SAAM 2035: South Africa can replicate these integrated AM strategies to localise production, decrease reliance on imported components, and create a more resilient supply chain. Coupling AM adoption with digitalisation and workforce development will be key to advancing the automotive sector's competitiveness and sustainability goals.

3.2.2 United States: Accelerating Innovation and Prototyping

The U.S. automotive industry has been a pioneer in leveraging AM for innovation, prototyping, and tooling optimisation. Companies such as Ford and General Motors (GM) have embedded AM into their engineering and production processes since the early 2000s. Ford's internal reports highlight a reduction in design-to-market time by approximately 25% due to AM's rapid prototyping capabilities [13]. Ford employs AM to create functional prototypes, custom tools, and even end-use components, particularly in its electric vehicle (EV) and autonomous vehicle platforms. This flexibility has allowed Ford to respond quickly to changing market demands and regulatory requirements, shortening feedback loops between design and manufacturing teams [13].

The U.S. government's America Makes initiative, a public-private partnership, has been instrumental in making AM technologies accessible to a wider range of manufacturers beyond large OEMs. This programme funds collaborative research projects, facilitates knowledge sharing, and supports workforce training across the additive manufacturing supply chain, especially targeting small and medium-sized enterprises (SMEs) [28].

GM has also invested heavily in AM, using it to develop complex parts such as brackets, housings, and prototypes for its Cadillac and Chevrolet brands. By integrating AM with traditional manufacturing, GM achieves cost savings and improved design freedom, enabling lightweighting and performance optimisation [30]. In addition to prototyping, the U.S. automotive industry utilises AM for low-volume production runs, enabling customisation and reducing inventory costs. This capability is particularly valuable in EV battery component production and specialty vehicle manufacturing [9].

Implications for SAAM 2035: South Africa can enhance its automotive innovation ecosystem by adopting AM technologies for rapid prototyping and tooling. Government-supported initiatives similar to America Makes could catalyse adoption among SMEs, expanding the technology's impact across the industry. These measures will improve product development efficiency and help South Africa compete globally in emerging automotive technologies.

3.2.3 China: Driving Employment and Industrial Scale Production

China's national strategic focus on AM, embedded in its "Made in China 2025" industrial policy, reflects a comprehensive approach to modernising manufacturing and advancing automotive production capabilities. Automotive giants such as SAIC Motor and Geely have been early adopters of AM, particularly for EV components and injection mould tooling. Geely, one of China's largest automakers, has reported that over 30% of its vehicle moulds are now produced using AM, significantly cutting lead times from months to weeks while reducing costs by up to 40% [20]. This shift has allowed Geely to rapidly iterate designs and scale production for new EV models to meet growing domestic and international demand. Beyond production efficiencies, China's AM deployment has stimulated job creation in advanced manufacturing roles [32]. document the emergence of specialised positions in digital design, AM machine operation, maintenance, and quality assurance. These roles require a higher skill level, contributing to workforce upskilling and aligning with national goals to increase high-tech manufacturing employment. China's coordinated investment in AM infrastructure includes dedicated manufacturing parks, research institutes, and cross-sector collaboration platforms

that integrate automotive firms with material suppliers and technology developers. This ecosystem accelerates technology transfer and fosters innovation clusters [33].

Implications for SAAM 2035: South Africa can leverage AM not only for production enhancement but also as a driver of industrial employment and skills development. Government-backed industrial parks and innovation hubs, coupled with targeted training programmes, can replicate China's success in creating a vibrant AM manufacturing ecosystem that supports broad-based economic growth.

3.2.4 Italy: AM for Niche and Custom Vehicle Markets

Italy's automotive sector, renowned for luxury and performance vehicles, offers a unique perspective on leveraging AM for specialised and low-volume manufacturing. Brands such as Ferrari, Lamborghini, and Maserati have embraced AM to produce complex components that would be difficult or costly to manufacture using conventional methods. Martina et al. [22] highlight that Italian manufacturers utilise AM to enable shorter product life cycles and rapid customisation, especially in high-performance parts such as turbocharger housings, aerodynamic elements, and lightweight structural components. AM's ability to produce intricate designs with high precision supports Italy's brand identity of craftsmanship combined with cutting-edge technology. The flexibility of AM also allows smaller Italian automotive firms and startups to enter niche markets, developing bespoke vehicles and aftermarket components that cater to enthusiast and luxury segments. This dynamic supports a decentralised innovation model where design houses and small manufacturers co-create alongside larger firms [4]. Italian universities and research institutions actively collaborate with industry to advance AM materials and processes, integrating academic research with industrial applications. This ecosystem nurtures skilled talent and drives continuous innovation in manufacturing techniques [16].

Implications for SAAM 2035: South Africa's growing aftermarket, customisation, and small enterprise sectors can benefit from adopting AM for niche vehicle parts and specialised production. Support for design innovation and collaboration between industry and academia will be critical in realising this potential, fostering entrepreneurship and enhancing local value creation.

3.3 Summary of Global best Practices

The following table summarises the key outcomes from each country's integration of AM technologies and their relevance to SAAM 2035 objectives:

Table 1: Summary of Global Best Practices in Additive Manufacturing and Their Relevance to SAAM 2035

	AM Use Case	Outcomes	Relevance to SAAM 2035
Germany	Tooling, lightweight components	Increased local content, supply chain resilience	Raise local content to 60%
USA	Prototyping, SME support	Faster innovation cycles, broader technology access	Improve competitiveness
China	EV component production, molds	Expanded employment, cost reduction	Double employment
Italy	Niche production	Customisation, SME growth	Stimulate local entrepreneurship

4 DISCUSSION

This section provides an integrated analysis of how AM adoption in the South African automotive industry can contribute toward achieving the three primary goals of the South African Automotive Master Plan 2035: increasing vehicle production output, raising local content, and doubling employment. Drawing from international best practices and contextual

realities in South Africa, this discussion critically evaluates both the opportunities and constraints associated with AM integration.

4.1 Potential Impact of AM on Vehicle Production Output

The integration of AM technologies has shown the potential to significantly improve both production efficiency and throughput in the automotive sector. In addition to accelerating design iterations and reducing time-to-market for new vehicle models, AM can also optimise production workflows by enabling faster tooling replacement, reducing downtime, and allowing for on-demand production of complex components. International case studies demonstrate that firms leveraging AM for both prototyping and manufacturing applications achieve measurable gains in output capacity. For example, Ford's implementation of AM shortened the development timeline for electric vehicle components by approximately 25%, which in turn freed production resources for scaling output. In the South African context, such efficiencies could enhance the production capacity of domestic OEMs and Tier-1 suppliers, directly supporting the Master Plan's objective of increasing vehicle production volumes to contribute 1% of global output. However, the sector currently lacks widespread access to AM infrastructure and skilled expertise, particularly among SMEs. Addressing these gaps through public–private partnerships, targeted investment incentives, and technology transfer programs will be essential to translating AM's rapid development advantages into sustained increases in production capacity.

4.2 Enhancing Local Content Through Additive Manufacturing

AM facilitates localised production by enabling on-demand manufacturing of complex components, reducing the need to import high-value parts. Germany's use of AM for tooling and jigs has demonstrated how localised capabilities can boost domestic value addition. In the South African context, AM presents a unique opportunity to develop local supply chains for specialised components such as brackets, air intake systems, and housings components that are currently sourced externally due to tooling constraints. Increased local sourcing through AM could significantly raise the percentage of local content in South African-assembled vehicles, moving toward the 60% target set by SAAM 2035. Furthermore, by enabling low-volume, high-complexity production, AM allows small enterprises and start-ups to enter the value chain as niche suppliers, potentially broadening the local supplier base and enhancing industrial diversification.

4.3 Job Creation and Skills Development in the AM Economy

One of the most debated aspects of AM is its dual impact on employment: while automation can displace traditional roles, it also creates new high-skill opportunities in design, software, digital maintenance, and operations. The Chinese case study illustrates this dynamic—specialised AM roles emerged in tandem with the growth of digital manufacturing platforms. In South Africa, AM could catalyse job creation in areas such as CAD modeling, AM machine operations, material science, and post-processing services. Importantly, AM adoption could benefit Technical and Vocational Education and Training (TVET) institutions by updating curricula to prepare students for future job roles in digital manufacturing. Policy incentives that encourage companies to invest in workforce reskilling and AM training centers could help mitigate displacement concerns and contribute toward the Master Plan's employment goals.

In South Africa, the integration of AM can catalyse employment in the following areas:

- **Design for Additive Manufacturing (DfAM):** Empowering engineers and technicians with DfAM skills enables the industry to fully exploit the geometric and functional advantages of AM.

- **Machine Operation and Maintenance:** As AM machines become more prevalent, demand for technicians who can operate, maintain, and calibrate these systems will rise.
- **Material Science and Quality Control:** Specialised knowledge will be required to manage AM material properties and ensure part reliability in safety-critical automotive applications.
- **Entrepreneurship and SME Growth:** Small-scale AM enterprises can enter niche markets, offering customised solutions and aftermarket products.

5 CHALLENGES AND BARRIERS TO ADOPTION

Despite the transformative potential of AM in advancing the goals outlined in SAAM 2035, particularly in enhancing localisation, reducing lead times, and improving competitiveness, its widespread adoption remains limited due to several interrelated barriers. One of the most prominent challenges is the high capital investment required to acquire industrial-grade AM equipment capable of producing functional, end-use automotive components. These costs, coupled with recurring expenses for specialised materials, skilled labor, and maintenance, are especially prohibitive for small and medium enterprises (SMEs) that dominate the Tier-2 and Tier-3 supplier ecosystem [14; 9]. The problem is further intensified by limited access to affordable financing mechanisms tailored to AM innovation [11]. In addition, the industry suffers from a significant skills gap; AM demands expertise in design for additive manufacturing (DfAM), materials science, and digital workflow management, competencies that are not widely available in the local labour market [16]. Although some academic institutions have introduced AM-related programs, these remain poorly integrated and often disconnected from the practical needs of the automotive sector [10]. The absence of standardised certification frameworks for AM parts also hampers their integration into safety-critical automotive systems, as Original Equipment Manufacturers (OEMs) and Tier-1 suppliers require strict quality assurance protocols [18]. Without recognised national standards for testing and validation, the reliability and compliance of AM components remain in question. Furthermore, the South African AM ecosystem is still emerging and characterised by uncoordinated efforts across academia, startups, and research entities, resulting in duplicated R&D, limited knowledge exchange, and underutilised infrastructure [3]. Adding to these challenges is the lack of explicit policy incentives and regulatory guidance to support AM adoption. Despite its strategic alignment with SAAM 2035, AM has not yet been incorporated into industrial policy instruments such as tax incentives or supplier development programs, which negatively impacts investor confidence and slows the pace of technology diffusion [10; 11].

6 RECOMMENDATIONS AND POLICY IMPLICATIONS

To fully harness the transformative potential of AM for achieving the goals of SAAM 2035, a coordinated, multi-faceted strategy is required. The following recommendations focus on creating an enabling environment that promotes innovation, strengthens industry capabilities, and accelerates adoption.

Table 2: Strategic Recommendations for Advancing Additive Manufacturing in South Africa's Automotive Sector (Aligned with SAAM 2035)

Recommendation Area	Action	Policy Implication / Impact
National AM Strategy	Develop a roadmap aligning AM with SAAM 2035 goals, targeting high-impact components and milestones.	Encourages focused development, coordinated stakeholder efforts, and incentivises early adoption.
Regional Innovation Centres	Establish shared AM hubs with equipment, training, and incubation facilities.	Lowers entry barriers for SMEs, boosts local innovation, and builds regional capacity.
Education & Skills Development	Integrate AM in higher education and vocational curricula; fund internships and apprenticeships.	Builds a skilled workforce ready to implement AM technologies across the automotive value chain.
Standards & Certification	Develop local standards with SABS and align with global benchmarks.	Ensures quality, improves trust, and supports market access for AM-produced components.
Financial Incentives	Offer AM-specific tax relief, grants, and procurement preferences.	Stimulates private investment, especially among local OEMs and Tier-2/3 suppliers.
Collaborative Research & Industry Partnerships	Create consortia for joint R&D, with matched funding mechanisms to reduce risks.	Drives innovation, fast-tracks commercialisation, and strengthens industry-academia-government collaboration.

7 CONCLUSIONS

This study examined the potential contributions of Additive Manufacturing (AM) to the South African automotive sector, with particular emphasis on advancing the objectives of SAAM 2035. Specifically, it addressed three critical questions: the impact of AM on vehicle production output, its influence on local content within automotive manufacturing, and its potential to foster high-skilled job creation. The findings indicate that AM holds considerable promise for enhancing production efficiency through flexible, cost-effective manufacturing processes. Additionally, AM adoption supports the development of a skilled workforce in advanced manufacturing roles, contributing to SAAM 2035's employment targets.

Despite these potential benefits, AM adoption in South Africa remains constrained by limited technological awareness, skills gaps, infrastructure deficits, and regulatory challenges. Strategic interventions such as coordinated policy, targeted capacity building, and public–private collaboration are essential to realise these benefits fully.

This study is primarily based on secondary data and selected international case studies, reflecting the current paucity of empirical evidence on local AM adoption. Consequently, the findings offer sector-level insights but may not capture firm-level variations in implementation, productivity, or local content outcomes. Future research could address this limitation by conducting in-depth case studies, pilot projects, or longitudinal analyses to quantify the real-world impact of AM on vehicle production, local supply chains, and employment within the South African context.

ABSTRACT

The mining industry has undergone digital transformation through the adoption of 4IR technologies such as IoT, CMMS, and AHS. The adoption is mainly for the purposes of a competitive edge and increasing the safety of mining operations. A key consideration, being cybersecurity, was overlooked during the integration of the new technologies, exposing the mining operations to potential cyberattacks with catastrophic consequences. These mining operations are most vulnerable through their weakest link, which is the human component of cybersecurity. A model was developed to address the correlation between personality traits, demographic factors and defence mechanisms. The model aims to relate these factors to susceptibility to cyberattacks in efforts to inform training and awareness programs, improve cybersecurity policy, and lend itself to creating a culture of digitally responsible employees within the industry.

Keywords: cybersecurity, human factors, social engineering, South African mining industry, five-factor model, personality traits, defence mechanisms

1 INTRODUCTION

1.1 Background

The mining industry has seen an increase in technological advances due to the 4th industrial revolution [1], [2]. Terms such as digitalisation and automation are becoming increasingly synonymous with the industry. Digital transformation is digitalisation at its core, but it significantly changes business practices, company culture and customer experiences [1]. Examples of Digital Transformation in the mining industry include Internet of Things (IoT), Computerised Maintenance Management Systems (CMMS), and Autonomous Haulage Equipment (AHS). A few reasons behind the trend in digital transformation for the mining industry are to allow for better integration both internally and externally, safety of operations, remaining competitive, enhanced productivity, greater control, increased profitability, and better monitoring [1], [2], [3].

The Digital Transformation movement, in the already data-sensitive sector, increases the risk of cyberattacks [2], [3], [4]. The risks associated with cyberattacks in the mining industry include financial loss, employee safety, damage to reputation, and data theft [4]. Given the severity of the cybersecurity risks, the mining industry has been slow to react, even after most of the mining industry has fallen prey to cyberattacks [2], [3], [4].

Common attacks that have been reported to plague the mining industry are cyber espionage, phishing, and vulnerabilities in third-party software [3]. From these attacks, phishing in the mining industry has seen the highest rate compared to other industries [3] and has the highest occurrence probability of all the cyberattacks [2]. Literature has mentioned a skills deficit in the mining industry with the coming of Digital Transformation and highlights that an organisation's cybersecurity is only as strong as its weakest link. Thus, investing in cybersecurity training is of significant value to the industry [1], [4], [5].

1.2 Research problem statement and objectives

1.2.1 Research problem statement

Cybersecurity threats are becoming an increasing occurrence in the mining industry, and due to the increased digitalisation, the cybersecurity threats could result in large losses of money, facility downtime, and in extreme cases, even sabotage, loss of life and closing of the facility.

The problem is that the defence against these attacks is only as strong as its weakest link, and in the case of cybersecurity attacks, that link is the human element, which can be manipulated and exploited through social engineering techniques.

1.2.2 Research objectives and questions

The objectives of the research are firstly to identify and analyse the human factors which contribute to cybersecurity breaches in engineering asset data systems (RO1) and, thereafter, to develop a conceptual framework linking human factors to cybersecurity defence mechanisms within the South African mining industry (RO2). These objectives will be achieved through the development and answering of research questions. The research questions which will aid in achieving the two research objectives are as follows:

RQ1) Which human factors have the most influence on a successful cybersecurity breach?

RQ2) Which human factors have the most influence on countering a cybersecurity breach?

RQ3) What are the essential components of a conceptual framework that effectively integrates human factors into cybersecurity defence mechanisms in the South African mining industry?

2 METHODOLOGY

2.1 Research design

A mixed methods approach was selected for the literature review as it is a relatively unexplored field. An initial scoping review served to identify the literature gap associated with cybersecurity in the mining industry.

The systematic literature review was then utilised to uncover human factors and the associated models that have been developed and utilised in other industries within the context of cybersecurity.

2.2 Database and search strategy

A database search was undertaken in Scopus and Web of Science due to the site's credibility and quality. Only peer-reviewed and published articles were considered. The strings utilised for the search can be seen in Table 1, where the highlighted cells indicate the datasets that were considered for screening.

Table 1: Database search

Key Phrase	Scopus	Web of Science
Cybersecurity AND “Mining Industry”	12	1
Cybersecurity AND Countermeasures	1404	119
Cybersecurity AND Countermeasures AND Mining	28	0
“Social Engineering” AND “Human Factors”	138	-

2.3 Screening process

The extracted articles were further screened using a scale of applicability, as information relating to data mining, cryptocurrency, and forensics was allowed through the filters and was irrelevant to the topic. The scale and results from the screening process are seen in Table 2.

Table 2: Screening criteria

Screening Description	Scale	No. of Articles
Not Applicable	1	214
Contains Information that could be useful	2	59
Applicable to the topic	3	25

The screening process was carried out according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA). The PRISMA diagram for the study can be seen in Figure 1.

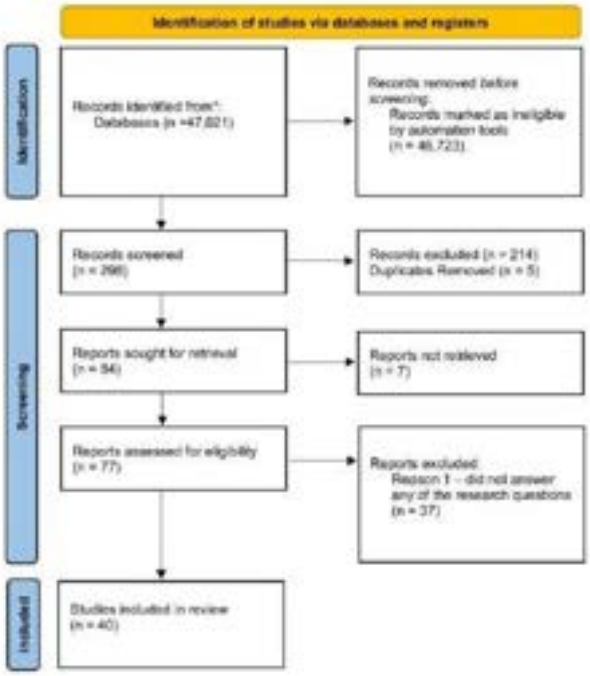

Figure 1: PRISMA diagram

2.4 Data analysis approach

The content from the 40 selected articles was reviewed within the frame of the research questions, and the extent to which each research question was answered. A summary of the data analysis exercise is presented in Table 3. Although all the papers addressed the research questions, they were only partially answered.

Table 3: Summary of data analysis

Description	RQ1	RQ2	RQ3
Cybersecurity AND "Mining Industry"	6	1	1
Cybersecurity AND Countermeasures	0	0	3
"Social Engineering" AND "Human Factors"	7	4	0
Percentage Contribution (Partial)	33%	13%	10%

3 LITERATURE REVIEW

The themes identified from the scoping review were consolidated into a Sankey diagram for each of the dataset strings from Table 3.

3.1 Cybersecurity AND the mining industry

The first dataset, being "Cybersecurity AND Mining Industry", yielded themes of cybersecurity threats and the need for cybersecurity prevention. There was a total of 6 articles which contributed to the identified themes. The visualisation of the interaction between the themes and articles is seen in Figure 2.

Figure 2: Cybersecurity AND mining industry Sankey diagram

The first theme being “the need for cybersecurity prevention”, was made up of a few topics. The first topic was the need for training and awareness of employees within the mines. The second topic involved employing individuals with an in-depth level of understanding of cybersecurity to ensure the IT networks in the mining operations are protected. The final point involved the implementation of certain high-level technical solutions to prevent cybersecurity attacks.

The second theme of “cybersecurity threats” describes that cybersecurity is one of the biggest threats to the mining sector, following the increased use of IoT devices. The cyberattacks specific to the mining industry that were described included phishing, malvertising, watering hole, 3rd party vendors, network spoofing and vulnerability exploitation. The body of knowledge in this sector was very limited, which further motivated the argument of the knowledge gap within the sector.

3.2 Cybersecurity AND countermeasures

The second dataset, being “Cybersecurity AND Countermeasures”, uncovered themes of “Cyber Attacks”, “Training”, and “Human Factors”. A total of 8 articles contributed to the uncovered themes. The visualisation of the interaction between the themes and articles is seen in Figure 3.

The “Cyber Attacks” topic reported on various types of cyberattacks experienced within industries other than mining. The cyberattacks that were reported, in addition to the mining-specific attacks, included system misconfiguration, ransomware, insider threats, dumpster diving, scareware, deepfakes, and shoulder surfing.

The need for training was discussed in the majority of the articles reviewed, and the articles began making mention of human factors associated with cybersecurity attacks; however, not provide an in-depth knowledge of how the human factors were responsible for successful cybersecurity attacks.

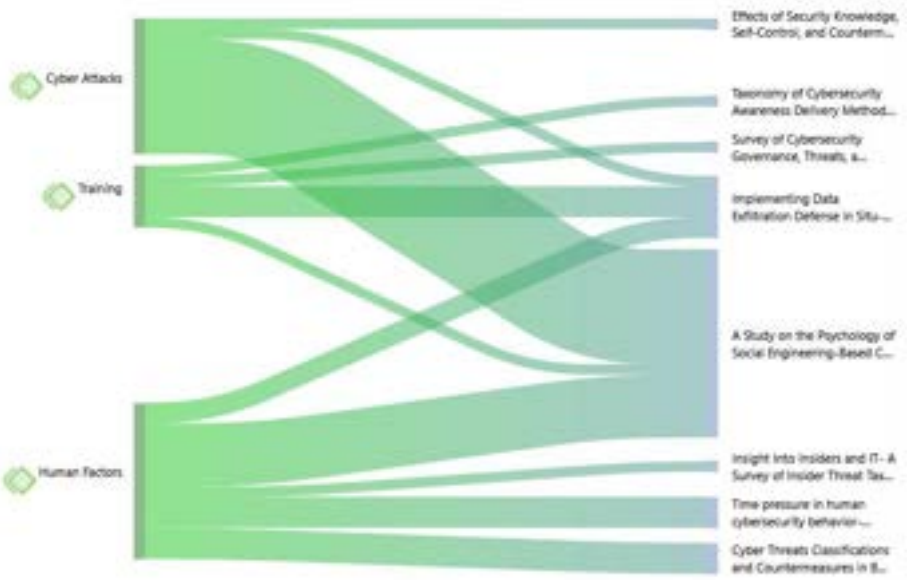

Figure 3: Cybersecurity AND countermeasures Sankey diagram

3.3 Social engineering AND human factor

The final dataset, being "Social Engineering AND Human Factors", uncovered themes of "Cybersecurity Defence", "Human Factors", and "Cybersecurity Motives". A total of 10 articles contributed to the uncovered themes. The visualisation of the interaction between the themes is seen in Figure 4.

Figure 4: Social engineering AND human factor Sankey diagram

The themes considered among the articles in the final dataset were specific to social engineering and included cybersecurity motives in the form of a social engineering attack model. The theme of "Human Factors" included an in-depth view of models that have been used in cybersecurity literature. These included psychological, personality traits, behavioural and criminology perspectives. The final theme was "Cybersecurity Defence Mechanisms" and proposed options of educational training, organisational policies, and cybersecurity tools to

defend against cyberattacks. The effectiveness of the training methods and the effectiveness of training delivery methods were also topics within the theme.

3.4 Social engineering attacks

Social engineering attacks are categorised into two types, namely, direct and indirect attacks. Direct attacks require the attacker to be present, while indirect attacks can be launched utilising an online medium [6]. An article by Tubis et al. [2] proposed a probability of attack occurrence ranking within the mining industry. The most frequent results can be seen in Table 4. A commonality between the most frequent mining attacks and the types of social engineering attacks is that the mining industry is mostly susceptible to indirect attacks. This is due to the difficulty in obtaining access to the sites to perform direct attacks.

Table 4: Probability of attack occurrence [2]

Attack method	Definition	Occurrence probability
Phishing	Scam emails that are sent by attackers, this method of Social Engineering (SE) attack is among the most successful [7].	72%
Vulnerability exploitation	Attackers capitalise on unaddressed vulnerabilities/bugs in system software to take control of the system [2].	33%
Watering hole	The attacker searches for information on the browsing habits of employees for a chosen organisation in order to compromise a frequently visited website and infect victims and networks when they visit the website [7].	27%
Malvertising	Attackers inject malicious advertisements containing malware onto legitimate advertising networks' webpages for victims to fall prey to [2].	27%

The new interaction of Large Language Models (LLMs) with social engineering attacks allows for high-quality, convincing phishing emails to be created in a fraction of the time, increasing the frequency at which all industries are attacked [8].

3.5 Social engineering models

The literature review uncovered two human factor-specific cybersecurity models which addressed the issue from the perspective of the victim. A description of the cybersecurity models can be seen in Table 5 which have all been developed from the Five Factor Model.

Table 5: Social engineering models summary

Model	Model context	Author
Social Engineering Personality Framework	A model which allocates correlation from literature and highlights how increases and decreases in individual personality traits allow for better or worse susceptibility to the principles of influence utilised by Social Engineers	Uebelacker et al. [9]
Adapted phishing susceptibility framework	A model that looked into personality traits that make individuals susceptible to phishing attacks in the workplace. Additional variables of a self-monitoring trait, as well as experiential factors, were also included.	Anawar et al. [10]

3.6 Demographic variables

Articles by Alshraif et al.[11] and Khonji et al. [12] explain that the demographic element also has an influence on cybersecurity. Gender and age were found to strongly correlate with phishing susceptibility in a demographic study conducted by Steve Shen et al. where he found that females would click on links more often when compared to males, and that individuals between the ages of 18 to 25 had a higher probability of falling victim to phishing attempts compared to other age groups [12].

The experiential factors addressed in the study by Anawar et al. [10] also fall into the category of demographic variables, where they have a probability of affecting cybersecurity susceptibility in employees.

3.7 Social engineering prevention strategies

Social Engineering prevention strategies are categorised into three groups. The first group is knowledge-based measures, where an individual is trained/educated. The second prevention strategy is achieved through software/tools enhancement to better classify SE attacks as well as prompt users on possible attacks. The final prevention strategy is organisational policies, which aim to enhance information security measures by outlining the desired personnel behaviours [12], [13], [14].

In a critical review by Aldawood & Skinner [13], contributions and limitations of the three prevention strategies were collected and summarised. The limitations associated with knowledge-based and policy-based defence mechanisms were the human element, being attributed to the difference in personalities, as well as their skill level.

The limitations proposed were also motivated in an article by Workman, as cited in [15] where not considering human factors in education-based measures leads to users "knowing better but not doing better".

3.8 Relevance of the research

A study by Dalal et al. [16] collected possible opportunities for research at the intersection of organisational science and cybersecurity, focused on employees. Dalal et al. stress that the most important requirement for contributing to this pool of literature is to minimise end-users' cyber misbehaviour through understanding and reporting on the organisational and individual difference factors that can predict this misbehaviour. A framework for future study was proposed within the study, as seen in Figure 5.

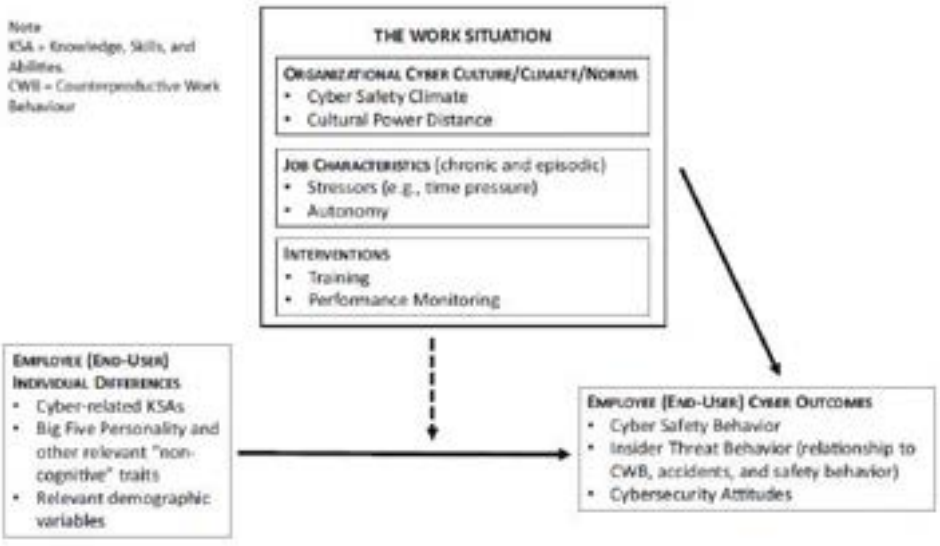

Figure 5: End-user future work organising model [16]

The framework considers personality trait models and relevant demographic variables as the starting point, bringing into consideration the work situation. The combination of individuals' differences and the work situation informs the end-user outcomes. This approach served as the starting point for the conceptual model development.

4 CONCEPTUAL MODEL

4.1 Approach

The non-comprehensive organising framework for future work was developed by Dalal et al. [16] shown in Figure 5 acts as the framework for the theoretical model. The literature study undertaken reports on psychological factors, personality traits, demographic variables and experience.

The Big Five Personality model is a suitable basis to cover both the psychological and personality traits and will be utilised in conjunction with the additional variables to cover the Human Factors/ Cybersecurity Behaviour of the study. The defence mechanisms will be considered in the conceptual model in order to comment on the correlation between human factors and defence mechanisms.

Social Engineering influence techniques have appeared in most of the models described in the body of knowledge; however, in the case of this study, the focus is on the human factor interaction with susceptibility, as well as human factor interactions with the defence mechanisms. Influence techniques are an enabler in the background, which is not considered for this study.

4.2 Conceptual framework

The conceptual model is shown in Figure 6 where the variables will be discussed in the rest of the section. The model is multivariate in nature, where in the first instance, the human and demographic variables are the independent variables, and the user susceptibility is the dependent variable, and in the second instance, the defence mechanisms are the independent variables, and human factors are the dependent variables.

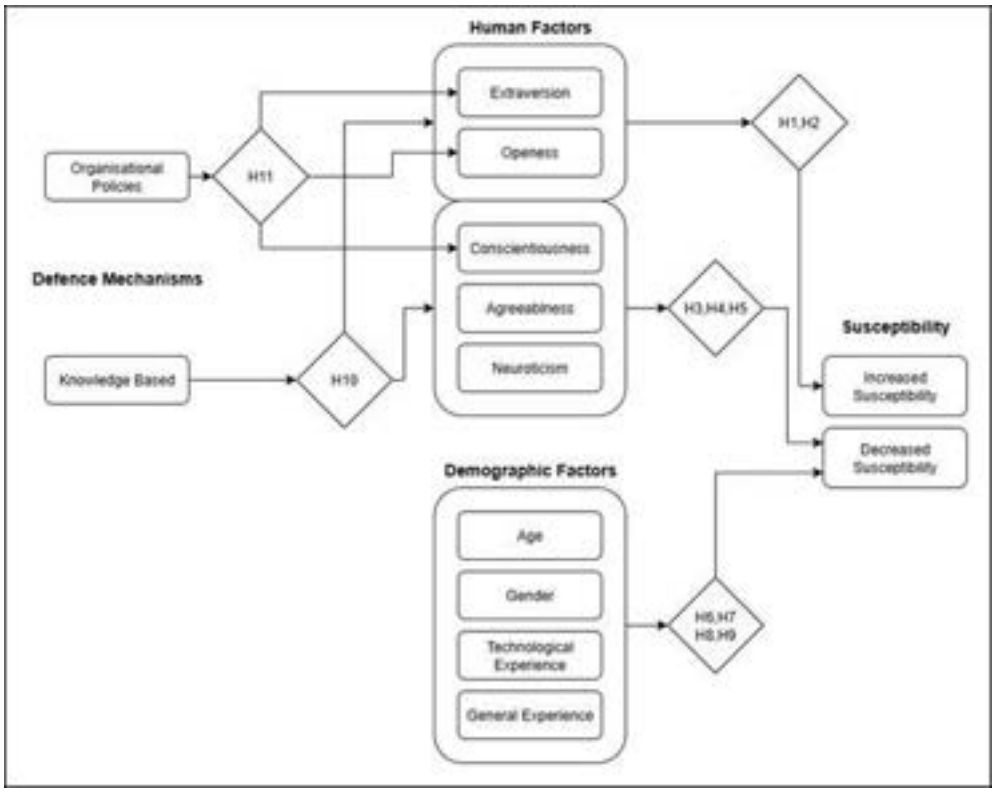

Figure 6: Conceptual Model

4.3 Big 5 personality traits

The big 5 personality traits model has been developed over an extensive period of time by experts in the field of personality psychology, which started off as an extensive pool of what makes humans unique and has been refined to the 5 traits of conscientiousness, extraversion, agreeableness, openness and neuroticism [17]. These traits exist as the broadest grouping of taxonomies, which allow for a distinction between the uniqueness of human beings and should be treated as a slider from a low affinity for the trait to a high affinity for it.

The Big 5 Personality Trait model is suitable for commenting on the human factors associated with cybersecurity in the South African mining industry. The model aligns with the direction provided in Dalal [16] and appears in a considerable amount of the social engineering cybersecurity literature.

4.3.1 Extraversion

Extraversion is made up of traits of Gregariousness, Assertiveness, Activity, Excitement Seeking, Positive Emotions and Warmth [17]. These traits stem from their Revised Personality Inventory (NEO PI-R) Facets.

The studies by Albladi & George [18], Gottker, Watson & Van Sintemaartensdijk [19], and Uebelacker & Quiel [9] hypothesise that high levels of extraversion increase individuals' susceptibility to falling victim to cyberattacks. The excitement-seeking/adventurous characteristic leads these individuals to click on phishing links and be more cooperative in social engineering attack attempts.

The paper by Albladi & George [18] found that high levels of extraversion correlated with an increase in user susceptibility to cyberattacks. The study by Gottker, Watson & Van Sintemaartensdijk [19], however, it was inconclusive around this personality trait.

The following hypothesis is suggested for Extraversion:

H1. High levels of Extraversion in personality increase user susceptibility to social engineering cyberattacks in the South African mining industry

4.3.2 Openness

Openness is made up of traits of Ideas, Fantasy, Aesthetics, Actions, Feelings, and Values [17]. These traits stem from their Revised Personality Inventory (NEO PI-R) Facets.

Studies by Albladi & George [18], Van De Weijer & Leukfeldt [20], Shappie [21], and Uebelacker & Quiel [9] hypothesise that high levels of openness in personality lead to a higher susceptibility to cyberattacks. The hypothesis is based on the fantasy associated with new experiences that lead these users to have a higher susceptibility.

Uebelacker & Quiel [9] also added that technological experience in the case of openness has the opposite effect, as the users then have better detection capabilities; however, the study by Anawar [10] found that technological experience only influenced extroversion and agreeableness, and general work experience impacted all personality traits except for openness.

The results from the paper by Albladi & George [18] found no correlation between the personality trait and cyberattack susceptibility; however, in the case of Van De Weijer & Leukfeldt [20], and Shappie [21], the results showed that users with high levels of openness are more susceptible to cyberattacks.

The following hypothesis is suggested for Openness:

H2. High levels of Openness in personality increase user susceptibility to social engineering cyberattacks in the South African mining industry

4.3.3 Conscientiousness

According to the work carried out by Costa and McCrae [22], Conscientiousness is made up of traits of Competence, Order, Dutifulness, Achievement striving, Self-discipline and Deliberation [17]. These traits stem from their Revised Personality Inventory (NEO PI-R) Facets.

Studies by Albladi & George [18], Van De Weijer & Leukfeldt [20], Shappie [21], and Gottker [19] all hypothesise that high levels of conscientiousness in personality reduce the susceptibility of an individual to fall victim to cyberattacks. The personality trait leads to behaviours of following company policy, exercising awareness online and keeping their laptops up to date with the latest malware software. Through their data gathering, these studies were able to uncover correlations between high conscientiousness in user personality and reduced susceptibility to cyberattacks.

In the model proposed by Uebelacker & Quiel [9], the hypothesis is agreed with on the basis that the company has good cyber security policies; however, a caution is given to social engineering influence techniques of Authority, Reciprocity and Commitment & Consistency.

The following hypothesis is suggested for Conscientiousness:

H3. High levels of Conscientiousness in personality reduce user susceptibility to social engineering cyberattacks in the South African mining industry

4.3.4 Agreeableness

Agreeableness is made up of traits of Trust, Straightforwardness, Altruism, Compliance, Modesty, and Tendermindedness [17]. These traits stem from their Revised Personality Inventory (NEO PI-R) Facets.

Studies by Albladi & George [18], Gottker [19], Shappie [21], and Uebelacker & Quiel [9] hypothesise that high levels of agreeableness in user personality lead to a greater susceptibility to cyberattacks. The reason for the hypothesis is that the trusting nature is seen as exploitable by social engineers; this is also described in Kevin Mitnick's social engineering attack cycle.

The results related to this hypothesis Gottker [19], and Shappie [21] were inconclusive; however, the results from Albladi & George [18] found a correlation between high agreeableness and a reduced susceptibility to cyberattacks. This opposition to the original hypothesis was attributed to the higher likelihood of these individuals adopting security software when compared to other users and a higher information security awareness.

The following hypothesis is suggested for Agreeableness:

H4. High levels of Agreeableness in personality decrease user susceptibility to social engineering cyberattacks in the South African mining industry

4.3.5 Neuroticism

Neuroticism is made up of traits of Anxiety, Angry Hostility, Depression, Self-Consciousness, Impulsiveness, and Vulnerability [17]. These traits stem from their Revised Personality Inventory (NEO PI-R) Facets.

The studies by Albladi & George [18], Gottker [19], and Uebelacker & Quiel [9] hypothesise that the anxiety and self-consciousness associated with high levels of neuroticism lead to a decreased susceptibility to cyberattacks.

The results of the studies in the case of by Albladi & George [18], and Gottker [19] found that heightened levels of neuroticism does lead to a reduced susceptibility to cyberattacks due to the untrusting nature coupled with anxiety. Albladi & George [18] also found that users with

medium levels of neuroticism find it difficult to deal with stressful situations making them less able to protect themselves in cyberattack situations.

The following hypothesis is suggested for Neuroticism:

H5. High levels of Neuroticism in personality decrease user susceptibility to social engineering cyberattacks in the South African mining industry

4.4 Demographic variables

The literature finds that the demographic variables of gender and age affect cyberattack susceptibility. In the work by Fadi Aloul, Ahmed El Zarka and Ali Darwish [9], it is stated that younger individuals and women have higher levels of agreeableness, providing a link between demographics and personality traits [9].

4.4.1 Age

Studies by Alsharif [11], Khonji [12], and, Van De Weijer & Leukfeldt [20] hypothesise that there is a difference in how individuals of different ages approach cybersecurity, all three papers found a correlation between employees of a younger age, between 18 and 25 and an increased susceptibility to cyberattacks.

The following hypothesis is suggested for Age:

H6. Employees above the age of 25 show a decreased user susceptibility to social engineering cyberattacks in the South African mining industry

4.4.2 Gender

Studies by Alsharif [11] and Khonji [12] found that women are more susceptible to cyberattacks when compared to men, this is specifically for phishing and saw that they activated two-factor authentication more often when compared to women and that they were less likely to click on links contained in emails. The study by Van De Weijer & Leukfeldt [20] however finds the opposite result, where men are more susceptible to online consumer fraud.

The following hypothesis is suggested for Gender:

H7. Male employees show a decreased user susceptibility to social engineering cyberattacks in the South African mining industry when compared to female employees.

4.5 Experience

The study by Anawar [10] investigated the effect of both general and technological experience on the big 5 personality traits with respect to cyberattack susceptibility.

4.5.1 Technological and general experience

The paper by Anawar [10] found that the technical experience of employees working in the IT field showed a correlation with extraversion and agreeableness. This correlation was attributed to individuals with technical experience having knowledge of the usage of security software and technologies.

General experience was found to correlate with the personality traits of extroversion, agreeableness, and conscientiousness; however, the study only obtained responses from individuals working in IT-related companies, which may result in the “general” experience not being as general as intended [10].

The following hypothesis is suggested for Technological Experience:

H8. Both the Technological and General Experience of an employee is synonymous with a reduced susceptibility to cyberattacks.

4.5.2 Technical versus general experience

Both Technical and General experience were found to correlate with a decreased susceptibility to cyberattacks [10], however, the contribution between each individual type of experience is relatively unexplored.

The following hypothesis is suggested for General Experience:

H9. The Technological Experience of an employee contributes more than the General Experience towards a reduced susceptibility to cyberattacks.

4.6 Defence mechanisms

The social engineering prevention strategies comprise of education/knowledge-based measures, software/tools, and organisational policies [12], [14], [13].

The software/tools defence mechanism still presents vulnerabilities to targeted SE attacks and has no way of defending against them [13]. The software/tools will therefore not be included in the model.

4.6.1 Knowledge-based

The knowledge-based defence mechanism is made up of three subcategories, which include training, awareness programs and self-education. The literature review by Aldawood & Skinner [13] reported improved cybersecurity behaviour and motivation for self-education, and increased awareness was reported for training and awareness programs. The limitations associated with this defence mechanism are reported as not a one type fits all due to the difference in personalities, skills and adaptation.

The paper by Uebelacker & Quiel [9] highlights that individuals differ according to their personality types and therefore a difference in defence mechanisms is proposed in their framework. Awareness programs and training are proposed for the personality traits of Conscientiousness, Extraversion, Agreeableness, and Neuroticism. Self-education and E-learning systems are proposed for the personality trait of Openness.

The following hypothesis is suggested for the Knowledge-Based Defence Mechanism:

H10. Knowledge-based defence mechanisms have a positive effect on all personality traits, leading to users of decreased susceptibility to cyberattacks.

4.6.2 Policies

Organisational policies have been reported by Aldawood & Skinner [13] to result in a better security culture and access control. The limitations reported were the skill levels of users and the time taken to completely understand and adhere to the organisational policy. Uebelacker & Quiel [9] proposes organisational policies for the personality traits of Conscientiousness, Extraversion, and Openness.

The following hypothesis is suggested for Policy-Based Defence Mechanism:

H11. Policy-based defence mechanisms have a positive effect on Conscientiousness, Extraversion, and Openness personality traits, leading to a decreased susceptibility to cyberattacks.

5 CONCLUSION

This study highlights the critical role of human factors in the cybersecurity landscape of the South African mining industry. As digital transformation continues to redefine operational processes through technologies like IoT and CMMS, the industry's susceptibility to cyber threats—particularly those exploiting human vulnerabilities—has grown significantly. The

literature review underscores a substantial gap in mining-specific cybersecurity literature, particularly concerning the human element.

By incorporating psychological and demographic variables through frameworks like the Five Factor Model, the research establishes a foundation for understanding user susceptibility to cyberattacks. It further links these human characteristics to effective defence mechanisms.

The proposed conceptual model serves as a guide for developing a workforce that is both aware of and resilient to social engineering threats. Improving cybersecurity in this context requires not only technical safeguards but also a strategic focus on the human dimension, being the weakest link, enabling mining operations to build a more secure digital future.

6 FUTURE WORK

6.1 Model outcome

The conceptual model was developed from existing social engineering models found in the literature, but centred within the context of cybersecurity in the mining industry. The model is to be empirically tested. Once the model has been validated, the practical uses of the model include:

- Development of personality-centred cybersecurity training and awareness programs which aim to educate individuals on the interplay between their personality types and cybersecurity susceptibility.
- Refinement of existing cybersecurity awareness programs to strengthen employees' understanding of the strengths and weaknesses associated with their personality traits.
- Informing the development of cybersecurity policy to include worst-case scenarios attributed to personality traits.
- Improving the cybersecurity awareness culture within the company by contextualising the personality traits, strengths and weaknesses.

These outcomes, once validated, provide possible use cases to inform industrial engineering, risk management, human resources and organisational psychology within industrial contexts as seen in Figure 7.

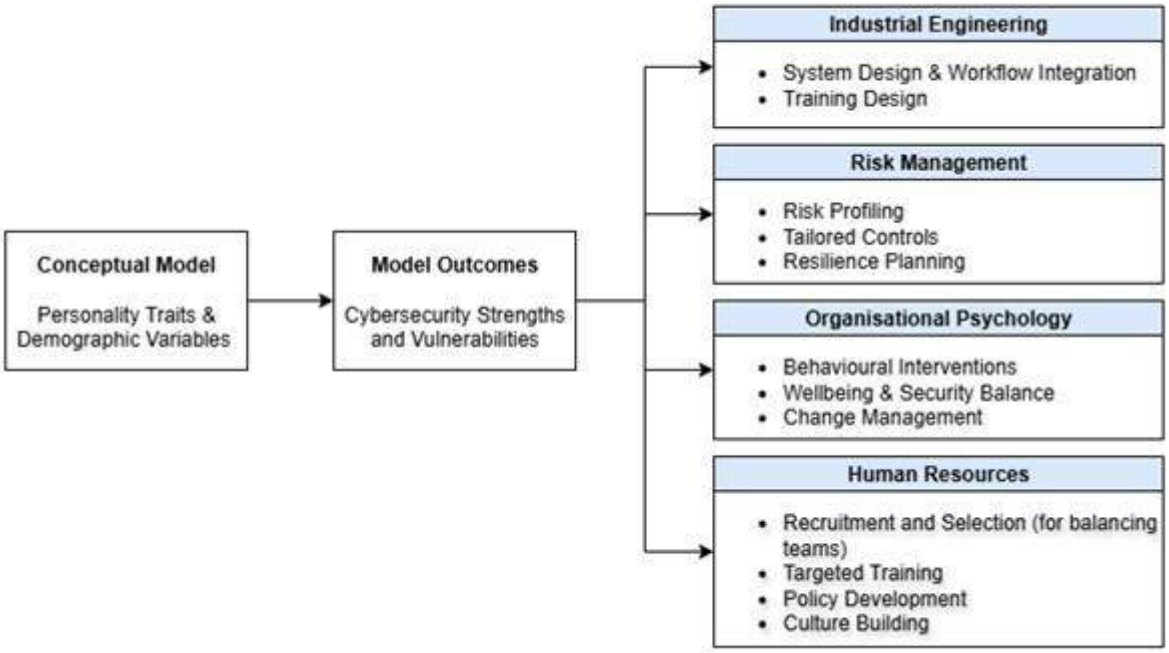

Figure 7: Model use cases

6.2 Model validation

The conceptual model was developed to undergo hypothesis testing in order to validate and uncover any additional topics within the field. A prominent limitation associated with experimental testing is gaining access to highly confidential mining house IT networks. This was considered through the development of the conceptual model. This limitation is a driving factor in a qualitative study as opposed to a quantitative one.

Qualitative data regarding the human factors, demographic variables and defence mechanisms will be collected and analysed. The target population for the study to validate the model is cybersecurity experts within the South African mining industry. These experts include IT security coordinators, cybersecurity consultants to the mining industry, and cybersecurity specialists.

The Delphi method was selected as the preferred research instrument as the literature relating defence mechanisms to human factors in the mining industry is not extensively developed as yet. The Delphi method proves to be suitable for exploring emerging issues like these. The method is primarily a quantitative technique, but can be used in conjunction with qualitative analysis [23].

A thematic analysis is proposed to analyse the Delphi survey response according to the 6-step framework developed by Braun & Clarke [24]. A thematic analysis provides the potential to generate rich insight from expert views on the topic. The experience-backed response from the participants will contribute to the credibility of the model.

Clarity. Alignment. Confidence in asset management.

Reduce costs. Manage risk. Boost performance.

Get a clear, objective view of your asset management maturity across all functions — with an Asset Management Improvement Plan (AMIP) assessment.

Find out where you are today, where you need to go, and how to get there.

Independent, expert-led assessment

- Benchmarking against:
  - ISO 55001 and all 40 subjects of GFMAM's Asset Management Landscape document
  - 20 key performance areas
  - 170 best practices evaluated on a 5-level maturity scale
- Clear visibility of strengths, weaknesses and quantified improvement opportunities
- A 2 – 3 year improvement roadmap with prioritised actions

Let's measure your maturity.

IMPROVING PRODUCT ENGINEERING PROCESSES IN MULTIDISCIPLINARY PROJECTS THROUGH MBSE

B.T. Katsande[1] and R. Oosthuizen[2]

[1,2]Department of Engineering and Technology Management, Graduate School of Technology Management, University of Pretoria, South Africa
[1]blessing.katsande@tuks.co.za, [2]rudolph.oosthuizen@up.ac.za

ABSTRACT

How can engineering processes in multidisciplinary manufacturing projects be optimised? This research explores improving product development in SMEs through model-based systems engineering (MBSE). Due to limited resources, expertise, and communication barriers, multidisciplinary projects often challenge SMEs. MBSE offers solutions by enhancing collaboration, integrating technical disciplines, and boosting efficiency. The study examines SMEs in manufacturing, detailing MBSE implementation processes and presenting a model guide. Results highlight MBSE's ability to streamline product development and foster team integration. Insights into MBSE adoption using a project management model provide practical strategies for SMEs to overcome challenges and optimise engineering processes.

Keywords: model-based systems engineering, SME, product engineering, multidisciplinary projects

1 INTRODUCTION

When companies design and build new products, the process is often managed as a project from idea to launch, for example, SpaceX's Falcon 9 project. The consistent fulfilment of requirements through systematic product development requires careful planning and attention to detail. Mandel et al. [1] state that today's product development processes must adapt to increasing customer requirements, especially regarding functionality, safety and environmental compatibility. Product development often occurs as part of interdisciplinary teamwork, increasing the complexity of the systems and the development process [2].

An unprecedented level of interconnectedness and integration of systems characterises today's world, driven by rapid advancements in technology and globalisation [3]. This trend introduces new challenges for systems engineering and demands a more robust and holistic approach to complex system development [4]. Czaja et al. [5] argue that future technical systems will surpass traditional mechatronic designs through inherent intelligence. They discuss how this depends on a change in conventional product development methods since a holistic and comprehensive understanding is now required to fulfil customer requirements. They argue that Model-Based Systems Engineering (MBSE) may be the most viable approach to address these complexities.

According to Czaja et al. [5], intelligence must be designed into systems to make production and product systems more reliable, user-friendly, and resource-efficient. Most of the benefits are realised from the interaction between different components and technologies. There are subsequent demands on developing products, such as a thorough appreciation of the system of interest (SoI) and upfront product lifecycle considerations [6]. There needs to be more than the traditional way of developing these by analysing individual specialist disciplines. One needs to consider the system components' short– and long-term interactions seriously. New ways of conceptualising SoI are thus required to meet the challenges of future systems.

Having established the complexity and increasing obscurity of product engineering as grounded above, the researcher then aims to address the following research questions:

1. How can digital engineering, particularly MBSE, improve design and decision-making activities during the product development process?
2. What is the value of applying meta-models early in product engineering projects?
3. Which frameworks help SMEs to implement effective communication of ideas, decisions, and specifications in complex, multidisciplinary projects?

In order to explore the above aims, this article will first explain the theoretical background of the key concepts on which the research is based. This includes defining the context encompassing African SMEs, systems engineering, MBSE and a particular project management model. The research methodology is outlined, and a conceptual model based on the theory is presented. Finally, the results concerning the objectives are discussed before conclusions and recommendations are made.

2 LITERATURE REVIEW

2.1 Defining Small and Medium-Sized Enterprises

Small and medium-sized enterprises (SMEs) are companies with relatively few employees and limited sales volumes [7]. They are the backbone of many economies and are crucial for job creation and economic growth. SMEs can be defined by, e.g., number of employees, annual turnover, or total balance sheet, with the exact definition varying from country to country. SMEs drive the economy by significantly contributing to GDP through employment opportunities and innovation. They also promote entrepreneurship and competition and help diversify the economy by providing goods and services in niche markets. With limited access

to capital, difficulties in obtaining credit, and limited resources for research and development, SMEs face many challenges. However, SMEs are critical to a balanced and diverse business landscape and continue to play an essential role in the growth and stability of the economy [7].

2.2 Systems engineering

Systems engineering is a collaborative, multidisciplinary approach that combines various engineering disciplines, such as structural, electrical, mechanical, power, and human factors engineering. It provides an integrated effort for designing, managing, and integrating complex systems throughout their life cycle [8]. Therefore, the goal is to create a coherent system not dominated by the perspective of a single domain [3].

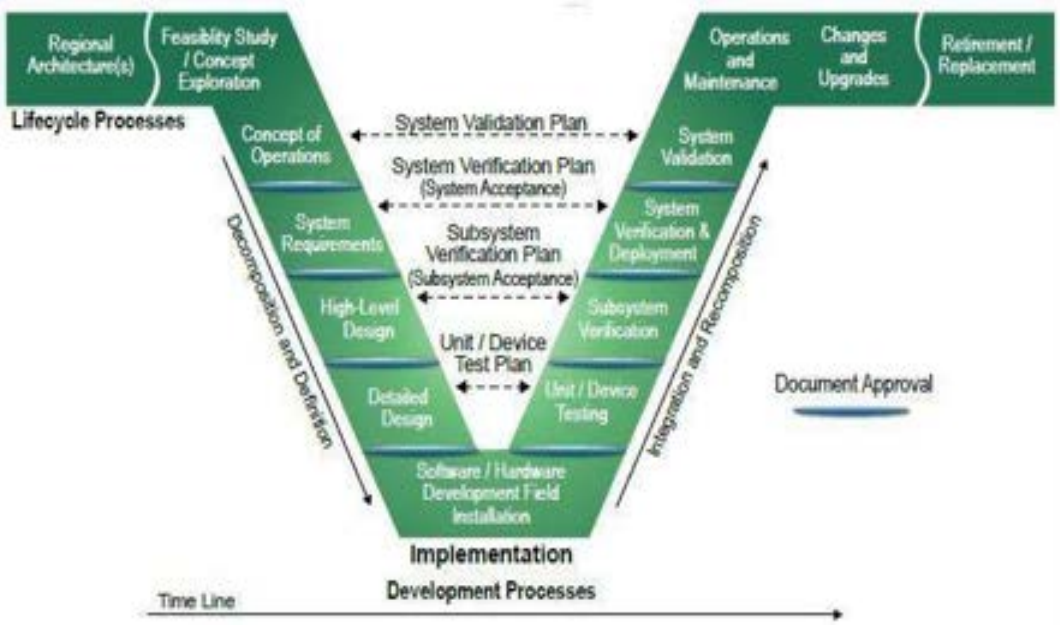

Figure 1: Systems Vee-model (adapted from [9])

The Vee model in Figure 1 is a widely recognised systems engineering framework that guides complex systems' systematic and structured development[10]. This model outlines a set of interconnected stages that guide the systems engineering process, beginning with the conceptualisation of the system and culminating in its final acceptance and deployment [10].

MBSE is defined as “the formalised application of modelling to support system requirements, analysis, design, verification and validation activities beginning in the conceptual design phase and continuing throughout development and later life cycle phases” [11]. It relies on models and simulations to represent the system under development [12]. MBSE has been widely applied in product engineering, as it helps reduce the time, risk and cost associated with complex product development [13]. Numerous research studies and papers have been published on MBSE in product engineering. Some key research areas include MBSE methodologies and frameworks, MBSE tools and technologies, and the benefits and challenges of using MBSE in product engineering [14].

The INCOSE Systems Engineering Vision 2020 envisions MBSE as part of a long-term trend. It expects a model-centric approach to widely replace traditional document-centric approaches in the near future [12], [15]. The manufacturing sector in Africa, particularly among Small and Medium Enterprises (SMEs), faces significant challenges in achieving sustainable and efficient production processes [16].

MBSE is a suitable methodology to address these challenges. It relies on creating and utilising system models to support complex systems' design, analysis, verification, and validation [17]. The Vitech systems meta-model, shown below in Figure 2, is a comprehensive framework to support MBSE. It facilitates the integration and management of the complex interactions between different system components throughout the lifecycle of a system. MBSE focuses on creating models that represent not only the physical aspects of a system but also its functional, behavioural and organisational elements. As described in detail by [17], the key aspects of the systems meta-model are:

- **Hierarchical structure**: the meta-model provides a multi-layered, hierarchical representation of systems, allowing engineers to break down a complex system into manageable subsystems, components and relationships.
- **Function-behaviour-structure (FBS) paradigm**: The meta-model is closely linked to the FBS paradigm in MBSE, making it possible to model a system's functions, behaviour and interactions.
- **Requirements traceability**: The meta-model supports the traceability of requirements through the design, verification, and validation phases. Traceability is critical to meet all stakeholder requirements throughout the system lifecycle.

This model-centric approach is central to MBSE's goal of simplifying the management of complex systems, thereby reducing errors and ensuring better collaboration between multidisciplinary teams. Figure 2 shows how the requirements link with functions, states and resources in the context of organisational risks and constraints.

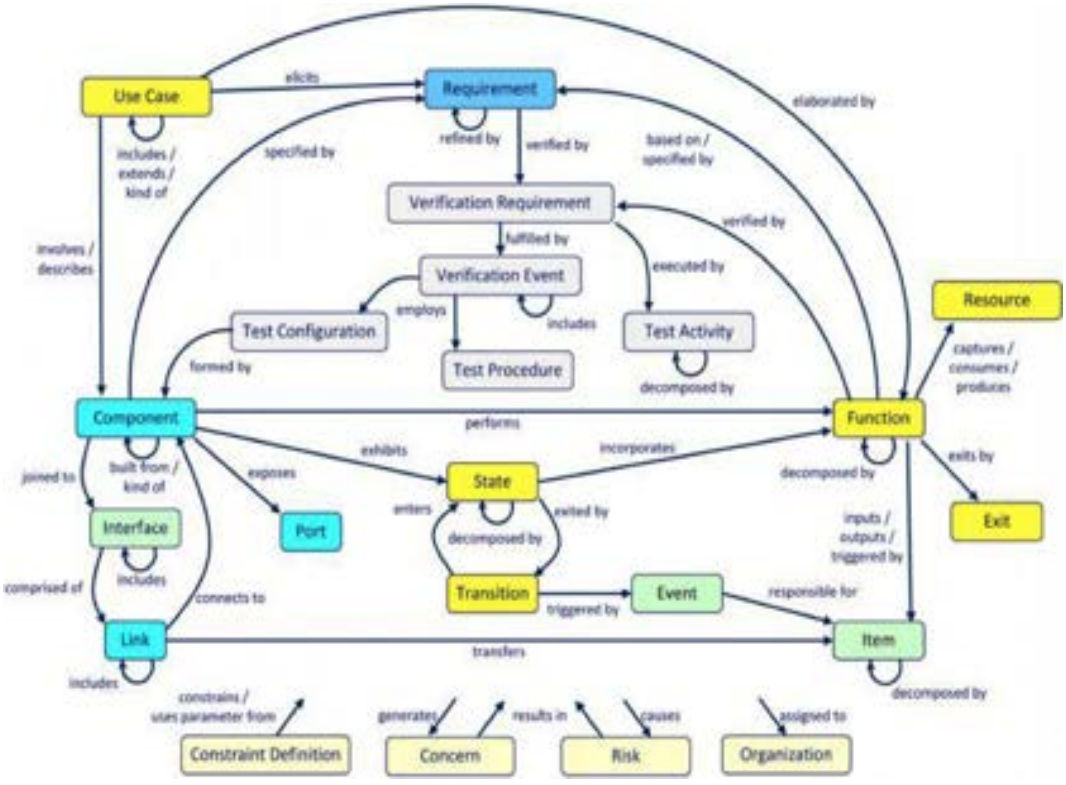

Figure 2: Vitech Systems Meta-Model (adapted from [17]**)**

The MBSE meta-model provides a key approach that aligns with the Vee model in Figure 1 by providing a model-centric and structured framework for systems engineering. In MBSE, a comprehensive system model is a central artefact for facilitating communication,

collaboration, and decision-making throughout the systems engineering process and possibly the system lifecycle [18].

The system model provides a digital system representation, which may include various views such as functional, behavioural, and structural, to enable engineers to simulate, analyse, and validate the system's design before physically producing it. By integrating MBSE into the Vee model, systems engineers can leverage the power of model-based approaches to enhance the traceability, consistency, and overall quality of the systems engineering process. Furthermore, the MBSE approach aligns well with the Vee model's emphasis on verification and validation because the system model can perform virtual testing and validation, reducing the risks and costs associated with physical prototype development [19].

Figure 3 illustrates how MBSE integrates with the Vee model. In the Vee model, systems engineering is a comprehensive and structured approach to developing complex systems. With MBSE, systems engineers can further enhance the reliability, transparency, and efficiency of the systems engineering process. In turn, this can ensure the successful realisation of systems and products that meet the diverse requirements of their stakeholders.

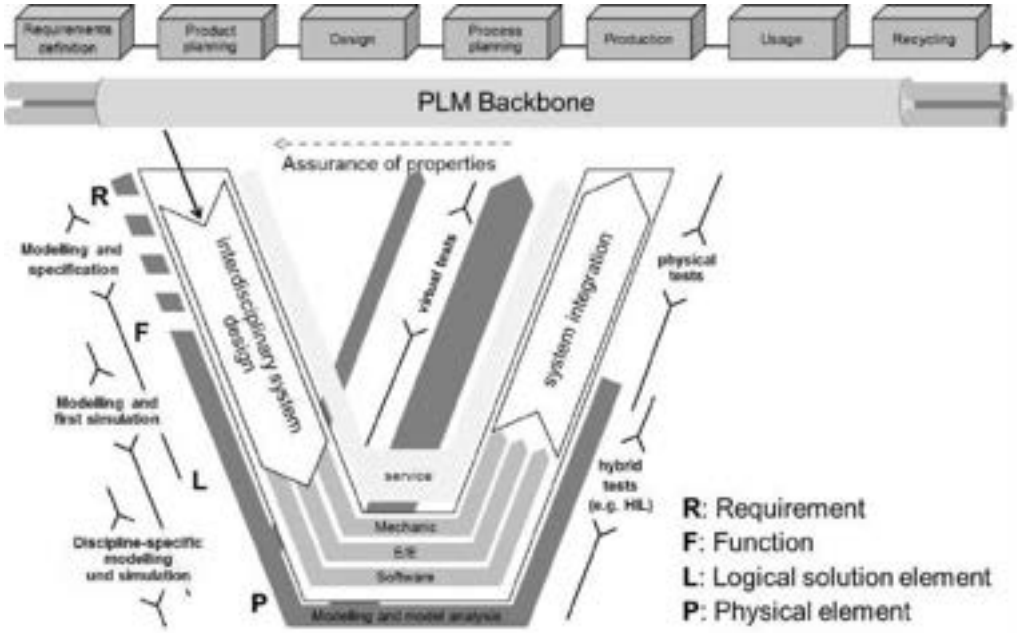

Figure 3: MBSE-tailored Vee-Model (adapted from [20]**)**

2.3 Agile-stage-gate project management

Edwards et al. [21] explore implementing a hybrid model of the Agile-Stage-Gate (ASG) in small to medium-sized manufacturing firms, as seen in Figure 4. The ASG hybrid model combines the two widely used approaches in product development: agile development principles and stage-gate methodology. Their paper presents case study results of three SME manufacturing firms that implemented the ASG hybrid model for their product development processes. This suggests that the ASG hybrid model can effectively improve the product development process in SME manufacturing firms. The model's flexible and iterative nature allows for more rapid development cycles and increased responsiveness to customer feedback. At the same time, the stage-gate framework provides a structured approach to managing risk and ensures that products meet the necessary quality standards.

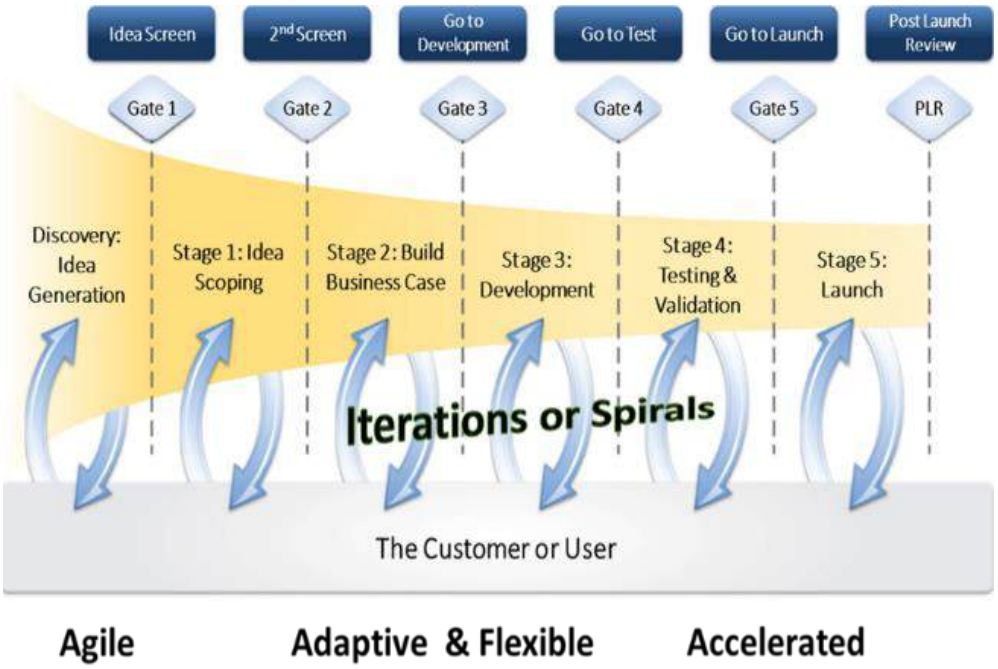

Figure 4: Agile-Stage-Gate Product Development Model (adapted from from [22])

The ASG model enables faster development cycles, greater responsiveness to customer feedback, increased collaboration and communication among team members and a quick, iterative workflow.

2.4 Summary of literature

The reviewed literature comprises current practices in product development and application (or lack thereof) of system engineering. Nanfuka and Oosthuizen [13] also expand on the value of MBSE in more detail, especially in African SMEs. The ASG model combines the principles of Agile and Stage-Gate methodologies, providing an iterative and flexible approach to product development while ensuring that projects are managed in a structured and disciplined manner. The ASG model enables faster development cycles, greater responsiveness to customer feedback, and increased collaboration and communication among team members. MBSE, on the other hand, provides a systematic and consistent approach to system development that enables the modelling of system requirements, behaviours and functions in a structured and consistent manner to manage complexity [21]. Therefore, the literature suggests that integrating the ASG model and MBSE can help improve the speed and quality of product development.

3 METHODOLOGY

3.1 Introduction

The application of MBSE harbours several challenges. Positivist ontology and objectivist epistemology have dominated research in this area [23]. However, this research assumes a relativistic ontology, where reality is viewed as socially constructed and fluid rather than fixed and independent of the researcher [24]. Multiple realities are believed to be shaped by the contexts and perspectives of the individuals involved [25]. The research follows a qualitative design and utilises a case study approach to investigate the adoption of MBSE in small and medium enterprises in South Africa. South Africa was chosen because the researcher is based there at the time of writing and because of the growing economy and increasing importance of systems engineering in our SME sector. The case study method lends itself well to the

relativistic and constructivist foundations of the study as it allows for the exploration of complex, contextualised phenomena through multiple data sources.

Data will be collected through semi-structured interviews with technical decision-makers in selected organisations. These include project managers, systems engineers and quality assurance engineers. The researcher, who now has a solid theoretical background in MBSE, will conduct these interviews. Other data sources may include project documentation, observation of systems engineering practices on the ground and other relevant organisational materials. An open-ended questionnaire structured around each development phase will guide the interviews (See Appendix B). Figure 5 below summarises the methodology followed by the researcher and notes the key activities and findings following the literature review and concept design.

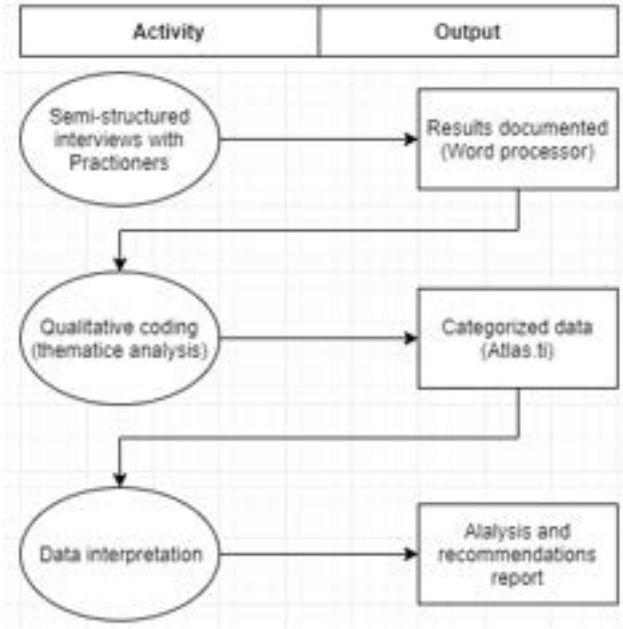

Figure 5: Methodology Overview

Qualitative methods are particularly well suited for this research as they enable the exploration of the complex socio-technical dynamics associated with multidisciplinary project teams and MBSE implementation [26]. The qualitative approach allows the researcher to capture rich, contextual data about the nuanced human and organisational factors that shape the effectiveness of MBSE processes in improving product development, which may not be easily quantifiable [26]. There are several reasons for choosing the qualitative rather than quantitative research method:

- **Flexibility**. Qualitative research is more flexible than quantitative research in this case. It allows the researcher to change the study design or the research questions if new findings emerge.
- **Understanding complex phenomena**. Qualitative research is well suited to understanding complex social and behavioural phenomena that cannot be easily reduced to numerical data. In this case, for example, some of the benefits of MBSE are felt rather than tangible.
- **Rich and in-depth data**. Qualitative research can provide in-depth and rich data, which is impossible with quantitative methods. The researcher can use some questions that relate to the people's subjective knowledge of the topic.

- **Exploring new or complex phenomena**. Qualitative research helps explore new or complex phenomena that may not yet be understood. Qualitative methods are used, for example, to understand the motivations of a new social context.

4 CONCEPTUAL MODEL

4.1 Introduction

MBSE and agile methods have emerged in recent years as complementary approaches to product development [27]. MBSE provides a structured framework for defining system requirements, modelling architecture, and managing system complexity. Similarly, ASG methods emphasise iterative development, rapid prototyping, and customer feedback to meet market needs better 22]. Integrating these two approaches has significant potential to improve the efficiency and effectiveness of the product development process [27]. In this section, the researcher proposes a conceptual model for implementing MBSE that addresses the challenges organisations face in adopting this approach. The model is based on a framework combining systems engineering theory and a project management model, the ASG model proposed by Cooper and Sommer [22].

4.2 Conceptual Model

From an in-depth literature analysis of the challenges in product development, systems engineering, and project management, the authors propose a conceptual process model combining the ASG model and MBSE to provide a structured yet flexible approach to product development, as shown in Figure 6. The model consists of six stages that align with the Vee model.

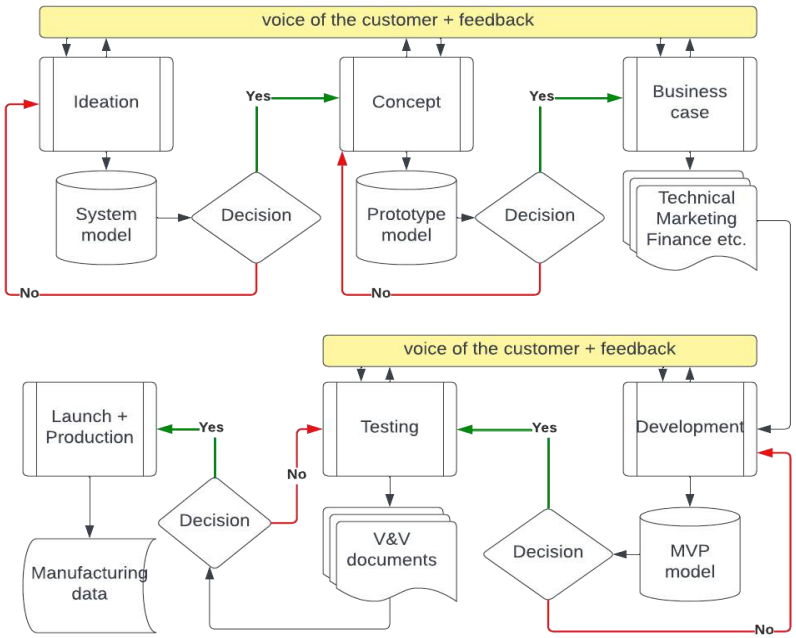

Figure 6: Proposed "Model-based Agile-Stage-Gate development"

The main advantage of the proposed model is that it combines the structured and disciplined approach of the stage-gate model with the flexibility and responsiveness of agile methods and the clarity of MBSE. MBSE provides a systematic and structured approach to system development that helps to manage complexity, while Agile methods offer the flexibility to adapt to changing customer needs and market conditions [21]. The model provides a framework that companies can follow to successfully implement this innovative approach. The model uses digital tools and platforms to enable remote collaboration, information sharing,

and model management. It is, therefore, particularly suitable for SMEs with limited resources or expertise in MBSE. In this model, teams from different geographical locations can successfully collaborate.

4.3 Advantages of the integrated framework over the stage-gate model

The stage-gate model is a standard process that divides new product development into different stages where a decision is made on whether to proceed to the next stage. It ensures rigorous decision-making, controls risks and improves resource allocation [22]. However, it can be challenging for African SMEs operating in a multidisciplinary environment. When multiple disciplines (mechanical, electrical, software, etc.) are involved, the lack of continuous integration can lead to mismatches, delays, or worse, bad quality and high costs. The integrated framework extends the stage-gate model by embedding MBSE processes that provide the following:

- **Better collaboration between disciplines**. By providing a standard system model, MBSE ensures that the specialists are aligned with system requirements, constraints and dependencies. This is particularly important for African SMEs, given the challenges arising from resource constraints. Collaboration and communication are critical factors for project success.
- **Continuous validation and feedback**. MBSE enables simulations and system validation at every stage and ensures that decisions made at every stage are based on real-time data. This prevents problems from manifesting only in the final stages, as is often the case with the traditional stage-gate model.
- **Informed decision-making**. Every gate decision is supported by system models that can simulate different outcomes, significantly reducing uncertainty and empowering the stakeholders to improve risk management.

4.4 Advantages of the integrated framework over the Vee model

The Vee model focuses on system development through rigorous verification and validation processes at each level of the system development lifecycle. It is beneficial for ensuring traceability from requirements to testing [9]. However, there are challenges associated with this model in the African SME context:

- **Dependence on upfront planning**: the Vee model requires a high level of upfront planning and design, which can be risky if requirements evolve or change during the project due to, say, economic or political volatility, for instance.
- **Rigid structure**: The rigid structure of the Vee model does not lend itself well to iterative or agile development, which SMEs often require due to the fast-paced, changing market and limited resources. By combining MBSE and stage-gate principles, the integrated framework negates such limitations.
- **Flexibility**: While maintaining the strong validation focus of the Vee model, the integrated framework integrates the gate structure of Stage-gate, enabling go/no-go decisions at key milestones. This reduces the risk of committing resources without a high probability of success.
- **Iterative refinement**: MBSE supports continuous refinement of the system model, even after some gates have been passed, allowing greater flexibility in responding to changing requirements. However, this requires solid configuration management.
- **Real-time data for better decision-making**: African SMEs often operate with limited budgets and resources in the face of fluctuating customer demands. MBSE enables engineers to simulate system designs and alterations early and throughout the

lifecycle, ensuring that changes can be validated before significant resources are committed.

4.5 The unique value of MBSE in the integrated framework

MBSE provides the synergy that integrates the Vee model and project management stage-gate development systems. In the context of manufacturing projects in African SMEs, MBSE offers remarkable advantages [12]:

- **Better interdisciplinary collaboration**: African SMEs often work on multidisciplinary projects spanning different specialist areas. By creating a central model, MBSE overcomes traditional silos and facilitates clearer communication between specialist practitioners and teams.
- **Scalable solutions**: Unlike large organisations, SMEs often have limited resources, making it difficult to manage complex, multidisciplinary projects. MBSE offers scalable solutions that provide robust systems engineering principles without requiring excessive overhead.
- **Intelligent risk management**: MBSE's ability to simulate, validate and trace requirements at every stage of product development reduces risk by identifying issues early in the process. Projects are almost always undertaken in risky environments with limited budgets.

Finally, the proposed integrated model addresses African SMEs' challenges when running multidisciplinary projects, such as effective collaboration with limited resources. This framework improves project/product development outcomes by combining the structured decision-making of the Stage-gate model with the rigour of the Vee model and MBSE's provision for real-time feedback and collaboration. African SMEs can use this integrated system to manage complex projects more effectively, reduce development risks, optimise resource allocation and bring innovative products to market faster.

5 RESULTS

5.1 Response rate

As discussed earlier, the study was conducted in South African SMEs. In particular, 38 interview requests were sent to companies in Gauteng, KwaZulu-Natal and Western Cape provinces. All 38 initially acknowledged the request and promised to avail themselves. In the end, only 18 participated, giving a response rate of ~47%. The rest could not make time or failed due to unknown constraints.

5.2 Industry sectors

All respondents operate in manufacturing; some operate in electronics design and assembly, some in mechanics, and some in optoelectronics. All respondents had software support systems in their product engineering and manufacturing. Table 1 below shows the distribution of respondents according to their niche. Appendix B (Table B.1) summarises the qualitative data obtained from the respondents and primes the reader with information on what each theme entails in terms of improving product engineering through MBSE. A more comprehensive version of the qualitative data is presented in Appendix A (Table A.1).

Table 1: Respondents by Industry Sector

Industry Sector	Respondents
Mechatronics manufacturing	38.88%
Electronics manufacturing	22.22%
Mechanics manufacturing	22.22%

Optics manufacturing	11.11%
Other	5.55%

The results from the survey were coded using the tool *Atlas.ti*, and the emerging themes are shown in Table A.1. Intentional coding was used, which aligns the themes with the research objectives and questions.

5.3 Aligning themes with research objectives

As a build-up to the discussion in the next section, the following select themes extracted from the analysis of the responses are elaborated on the research objectives outlined in the first chapter. This sets the researcher up for a grounded relativist argument for MBSE's value in projects involving product engineering.

5.4 Return on investment (MBSE frameworks)

5.4.1 Perceived costs and concerns

Almost all SMEs surveyed see MBSE as an expensive investment with unclear immediate benefits, discouraging them from implementing it. There is a lack of understanding of how MBSE will bring benefits in the short term.

- Keywords from respondents: hesitation, cost-benefit concerns, capital, gain

5.4.2 MBSE expertise/skills

None of the SMEs surveyed had the in-house expertise to implement MBSE frameworks. Of course, it can be challenging to make the paradigm shift. Training and upskilling staff to use MBSE tools would require additional investment, and SMEs are often uncertain if the risk is worth it. They have not expressed any intention of hiring MBSE experts anytime soon.

- Respondent keywords: skills, systems engineer, implement, training

5.5 Contemporary engineering processes

5.5.1 Collaborative sketching/ideation

The findings show that SMEs predominantly rely on traditional collaborative sketching techniques (brainstorming, workshops) without digital tools. While this approach is familiar, it carries inherent efficiency and traceability limits. Ideas are often recorded and repeated manually or in fragments, which can suppress the full innovation potential.

- Keywords used by interviewees: brainstorming, workshops, CAD, meeting

5.5.2 Iterative development

Iteration is a core element, but most SMEs rely on expensive physical prototypes, which lengthen development cycles. SMEs lack simulation tools to test design functions and behaviours early in the process, which could reduce errors and risks.

- Keywords from interviewees: feedback loops, risk management, iteration

5.6 Conclusions and Summary

This section summarises the study, drawing conclusions and highlighting the contributions made by the study. The researcher also reflects on the limitations and recommendations for future researchers around the said topic. Table B.1 (Appendix B) summarises the challenges relayed by respondents. It also shows how MBSE fits into the project context, notably which engineering challenges can be improved through MBSE and its benefits.

5.7 Proposed framework congruence (concept improvement)

The researcher now presents a culmination of the conceptual model presented earlier, incorporating the "lessons learnt" from the analysis of the results in this chapter. The model integrates systems engineering with project management more seamlessly in an easy-to-follow but rigorous manner. The integrated model combines the Stage-gate and Vee models, which are integrated with MBSE processes. Each stage on the left (Stage-gate model) corresponds to a parallel Vee-model phase on the right. It shows how MBSE activities can support decision-making and validation throughout the product development lifecycle.

The model below (Figure 7) was developed to optimise multidisciplinary teamwork in six phases, each of which feeds into the corresponding phases of the V-model. MBSE plays a role in improving communication and decision-making at each stage:

- **Ideation/Requirements**: High-level system requirements are defined, with MBSE capturing all stakeholder needs and constraints.
- **Scoping/Concept of Operations**: Detailed system requirements are linked in a model-based environment to ensure traceability to the high-level requirements.
- **Business case/System design**: Modelled system architecture and behaviour to support informed gate decisions.
- **Development/Function design**: System functions and subsystems are developed in parallel, with MBSE enabling the seamless integration of contributions from different disciplines.
- **Validation/Subsystem integration**: Testing is performed using digital twins and MBSE simulations to verify that all subsystems work together
- **System validation**: The complete system is validated against the original stakeholder requirements to ensure that the contributions of all multidisciplinary teams are consistent with the requirements.

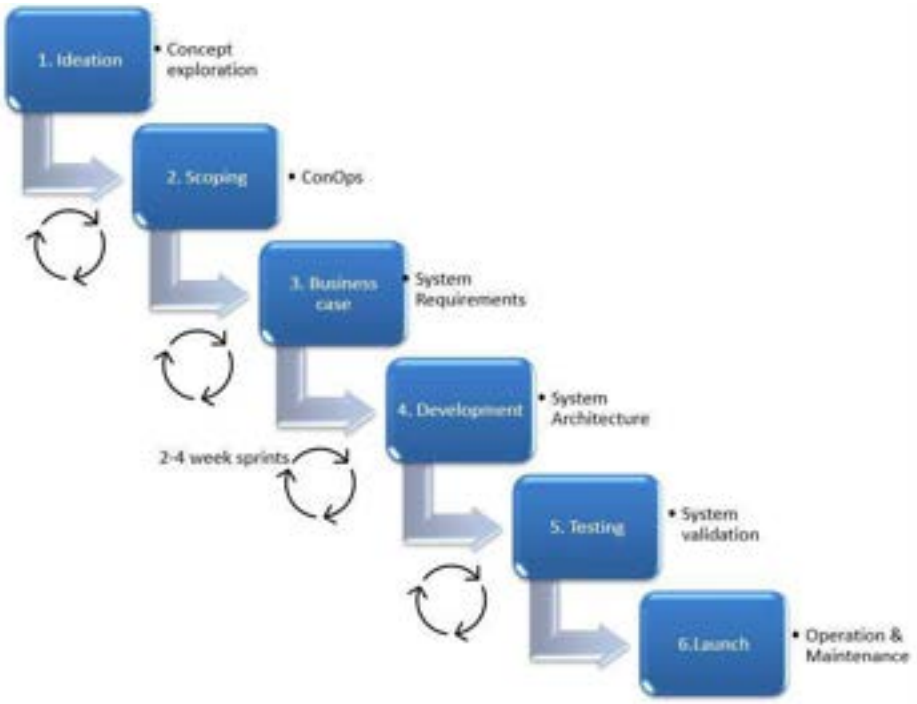

Figure 7: Proposed Concept Model for Process Optimisation

The proposed integrated framework combines the stage-gate model, the Vee-model systems, and MBSE, representing a superior approach to improving product development, especially in multidisciplinary projects undertaken by African SMEs. Each of these models has unique strengths and weaknesses. However, when integrated, they provide an improved model that promises to address the complexities and challenges SMEs face in product engineering.

6 CONTRIBUTIONS OF THE STUDY

6.1 Key challenges faced by South African SMEs

The study provides a detailed overview of the challenges SMEs face in South Africa when implementing MBSE in product development. Some examples from the survey are a lack of digital tools, economic and political volatility, financial and skills resource constraints, complexity and a lack of systems engineering expertise (MBSE in particular).

6.2 Reluctance towards MBSE adoption

The analysis shows why SMEs are reluctant to invest in MBSE frameworks, citing concerns about cost, lack of skilled labour and unclear short-term benefits. This provides valuable insights for researchers and policymakers looking to support the adoption of systems engineering in general and MBSE in particular. To promote uptake, African governments could consider measures such as:

- Establishing public-private partnerships to finance beneficial MBSE projects
- Providing tax incentives and subsidies for digital engineering technologies
- Supporting and promoting systems engineering education, including sending students to the best systems engineering institutions in the world
- Creating an attractive business environment for international systems professionals and digital tools vendors
- Accelerating regulations for the adoption of systems engineering /MBSE

Researchers, on the other hand, could use the findings of this study to:

- Expand research on demonstrating tangible ROI for MBSE investments
- Further, simplify and better align MBSE frameworks
- Work with SMEs (via educational institutions) to deliver real MBSE projects
- Conduct workshops and webinars to transfer MBSE knowledge progressively
- Pursue research partnerships between academia and industry

6.3 Limitations

6.3.1 Sample size

The study is limited by the small sample of SMEs, mainly from South Africa, which may not fully represent the broader SME landscape or the international context.

6.3.2 Lack of longitudinal data

The research does not characterise MBSE adoption over time. It cannot account for how human behaviour, processes or outcomes evolve as organisations become more familiar with MBSE frameworks.

6.3.3 Geography

The geographical focus on South African SMEs limits the scope of the study. The results may only be partially transferable to SMEs in other regions, especially those with significantly different economic and technological environments, such as skillsets or infrastructure.

6.3.4 Scope

The research focuses exclusively on manufacturing companies and does not include models that non-manufacturing projects or SMEs could utilise.

6.4 Conclusions

The conclusions from the qualitative data analysis show that SMEs use a wide range of processes and tools for collaboration, idea generation, quality control and stakeholder alignment. However, manual processes often constrain them and lack advanced tools such as MBSE. Key areas where improvements are needed include:

- Better integration and alignment between disciplines to avoid rework and meet or exceed all requirements.
- More efficient iteration and risk management processes, ideally supported by digital simulations.
- Stronger traceability and documentation systems, particularly for regulatory and quality compliance.
- Improved quality control throughout the development cycle, where system-level modelling can identify defects and risks earlier.

6.5 Recommendations for future research

The study lays the foundation for future research on implementing MBSE in SMEs by identifying the key issues and challenges. It opens the door for a more in-depth examination of specific industries or SMEs from a broader geographical spectrum. Some of the areas of research which could follow from this study are:

- Expanding research to examine the adaptation of MBSE to non-manufacturing projects and companies. For example, how can we fully utilise MBSE in construction projects?
- Investigate the development of systems engineering skills on the African continent. What can be done to raise awareness and produce more systems engineering professionals in the economy?
- Longitudinal studies of MBSE adoption: What happens over time as organisations adopt MBSE, and how does it fit with economic, political and technological changes over the years?

Appendix A

Table A.1: Summary of coded qualitative data from respondents

Parent Theme	Sub-Themes	Manufacturing electronics+mechanics	Manufacturing (mechatronics)	Manufacturing (optronics)	Manufacturing (other)	Opportunity for improvement (OFI)
Alignment with stakeholders	Requirements management Customer satisfaction	Regular stakeholder meetings	Early involvement of key departments	Early customer engagement feedback loops	Occasional customer reviews	Mostly ad-hoc reviews. There is room for systematic requirements management.
Multidisciplinary collaboration	Collaboration Standardised notations Effective communication	Regular cross-functional meetings	Involving machinists, engineers, and supervisors early	Informal collaboration between engineering teams	Regular workshops involving all teams	Effective but inconsistent, lacks formal structure.
Ideation	Methods for Idea Generation Meta-models	Brainstorming, CAD tools	Collaborative sketching with CAD	Early prototyping, manual processes	Brainstorming, sketches	Largely manual, fragmented systems for data capture.
Concept development	Data capturing System interactions	Captured using CAD tools	CAD files, meeting logs	CAD models, manual documentation	Manual notes, document processors	Fragmented; there is no central system for ideation capture.
Quality Control (QC)	Built-in quality Inspections	Manual inspections, QC reviews	In-process inspections, Config checks	Quality checks during development	In-process checks, audits	Limited digital integration with development, manual controls
Iterative development	Iteration Cycles Verification Testing	Iterative reviews based on feedback	Prototyping, physical iterations	Iterative testing, limited digital simulation	Relies on customer feedback	Lacks simulation tools for efficient, cost-effective iteration.
Traceability	Documentation Requirements management	Meeting notes, spreadsheets Word processors	Traceability via documentation, CAD files	Excel sheets, CAD-based notes	Documentation on word processors	Manual, hence prone to error. Automated traceability is needed.
Simulation & MBSE use	MBSE tools Visualisation Source of truth	Not implemented	Not implemented	Not implemented	Not implemented	All respondents indicated a lack of MBSE tools or simulation.

Parent Theme	Sub-Themes	Manufacturing electronics+mechanics	Manufacturing (mechatronics)	Manufacturing (optronics)	Manufacturing (other)	Opportunity for improvement (OFI)
Minimum viable product validation	Specs for MVP Approval process	Customer reviews internal checks	Engineers, QC and customer feedback	Internal review, QC feedback	Customer & QC review	Unclear decision criteria for MVP.
Risk management	Technical viability Commercial Viability Risk monitoring and control	Stakeholder reviews Market reviews	Cost-benefit analysis, supply chain review	Technical viability reviews	Cost-benefit analysis	Risk management is ad-hoc; digital risk modelling is absent.
Post-launch support	Support Tools Warranty Reliability	A mix of virtual and physical support	Mostly on-site support	Partly virtual, partly on-site support	On-the-phone troubleshooting	Limited virtual support tools. Scenarios could be simulated through MBSE
Challenges faced by SMEs	Resource constraints Complexity Lack of digital integration	Automating manufacturing processes Skills	Complex designs Lack of skilled labour	Limited digital infrastructure	Lack of skilled labour No digital integration	General lack of resources. Most rely on manual processes and fragmented systems
Return on investment	Perceived costs MBSE expertise/skills	Raw materials cost Labour costs	Expensive software resources	Import/export expenses	Financial constraints	All respondents were reluctant to invest in MBSE due to ROI uncertainty
Contemporary engineering processes	Iterative development sketching	Sketching Physical prototypes	Physical testing and simulation	Limited simulation Optics calculators	Brainstorming No simulations	They all still use traditional methods. Minimal digital integration

Appendix B

Table B.1: Recommendations for process improvement through MBSE

Theme/Code	Associated challenge	Process Improvement through MBSE	Benefits
Multidisciplinary collaboration	Collaboration is informal, with limited structure	MBSE framework provides centralised, digital collaboration	Improved communication, less rework, quicker iterations
Ideation & concept	Ideas captured manually or in fragmented systems	Use MBSE to document and iterate on concepts digitally	Centralised ideation data, single source of truth, better concept tracking
Stakeholder alignment	Manual processes for managing stakeholder requirements	MBSE for systematic requirements capture and validation	Unequivocal alignment, avoidance of miscommunication risk
Iteration & risk management	Physical iterations are resource-intensive, with limited risk modelling	Use MBSE with simulation tools for virtual prototyping	Faster iteration, reduced cost, better risk mitigation
Quality Control	Quality checks are manual and prone to error & delays	MBSE integrated with QC comes close to real-time monitoring	Early defect identification, streamlined quality processes
Traceability	Manual documentation is slow & tedious (lacks automation and traceability)	MBSE allows for automatic traceability and documentation updates	Improved compliance, better oversight, fewer errors

A MODEL-BASED SYSTEMS ENGINEERING APPROACH TO SUPPLEMENTAL TYPE CERTIFICATION OF TRANSPORT CATEGORY AIRCRAFT IN SOUTH AFRICA

M. Molapo[1] and M.T. Dewa[2]

[1,2]School of Mechanical, Industrial and Aeronautical Engineering
University of the Witwatersrand, Johannesburg, South Africa
[1]882439@students.wits.ac.za, [2]Mncedisi.Dewa@wits.ac.za

ABSTRACT

The Supplemental Type Certification (STC) process ensures the safety and regulatory compliance of modifications to transport-category aircraft. However, traditional STC methodologies face inefficiencies, lengthy timelines, and challenges in managing complex aviation systems. This study examines the integration of Model-Based Systems Engineering (MBSE) into the Supplemental Type Certification (STC) process to enhance efficiency, traceability, and compliance. It compares document-centric certification with digital, model-based approaches and examines international best practices. A framework is proposed for integrating MBSE into South Africa's Supplemental Type Certification (STC) process, leveraging digital models, automation, and simulations to streamline compliance verification. The study highlights the potential benefits of MBSE, including reduced certification time, improved regulatory traceability, and enhanced integration of complex aircraft modifications. This research is qualitative, desk-based, and exploratory, with no empirical implementation, aiming to align South Africa's aviation certification processes with global best practices to improve operational efficiency and industry competitiveness.

Keywords: Supplemental Type Certification (STC), Model-Based Systems Engineering (MBSE), Federal Aviation Regulations 25 (FAR 25).

1 INTRODUCTION

The aviation industry is a cornerstone of modern transportation, playing a pivotal role in global connectivity, commerce, and economic growth [1]. Within this industry, ensuring the safety, reliability, and operational efficiency of transport-category aircraft is paramount [2]. Regulatory frameworks governing aviation are designed to uphold these standards, with the Supplemental Type Certification (STC) process serving as a critical mechanism for certifying modifications and enhancements to existing aircraft [3]. An STC is a type of certificate (TC) issued when an applicant receives approval from the relevant aviation authority to modify an aeronautical product from its original design. The STC, which references the associated TC, authorises not only the modification but also its impact on the original design [4]. In South Africa, stringent regulations mandate adherence to rigorous certification standards, reflecting a commitment to maintaining the highest levels of safety and compliance [5].

Despite the importance of the STC process, the traditional methodologies employed in its execution are increasingly challenged by the evolving complexity of modern aircraft systems. Traditional STC processes often face challenges such as lengthy timelines, high costs, and difficulties managing complex system integrations. Integrating advanced technologies and sophisticated subsystems into aircraft design has amplified the demand for streamlined and efficient certification processes [6]. Current practices in South Africa, which often rely on disconnected and manual systems, cannot fully address the intricacies of these advancements. This has led to inefficiencies, extended timelines, and heightened risks of non-compliance, which pose significant challenges for stakeholders in the aviation sector. Globally, adopting innovative methodologies such as Model-Based System Engineering (MBSE) has emerged as a transformative approach to managing the complexities inherent in engineering projects [7], [8]. MBSE emphasises the use of models to improve communication, traceability, and overall system development efficiency. This paradigm shift is particularly relevant to the STC process, where the coordination of multiple stakeholders, systems, and regulatory requirements necessitates a robust and integrated approach [9]. While the benefits of MBSE have been demonstrated in various industries and international aviation certification frameworks, South Africa has yet to fully embrace this methodology within its STC processes [10].

This gap in adoption limits the ability of local stakeholders to leverage MBSE's potential for enhancing operational efficiency and reducing errors. Given the global trend towards MBSE, there is an urgent need to explore its integration into South Africa's aviation certification practices to remain aligned with international standards and best practices. This research is conducted in the context of South Africa's dynamic yet challenging aviation regulatory environment, characterised by the dual pressures of maintaining compliance and fostering innovation. By investigating the applicability of MBSE to the STC process, the paper seeks to address critical inefficiencies and unlock opportunities for improvement. The research aims to provide a framework for integrating MBSE into certification practices, thereby enabling South Africa's aviation industry to achieve greater operational excellence, mitigate risks, and position itself competitively in the global aviation market.

The paper is structured as follows. Section II outlines the research problem, objectives, and methodology employed in this study. Section III reviews the relevant literature on applying Model-Based Systems Engineering (MBSE) in civil aircraft certification. Section IV discusses case studies comparing document-centric and MBSE-based certification approaches. Section V identifies the key challenges and limitations within the current South African STC framework. Section VI provides recommendations for reform, outlines future research priorities, and Section VII concludes the paper with final remarks.

2 PROBLEM STATEMENT

The South African aviation industry faces significant challenges in the Supplemental Type Certificate (STC) process, primarily due to outdated methods, system fragmentation, and the increasing complexity of aircraft. These issues lead to inefficiencies, increased certification costs, delays, and a higher risk of non-compliance. Despite global momentum towards Model-Based Systems Engineering (MBSE) as a means to enhance communication, traceability, and system integration, South Africa has yet to adopt this approach within its STC processes formally. This paper addresses the urgent need to modernise certification practices by exploring the integration of MBSE to improve operational efficiency, ensure regulatory compliance, and align with international best practices.

3 RESEARCH QUESTIONS

The critical research question for the study is:

(1) How can the MBSE approach enhance the STC processes for transport category aircraft in South Africa?

The supporting research question is:

(2) What are the key challenges and opportunities in integrating MBSE into the current STC framework for transport category aircraft in South Africa?

4 RESEARCH OBJECTIVES

The objectives of this paper are to:

- Investigate how the Model-Based Systems Engineering (MBSE) approach can be effectively applied to enhance the Supplemental Type Certificate (STC) processes for transport category aircraft in South Africa, with a focus on improving efficiency, traceability, and regulatory compliance.
- Critically evaluate the existing challenges and inefficiencies within South Africa's current STC framework, particularly regarding complex aircraft modifications and systems integration.
- Identify the opportunities and potential benefits of integrating MBSE into the STC process, including its influence on cost reduction, timeline optimisation, and adherence to rigorous aviation standards.

5 RESEARCH METHODOLOGY

This study adopts a qualitative, desk-based, and exploratory research design to examine the potential integration of Model-Based Systems Engineering (MBSE) into the Supplemental Type Certification (STC) process for transport category aircraft in South Africa. It is structured around principles of desktop-based document analysis, systematic literature review (SLR), and comparative case study reflection. The purpose is to assess the effectiveness of MBSE relative to traditional document-centric certification approaches in improving efficiency, regulatory traceability, and compliance. The methodology draws exclusively on secondary data sources, enabling a comprehensive assessment of both local and international certification practices without direct empirical implementation. The qualitative focus reflects the study’s aim to identify indicative trends, challenges, and opportunities, rather than to produce performance metrics. In addition, the research is guided by policy-oriented goals, seeking to generate insights that can inform regulatory frameworks, support evidence-based decision-making by the South African Civil Aviation Authority (SACAA), and contribute to aligning national certification processes with emerging global best practices. By doing so, the study aims to provide a knowledge base that is both academically robust and practically relevant for future policy development in the South African aviation sector.

5.1 Methodological Approach

Following recognised systematic literature review (SLR) protocols, including adaptations from PRISMA 2020, and established qualitative engineering research practices, the study was conducted in two main phases:

1. **Document Analysis** – An in-depth review of regulatory frameworks, guidance materials, and industry publications was undertaken. Sources included the South African Civil Aviation Authority (SACAA), the United States Federal Aviation Administration (FAA), the European Union Aviation Safety Agency (EASA), and the International Civil Aviation Organisation (ICAO). These documents were examined for insights into certification efficiency, process timelines, traceability, verification and validation workflows, digital artefact utilisation, and stakeholder coordination.
2. **Comparative Evaluation** – Drawing on the literature and two real-world case studies (including one from the researcher's professional experience within SACAA), the study compared traditional document-centric certification with MBSE-based approaches. Structured comparison matrices, conceptual modelling, and document mapping tools were used to analyse differences in traceability, efficiency, accuracy, scalability, change management, standardisation, and regulatory engagement.

The thematic analysis was guided by five core domains:

- Certification efficiency and process timelines
- Regulatory traceability and oversight
- Verification and validation workflows
- Digital artefact utilisation and modelling tools
- Stakeholder coordination and information flow

Where abstracts were insufficient for extracting value, full-text reviews were conducted to ensure data completeness. The findings are framed as policy-oriented and indicative rather than empirical, to inform future applied research and pilot implementations within the South African STC context.

6 LITERATURE REVIEW

6.1 Application of MBSE in Civil Aircraft Certification

Mirabella et al. proposed a digital certification pipeline (DCP) to replace traditional document-based processes, using MBSE to streamline compliance with EASA CS-23. The framework integrates SysML-based regulatory modelling, Simulink-driven test validation, and automated report generation. It enhances traceability through structured requirement mapping and supports emerging technologies like electric propulsion. While effective for general aviation, its application to CS-25 remains complex due to the scale of commercial aircraft certification [9].

Bendarkar et al. developed an MBSE-based certification framework to improve efficiency and accuracy in type certification for normal category aeroplanes. Built-in MagicDraw using SysML, the framework formalises certification rules and means of compliance into structured models. It comprises a Type Certification Profile, a Type Certification Package, and a Simulation Package, enabling automated compliance tracking, traceability, and rule filtering based on aircraft specifications. The system supports GUI-based inputs, generates compliance checklists, and facilitates gap analysis, particularly useful for emerging technologies like

electric propulsion. It benefits both regulators and manufacturers, aiding the shift toward fully digital certification [11].

Fazal et al. introduced an MBSE framework for modelling regulatory requirements under 14 CFR Part 25 for transport category aeroplanes. Using SysML in MagicDraw with the Cameo Simulation Toolkit, the framework structured regulations, compliance methods, and test activities into a traceable model. A dependency matrix enabled cross-referencing and automated compliance tracking. The approach improved traceability, regulatory transparency, and adaptability to emerging aircraft technologies such as electric and hybrid propulsion systems [12].

Xie et al. developed a simulation-based certification analysis module to embed regulatory compliance assessment, specifically FAR-25 Subpart B, into the early design phases of transport category aeroplanes. By converting textual regulations into quantitative MATLAB constraint functions, the module enabled dynamic simulation of key flight performance criteria using a six-degree-of-freedom flight dynamics simulator. Tested on a Boeing 737-800 model, the tool demonstrated high accuracy (error <8%) and supported early identification of compliance margins, enhancing traceability, reducing redesign effort, and supporting novel aircraft configurations. The approach lays the groundwork for integration into MDAO frameworks [13].

7 CASE STUDY STC PROJECT IN SOUTH AFRICA AND ABROAD

7.1 **Case Study 1:** The Role of the Lead Certification Engineer in the STC Approval for Installation of the L-3 Communication F1000 Flight Data Recorder on a Cessna Citation S550 – An Expert Certification Perspective.

This case study documents the researcher's professional experience as Lead Certification Engineer during a Supplemental Type Certificate (STC) project involving the installation of an L-3 Communications F1000 Flight Data Recorder (FDR) system on a Cessna Citation S550 aircraft. The project, undertaken while employed at the South African Civil Aviation Authority (SACAA), provides a real-world example of the application of systems and regulatory engineering principles explored in this research.

The scope of the modification focused solely on avionics integration, including the FDR unit, an accelerometer, a G-switch, and associated mounting hardware. Structural modifications, such as support brackets, were addressed separately under a minor modification process and thus excluded from the STC's certification basis.

The certification process was governed by FAR Part 25, as amended through Amendment 25-17, with voluntary compliance extended to Amendment 25-144. No changes to emissions or noise certification status were introduced.

As part of the compliance demonstration:

- A comprehensive Electrical Load Analysis (ELA) was submitted by the applicant and reviewed by the researcher to confirm electrical compatibility with existing systems.
- A functional test flight was carried out to verify the FDR's operational performance and data capture capabilities, with results reviewed and accepted.
- While formal conformity inspections were not required, engineering verification activities were conducted to ensure adherence to approved design data, forming part of a risk-based oversight strategy.

The researcher also reviewed and approved key airworthiness documents, including:

- The Master Data List (MDL) is used to establish the configuration baseline,

- A Flight Manual Supplement reflecting operational implications,
- Instructions for Continued Airworthiness (ICA) detailing maintenance and inspection requirements.

Following the successful completion of technical evaluations and documentation reviews, the researcher formally recommended the issuance of the STC. The modification was determined to meet all applicable airworthiness standards, introduced no adverse safety or environmental impacts, and demonstrated full conformity to approved specifications. This project not only reinforced regulatory compliance knowledge but also demonstrated the practical value of structured certification processes. It highlighted the importance of traceability, stakeholder coordination, and systems thinking in delivering safe and compliant aviation modifications. Figure 1 below shows the SACAA STC Approval process.

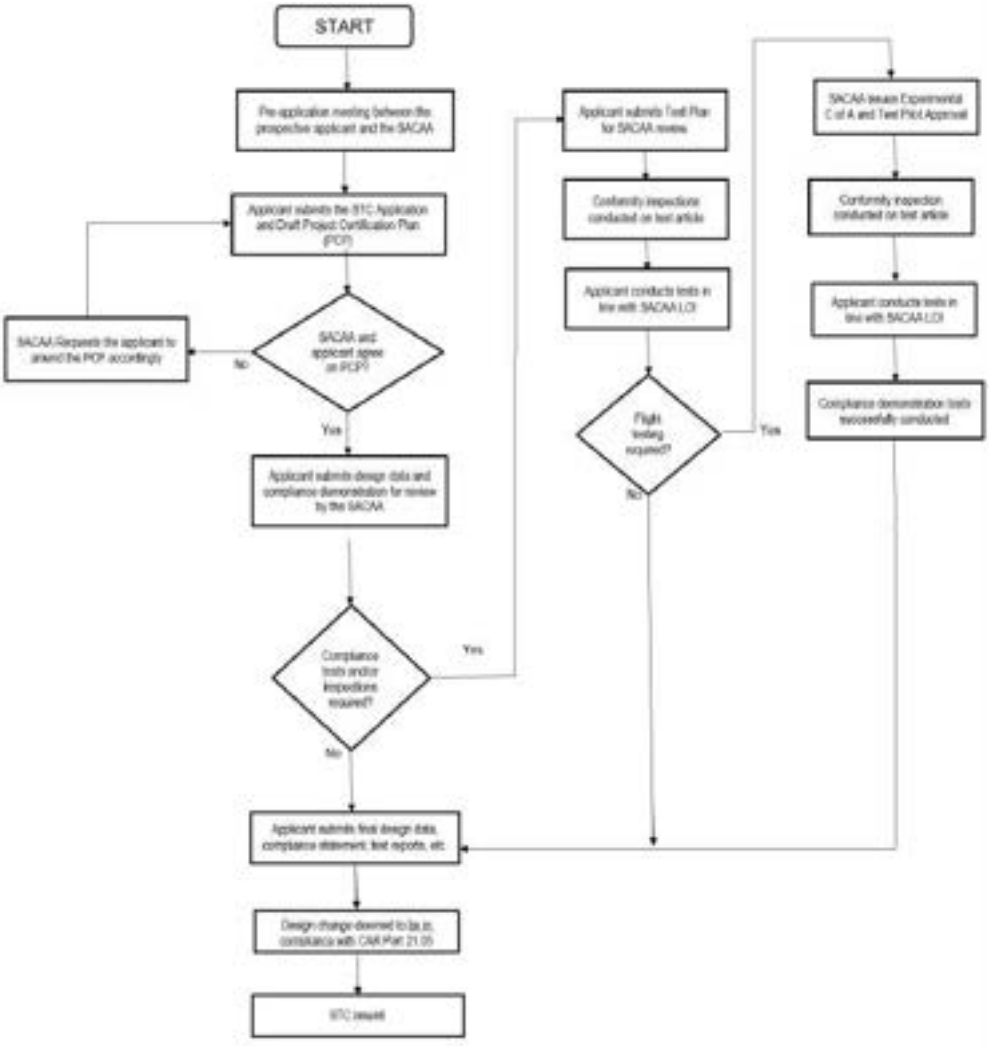

Figure 1:SACAA STC Approval process

7.2 Case Study 2: The Role of Analysis and Simulation in Aircraft Structural Certification

This case study, based on a white paper by Siemens Digital Industries Software, highlights the transformative role of digital analysis and simulation in modern aircraft structural certification. Traditionally reliant on extensive physical testing, the certification process is now increasingly enhanced by advanced simulation tools that improve efficiency, accuracy,

and cost-effectiveness. Structural certification requires compliance with strict FAA regulations, accounting for variables such as aerodynamic loads, speeds (Vs, Va, Vc, Vd), and worst-case scenarios. Engineers determine structural adequacy through static strength tests and design for ultimate loads, while fatigue and aeroelastic assessments address long-term integrity. Tools like stress-strain curves and S-N diagrams support predictions of fatigue life and stability under cyclic loading and flutter conditions. Digital simulation complements physical testing by enabling high-fidelity modelling of structural responses. Integrated platforms perform finite element analysis (FEA), margin of safety calculations, and automated reporting, improving traceability and standardisation. This digital approach, rooted in digital twin technology, supports faster, more consistent certification outcomes and aligns with evolving industry demands for safety, innovation, and efficiency [14], [15].

7.3 Comparative Analysis: Document-Centric vs MBSE-Based Certification Approaches

- Case Study 1: A document-centric approach, based on the researcher's professional experience during an STC for an FDR installation on a Cessna Citation S550.
- Case Study 2: An MBSE-driven approach, based on Siemens' digital simulation framework for aircraft structural certification.

Below is a structured comparison table that contrasts both approaches across key certification dimensions such as traceability, efficiency, accuracy, scalability, and regulatory alignment, and explains why MBSE proves superior in most areas.

Table 1:Comparative Analysis: Document-Centric vs MBSE-Based Certification Approaches

Dimension	Case Study 1: Document-Centric (STC for FDR)	Case Study 2: MBSE-Based (Structural Simulation)	Comparison summary
Traceability	Moderate – compliance linked via manual reports and documents [15]	High–traceability embedded within the system model using structured relationships [12]	MBSE provides automated, visual, and bidirectional traceability across requirements, design, and testing
Efficiency	The process relies on manual reviews, physical inspections, and sequential document handling [4], [6]	Simulation tools automate testing, calculations, and reporting [9]	MBSE significantly reduces time and workload through automation and integration
Accuracy	Dependent on manual interpretation and cross-checking [15]	High–FEA and simulation reduce human error and enhance result fidelity [13]	MBSE-driven certification ensures consistent validation across multiple load cases and failure modes
Scalability	Suitable for low-complexity modifications with narrow scope (e.g., FDR) [16]	Designed for high-complexity, system-wide evaluations (e.g., structural analysis) [17]	MBSE scales better with increasing system complexity and data volume
Change Management	Manual tracking of technical data and drawings [6]	The impact of changes propagated automatically across the digital model [11]	MBSE enables dynamic change management, improving configuration control
Standardisation	Dependent on the engineer's workflow and interpretation of SACAA/FAA procedures [3], [5]	Enforced by model constraints, parameter libraries, and digital certification logic [18]	MBSE promotes process consistency and regulatory alignment
Regulatory Engagement	Document-driven submissions are reviewed manually by the regulator. [19]	Digital twin environments support collaborative, visual compliance reviews [14]	MBSE enables a more interactive, model-based engagement with authorities like the FAA or EASA

7.3.1 Which Approach Was Better — and Why?

MBSE (Case Study 2) demonstrated clear advantages in:

- **Traceability**: With requirements, design logic, test cases, and simulation outputs all embedded within a single model, MBSE allows for real-time verification and transparent regulatory audit trails.
- **Efficiency**: The use of simulation tools, finite element analysis, and automated report generation reduces the need for redundant reviews and accelerates certification timelines.
- **Error Reduction**: Structured modelling eliminates inconsistencies common in document-based workflows and improves result accuracy.
- **Adaptability**: MBSE frameworks support novel technologies such as hybrid-electric propulsion, which require fast iteration and rigorous performance modelling.
- **Scalability**: Ideal for large, complex systems and early design phases where iterative assessments are essential.

Document-Centric Approach (Case Study 1), while effective in narrow, well-scoped certification projects like the **FDR integration**, faces limitations when:

- Multiple disciplines must coordinate
- Revisions and traceability are critical
- Real-time simulations or dynamic verification are needed.

7.3.2 In Summary

While document-based approaches remain viable for smaller, less complex projects, the shift toward Model-Based Systems Engineering offers transformative benefits for modern aviation certification. MBSE ensures greater traceability, regulatory consistency, efficiency, and scalability, making it the preferred approach for future-ready and safety-critical aerospace systems.

8 CHALLENGES AND LIMITATIONS OF DOCUMENT-CENTRIC STC CERTIFICATION APPROACH IN SACAA

8.1 Regulatory Complexity and Bureaucracy

The SACAA follows an intricate regulatory framework in line with ICAO guidelines, supplemented by FAA and EASA principles. However, the STC approval process is often characterised by:

- Inconsistencies in regulatory interpretation lead to delays in certification outcomes.
- Protracted approval timelines are due to administrative inefficiencies and an absence of a streamlined MBSE approach.
- Redundant regulatory requirements result in unnecessary documentation demands that hinder efficiency.
- “According to [16], delays in updating regulatory standards often hinder the certification of modern aircraft systems. Similar delays and policy lags are evident in SACAA’s current STC processes.”

From my first-hand observations, a lack of clear interpretation exacerbates regulatory bottlenecks, creating significant hurdles for applicants seeking timely certification.

8.2 Limited Technical Expertise and Resources

There is a critical shortage of qualified Designated Engineering Representatives (DERs) and aviation safety inspectors with the specialised technical knowledge required for evaluating advanced STC modifications. This limitation particularly affects:

- Avionics modernisation, including advanced digital flight control systems.
- Emerging propulsion technologies, such as hybrid-electric and hydrogen-powered systems.
- New structural materials, including composites and additive-manufactured components.

Without a well-resourced pool of experts, the certification process remains slow and vulnerable to knowledge gaps in assessing novel aviation technologies.

8.3 Integration of New Technologies

The global aviation industry is witnessing rapid technological advancements, particularly in:

- Unmanned Aerial Systems (UAS) integration.
- Hybrid-electric and alternative propulsion systems.
- Advanced materials and smart monitoring technologies.

However, the current STC framework in South Africa lacks the adaptability to efficiently evaluate and validate non-traditional aircraft modifications, slowing down innovation and the adoption of sustainable aviation solutions.

8.4 Harmonisation with International Standards

While South Africa aligns with ICAO, FAA, and EASA standards, there remain discrepancies in compliance pathways and certification requirements, creating challenges in obtaining international validation for locally developed STCs. These regulatory misalignments:

- Increase approval times for international STC recognition.
- Reduce the competitiveness of South African-developed modifications in global markets.
- Create inefficiencies in reciprocal certification agreements with foreign regulatory bodies.

8.5 High Costs and Financial Constraints

The STC process entails extensive engineering analysis, compliance demonstrations, and regulatory documentation, resulting in significant financial burdens for operators, ADOs, and local aviation innovators. Challenges include:

- Lack of financial incentives for research, development, and certification.
- High costs are associated with flight testing and compliance demonstrations.
- Limited funding support from government agencies and aviation industry stakeholders.

8.6 Inefficiencies in Aircraft Reliability Programmes

Many STCs involve modifications aimed at enhancing aircraft reliability and operational efficiency. However, the absence of robust data-driven reliability assessments within the certification framework leads to:

- Limited integration of Six Sigma methodologies in STC evaluations.

- Suboptimal maintenance strategies are due to inadequate reliability engineering considerations.
- Reduced effectiveness in operational performance enhancements.

8.7 Lengthy Approval Timelines

The prolonged STC approval process remains a significant bottleneck due to:

- Administrative inefficiencies and paperwork bottlenecks.
- Incomplete documentation reviews require multiple rounds of corrections.
- Lack of a digitised submission and tracking system, leading to process opacity.

These inefficiencies adversely affect airlines, ADOs, and STC applicants requiring urgent modifications for fleet performance, operational cost reductions, and regulatory compliance.

8.8 Lack of Industry Collaboration and Innovation Drive

The South African aviation sector lacks strong collaborative frameworks between regulatory authorities, industry stakeholders, and research institutions. This results in:

- Limited knowledge exchange and best-practice sharing for STC development.
- Minimal participation of academia in certification research and policy development.
- Reduced synergy in advancing cutting-edge aviation innovations.

8.9 Potential Solutions for Reforming the STC Process in South Africa

To address these challenges, a comprehensive reform strategy is essential. The following interventions are proposed:

- Adopting MBSE to streamline the STC process and enhance regulatory efficiency.
- Expanding training programmes for regulatory personnel and engineers to strengthen expertise in advanced aviation technologies.
- Developing a digital STC submission and tracking system to reduce administrative delays and enhance transparency.
- Introducing financial incentives to support ADOs, operators, and innovators in funding certification projects.
- Strengthening international partnerships to ensure harmonisation with global certification standards, facilitating international STC recognition.
- Integrating Six Sigma methodologies and reliability engineering principles to improve aircraft performance modifications.
- Enhancing collaboration between academia, industry, and regulatory bodies to drive innovation and accelerate the adoption of new technologies.

8.10 Corroborating Literature Supporting Expert Testimony in Section 7 (Case 1)

The insights shared by the expert in Section 7 reflect and are strongly supported by existing academic and technical literature on STC processes. A central theme across these sources is the persistent inefficiency and procedural rigidity embedded within traditional document-based certification methods. For example, Mirabella et al. [9] and Bleu-Laine et al. [17] critique the limitations of linear, document-centric certification pipelines, highlighting how these obstruct the effective integration of emerging technologies into civil aviation. These findings align closely with the researcher's account of SACAA's difficulty in certifying complex modifications such as hybrid-electric propulsion systems and advanced avionics.

The challenge of regulatory misalignment with modern technology is further echoed by Glinski et al. [19], who demonstrate that existing frameworks are ill-equipped to assess novel aircraft configurations, particularly those not based on legacy fuel or propulsion systems. This corroborates the researcher's view that South Africa's current STC framework lacks the flexibility needed to support innovation. The observation that South Africa suffers from a shortage of technical expertise, especially among Designated Engineering Representatives (DERs) and safety inspectors, is consistent with findings by Fazal et al. [12]. These authors stress the necessity for multidisciplinary proficiency in MBSE and simulation tools as a prerequisite for modernising certification procedures and resources, which, according to the expert, are presently lacking within the South African context.

Additionally, the issue of administrative inefficiencies and bureaucratic delays is well documented in studies by Bendarkar et al. [11] and Mirabella et al. [9], who cite fragmented documentation practices and poor traceability as key barriers to efficient certification. These issues are similarly highlighted in the researcher's analysis, where the lack of digitised submission systems and the reliance on repetitive manual reviews were identified as major contributors to prolonged approval timelines. In terms of international harmonisation, the literature underscores the importance of aligning local regulatory practices with those of global bodies such as the FAA and EASA. The researcher's concerns regarding the misalignment between South African regulations and international standards are validated by Bleu-Laine et al. [17], who argue that such discrepancies hinder mutual recognition of STCs and limit the international competitiveness of domestic aviation products.

Financial barriers to certification also emerge as a consistent theme. The expert's commentary on the high cost of compliance and the lack of financial support for innovation is reinforced by Mirabella et al. [9], who note that the transition to digital certification entails significant upfront investment, often unattainable without government or industry support. Finally, the researcher's advocacy for integrating Six Sigma methodologies and MBSE into the STC framework is well-supported by empirical studies. Case-based applications in the literature show that MBSE, combined with simulation-driven compliance tools, can significantly improve process traceability, regulatory alignment, and certification efficiency, thus validating the proposed reform strategy.

9 RECOMMENDATIONS

This paper highlights the transformative potential of MBSE in modernising the Supplemental Type Certification (STC) process for transport category aircraft in South Africa. Based on the research findings, the following strategic recommendations and research directions are proposed:

9.1 Policy and Practice Recommendations

- **Develop Regulatory Guidelines**: SACAA should issue formal guidance recognising MBSE artefacts in certification submissions, aligned with FAA/EASA practices.
- **Invest in Training and Capacity Building**: Introduce accredited MBSE training for engineers, regulators, and ADOs to ensure consistent and competent implementation.
- **Launch Pilot Projects**: Demonstrate MBSE's effectiveness through SACAA-led pilot STC programmes to build institutional confidence.
- **Standardise Tools and Infrastructure**: Promote interoperability by defining standard SysML tools and digital submission platforms.
- **Align with International Standards**: Harmonise certification approaches with global regulatory norms to ensure international recognition of South African STCs.

- **Encourage Cross-Sector Collaboration**: Foster partnerships between regulators, academia, and industry to co-develop MBSE frameworks and share expertise.
- **Incentivise Adoption**: Introduce policy incentives, such as grants or fast-track reviews, for organisations implementing MBSE.
- **Integrate MBSE into Education**: Embed MBSE in engineering curricula and professional development programmes to build a future-ready workforce.

9.2 Future Research Priorities

- **AI-Driven Compliance Tools**: Explore artificial intelligence for automated model verification and compliance assessment.
- **Performance-Based Certification**: Investigate real-time, data-driven compliance models using flight data and sensor feedback.
- **Extension to Emerging Aircraft Types**: Adapt MBSE frameworks to support UAS, UAM, and electric aircraft certification.
- **Digital Twin Integration**: Leverage digital twins for continuous compliance monitoring and predictive maintenance validation.
- **Toolchain Standardisation**: Develop interoperable MBSE modelling protocols to support digital continuity across jurisdictions.
- **Regulatory Impact Assessment**: Evaluate legal, audit, and data governance implications of digital certification adoption.
- **Change Management Research**: Study organisational strategies for transitioning from document-based to model-based workflows.
- **MBSE Education Impact**: Assess the long-term effectiveness of MBSE education and training in supporting sustainable implementation.

10 CONCLUSION

This paper proposes modernising South Africa's Supplemental Type Certification (STC) process for transport category aircraft through the integration of Model-Based Systems Engineering (MBSE). Current document-centric methods struggle to address the complexity of modern aircraft, leading to inefficiencies, delays, and challenges with traceability and compliance. Key weaknesses in the South African framework include reliance on manual processes, fragmented data handling, and limited adaptability to emerging technologies such as electric propulsion and digital flight control systems. In contrast, MBSE employs digital models, structured system architectures, and simulation-based verification to enhance compliance efficiency, traceability, and regulatory oversight. Drawing on global literature and industry practice, the study synthesises MBSE frameworks developed by Mirabella et al., Bendarkar et al., Fazal et al., and Xie et al., all of which demonstrate improved traceability, faster certification timelines, and reduced errors. Two case studies illustrate this comparison: a document-based STC project for installing an FDR system on a Cessna Citation S550, and a simulation-driven structural certification using Siemens Digital Industries Software, with the analysis showing MBSE to be more efficient, scalable, and accurate.

The study makes four key contributions: identifying limitations in the current South African STC framework; providing a comparative analysis between document-centric and MBSE-based certification methods; presenting a policy-oriented framework for integrating MBSE into the STC process; and proposing a structured roadmap for MBSE adoption, including regulatory guideline development, training programmes, pilot projects, tool standardisation,

international alignment, and innovation incentives. Looking ahead, future research priorities include AI-enabled compliance verification, the use of digital twins for real-time certification, extending MBSE to emerging aircraft categories such as UAS and AAM, and standardising MBSE toolchains for regulatory interoperability. As the findings are based on literature, regulatory analysis, and professional experience, the study is qualitative, desk-based, and exploratory, with no empirical implementation or performance measurement, and should therefore be interpreted as indicative and policy-oriented rather than definitive. Future work should include empirical validation through operational trials, simulations, or pilot projects to assess MBSE's practical value in the South African STC context and refine the proposed framework using real-world evidence.

ASSESSING THE PERCEIVED USABILITY OF FIGJAM AND THE EXTENDED STORY CARD METHOD DURING PARTICIPATIVE ENTERPRISE MODELLING

M. De Vries[1*] and A. Venter[2]

[1,2]Department of Industrial and Systems Engineering
University of Pretoria, South Africa
[1]marne.devries@up.ac.za, [2]anthea.venter@up.ac.za

ABSTRACT

Participatory enterprise modelling (PEM) is an emerging research area that promotes a collaborative online approach when multiple stakeholders are involved during enterprise modelling. Multiple online modelling tools are emerging to support PEM. However, limited research exists on assessing and comparing these modelling tools regarding their perceived usability. This article assesses the perceived usability of a collaborative online tool, FigJam, when used in combination with the extended story card method (eSCM). The study contributes towards knowledge about the combined use of online tools within a particular method context. Assessing perceived usability, the System Usability Scale (SUS) extracts survey feedback on both the online tool, FigJam, as well as the modelling method, the eSCM. In addition, we use an interactive online discussion session to identify method frustrations, suggesting further enhancements to the eSCM, named the e1SCM.

Keywords: enterprise engineering, FigJam, system usability scale, participative modelling, extended story card method

1 INTRODUCTION AND RELATED WORK

Disruptive technologies brought about fundamental changes to society's culture, including that of enterprises. Some of the disruptive information technologies include robotics, cloud computing, big data, robotics and artificial intelligence that change the *way in which enterprises operate*. Prior to understanding enterprise operation and how these operations need to transform, we start with some definitions of the *enterprise*. Giachetti [1] defines the enterprise as a "socio-technical system that comprises interdependent resources of people, information, and technology *that must interact* with each other and their environment in support of a common mission". Dietz and Mulder [2] define the *enterprise* as: "all kinds of *organised human activities"* including companies, agencies, institutions, and supply chains, but also the organisation of a birthday party." Both definitions highlight the role of the human being and its *interaction* with other human beings as well as with technical systems.

Changes in the environment and the advancement of technology, require a continuous effort of enterprise re-design, where various design domains of the enterprise need to be re-designed concurrently [3, 4]. Although many enterprises still emerge in an ad hoc way, the discipline of enterprise engineering (EE) pursues coherent and consistent design, emphasising employee involvement for improved enterprise productivity, customer satisfaction, product and service quality, and coping with enterprise complexity, uncertainty and dynamics [5].

When human beings at an enterprise coordinate around work that needs to be done in delivering products and services to customers or clients, they need some guidance on how this coordination should proceed. Dietz and Mulder [2] propose that the enterprise designer starts with an understanding of the *essence of enterprise operation*, using a modelling language named the Design and Engineering Methodology for Organisation Specification Language (DEMOSL) to depict the *essential model* via four aspect models, i.e. cooperation model, action model, process model and fact model.

We use the supply chain operations reference (SCOR) framework, as discussed by Harmon [6] as a benchmark, to understand how the aspect models provide a different representation of operations. The SCOR framework decomposes supply chain operations, using 4 different levels: Level 0 (indicating the scope of the investigated value chain, i.e. the products and services that form part of the value chain; Level 1 (the value chain processes, consisting of *plan*, *source*, *make*, *deliver*, and *return*); Level 2 (decomposing each value chain process); Level 3 (using *flow-chart notation* to indicate sequential tasks per value-chain sub-process).

Whereas SCOR mainly focuses on the decomposition of processes, without linking an actor role to any of the detailed tasks, aspect models depict essential *human* coordination and production acts and facts. Since human beings are activated through commitments towards each other, aspect models highlight the essential chunks of responsibilities to produce products and services for a predefined scope of analysis.

Deviating from flow-chart thinking, one of the aspect models, the cooperation model (CM), depicts enterprise operation, emphasising the interaction patterns between actor roles. Using this new way of thinking, additional facilitation is required when a DEMOSL-knowledgeable enterprise designer extracts operational knowledge from enterprise stakeholders. The extended story card method (eSCM) creates a bridge between storytelling that uses flow-charts or narratives about enterprise operation, and aspect models that use a different symbolism to depict the essence of enterprise operation [7]. Encouraging real-time interactive modelling between a DEMOSL-knowledgeable *facilitator role* and an enterprise representative as *colleague role*, a software tool, MURAL [8], was used by De Vries and Opperman [7] to experiment with the eSCM. The experimental study evaluated whether MURAL *encouraged participative modelling* and evaluated the *level of participation* during interactive modelling.

In addition, the study evaluated the quality of the resulting models [7], indicating that participants experienced numerous difficulties in applying the eSCM.

Since the study of De Vries and Opperman [7] did not focus on the usability of MURAL, a different study applied a standardised usability questionnaire, the System Usability Scale (SUS), indicating that MURAL scored above average on usability [9]. The study of [7] did not address the quality issues of the resulting models. Since both studies ([7] and [9]) reported on several tool frustrations that participants experienced, when using MURAL in combination with the eSCM, an opportunity existed to experiment with a different participative modelling tool, such as FigJam [10].

The eSCM, used by [7] and [9], was based on the 2020 publication of Dietz & Mulder [11], whereas a new book has since been published in 2024 [2], associated with a new version of DEMOSL [12]. The previous experimentation context provided an opportunity to pose new research objectives.

In summary, the aim of this study is to address 3 objectives: *Objective 1:* Extend the eSCM towards an e1SCM, addressing the DEMOSL changes, incorporated in [2, 12]. *Objective 2:* Indicate how the e1SCM should be implemented within a new tooling environment FigJam [10], as compared to the implementation within the previous tooling platform MURAL. *Objective 3:* Measure the usability of FigJam and the usability of the e1SCM separately.

2 RESEARCH METHODOLOGY

This study applies a Design Science Research Methodology (DSRM) where DSRM may start with "an already designed version of an artefact" [13], such as the eSCM developed by [7]. Given the context provided in the previous section, we apply DSR to answer the following research question:

How can the eSCM be extended towards an e1SCM and what is the usability of the e1SCM and the usability of FigJam when the e1SCM is used in combination with FigJam to model the essential operations of an enterprise?

2.1 Design science research

The eSCM is a *method* artefact [7] that complies with Mingers' [14, p 675] definition of a method, namely "a structured set of processes and activities that includes tools, techniques, and models, that can be used in dealing with a problem or problem situation". We followed the *five steps* of the design science research cycle (presented in [15]) in the following way:

Identify a problem: The eSCM [7] requires further extension, to accommodate the most recent changes of DEMOSL, as documented in [2, 12]. The eSCM was initially deployed within MURAL as the modelling tool, indicating some *frustrations* with the modelling tool, but also indicating that participants often reported on eSCM method frustrations and not tool frustrations [9]. An opportunity exists to experiment with a different modelling tool regarding its usability. In addition, tool usability and method usability should be clearly separated.

Define objectives of the solution: Addressing the two main problems, the study includes three main objectives, stated at the end of section 1.

Design and development: Addressing *Objective 1:* We extended the eSCM towards an e1SCM, addressing the DEMOSL changes, incorporated in [2, 12], presenting the e1SCM in section 4.1. Addressing *Objective 2:* We indicate, in section 4.2, how the e1SCM should be implemented within a new tooling environment FigJam [10], as compared to the implementation within the previous tooling platform MURAL.

Demonstration: The e1SCM, embedded in FigJam, was demonstrated to post-graduate participants during an interactive in-person session, using a comprehensive real-world case, at a research-intensive institution.

Evaluation: Addressing *Objective 3*, we focused on measuring usability separately, i.e. usability of the software tool versus the e1SCM usability, where 27 research participants applied the e1SCM to a real-world event management (EM) case with the opportunity to voluntarily complete a survey of 50 items. In addition, an interactive session was used to obtain further clarification on the frustrations that participants experienced.

2.2 Evaluating e1SCM artefact

This section provides additional context on preparing participants prior to applying the evaluation instruments, also providing context on participants' background.

2.2.1 Training sessions

The primary researcher used several mechanisms to ensure that participants were well-prepared in using both FigJam and the e1SCM:

- Participants received training on *aspect model theory* and DEMOSL, where all participants had full access to [2] and [12].
- The aspect models were demonstrated using several cases, including the Volley case and Rent-A-Car case from [2].
- We used a separate case to demonstrate the e1SCM, implemented within FigJam, also demonstrating how the participant, assuming the *facilitator* role, should be sharing their electronic whiteboard with their co-modeller, i.e. the participant assuming the *colleague* role.
- Participants completed a multiple-choice *knowledge test on aspect model theory*, with automatic feedback to ensure that they grasped essential concepts prior to applying the concepts to a new case, i.e. the EM case. The EM case was supplemented with detailed instructions on how each group had to systematically provide evidence of the graphical constructs that were developed when applying the e1SCM.
- Reducing the risk of facilitation influence and group dynamics, participants had to use FigJam's version history feature to save incremental versions of their electronic whiteboard. The assessor could thus validate that both group members modelled participatively, following the guidance of the e1SCM.

2.2.2 Research participants

The primary researcher introduced FigJam and the embedded e1SCM method to participants that enrolled for a post-graduate module in Enterprise Engineering. The primary researcher then created 15 groups on the web-based learning management system 'Blackboard' [16]. Members were assigned randomly, where each group consisted of two members. Participants had to indicate their existing role, tertiary education background, industry background and experience with other modelling tools. Only 21 participants chose to complete the survey, whereas 28 participants were present during the interactive e1SCM method evaluation session.

2.2.3 Survey participants background

Survey participants completed an engineering degree or engineering diploma, mostly full-time students (7 of 21), business process analysts (4 of 21), or engineers (4 of 21). Other than full-time students (7 of 21), participants represented different industries, i.e. mining (5 of 21) and single-instance representation from the following categories: retail, financial services, industrial manufacturing, oil and gas, utilities, consumer sector and the automotive sector, whereas 2 participants did not answer the question. Participants had modelling experience

with one or more tools, mostly using Visio (11 of 21) and Diagrams.net (5 of 21), whereas only 1 participant had no modelling experience.

2.2.4 Obtaining evaluation results

Evaluation results were obtained via multiple data-gathering instruments. We used a survey to obtain feedback about the usability of FigJam and the usability of the e1SCM. Assessing the quality of the models, the main researcher *extracted observations* regarding common problems that emerged, validating these problems during an *interactive e1SCM feedback session* to obtain further insight into the modelling errors produced by the participants. The *observations*, together with the *interactive e1SCM feedback session*, were used to corroborate findings in the survey.

Regarding the survey, participants were informed, according to the ethical clearance conditions for the study, that participation in the survey is voluntary, that a participant could withdraw at any stage without penalty, that their privacy would be protected throughout the survey, and that their participation would remain confidential. Question 1 was used to obtain consent from the participant to continue with the survey, as required by the conditions for our approved application for ethical clearance.

Questions 2 to 7 obtained background information about the participants regarding their undergraduate qualification, industry working context and modelling experience. After these initial questions, the survey included questions from the System Usability Scale (SUS) by Brooke [17]. Question 8 to 28 evaluated the usability of FigJam, whereas questions 29 to 48 evaluated the usability of the e1SCM. We adapted the phrasing of the SUS items slightly to ensure clarity on evaluating the usability of FigJam versus the e1SCM. Each SUS item also included a free-text question to encourage motivational feedback from the participant.

Questions 49 encouraged additional feedback on steps in the e1SCM that were problematic, and Question 50 inquired about the duration of completing the modelling effort when applying the e1SCM to the EM case.

3 LITERATURE

We provide background on one of the aspect models, used to model the essence of enterprise operation, called the cooperation model (CM) in section 3.1, whereas section 3.2 introduces the eSCM that translates sequential thinking into human-interaction thinking, using a participative/collaborative approach. Section 3.3 provides background on usability evaluation methods (UEMs) to measure tool usability.

3.1 The cooperation model

Dietz and Mulder [2] present four aspect models, the cooperation model (CM), action model (AM), process model (PM) and fact model (FM) to represent the essence of enterprise operation. The models are based on core theories about enterprises and their operation [2], summarised in subsequent paragraphs.

In this section, we explain some of the theoretical content of the CM, using the same case, applied by our participants, i.e. some event management (EM) operations. Some of the primary activities of the EM operations include *event identifying*, *event date selecting* and *event entrance controlling*.

The CM acknowledges that enterprise operations can be perceived as actor roles that perform multiple coordination acts and production acts. The coordination acts and production acts are performed in a particular sequence, called transaction patterns. Instead of modelling the detailed transaction patterns for each *kind of transaction* evident at the enterprise, the CM hides the detail of these consistent transaction patterns between two actor roles to hide some of the complexity, enabling human understanding [2]. Therefore, The CM will extract the

different *kinds of transactions* (e.g. *event identifying*, *event date selecting* and *event entrance controlling*), hiding the detailed coordination activities that form part of these transaction kinds.

The CM abstracts from technological implementation and realisation details, only representing *original* transaction kinds, excluding the informational, documental and material transaction kinds [2]. Using the EM context, the CM will include the original transaction kind *event entrance controlling*, but it will *exclude* its supporting transaction kinds to hide complexity. Even though *event entrance controlling* should be supported by informational transaction kinds, such as *guest entrance identity information sharing*, and technological details, such as *using a scanner to scan a QR code to obtain the guest's ticket information*, the CM will only include *event entrance controlling* as an original transaction kind.

The CM indicates that three different structures guide the operations of an enterprise, namely the *interaction structure*, *interstriction structure* and *interimpediment structure* [2]. We will elaborate more on these structures when we discuss the CM in more detail. The CM can be represented by a Coordination Structure Diagram (CSD) and Transactor Product Table (TPT) [2], using Figure 1 and Figure 2, where we only provide an extract of the TPT in Figure 2.

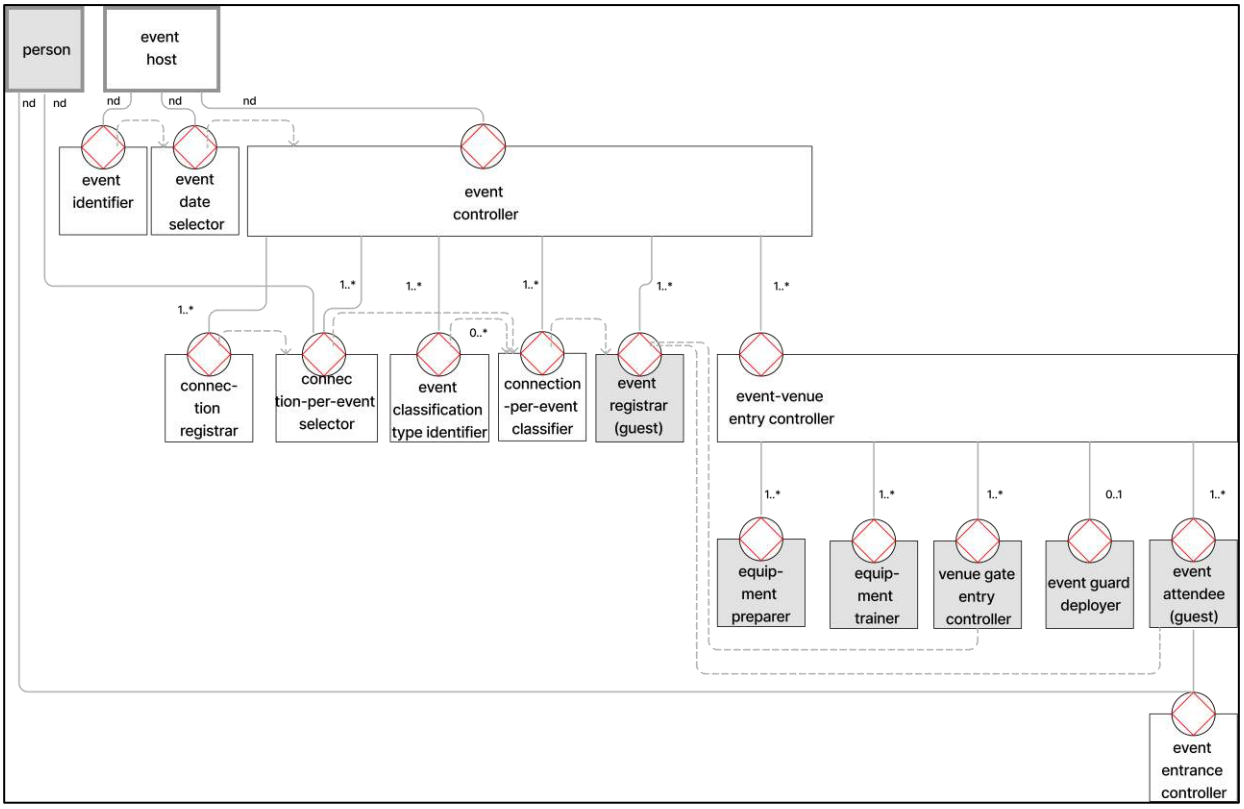

Figure 1: The cooperation structure diagram (CSD) modelled using FigJam

In discussing the main constructs of a CSD, Figure 1 provides a graphical representation of a CSD that consists of fifteen transactor roles. Each of the *elementary transactor roles* include two components, an actor role (quadrilateral) and a transaction kind (diamond-disc). The description of the transaction kind is provided on the TPT, indicated in Figure 2. Thus, the transactor role named *event identifier*, indicates that the actor role *event identifier* is the executor of a single transaction kind, called *event identifying*. The transactor role is a representation of a complete transaction pattern that exists when an initiator starts the transaction pattern for the transaction kind.

transaction kind	product kind (independent P-fact kind)	executor role
event identifying	[event] is identified	event identifier
event date selecting	the date of [event] is selected	event date selector
event controlling	[event] is controlled	event controller

Figure 2: An extract from the transactor product table (TPT) modelled using FigJam

The CSD and TPT presented in Figure 1 and Figure 2 respectively, provide a concise representation of *some* EM operations. The analyst must decide on the scope of interest (SoI), where all white quadrilaterals indicate human actor roles that are considered to be *inside* the selected SoI (e.g. event identifier), whereas grey-shaded quadrilaterals with a white diamond-disc indicate human beings that are within the direct *environment* (e.g. event registrar). Furthermore, the thin-bordered quadrilaterals indicate elementary transactor roles, whereas thick-bordered quadrilaterals indicate composite transactor roles.

The CSD, highlights three different kinds of *coordination structures*, including the (1) interaction structure, (2) interstriction structure, and the (3) interimpediment structure [2]. Partially explaining Figure 1 as a representation of *some* EM operations, demonstrating the three coordination structures, we use underline constructs that appear in Figure 1.

Interaction structure. Figure 1 includes solid lines between some constructs, to indicate interaction, e.g. an event host initiates interaction with an event controller. The event controller also initiates interaction with a connection registrar. Each of the initiation links includes an annotation to indicate the minimum and maximum number of initiation instances. The annotation "nd" should be interpreted as non-definable, whereas "1..* should be interpreted as *one-to-many*, i.e. for every one instance of event controlling promised, the event controller may initiate *one-to-many* instances of connection registering, executed by the connection registrar.

Interstriction structure. Figure 1 also includes a dotted line with no arrowhead, to indicate information access. The dotted line between the venue gate entry controller and the diamond-disk associated with the event registrar indicates that the venue gate entry controller needs to have access to facts that have been created already. The event registering facts restrict the operating behaviour of the venue gate entry controller, e.g. only guests registering for the event, will be allowed access to the venue gate.

Interimpediment structure. The dotted line with arrowhead, in Figure 1, is a wait link. Similar to the interaction links, interimpediment links may also include annotations, where an absent cardinality assumes the default of 1..1, interpreted as one-and-only-one. As an example, the coordination facts associated with one instance of event identifying, executed by event identifier, e.g. *accepting* that an event has been identified, impedes the progress of the event date selector for one-and-only one instance of event date selecting.

3.2 The eSCM and participative enterprise modelling tools

In this section, we explain the purpose of the eSCM as a participative enterprise modelling method, and different modelling technologies that are available to support the eSCM steps. The eSCM transforms a story about some enterprise operations into a CM to highlight the essence of the enterprise operations [7]. The eSCM content consists of 3 inputs and 13 method steps. A participative modelling tool is used to encourage interactive participation between a *facilitator role* and a *colleague role*, during the modelling process. Within an enterprise modelling context, the main objective of collaborative, participative and interactive modelling, is to obtain extended participation from actors that offer insight into enterprise operations [18, 19]. Voinov et al [20] define participatory modelling (PM) as a "purposeful

learning process for action that engages the implicit and explicit knowledge of stakeholders to create formalized and shared representations of reality".

Software tools that support participative enterprise modelling (PEM) are still emerging [21]. Previous studies ([7] and [9]) embedded the eSCM within MURAL as the PM software, but other software options are also available, such as FigJam [10] and Miro [22]. Since limited studies exist on measuring the usability of software tools that support PEM [9], this study experimented with FigJam, used in combination with the e1SCM. An extract of the 13-step e1SCM, deployed within FigJam, is shown in Figure 3.

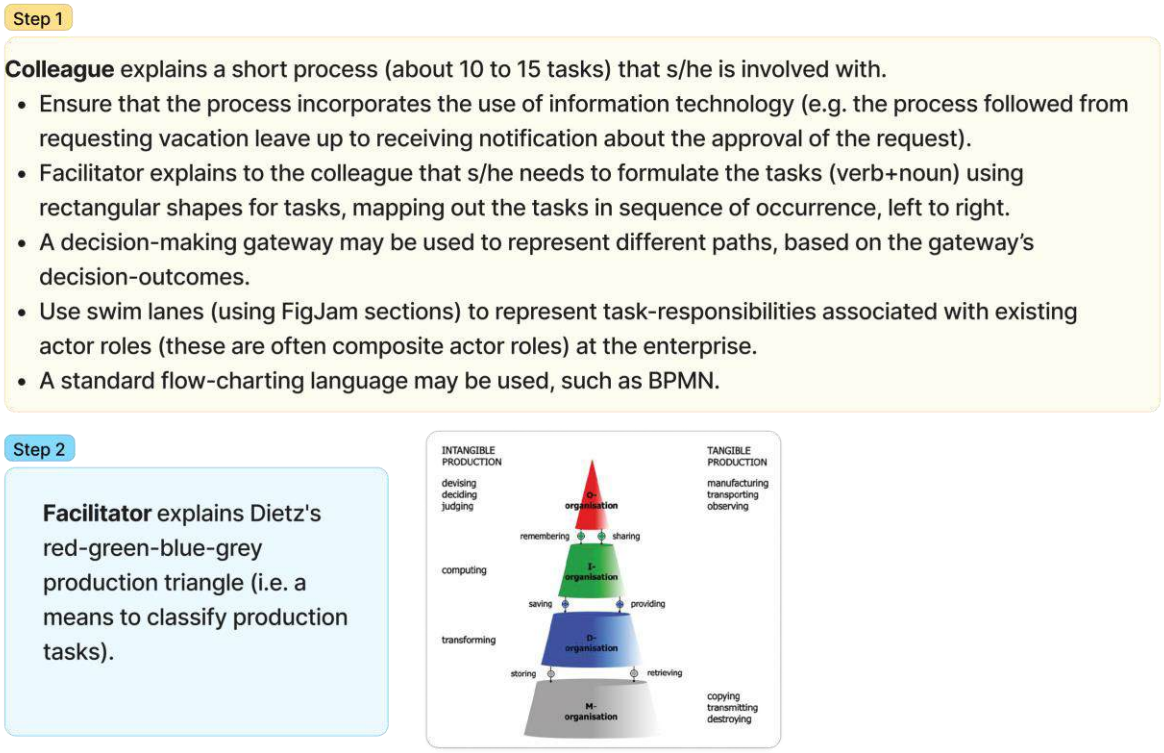

Figure 3: An extract of the e1SCM deployed within FigJam, including Step 1 and Step 2

3.3 Usability evaluation methods

This section provides some background on how practitioners can evaluate the *usability* of software tools, with the objective of evaluating FigJam, when used in combination with the e1SCM.

The human-computer interaction (HCI) community defines *usability* as a "desired quality of interactive systems and product" [23]. The ISO 9241-11 standard [24] also extends the definition of usability to a service, i.e. "the extent to which a system, product or service can be used by specified users to achieve specified goals of effectiveness, efficiency, and satisfaction in a specific context of use". Sauro [25] believes that usability should be viewed in a broad sense, i.e. considering multiple interconnected psychological constructs such as appeal, trust, and loyalty, contributing towards the product's success.

When evaluating usability, Ivory and Hearst [26] suggested four dimensions to classify Usability Evaluation Methods (UEMs), distinguishing between method classes, method types, automation types and effort level, where a specific UEM is classified as a combination of the four dimensions. As an example, inquiry as *method class*, can be used with a survey as *method type*. Using the classification scheme of Fernandez et al.[27], with their focus on Web applications, UEMs can also be classified based on whether *empirical* or *inspection* methods

are used. *Empirical* methods capture and analyse usage data from end-users, whereas *inspection* methods are performed by experts, evaluating conformance to guidelines. Within the empirical methods category, questionnaires are often used [28], where three of the questionnaires demonstrate acceptable validity and reliability evidence, namely the Computer System Usability Questionnaire (CSUQ), the Post-Study System Usability Questionnaire (PSSUQ) and the System Usability Scale (SUS) [28].

The SUS is used "for global assessments of systems usability", consisting of a ten-item 5-point scale, position 1 to 5, where 1 is interpreted as *strongly disagree* and 5 is interpreted as *strongly agree* [29]. The 10 items include an alternation of positive and negative items to ensure that a respondent reads each statement and make an effort to think on agreeing or disagreeing with the statement [29]. An overall usability score is calculated, rather than focusing on the score of a single item [29].

To calculate the SUS score, the scale is first converted to a rating, where *strongly disagree* scores one point, and *strongly agree* scores five points. For positively worded items (i.e. odd-numbered items), the score contribution is calculated as the *scale position minus 1*. For negatively worded items (i.e. even-numbered items), the score contribution is calculated as *5 minus the scale position* [30]. The adjusted scores for the 10 items are then summed and multiplied by 2.5 to obtain a score range from 0 to 100. The SUS score can be used to address some of the following objectives: (1) Estimating the SUS for a population from one sample; (2) Determining whether a SUS score exceeds a benchmark; and (3) Comparing SUS scores for comparable products [30].

4 THE E1SCM ARTEFACT

This section focuses on the adaptations, converting the eSCM into the e1SCM, prior to embedding the e1SCM within the FigJam modelling platform.

4.1 Extending the eSCM

The new book on enterprise ontology 2024 [2], associated with a new version of DEMOSL [12], affected steps 2 and 3 of the eSCM. Both these steps are facilitator steps where the facilitator provides some *explanation* of aspect model theory that could affect modelling tasks, associated with Steps 4 and 5. The content of Steps 4 and 5 did not change, but the modelling results may be affected. Rather than repeating the eSCM construct, also available in [7], we only present Steps 2 to 5 in Figure 4 to highlight the main changes incorporated in the e1SCM.

- Step 2: Whereas [11] included three production sorts of original (red), informational (green) and documental (blue), [2] added a fourth category of production, namely material (grey), where "material production comprises storing, retrieving, copying, transmitting and destroying files" [2]. The implication for Step 4 is that modellers should find this additional category useful in excluding production acts that are not of an original sort.
- Step 3: The complete transaction pattern presented in [11] was extended in [2], allowing for a more comprehensive set of revocation acts. As an example, the act of *revoking* a *promise*, now accommodates the act of *revoking* either a *promise* or *decline* indicated as "rv/pm|dc" in Figure 4. The implication for Step 5 is that modellers could now identify tasks in the flow-chart that represent a *revocation* of a *decline*, due to the extended theory.

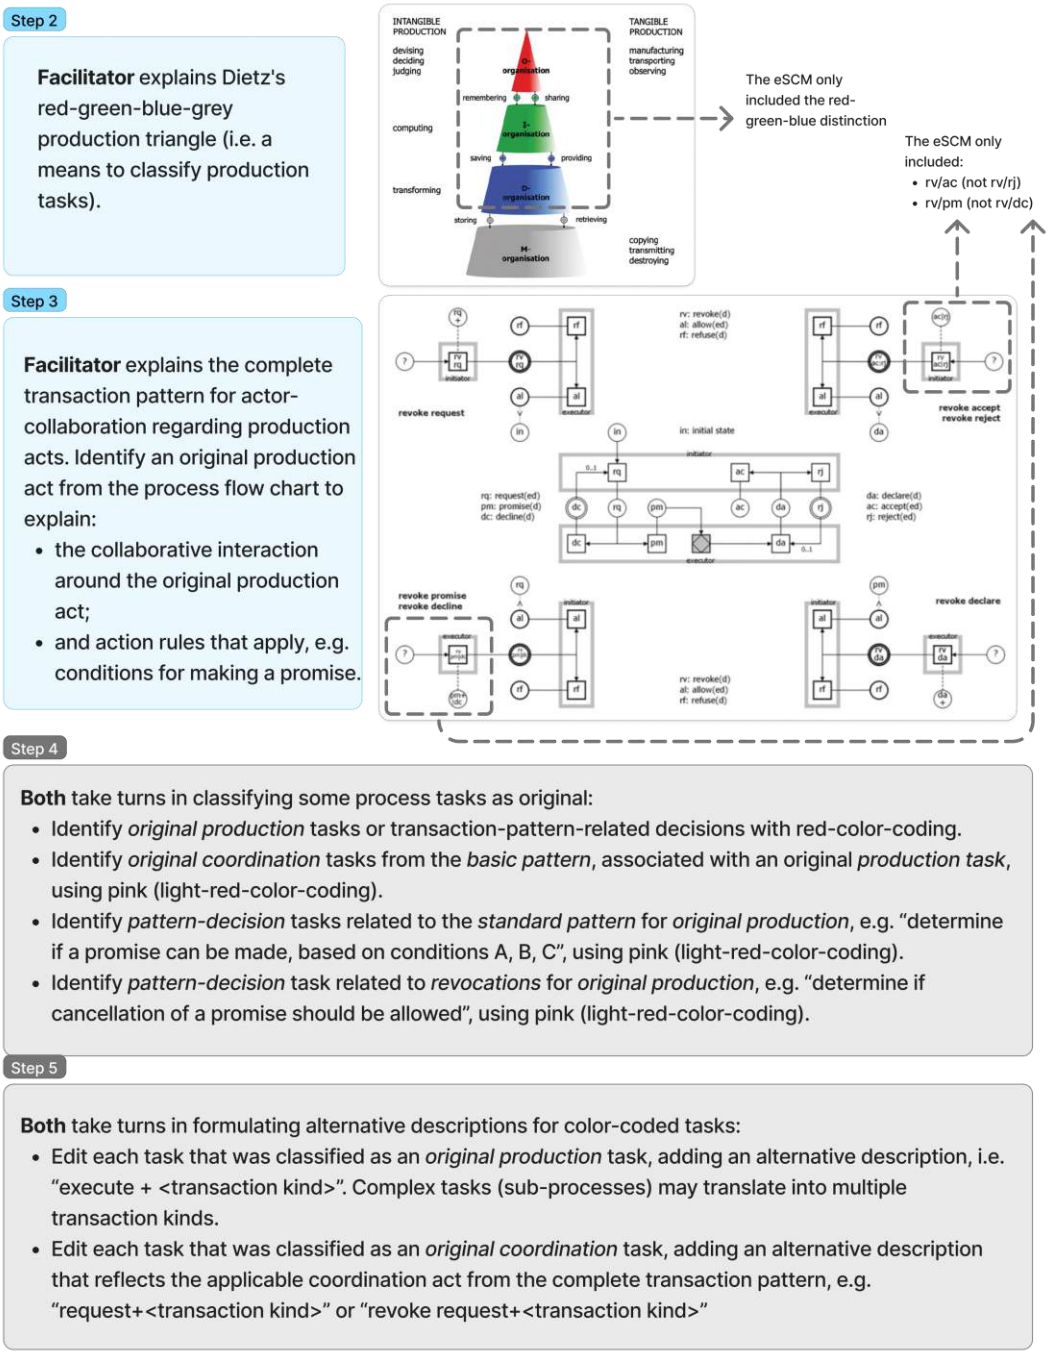

Figure 4: Steps 2 to 5 of the e1SCM, using dotted lines to compare with the SCM

4.2 Embedding the e1SCM within FigJam

From a designer's point of view, i.e. embedding the e1SCM into the FigJam platform, had the following restrictions when compared to the MURAL-embedded version discussed in [7]. MURAL [8] includes an *outline* feature, used to package the different steps of the eSCM. When a modeller clicks on a step in the outline, the modeller can be directed to the area on the whiteboard that is relevant for the step. FigJam [10] does not offer this feature and hence the instructions per step were positioned on the left-hand side of the whiteboard. For ease of

differentiation between responsibilities, i.e. the *facilitator* the *colleague* and *both* facilitator and colleague, we added colour coding to the steps, i.e. *blue*, *yellow* and *grey* respectively.

For Step 1 of the e1SCM, the *colleague* has to model the existing process, using a process flow chart. The MURAL-embedded version discussed in [7], provided some basic process modelling symbols as part of a template to support the modelling for Step 1. Due the extended design functionalities offered by Figma [31], the primary researcher extended the process model symbols that allowed for more freedom of expressing the flow-chart logic. The intent was to reduce the ambiguity of interpretation when using a very rudimentary set of process model symbols.

5 EVALUATION RESULTS

Three inquiry method types, as identified by [26], were used in our study. The study included: (1) *surveys* (the interviewer asks user-specific questions), (2) *user feedback* (the user submitted comments on FigJam frustrations and SCM frustrations), and (3) *assessor feedback*, i.e. when assessing the quality of the diagrams, the assessor identified common mistakes and provided feedback during an interactive online session.

5.1 System Usability Scale (SUS) results

We obtained survey feedback from 21 participants. Of the 21 participants, 2 participants submitted blank responses, leaving all questions (SUS and user comments) unanswered. These two responses were excluded from the study as it would impact the reliability of the SUS score. In addition to this, each survey section had two participants that only partially completed the survey. These partially completed surveys were included in the results, with unanswered questions being updated to "neither agree nor disagree".

The margin of error of the SUS scores calculated at a 95% confidence level would therefore be approximately ±7,95 points. This is using a standard deviation of 17,7 based on an average calculated by Lewis and Sauro [32].

5.1.1 FigJam usability as online tool

The average SUS score for FigJam is 73,82, indicating *acceptable usability*, when the 3-category grading scale of [33] is used, i.e. not acceptable, marginal, and acceptable. The SUS scores per participant are shown in Figure 5. All participants scored FigJam as Marginal or Acceptable.

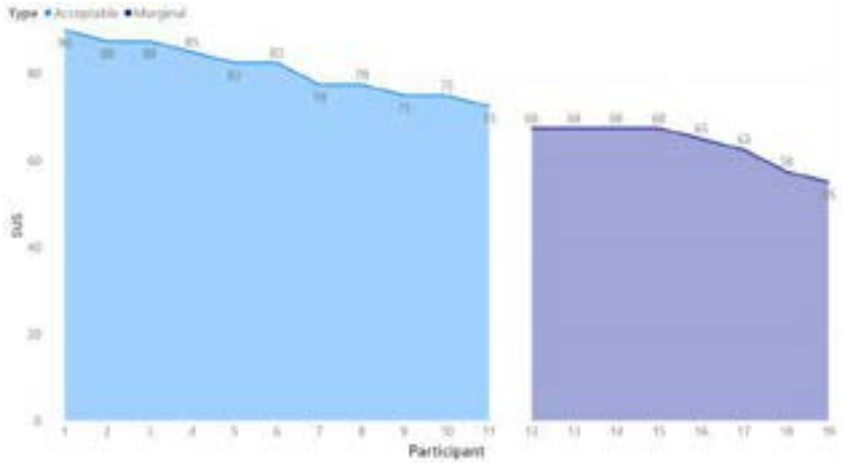

Figure 5: SUS score per participant for FigJam as an online tool

Responding to the ten SUS questions, participants provided feedback on how they felt regarding the statement by providing a ranking of strongly disagree, disagree, neither agree

nor disagree, agree or strongly agree [17]. The odd-numbered SUS questions are positive-oriented. In these questions, we would expect participants to agree or strongly agree to the statements, if they are satisfied with FigJam in the evaluation context. The positive-oriented SUS question feedback is summarised in Figure 6. Unfortunately, the participants that disagreed with Q 03 and Q 05 did not provide additional motivation.

Question	1. Strongly Disagree	2. Disagree	3. Neither	4. Agree	5. Strongly Agree
01 - I think that I would like to use Figjam frequently				13	6
03 - I thought Figjam was easy to use		1	4	8	6
05 - I found the various functions in Figjam were well integrated	1		4	13	1
07 - I would imagine that most people would learn to use Figjam very quickly			2	13	4
09 - I felt very confident using Figjam			2	15	2

Figure 6: SUS positive-oriented question summary

The even-numbered SUS questions are negative-oriented. In Figure 7 we summarise the answers per negative-oriented SUS question. None of the participants strongly agreed to any of the negative-oriented SUS questions.

Question	1. Strongly Disagree	2. Disagree	3. Neither	4. Agree
02 - I found Figjam unnecessarily complex	6	9	3	1
04 - I think that I would need the support of a technical person to be able to use Figjam	7	9	2	1
06 - I thought there was too much inconsistency in Figjam	4	12	3	
08 - I found Figjam very cumbersome to use		13	4	2
10 - I needed to learn a lot of things before I could get going with Figjam	2	10	4	3

Figure 7: SUS negative-oriented question summary

For Q 02, the participant did not provide a motivation. The participant agreeing with Q 04 indicated little support on the internet. Two participants agreed on Q 08, indicating that FigJam was very cumbersome to use, where one participant provided a motivation: “having to drag, minimize or maximize to work on something is quite time consuming and you are never sure about the right size of your text”.

5.1.2 The e1SCM usability as method

The average SUS score for e1SCM as a method embedded in FigJam, when combining all participants’ scores, is 58,55, indicating *marginal* usability, when the 3-category grading scale of [33] is used, i.e. not acceptable, marginal, and acceptable. The SUS scores per participant are shown in Figure 8. Five participants scored the e1SCM 50 or less (i.e. as “not acceptable”).

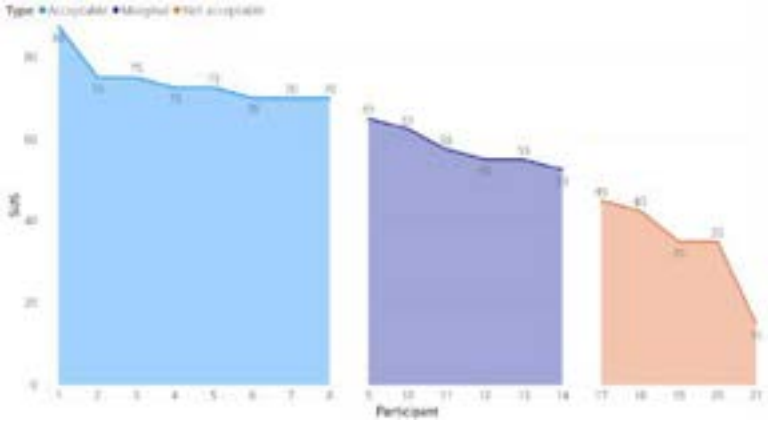

Figure 8: SUS score per participant for the e1SCM as a method

As aforementioned, the odd-numbered SUS questions are positive-oriented. In these questions, we would expect participants to agree or strongly agree to the statements, if they are satisfied with the e1SCM method, summarised in Figure 9.

Question	1. Strongly Disagree	2. Disagree	3. Neither	4. Agree	5. Strongly Agree
01 - I think that I would like to use the story card method (SCM) frequently		1	5	12	1
03 - I thought the story card method (SCM) was easy to use	1	3	5	8	2
05 - I found the various method steps of the story card method (SCM) were well integrated		1	4	12	2
07 - I would imagine that most people would learn to use the story card methods (SCM) very quickly	3	1	5	10	
09 - I felt very confident using the story card method (SCM)	1	3	7	8	

Figure 9: SUS positive-oriented question summary

Feedback on Q 03 for the participant that strongly disagreed on whether the SCM was easy to use indicated: "I had no idea what I was doing". The statement is corroborated with the results of the *knowledge test on aspect model theory* (see section 2.2.1) indicating an average score of 8.9/20, where 28 candidates participated in the knowledge test.

Three participants indicated for Q 07 that they strongly disagreed that people would learn to use the SCM very quickly, where additional feedback indicates: "We still need time to fully understand the content" and "Understanding is required, and the colour coding can be difficult".

The even-numbered SUS questions are negative-oriented, i.e. we expected disagreement. In Figure 10 we summarise the answers per negative-oriented SUS question.

Question	1. Strongly Disagree	2. Disagree	3. Neither	4. Agree	5. Strongly Agree
02 - I found the story card method (SCM) unnecessarily complex	1	11	4	2	1
04 - I think that I would need the support of a technical person to be able to use the story card method (SCM)	1	9	4	3	2
06 - I thought there was too much inconsistency in the story card method (SCM)	1	13	3	2	
08 - I found the story card method (SCM) very cumbersome to use		12	4	2	1
10 - I needed to learn a lot of things before I could get going with the story card method (SCM)		2	8	6	3

Figure 10: SUS negative-oriented question summary

A participant that strongly agreed with Q 02, i.e. that the SCM was unnecessarily complex, indicated that "there are just too many things to remember". Two participants strongly agreed with Q 04, i.e. that support of a technical person is required to use the SCM, indicating that "the terms are too confusing" and "we needed more time to process the content of the lecture". The participant strongly agreeing to Q 08, i.e. that the SCM was cumbersome to use, indicated that there are "too many terms to remember".

Three participants strongly agreed with Q 10, i.e. that they had to learn a lot of things before they could use the SCM, elaborating that "I had to learn and remember too many things", and "Coming from a different engineering discipline almost all the concepts were unfamiliar".

5.2 User survey feedback on FigJam frustrations

Participants were asked to share any frustrations they experienced with FigJam. The frustrations can be grouped into the following main themes:

- *Linking lines to symbols*. Links snap to a different position on a symbol than required, mentioned by three participants.
- *Difficulty in navigating on the board*. "The maximizing and minimizing are exhausting". Also, "it was difficult to move around the board or select shapes etc. without a mouse".
- *Board glitches*. A single participant indicated board freezing, which could also be linked to the computer hardware. Another participant indicated modelling glitches – "This can be solved by reloading the page."

- *Button to undo.* "Except for the Crtl Z function I wish there was an actual undo and redo button."
- *Lines.* When creating flow charts, some lines move. Also, "the links on the template made it difficult to set them straight on the model."

5.3 User feedback on the e1SCM

Some of the survey feedback was linked to particular steps in the e1SCM, whereas other feedback provided general feedback on using the e1SCM.

- *Step 4:* "Colour coding some of the tasks in step 4 was a bit challenging."
- *Step 9:* "Difficult to effectively translate the flow diagram into the CSD as there was a lot of abstraction that needed to happen."
- *Step 7 to 12:* "I Personally still need a lot of clarity, in understanding the CSD".
- *Combining steps.* "I believe some of the steps need to be combined together to work on the story card method effectively".
- *Interpretation of the problem.* "I believe the issue was with the analysis and interpretation of the problem".
- *Benefits of using the e1SCM.* "Dealing with someone with no technical background and you have to explain to them how they should contribute to model the SCM. It does not seem they would see this experience as beneficial."
- *Theory complexity.* "Basically, learning the theory covered in class was necessary so there were still a few challenges identifying what was what. But that is just because I think I didn't fully grasp all concepts".

For the 18 participants that answered Question 50 regarding the duration of the interactive modelling when using the SCM, participants spent an average of 7.6 hours with a standard deviation of 1.8 hours.

When presenting the memorandum of the constructs developed when applying the e1SCM to the EM case, participants provided the following feedback:

- Two participants indicated that the flow-chart, provided to all participants, about the real-world enterprise that offers *some* EM operations, could be interpreted in multiple ways. Even though additional flow-chart symbols were used, as indicated in section 4.2, to reduce ambiguity, the description per task still allowed for multiple interpretations.
- Another participant inquired about the positioning of cardinalities associated with the initiation links, since the current positioning, i.e. close to the initiator, also creates confusion. A suggestion was made to move the cardinality annotation to the executor side of the initiation link, indicating that the indicated cardinality only applies to one direction.

5.4 Assessor feedback on the e1SCM

From an assessment perspective, the main researcher observed the following:

- Some participants classified documental or material transaction kinds (TK), e.g. "Close the invite-acceptance link", as an original TK, named "invite-acceptance link closing". Another example is that "Scan-in guests for event attendance" is translated into a material TK, "guest scanning", but incorrectly classified as an original TK. Also "ticket generating" is incorrectly identified as an original TK. A possible explanation is that many of the participants do not have an information system background. Hence, they may have difficulty in classifying tasks that involve information system technology.
- Informational TKs synthesise, consolidate, or calculate existing facts. Hence, when reports or lists are generated from existing facts the reporting task should be classified as

informational. It seems though participants automatically translate the word “generate” into an original TK.

- A reminder for event registering is a duplication of a previous request. Some participants define a separate transaction kind, associated with the reminder request. Thus, whereas a single TK “event registering” should exist, an additional incorrect TK “event registration reminding” is created. The use of reminders are currently not included in [2].

6 CONCLUSION, LIMITATIONS AND FUTURE WORK

In this section, we present our findings in relation to the research objectives outlined in Section 2.1.

Extending the eSCM towards an e1SCM, section 4 presented the e1SCM embedded in FigJam, confirming that it is possible to create the e1SCM within a different participative modelling tool than MURAL. However, the combination of using the e1SCM within FigJam, presented some usability challenges. FigJam did not offer the functionality of embedding the 13 steps within an *outline*, a function that was possible in MURAL, where clicking on a step in the outline would automatically navigate the user to the position on the board where modelling actions were required. As expected, user feedback on using FigJam, highlighted the navigation challenges on the board.

The *FigJam usability results*, indicated an average SUS score of 73,82, indicating *acceptable usability*. Qualitative feedback highlighted that modelling was time-consuming and using the appropriate font size for text is a challenge. Participants also highlighted required features including: (1) Improving the ability to snap lines to different positions on a symbol; (2) A button to undo, rather than using the Ctrl-Z keyboard shortcut; (3) Improving the ease of converting angled lines into straight lines on the diagram; and (4) The ability to move around on the board or select shapes without using a mouse.

The e1SCM usability results, indicated an average SUS score of 58,55, indicating *marginal usability*. Qualitative feedback indicated that participants had to deepen their knowledge on aspect model theory, prior to using the e1SCM. The required knowledge in grasping multiple new concepts created a barrier in using the e1SCM. Participants had to use a pre-defined flow-chart as a representation of some EM operations, and participants expressed the challenge to interpret these operations, also since the flow-chart could have multiple interpretations. An additional discussion of the operating context would be beneficial, prior to applying the e1SCM. A participant indicated that some ambiguity exists when interpreting the cardinality text associated with an initiating link. Some additional training is required to emphasize that the cardinality is one directional, i.e. from the initiating transactor towards the executing transactor.

Using SUS to evaluate the usability of the e1SCM, has *some limitations* to investigate other aspects of the e1SCM, such as the modifiability of the method and accuracy of the resulting representations, offering the opportunity for future work on usability assessment, as encouraged by [34]. The sample size of 21 valid responses limited the generalizability of the findings and we suggest future work where a broader participant base is involved. Although we used several methods to corroborate our findings, using survey results, assessor observations and an interactive feedback session, additional interviews with participants would further validate our findings.

Gill and Hevner [35] claim that DSR has thus far overemphasized immediate utility of an artefact to the expense of sustainable impact, encouraging research on the long-term impact of artifacts on organisations. Similar to the real-world demonstration of using aspect models when merging Air France Cargo and KLM Cargo into AFKL Cargo (see [2]), the e1SCM should be

used in an industrial setting, to further assess its useability, but also its scalability and adaptability across organizational levels.

Although we do not measure the effective use of the e1SCM at organisations, the e1SCM already encourages knowledge transfer between a DEMO-knowledgeable *facilitator* role and *colleague* role with no prior knowledge about DEMO. The successful transfer of DEMO knowledge, via the facilitator role, could be further enhanced in future, using hyperlinks to videos embedded in FigJam, to provide more explanation regarding different abstractions of production, and an explanation of the transaction pattern.

ABSTRACT

This study investigates the preparedness of students and lecturers to integrate Fourth Industrial Revolution (4IR) technologies into engineering education. A mixed-methods approach was followed, surveying six lecturers and 245 students to assess familiarity, confidence and challenges. Results show strong support for 4IR integration but highlight barriers like inadequate access, training gaps and infrastructural constraints. Students showed enthusiasm despite inadequate access, while lecturers pointed out the need for institutional development. The findings underscore the necessity of curriculum restructuring, professional development and strategic support to enable effective 4IR adoption, aligning educational outcomes with evolving industry demands and enhancing graduate employability.

Keywords: mixed-methods approach, 4IR, curriculum restructuring

1 INTRODUCTION

The fourth industrial revolution (4IR) is the convergence of technologies, blurring the boundaries between the physical and digital domain, IoT and robotics[1], and is greatly changing industrial engineering (IE) practices. 4IR Lecturers are required to reevaluate traditional educational concepts such as lecture-based instruction and standardised assessments by integrating 4IR technologies (4IRT in short) into engineering education (EE) to fulfil and anticipate industry demands. 4IR has integrated engineering innovation into broader systems production and labour, thereby reshaping infrastructure and social frameworks[2]. Subsequently, production and social needs have been transformed on a global scale. Today, the engineering discipline requires continuous change to meet the ever-changing demands of industry[3]. The Industrial Engineering (IE) profession is industry-driven, and with IE's unceasing transformation, the changes between the past, present and future are remarkable[4]. Developing skills that align with technological advancements is essential for reducing graduate unemployment. To prepare students effectively, EE requires the inclusion of both technical and adaptive skills, encouraging a culture of lifelong learning that prepares graduates with succeeding in dynamic, technology-driven workplaces.

With the introduction of 4IR worldwide, technology and the need for technology in industry has increased rapidly. As 4IRT continues to evolve, the growing impact on industry highlights the urgent need for education systems to adapt accordingly. Digital transformation in education has been accelerated and fast-tracked by rapid changes in information and communication technologies (ICTs). The integration of ICT has reshaped modern learning environments, thereby enabling educators to adopt innovative teaching strategies at an unprecedented pace[5]. Similarly, advancements in ICT not only transformed teaching methodologies but also enhanced learner engagement in 21st century classrooms[6].

Students must be prepared to leverage innovative technologies for academic growth and industry application. Engineering accreditation bodies like the Engineering Council of South Africa (ECSA), are responsible for ensuring that graduates are equipped with appropriate skills relevant to current and future industry demands[7]. The curriculum needs to prepare students for a work environment characterised by rapid technological advancements such as those driven by 4IRT[4]. ECSA requires programs to embed graduate attributes and show industry relevance. These attributes—problem-solving, lifelong learning and the application of modern tools—align closely with 4IR's emphasis on digital literacy, systems thinking and the ability to adapt to emerging technologies.

Just as industrial revolutions transformed education in the past, recent global disruptions like the COVID-19 pandemic have accelerated the shift towards digital learning. The mode of education is continuously undergoing significant changes, and COVID-19 acted as a disruptive catalyst[8], pushing the boundaries of innovation and adaption even further. The adoption of 4IRT in education was hastened, highlighting the potential to bridge gaps in availability, enhanced collaboration and developing problem-solving skills. Tertiary education underwent a complete digital transformation, with online platforms becoming more flexible and accessible [9] and innovative technologies such as simulations and 4IRT enhancing students' learning experiences. The focus shifted from merely providing information to students, to the emergence of critical thinking and problem-solving skills, preparing students to adapt to a fast-changing world. In South Africa, the integration of 4IRT into higher education is important for aligning global industry standards and enhancing the employability of graduates. Despite the potential benefits, studies indicated a low level of 4IRT adoption in EE in South Africa[10], often attributed to limited awareness among educators of the critical role these innovations play.

The study aims to identify factors such as lecturers' and students' preparedness that may negatively affect successful 4IRT integration into the engineering curriculum. Two research questions (RQs) were developed to explore the dimensions of 4IRT: ***RQ1****: How well-prepared are IE lecturers in implementing 4IRT into the curriculum?* and ***RQ2****: What are students' attitudes and levels of preparedness towards using 4IRT in their learning, and how do these factors influence student engagement and academic success?*

By gaining insight into student and lecturer attitudes towards 4IR, it becomes feasible to ensure purposeful strategies designed to promote an innovative culture and contribute towards optimising learning outcomes. The emergence of 4IR enables students to better equip themselves with skills that meet future industry demands.

2 LITERATURE REVIEW: PREPAREDNESS FOR 4IRT IN EDUCATION

The preparedness and readiness of students and lecturers using 4IRT in their teaching and learning is extensively covered in literature. The sections below explore themes around the preparedness, perceptions, challenges and opportunities of using 4IRT in education, thereby establishing the foundation for answering the RQs and achieving the study's aim.

2.1 Educational strategies supporting 4IR integration

As noted in[11], there is a need towards the integration of 4IR technologies into education to address the evolving needs of students within a rapidly changing technological landscape. Similarly, [12]found that transitioning to interactive and experiential learning methods better equip students with practical skills that align with industry demands. Integrating 4IRT modernizes pedagogical strategies and directly addresses the gap in areas like data analytics, automation and artificial intelligence. 4IR is reshaping how students engage in learning[13], while simultaneously bridging industry demands with academic outcomes[14]. By incorporating approaches like problem-based learning and challenge-based learning[15], lecturers are developing innovation and preparing students for the complexities of modern industries. The researchers in [16] argue that these methods enable students to address real-world challenges more effectively. Such advancements are essential to keeping EE relevant and equipping students with competencies needed to thrive in the 4IR era [17]. In[18], it is evident that these innovations enable more flexible, personalised and accessible learning experiences. AI-powered tools allow real-time feedback, and virtual labs replicate hands-on technical training in a virtual environment, addressing gaps in practical exposure. COVID-19 acted as significant catalyst for digital adoption, forcing educational institutions worldwide to embrace online learning platforms and other digital tools to ensure continuity[19].

2.2 Lecturer preparedness to use IR tools

Lecturers play a critical role in integrating 4IRT into education, but their ability to do so depends on training, resources availability and institutional support. Using XR tools to create immersive environments has the transformative potential to create interactive and engaging learning environments, but challenges like user fatigue and resource-intensive technical support remain noteworthy barriers[20]. To address these issues, practical exposure and targeted training programs are crucial for preparing lecturers. Virtual laboratories and online collaborative tools were highlighted as effective means to improve engagement and confidence among lecturers, preparing them for the technical demands of 4IR integration[21].

Generative AI tools like Scholar GPT offer a practical solution through personalised, real-time insights, thereby enabling lecturers to adapt their teaching strategies according to diverse learner needs[22]. These tools streamline routine tasks such as content creation so that educators can focus on deeper pedagogical strategies and design interactive, experiential lectures that meet the innovative and adaptive demands of 4IR[23]. Digital tools are critical

in overcoming resource limitations and facilitating the effective integration of 4IR principles in education[24]. It supports innovative curriculum design, encourages higher-order thinking skills, and enable lecturers to stay updated with the latest research and trends[25]. However, institutional support remains a fundamental factor in ensuring the sustainability and effectiveness of these initiatives. Institutional support, in the form of professional development opportunities and robust infrastructure, is required to aid these efforts in addressing systemic barriers[26].

Continuous professional development (CPD) plays an important role in assisting lecturers with keeping up with rapid technological developments. Studies highlight the importance of interdisciplinary competencies that enable educators to navigate the multifaceted demands of 4IR environments[27]. Despite optimism about adopting 4IR tools, systemic challenges like insufficient infrastructure and inadequate training opportunities remain prevalent[28]. Addressing these barriers requires targeted reforms and accessible training initiatives adapted to institutional and individual needs.

Personal barriers, including time constraints and skill gaps, also block lecturers' readiness to engage with new technologies and tools effectively[29]. Resource shortages worsen these issues, leaving many educators feeling powerless about implement 4IR solutions efficiently[30]. To overcome these challenges, comprehensive strategies involving systemic support, resource allocation and targeted professional development must be prioritised.

Institutional support is critical for effective 4IRT adoption in higher education. Universities in developing regions often struggle with limited infrastructures, weak policy frameworks and inadequate development opportunities for educators. Targeted training, curriculum alignment and robust institutional support is imperative for equipping lecturers with the technical and pedagogical competencies important for 4IR integration[31].

2.3 Student preparedness to use 4IR tools for learning

While students showed high levels of enthusiasm towards 4IR-based learning, unequal access to technology and skills gaps remain persistent challenges[32]. Institutions should provide subsidised access to digital tools with low bandwidth for AI learning platforms and university supported mobile applications to address inequalities[26]. Students, as primary beneficiaries of 4IR tools, displayed a mix of enthusiasm and obstacles in studies conducted by [36,37]. Their research highlights motivational beliefs of students and facilitating conditions as critical factors in technology adoption. While researchers in [36], emphasise the accessibility of low-cost tools such as Google Cardboard for younger students, the researchers in [33] focus on rural students' acceptance of Industry 4.0 technologies using the Technology Acceptance Model (TAM).

Discussing the educational potential of 4IR tools, the focus in [34] was on risk-free and interactive experiences provided by IVR games in Chemical EE, but caution against the steep learning curve and cost of high-end devices. Similarly, the researcher in Zatarain-Cabada, et al. [35] investigated how XR technologies have improved engagement and learning outcomes, particularly in physics education. In support, [36]note that AR and VR tools will enhance engineering students' comprehension of complex processes. Despite the advantages, systemic barriers like cost and difficulty to accessibility persist, echoing the concerns raised by[37]. Using gamified learning tools and AI learning platforms with university-supported mobile applications can address these inequalities and enhance student readiness by offering personalised, interactive and self-paced learning experiences[38].

2.4 Comparative perceptions of using 4IR tools in EE

Students and lecturers recognised the transformative potential of using 4IR tools to learn, but they also encountered systemic and practical challenges. While both groups valued the

interactivity of AI, IoT and XR tools, their concerns were different. Lecturers expressed concerns about AI's impersonal nature and the potential of being replaced in the classroom, losing their influence. Students were more concerned about accessibility and the high costs associated with content creation [31,41]. Lecturers' reluctance to adopt 4IR tools, rooted in fears of being overshadowed by AI, could slow adoption, while students' financial concerns may delay engagement and equitable access.

2.5 Challenges and opportunities in adopting 4IR Tools in EE

While 4IR tools offer significant advantages, their adoption into EE faces critical challenges, including high financial costs, infrastructure technical limitations, resistance to change and data privacy concerns [19, 21, 30]. Institutions need to address these barriers systematically to unlock the full potential of using 4IRT. As noted in [36] the impracticality of high-end devices like the Oculus Rift for classroom use, calling for more scalable and affordable alternatives.

The biggest barrier is financial cost, especially in resource-limited institutions. Small enterprises influence public-private partnerships in funding digital transformation[39], and universities could collaborate with technology firms such as Google, Microsoft and IBM to provide subsidised software licenses, cloud-based platforms and sponsored VR labs. A good example of this practice is the University of Cape Town partnering with Siemens to introduce IoT-enabled smart classrooms, reducing hardware dependencies while industry-aligned learning is being maintained. Another barrier is the lack of a structured faculty training program in using 4IR tools. The emphasis in [40] was on the importance of compulsory professional development programs with hands-on training session on XR, AI and IoT tools[41].

Ethical concerns around AI and the replacement of human instructors by AI also have a negative effect on lecturers' perceptions of using 4IR tools. AI should be used as teaching assistant [15], and not lecturer replacement. Universities can accomplish this by implementing AI-driven personalised learning assistants to automate grading and administrative tasks, allowing lecturers to focus on higher order pedagogical strategies[42].

Notwithstanding the challenges, 4IRT offers transformative opportunities to students and lecturers. 4IR can bridge the gap between theoretical knowledge and practical application through immersive and interactive learning experiences [1]. One of the most promising benefits is stronger global competitiveness. Students proficient in using XR tools are better prepared for the demands of global industries[35], and these tools help learners acquire critical technical skills and develop a deeper understanding of complex industrial processes, e.g., manufacturing systems, supply chain optimisation and industrial automation.

Big Data, IoT and AI can, if integrated into university curricula, modernise educational methodologies as explored in the context of Dubai University [43] and prepare students for the digital future by aligning learning pathways with industry demands. These technologies simulate real-world environments, fostering cross-cultural collaboration and nurturing team-based problem-solving in virtual spaces[44]. Aligning classroom learning with industry demands through using 4IRT prepares students to perform well in competitive global markets, making them attractive candidates for multinational corporations. Recent finding in [27] encourage interdisciplinary learning and adaptive curricula that align with both educational systems and modern workforce needs. This study recognises and establishes the transformative potential of 4IRT for both students and educators. However, systemic barriers like infrastructure limitations, excessive costs and insufficient training persist across contexts. To fully recognise the benefits of 4IR, professionally developed infrastructure and policy frameworks are needed.

3 METHODOLOGY

This study adopted a convergent parallel mixed methods approach, incorporating quantitative and qualitative data to explore both lecturer and student perceptions and preparedness of using XR technologies in education. The data was collected through an online survey via QuestionPro. A purposive sampling strategy was used for both participant groups to ensure relevance to the study's objective. The lecture sample comprises of 6 IE lecturers at a university of technology were targeted. This represented the entire department population, excluding the researcher and was the maximum available in the study context. While the small size limits generalisability beyond the department, it allowed complete coverage of the available cohort. The student survey was distributed in two phases: in 2024 (March—May), the survey was sent to 263 students across study levels 1 to 3, and in 2025, to 128 students on study level 1. The survey was viewed 437 times, suggesting multiple access attempts. The response rate was 30.43%, with 119 responses from the 391 surveys sent out. In total, 101 students completed the survey, yielding an 84.87% completion rate.

3.1.1 Data overview

The quantitative data includes demographics (age, gender), self-reported familiarity with 4IR and XR technologies, occurrence of XR technology use in the learning environment, self-rated knowledge and confidence in using XR tools. The qualitative data captured open-ended responses on perceived benefits and challenges of XR integration, recommendations to improve access, engagement and training, and views on the relevance of 4IR tools for industrial EE and careers.

3.1.2 Ethical considerations

Participation in the survey was voluntary. All respondents provided informed consent prior to completing the questionnaire. They were informed of the study's purpose and how their data would be used. Participants had the right to withdraw at any time without being penalised. The survey was designed to ensure anonymity, and confidentiality was retained throughout the research process. Ethical approval was obtained from the relevant institutional ethics committee, ensuring compliance with academic research standards (Ethical Clearance number IREC 226/23).

3.1.3 Data analysis

Data was collected using a survey managed through QuestionPro an online platform that supports both quantitative and qualitative data collection. The closed-ended survey responses were analysed by means of descriptive statistics, using frequencies and percentages, presented in bar charts and tables, to summarise lecturer and student responses. The open-ended survey responses of the students and the lecturers were analysed using a hybrid thematic approach. The survey included questions such as "Briefly describe what you understand by the term *Fourth Industrial Revolution (4IR)*" and "Do you believe there is a need for integration of 4IRT in industrial EE?" QuestionPro, used to administer the survey, provided built-in tools such as word clouds to help visualise recuring terms and identify thematic patterns. Additionally, the Advanced Data Analysis features in ChatGPT were used to detect semantic patterns across responses. The AI-generated themes were manually reviewed and refined by the researcher to ensure an accurate reflection of the student and lecturer perspectives in alignment with the research objectives.

Inferential analysis was not conducted as the study was exploratory, focusing on patterns, preparedness and perceptions of participants rather than testing statistical significance across groups.

4 RESULTS

The survey trends offer valuable insights into the level of engagement and response behaviours of lecturers and students. The lecturer survey achieved 100% response rate, indicating a willingness to engage in the study. The student survey was conducted in two phases. A combined response rate of 30.43% and completion rate of 84.87% indicates that most participants were motivated to complete the survey. Despite the difference in response rate between lecturers and students, the high student completion rate suggests a meaningful level of engagement, strengthening the reliability of the findings.

4.1 Student perceptions

4.1.1 Demographics overview

Students were asked to indicate their age and gender. The demographics provide context for interpreting the findings, as age may influence prior exposure to technology and gender balance reflects inclusivity within Industrial Engineering. Many respondents (89.7%) were in the age range 18-24 years, and the gender distribution was nearly balanced, with 56,2% male and 43,8% female participants, illustrated in figures 1(a) and 1(b). The age distribution of students (89.7% between 18–24 years) replicates a typical undergraduate cohort who are generally more open to emerging technologies through early exposure to digital tools. Prior studies linked these demographics to higher self-confidence in adopting interactive and immersive learning platforms such as AR/VR [6].The gender distribution among students (56.2% male, 43.8% female) gives a balanced representation of perspectives. Gender inclusivity is important, as previous research notes that differing engagement patterns between male and female students can influence perceptions of technology-enhanced learning[32].

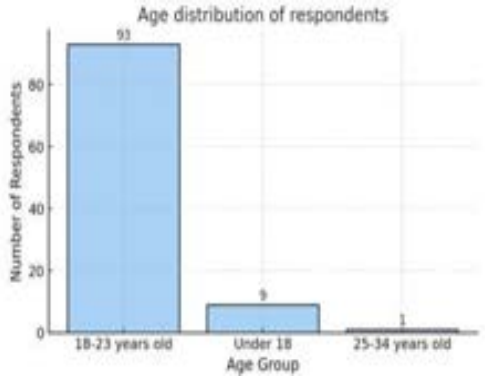

Figure 1(a): Age distribution of respondents

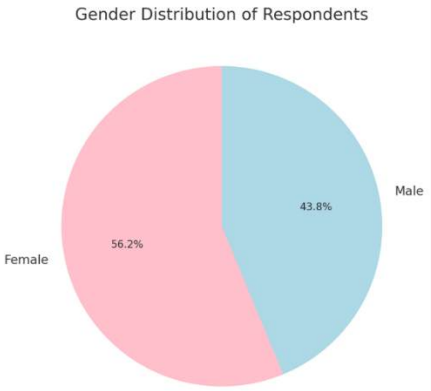

Figure 1(b): Gender distribution

4.1.2 Understanding vs. awareness: Gap in 4IR knowledge

In response to the question on how familiar the students are with the concept of 4IR, 82% reported familiarity with the concept. Only 41% rated their knowledge as “moderate”, indicating a gap between awareness and deeper understanding. Those who engaged with 4IR tools expressed optimism about the potential of enhancing learning, citing benefits such as improved engagement, better comprehension of industrial processes, and skills development. However, students lacking experience emphasised barriers like limited access to technology and infrastructure. Approximately 28% of students rated their familiarity “limited” or “very limited”. Figure 2(a) breaks down students’ familiarity with 4IR. Figure 2(b) indicates students’ knowledge levels.

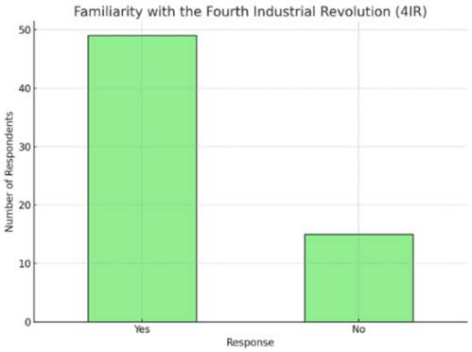

Figure 2(a): Self-rated knowledge

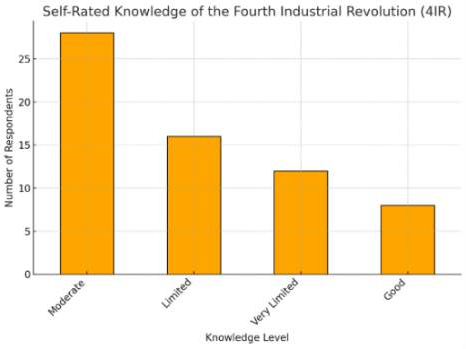

Figure 2(b): Students' self-rated knowledge of area of 4IR

It is evident that the students have a positive attitude towards using 4IR technology, based on a sentiment analysis conducted in QuestionPro (figures 3 and 4). Based on their responses, 37% of the respondents used 4IRT at some stage, 4% said they are uncertain, and 59% did not use any form of 4IRT. This low usage number could have been influenced by the modules students are currently registered for, as not all modules have incorporated 4IR yet.

Figure 3: Distribution of 4IR used by students

The sentiment analysis of students' views on integrating 4IRT into the education of IE (figure 4) reveals positive results, with an average score of 3.5 out of 5. Most of the respondents strongly agreed that such integration of 4IRT may bring greater productivity, innovation and preparedness for industry. This can be realised by enhancing the skills of students to align with modern competencies. The conditional advocates underline the cruciality of such development, but participants expressed concerns about implementation challenges, e.g., infrastructure, societal impacts and job displacement. Despite these concerns, consensus seemed to emerge that 4IRT integration into education is important to develop adaptable and future ready professionals, bridging resource gaps and minimizing potential negative effects to guarantee successful technology adoption.

Figure 4: Students believe if 4IR is needed in Education

4.2 Lecturer preparedness for 4IR technologies

This section explores how IE lecturers feel about using 4IRT to enhance EE. The results are divided in quantitative analysis (close-ended responses) and qualitative analysis (open-ended responses) to provide a deeper understanding of lecturer perspectives.

4.2.1 Teaching experience distribution

Shown in figure 5(a), 33% of lecturers have over 20 years of teaching experience, while the remaining have between 1 and 20 years. Figure 5(b) presents their self-rated knowledge of 4IR, with most reporting a "moderate" or "good" understanding despite not having received formal training. Fifty percent (50%) hold either a master's or doctoral degree.

Figure 5(a): Teaching experience

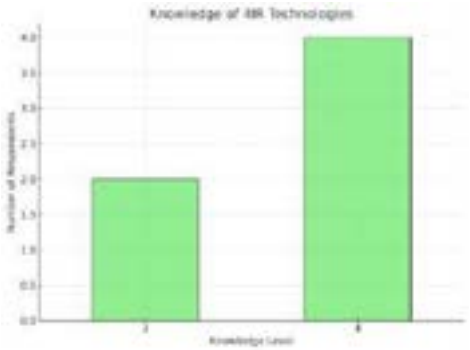

Figure 5(b): Lecturers' knowledge levels

4.2.2 Confidence in integrating 4IR technologies

In response to the survey questions about confidence using 4IR tools, the lecturers indicated "moderately confident" or "very confident" (figure 6(a)). When asked how often they use 4IRT in their teaching, most stated "occasionally" or "often" (figure 6(b)).

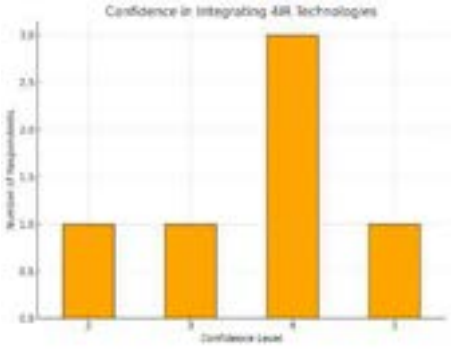

Figure 6(a): Confidence levels in using 4IRT

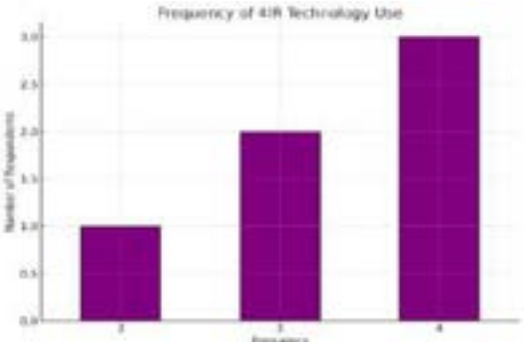

Figure 5(b): Frequency of 4IR integration in curriculum

Using an open-ended question, lecturers were asked whether they have experienced any improvement in student learning or interest after using 4IR tools. Three lecturers expressed positive sentiments, citing improved engagement and interest. Figure 7 reflects lecturers' overall sentiment towards using 4IRT in teaching.

Figure 7: Lecturer sentiment towards using 4IR technology in the curriculum

4.3 Themes identified

Five themes emerged through an AI-assisted analysis process conducted on the open-ended response data, reflecting student and lecturer perceptions on using 4IR in industrial EE. Each theme is supported by selected quotes to illustrate shared ideas and sentiments.

4.3.1 Improved learning

Students frequently emphasised how 4IRT, particularly immersive tools like XR, enhances engagement, skills acquisition and overall learning experiences. Many noted the innovative ways in which these technologies help to understand complex concepts. Responses included: "*Integrating 4IRT will improve learning outcomes and help students acquire industry-relevant skills*" and "*4IR tools like virtual reality can make learning more engaging and interactive*".

Lecturers echoed these sentiments, highlighting increased student engagement and improved learning outcomes because of incorporating 4IRT in teaching. Furthermore, second-year design students demonstrated improved design skills after completing 3D projects. Additionally, simulation tools were noted to deepen students' understanding of systems and processes. One lecturer commented on the strong interest students displayed in utilising 4IRT for their learning, further emphasising the potential to enhance engagement and comprehension.

4.3.2 Skills development and educational innovation

The potential of XR fostering new skillsets and sparking innovation was a recurring theme. Students appreciated how these technologies enable immediate feedback, facilitate energy efficiency and prepare them for advanced industrial environments. Responses included: "*4IR has really helped students/learners to get good education from the online learning platforms"* and *"It is important to include 4IR tools in industrial EE so that graduates can be equipped with the skills, knowledge, and mindset required to work in the continually evolving industrial landscape"*.

4.3.3 Technological advancement and industrial transformation

Respondents recognised 4IRT as a necessary requirement to stay updated with rapid technological developments vital for industrial transformation. Students linked XR adoption to improved efficiency, cost reduction and enhanced production capabilities. Responses included: "*Technology is improving every day, and integrating 4IR in education ensures students are ready for the future*" and "*Industries are massively investing in these advanced technologies to improve the functionality of the production process. So yes, it's very necessary to integrate 4IR into industrial engineering*".

4.3.4 Industry alignment and global competitiveness

Students highlighted the alignment of 4IRT with industry demands, emphasising the importance of preparing for the global industrial landscape. Many viewed XR as a bridge between academic theory and industrial practice, enabling graduates to meet global standards. Students responded as follows: "*Implementing 4IRT will establish a background for an evolving job market due to the increasing weight of automation and digitalisation on today's workforce*" and "*The 4IRT, including IoT, big data analytics, AI, and automation, are reshaping industries. Industrial engineers must understand and leverage these tools to optimise processes, enhance productivity, and drive innovation*".

4.3.5 Challenges and ethical concerns

Despite overwhelmingly positive sentiment, students expressed concerns about automation's social impact, particularly its potential to displace human labour. These apprehensions underscore the need for systematic evaluation and risk management. Responses included: *"I am not sure about integrating 4IRT because of the state of unemployment and the potential for automation to replace human labour"* and *"It will decrease job chances and increase unemployment because instead of a person, [they] use robots"*. While the concerns about job placements because of automation are valid[45], universities should balance automation with human-centric skills development.

5 DISCUSSION

There is strong alignment between literature and the participants' responses. Both students and lecturers acknowledged 4IRT's crucial link between theoretical learning and real-world industrial applications. From literature, it is evident that students and lecturers have mixed perceptions of using 4IRT in EE. While [28] highlights the impersonal nature of using AI and the possible reduction of lecturer attendance, lecturers acknowledged that using blockchain technologies improved classroom management. The systematic methodological approach followed in this study enhanced the ability to directly compare the findings with previous research, reinforcing the validity of the observed trends. While the primary focus of this study was not on contrasting smart machines with human values, the literature indicates that 4IR integration in engineering education should balance technological efficiency with human-centric considerations. Smart machines and automation can rationalise processes, improve accuracy, and enhance productivity; however, embedding human values such as ethics,

fairness, sustainability, and creativity ensures that technology adoption remains inclusive and socially responsible [49, 51].

Participants' responses to familiarity with 4IR reveals a gap between undertaking and deeper understanding. Students who engaged with 4IR tools cited benefits like improved engagement, increased comprehension of industrial processes and enhanced skills development. The students with limited experience reflected on barriers like restricted access to technology and infrastructure. Figures 2(a) and 2(b) illustrate survey responses corresponding with the study's key findings, reinforcing alignment between the data collection instrument and participants' experiences. The sentiment analysis in figures 3 and 4 indicates an overall positive attitude towards utilising 4IRT despite a low usage of these technologies.

Limited access to advanced tools and infrastructure, particularly in under-resourced educational institutions, may play a role in the high percentage of students not engaging with 4IR. In addition, there is a lack of awareness about 4IRT and applying 4IR in education and industry. Students may also face financial constraints, as some technologies, such as XR and IoT tools, often require significant investment in hardware or software. This limited engagement highlights the importance of integrating 4IRT into curricula to bridge the gap between academic preparation and industry requirements. By providing structured exposure to 4IRT through institutional support, subsidised access and targeted awareness campaigns, educational institutions can help students develop critical competencies and familiarity with emerging technologies. Participants who engaged with 4IRT during their studies found that using 4IRT enhanced their learning experiences and developed their skills. Some students however raised concerns about job displacement because of automation in industry.

The lecturer survey analysis shows all IE lecturers having a good understanding of 4IRT, but their familiarity with 4IRT varies. Fifty percent indicated familiarity with 4IRT, making use of it in their classrooms. Thirty-three percent had over 20 years of teaching experience (figures 5a and 5b), which could influence their adaptability and enthusiasm towards newer technologies. These positive perceptions align with the findings of [28] and [29] that the lecturers recognised the potential of 4IRT's positive impact on student learning and engagement. When asked about confidence in using 4IR tools, the lecturers were "moderately" or "very confident" (figure 6a) and indicated integrating these technologies/ tools "occasionally" or "often" in their teachings. The open-ended question on improvement of student learning had a positive response (figure 7). This segmentation, directly link to the survey questions, enhances the reliability of the findings.

6 THEMATIC INSIGHTS

AI-assisted thematic analysis of the open-ended responses, validated through manual review, revealed several key themes, reflecting both student and lecturer perspectives.

6.1 Improved learning

Students frequently noted that 4IRT, particularly immersive tools such as XR, can enhance student engagements and help facilitates learning. Students responded as follows: *"I integrated 4IRT will improve learning outcomes and help students acquiring industry relevant skills"* and *"4IR tools like virtual reality can make learning more engaging and interactive"*. The lecturers also observed improvements in designing skills and the comprehension of complex systems through simulation-based learning. [37]and [35] found that the students in their studies felt using XR technologies improved their learning outcomes and engagement with the study material. Concerns highlighted included data protection and the high cost of the software and hardware being used.

6.2 Skills development and educational innovation

A recuring theme was the ability of XR fostering new skillsets and stimulating innovation. Students appreciate the immediate feedback and preparation provided for advanced industrial roles. The hybrid analytical approach confirmed consistency of these findings across responses.

6.3 Technological advancement and industrial transformation

Students and lecturers recognised the necessity of 4IRT being current and aligned with rapid technological developments. Students linked XR adoption to improvements in efficiency, cost reductions and enhanced production capabilities.

6.4 Industry alignment and global competitiveness

Students and lecturers emphasised 4IR tools' help with bridging the gap between academic theory and industrial practice, thereby preparing graduates for global market demands.

6.5 Challenges and ethical concerns

Despite the positive outlook, some students expressed concern about potential social impacts of automation, specifically job placement. A responded stated the following: *"I am not sure about integrating 4IRT because of the potential for automation to replace human labour".* This theme underlines the need to address ethical and practical challenges in adopting 4IRT.

7 RECOMMENDATIONS

To address challenges and take advantage of 4IRT, the following recommendations are made:

7.1 Professional development

CPD for lecturers is crucial in preparing them for 4IRT use in teaching. Tailored training programs focusing on tools like AR/VR and AI are highlighted in studies as effective methods to promote immersive learning[46], thereby emphasising the importance of workshops and training programs empowering educators to integrate 4IRT. Educators' technical capabilities are further enhanced through peer collaboration programs sharing innovative teaching strategies [47] and specialised certifications in emerging technologies like IoT and robotics[48].

7.2 Infrastructure investment

Investing in effective infrastructure for 4IRT is important. Institutions should prioritise creating AR/VR labs with advanced virtual reality devices, augmented reality controllers and other tools for immersive learning[49]. It is equally important to provide software platforms and licenses for educational simulations[50]. Hossain [47] highlights the need for robust technical support teams to assist in technology integration, while Grinshkun and Osipovskaya [51] emphasise upgrading network infrastructure to support high-performance applications and ensure uninterrupted, smooth learning experiences.

7.3 Strategy for balanced integration

The potential downsides of automation, especially job displacement, need to be addressed. Grinshkun and Osipovskaya [51]suggest integrating human-centric skills like creativity, problem-solving and emotional intelligence into curricula. Career counselling programs Ngomana [50] and proactive communication efforts can reassure students of the long-term relevance of these skills. The researchers in [52]encourage combining automation skills with teamwork, leadership, adaptability and negotiation attributes to enable students' success in roles that require strategic and creative thinking.

7.4 Proactive student engagement

Encouraging students to participate and become proactive in using 4IR initiatives is important. Partnerships with industry to offer real-world experiences like internships and capstone projects are critical[48]. Organising competitions and hackathons can further motivate students to solve real-world problems using 4IRT[52]. Participation in 4IR-focused clubs and activities, e.g., building prototypes for smart cities or developing AR/VR training tools, provides hands-on experience[49]. Recognising student achievements through awards and public showcases fosters confidence and creates a culture of innovation.[47]. In addition, blended learning modules can be considered as an effective way of relieving lecturers' concerns.

7.5 Recommendations based on thematic analysis

The thematic analysis revealed that infrastructure remains a critical barrier. Institutions should prioritise investments in robust technological infrastructure (highspeed internet, AR/VR labs and digital collaboration tools). To enhance lecturers' and students' proficiency in 4IR use, hands-on workshops, hackathons and project-based learning applications can be introduced. The analysis further revealed that many students are aware of 4IR, but practical use of these technologies is limited. Curricula should include mandatory modules on 4IR tools and relevant real-world applications. Another issue highlighted is the lack of collaborative learning environments. Establishing interdisciplinary programs and cross-departmental projects can foster a collaborative culture among students, preparing them for future team-based projects in industry. Concerns about job loss caused by 4IRT automatization were raised. Career counselling programs can raise students' awareness of human-centric skills, ensuring development competencies that complement rather than compete with automation. Furthermore, to maximise 4IR integration, targeted solutions that address blended learning models and institutional support are critical.

7.6 Blended learning and institutional support

Solutions bridging the gap between potential and implementation must be prioritised. Blended learning models arise as a promising method to relieve lecturer concerns. By integrating AI-driven automation with human-led interaction, lecturers can still retain their central role in promoting meaningful discussions, mentoring students and shaping the learning environment. AI can assist with managing everyday administrative tasks such as grading and attendance tracking, releasing lecturers to focus on higher-order teaching responsibilities. Professional development programs should focus on how these tools complement rather than replace their expertise. Workshops and hands-on training can help educators build confidence in using AI and IoT as resources that enhance, rather than diminish, their classroom presence.

Institutional support plays a key role in overcoming financial obstacles for students, e.g., subsidised access to XR tools, partnerships with technology providers, and creating open educational resources to make this advanced toolset more accessible. Clear and structured guidance on using these technologies effectively will ensure students and lecturers realise the full potential of 4IR [20, 34]. AR evokes better learning gains than VR and presents fewer technical and financial challenges [35]. Framing 4IRT beyond logistical solutions through advancing human connectedness and collaboration can address deeper apprehension about its place in education. For example, AI's capacity for personalised feedback can make interactions more rather than less meaningful. Addressing systemic issues and emphasising the practical benefits of enhanced engagement and improved readiness to the workforce are ways to make 4IRT integration achievable and transformative. With a balanced approach, educators will feel empowered, and students will be enabled to participate more in the learning process, thus allowing both parties to benefit from a technology-enhanced learning environment.

8 CONCLUSION

The study's results show a positive outlook towards using 4IRT in EE, with lecturers and students seeing the potential of 4IRT enhancing learning and aligning EE with industry needs. Challenges, including insufficient infrastructure, time management and fears of job displacement due to automation, need to be addressed. Investing in CPD for lecturers is important, equipping them with skills to use 4IR tools effectively. Investing in the necessary infrastructure is also important to support the technological shift. Balancing the introduction of automation with developing human skills can help minimise concerns about job displacement. As the landscape of education continues to evolve, proactive strategies and institutional investments in 4IR integrations will determine how effectively students and lecturers adapt. Future research should explore longitudinal impacts of 4IR adoption in EE.

CONTINUOUS IMPROVEMENT CULTURE ASSESSMENT USING THE 20 KEYS METHODOLOGY: FMCG FOOD MANUFACTURING

A.B. Jughoo[1*]

[1]Department of Industrial Engineering
University of Johannesburg, South Africa
Bhanujughoo9@gmail.com

ABSTRACT

In the fast-moving consumer goods (FMCG) sector, continuous improvement is critical for maintaining quality, cost efficiency, and lead times. This study evaluates the effectiveness of the 20 Keys methodology in an organisation that has applied it for 23 years. Despite its long-term implementation, only 26% of employees actively engage in continuous improvement, with an overall performance score of 1.89 out of 5, significantly below the 2.75 operational excellence benchmark. Key challenges include cultural misalignment and a tendency to revert to old habits post-implementation. The study focuses on Key 2 (Goal Alignment) and 10 (Workplace Discipline), identifying gaps in leadership commitment (2.05) and communication (2.16), alongside moderate strategic alignment (2.67) and employee engagement (2.78). Recommendations include enhancing leadership visibility, structured performance appraisal systems, and employee involvement in workplace standards. This approach aims to elevate performance to a score of 2.5 for Keys 2 and 10, fostering a sustainable culture of continuous improvement.

Keywords: 20 Keys methodology, FMCG, Operational Excellence, Organisational Culture, Lean Manufacturing

1 INTRODUCTION

In the fast-moving consumer goods (FMCG) environment, there is always pressure around the need to deliver high-quality products, at the best cost within the shortest lead times. This is the reason behind adopting the 20 Keys methodology (20Ks) for continuous improvement. The methodology focuses on working better, faster, and cheaper but is also centred around building an energised workplace.

The organisation has used the methodology for 23 years, however, a recent cultural engagement survey showed that only 26% of employees understand and implement continuous improvement-related initiatives. Using the 20Ks guidelines, on a scale of 1 – 5, the organisation has scored an average of 1.89 for the last 3 years. The requirement for operational excellence is an average score of 2.75 for all departments within the organisation.

The main concern is that in many instances projects fail after implementation as employees tend to reset to old habits when a new challenge occurs instead of viewing it as an opportunity for improvement. Operational resources, such as machines, tools, facilities, supplier support, among others, are readily available, however, cultural misalignment plays a role in the inefficient and ineffective use of the resources. This project analyses and assesses the current culture towards continuous improvement and the underlying reasons that prevent the organisation from reaching the status of operational excellence.

1.1 Problem Statement

Over the past three years, an FMCG organisation has achieved a score of 1.89 on a scale of 1 to 5 regarding operational excellence, falling short of the desired 2.75. Cultural misalignment is evident with only 26% of engaged employees and limited commitment to continuous improvement initiatives. Despite access to top-tier operational resources, the organisation's pursuit of excellence remains out of reach, risking its competitive advantage and vision of becoming Africa's most cost-effective manufacturer.

1.2 Aim

This project aims to develop and implement a sustainable approach towards continuous improvement initiatives and improve employee engagement levels using Key 2 and 10 from the 20Ks.

1.3 Research Objectives

The research objectives are to:

- Analyse the current organisational culture and employee engagement levels in alignment with Keys 2 and 10, within the 20Ks
- Develop a structured framework for enhancing employee engagement and aligning the continuous improvement culture with the 20Ks
- Develop an implementation plan necessary to achieve a benchmark score of level 2.5 for Key 2 and Key 10 within the 20Ks

1.4 Significance of Research

The research focuses on developing a positive organisational culture that will support continuous improvement initiatives. Therefore, focusing on the social impact within an organisation and its influence on improvement project sustainability.

The key contributions will be to (1) Identify cultural challenges, (2) provide mitigation actions for challenges, (3) align with the organisational vision.

1.5 Scope of Work

The scope will be focused on the implementation and development of Key 2 and 10 which is focused on the employee cultural alignment of the organisation. The aim of improving productivity will be focused on the human factor in relation to the employee's engagement within the organisation and the effect of misalignment on project sustainability.

1.6 Limitations

The study examines operational performance and cultural dynamics within a single organisation, which may introduce bias. Its focus on cultural alignment excludes factors like market dynamics, investments, technology, and employee skills. Time constraints may limit deeper issue resolution, and the lack of an industry benchmark hinders comparison. Despite these limitations, precautions will be taken to minimize bias, ensuring the research lays a foundation for improving project sustainability.

2 LITERATURE REVIEW

2.1 What is the 20Ks?

The 20Ks was designed by Prof. Iwao Kobayashi who is considered as an expert in the field of Industrial Engineering focused on Continuous Improvement. The 20Ks can be adapted by any organisation to work better, faster, cheaper and building an energised workplace [1]. The principles, if implemented correctly, can help organisations increase productivity, reduce cost, and improve quality (Figure 1). However, the Keys are also focused on creating a culture of continuous improvement within the organisation. Each Key has a standard guideline which allows you to benchmark your organisation against world class practices.

The aim of the 20Ks is to assist organisations in identifying and eliminating wastes that affect the organisation's ability to provide high quality products at the right cost and within the stipulated lead times. Thus, giving light to the focus on improving Quality (Working Better), Cost (Working Cheaper) and delivery (Working Faster). The methodology is unique as it is centred around the focus of creating an energised workplace that creates a holistic approach to continuous improvement. The Keys are specifically focused on creating a foundation of a "Thinking Learning" workforce that is focused on continuously improving the organisations performance through the implementation of the 20Ks.

Figure 1: 20Ks Relationship.

2.2 Systematic approach to continuous improvement using the 20Ks.

The 20Ks was developed as a systematic approach towards continuous improvement. Each principle has measurable milestones that management can use for implementation. Prof. Iwao Kobayashi emphasised the role of managers for implementation. In a sense that, they are responsible to determine the room for improvement and the steps to take towards such improvement [2].

Therefore, the 20Ks Guidelines provides the systematic approach by: -

- Being based on the Plan–Do–Check–Act problem-solving cycle.
- Having a holistic view of the organisation and understanding the interrelations of factors. (Key 2 [1]).
- Developing a sustainable foundation to move forward in improvements.

The 20Ks also can be divided into 5 categories of improvement which is the basis of the programme and specific keys can be allocated accordingly (Figure 2). For the focus of this research to assess the workplace culture, Key 2 and 10 will be used as a baseline.

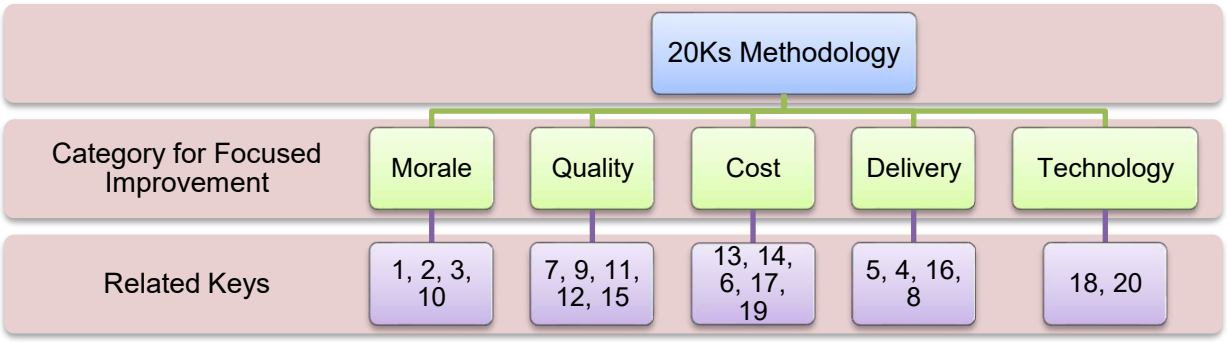

Figure 2: Keys Related to Category of Focused Improvement

2.3 What are the benefits of the 20Ks?

The 20Ks benchmarking standards help organisations improve productivity, reduce defects and costs, enhance employee skills and morale, and align teams toward operational excellence. The five-level framework allows organisations to assess their progress and set strategic goals. Departments can use the benchmarking to collaborate effectively, with a facilitator aiding implementation. Initial challenges may arise due to unfamiliarity with the program. However, the 20Ks approach is flexible, cost-effective, and accessible to all employees, making it suitable for any organisation, regardless of industry or financial position [3].Successful Implementation of the 20Ks.

Many organisations use the 20Ks to improve their businesses. Some of these organisations are based in Croatia, Egypt, South Africa, and Japan. Various industries have also adapted the 20Ks as the chosen continuous improvement strategy.

A case study conducted in Croatia by Erceg, showed that the organisation was able to decrease costs while increasing productivity by implementing the 20Ks. It is also highlighted that when the 20Ks were introduced, majority of the staff were reluctant to change as there had been previous attempts to improve that had failed. However, the 20Ks emphasis on management commitment and support allowed the team to develop and engage positively thus resulting in positive improvements [4].

The 20Ks is also not limited to the production environment, it can also be used within the service industry. As per Dabic's study conducted in Croatia, 18.75% of organisations studied operated in the service industry. The group of organisations studied showed an increase in

profit margins by 3.3%, employment growth of 14.1% and annual productivity growth of 6.9% that was achieved through the structured implementation of the 20Ks over a period of 4 years. This was also an indication of strong sustainable results achieved by using the program. The key point also revolved around the importance of employee understanding and employer support around the 20Ks to ensure effective and sustainable results [5].

2.4 Culture Alignment and Continuous Improvement

At the centre of the 20Ks relationship diagram (Figure 1), is an "Energised Workplace" which highlights that the methodology is centred around creating a culture of continuous improvement and ensuring energised employees [3].

Employee engagement plays a role in continuous improvement, especially for project sustainability. Every organisation consists of a human resource department that is responsible for employee relations and to some extent employee satisfaction. The research conducted by Rode showed that human resource practices have a direct effect on continuous improvement initiatives [6].

Erceg investigated the use of the 20Ks and its effectiveness for implementation within today's Global Market as the methodology was developed in 1995 and a lot has changed since then [4]. The research confirmed that the systematic approach used with the 20Ks guidelines is effective and efficient and strongly linked to the systematic implementation following from level 0 to 5. With Level 1 being the most crucial point that addresses and guides the development of the organisation culture focused on alignment and training [7].

In reviewing the methodologies available for process improvements, there is a clear link between the need for culture alignment to ensure the sustainability of continuous improvement projects. The points of employee engagement and management leadership plays a strong role in continuous improvement [7].

3 METHODOLOGY

A quantitative research study approach has been chosen to conduct the case study. This method is a systematic, formal, and objective process to collect the necessary data required. A detailed survey focusing on key organisational culture indicators was used to collect data. This data will allow a descriptive, exploratory, and explanatory review of the organisational culture.

3.1 Study setting.

The organisation is based in South Africa and operates within the FMCG industry. The plant to be studied currently employs ±3000 people. The organisation has been using the 20Ks for 23 years as the selected continuous improvement methodology but has been unsuccessful in sustainable implementation.

3.2 Sampling methods

The organisation consists of +3000 employees across the various departments and organisational levels. A stratified random sampling technique was used to ensure representation from different departments, levels of hierarchy, and functional areas within the organization. Stratification was based on factors such as departmental affiliation, job role, tenure, and demographic characteristics to ensure diversity and representativeness in the sample.

4 ANALYSIS AND DISCUSSION OF RESULTS

The data analysis for this research focused on evaluating the organization's cultural readiness across five key categories: Leadership Commitment, Communication, Training & Development, Strategic Alignment and Employee Engagement using responses from a 5-point Likert scale

survey. The Likert scale data is treated as ordinal data, non-parametric statistical methods, including descriptive statistics such as median and mode, was used to assess central tendencies in each category. There was a total of 90 employees that participated in the survey, which consisted of specifically supervisory and management roles within the organisation. The employees were asked to answer the survey questions by rating their agreement to each statement ranging from "Strongly Disagree" to "Strongly Agree".

4.1 Data analysis

The tables and graphs provide a summary of the survey responses in relation to the 5 categories tested. To assess the overall data distribution for each category, the mean was calculated, along with the percentage distribution of responses (Table 1).

The internal consistency of the questionnaire was assessed using Cronbach's Alpha. The overall reliability of the scale was excellent, with a Cronbach's Alpha of 0.95734, indicating high reliability.

Table 1: Summary of Responses Related to Categories

Category	Strongly Disagree (SD)	Disagree (D)	Neutral (N)	Agree (A)	Strongly Agree (SA)	Mean
Leadership Commitment	40%	34%	13%	7%	6%	2.05
Communication	41%	27%	15%	8%	9%	2.16
Training & Development	25%	30%	21%	15%	9%	2.52
Strategic Alignment	19%	33%	23%	14%	12%	2.67
Employee Engagement	22%	29%	15%	19%	15%	2.78
Overall Survey Response	30%	31%	17%	12%	10%	2.44

The data is presented for both the lowest-rated results (Table 2) and the highest-rated results (Table 3) in the survey, enabling a focused analysis of the most relevant cultural gaps.

Table 2: Summary of Questions with Most Negative Responses

Category	Sub-Category	SD	D	N	A	SA	Mean
Communication	Employee Voice	57%	26%	9%	2%	6%	1.73
Leadership Commitment	Recognition & Praise	55%	32%	2%	3%	8%	1.78
Leadership Commitment	Feedback	50%	36%	6%	0%	8%	1.79
Communication	Organisational Environment	47%	32%	16%	2%	3%	1.83
Communication	Wellbeing & Resilience	52%	22%	19%	4%	3%	1.87

Table 3: Summary of Questions with Most Positive Responses

Category	Sub-Category	SD	D	N	A	SA	Mean
Employee Engagement	Willingness	13%	27%	23%	24%	13%	2.97
Training & Development	Resilience & Change Readiness	10%	21%	26%	27%	16%	3.14
Communication	Team Relations	11%	19%	29%	12%	29%	3.29
Employee Engagement	Commitment	10%	23%	14%	17%	36%	3.44
Strategic Alignment	Strategic Alignment	12%	16%	11%	37%	24%	3.46

In relation to the 20Ks benchmark framework, the overall mean of 2.43 indicates that the organisation is on a level 1.17 which is below the internal benchmark of 1.89 and the required standard of 2.5 for operational excellence.

4.2 Discussion of Results

The metrics for Keys 2 and 10 were used to develop the survey based on the requirements of level 2.5.

The results showed an overall mean of survey is 2.43 which is linked to the response of "Disagreement" towards each factor evaluated within the survey. This indicates that there is a need for improvement in the overall organisations culture toward continuous improvement. The overall mean established a baseline view to show that the level 2 requirements of Keys 2 and 10 are not met and, therefore, the organisational culture needs work to cultivate continuous improvement.

With a Cronbach's Alpha of 0.95734, the study demonstrated high reliability; however, this may suggest that the survey questions test multiple categories. Additionally, the mean of each criterion is skewed toward disagreement, complicating the identification of clear priority areas. To enhance the reliability and confidence of the results, it is recommended to conduct individual surveys for each category to better pinpoint key areas for improvement.

The overall results indicated that the organisation's employees are significantly dissatisfied with the culture of continuous improvement. The most negatively indicated categories of leadership commitment and communication indicate that the foundation implementation of the 20Ks needs attention. The basis of the benchmark score of 1.17 indicates that the organisation does not have the foundational factors in place to cultivate an operationally excellent organisation.

4.2.1 Leadership Commitment

The low mean score for this category indicates that there is a significant dissatisfaction from the survey sample. 74% of the participants disagreed with the statements posed. This is a clear indication that the participants felt that leadership is not committed to the goals of the organisation.

Key 2 is focused on goal alignment and leadership commitment, due to the low perception of commitment that may hinder the progress towards operational excellence. This may also be an indication of the participants' perception that leadership is disconnected from the overall organisation vision. There may also be a lack of leadership visibility and involvement that can negatively influence the overall organisational culture.

The results showed that 87% of participants indicated that they had only received feedback on performance less than once in the past year. 54% of participants indicated that they have

never received recognition or praise from their manager. This is an indication that there are no leadership communications. There are also no formal performance-based discussions in place which is a requirement for operational excellence as per the 20K guideline for Key 2.

4.2.2 Communication

41% of participants strongly disagreed and only 17% agreed with the statements that were focused on testing if communication within the organisation is effective. The mean score of the data is also low at 2.16. This is an indication of poor communication within the organisation. This directly impacts the achievement of goals within the organisation. If participants are not well informed it can lead to misalignment and a lack of understanding about the organisational strategy.

The survey also showed that 84% of participants indicated that their managers did not include them in decisions that impact them. This showed that participants feel disconnected from management and a gap in communication from when decisions are made to their execution. 73% of participants indicated that they believe that the organisation has not communicated openly and transparently with its employees. This aligns with the participants' indication that leadership commitment is lacking within the organisation. Despite this, 41% of participants feel that they can reach out to their extended teams for assistance if required. This showed that the teams work well together regardless of the lack of leadership commitment and communication.

4.2.3 Training and Development

The mean score of 2.5 indicates that the participants are not highly satisfied or dissatisfied. Even though 72% of participants are neither neutral nor dissatisfied, only 28% of the participants felt satisfied with the training and development opportunities within the organisation. This may also be related to the split between participants seeing value in the current initiatives provided and those who feel that there should be more opportunities provided.

68% of participants felt that they do not have sufficient opportunities to develop and use their skills within their roles. This is a concern as it leads to disengagement and a lack of continuous improvement initiative as employees are not utilising their strengths and investigating ways to develop personally that can also positively impact the organisations performance.

43% of participants had confidence that the team would be ready to accommodate changes in the future. This showed that the participants were confident in the team’s capability to adapt to change and develop within the organisation and align with requirements.

4.2.4 Strategic alignment

The mean score of 2.67 indicates that the participants are generally neutral but are leaning towards dissatisfaction concerning this category. However, 33% of participants agree or strongly agree that there is some level of alignment between their roles and the organisation’s goal. Even though there is an indication of alignment, the results still indicate that majority of participants are unclear or disconnected from the organisational strategy.

This may also be linked to the previous category of leadership commitment, and communication. As 61% of participants indicated that they understood the organisations strategy, therefore the gap may lie in the execution and communication of the strategy into day-to-day tasks. 80% of participants indicated that leadership has only communicated the organisational goals achieved once in the past year as opposed to every quarter recommended by the 20Ks.

The majority of participants (63%) indicate that they do not link their own strategic goals to the organisation’s goals. For operational excellence using Keys 2 and 10, it is required for

every employee Key Performance Indicator to be linked to the organisational strategy and goal to ensure alignment and achievement of such goals. This showed that the employees may understand the organisational strategy on a high level but have not developed the ability to link their tasks to its impact on achieving the organisations goals.

4.2.5 Employee Engagement

This category was rated best out of the 5 categories with a mean of 2.78. Although 66% of participants are disengaged or neutral, 45% of participants agree or strongly agree that they are engaged. This is a positive indication as it suggested that with improvement within the other 4 categories could result in additional improvement and will be received positively by the team.

Only 23% of employees felt appreciated within their roles and this may also be linked to the lack of leadership commitment and communication.

52 % of employees indicated that they believed in what the organisation stands for yet 55% of participants indicated that they feel like their ideas do not count within their roles. This can negatively impact the progress of continuous improvement as employees may be reluctant to engage or share ideas because of this.

5 SOLUTION DESIGN BASED ON RESULTS

Based on the gaps identified by the survey, a 3-phase action plan (Figure 3) is recommended to assist in the development of the culture required to cultivate continuous improvement. The plan is developed using the standard guidelines of Key 2 and 10, specifically focused on the requirements for Level 0 – 2.

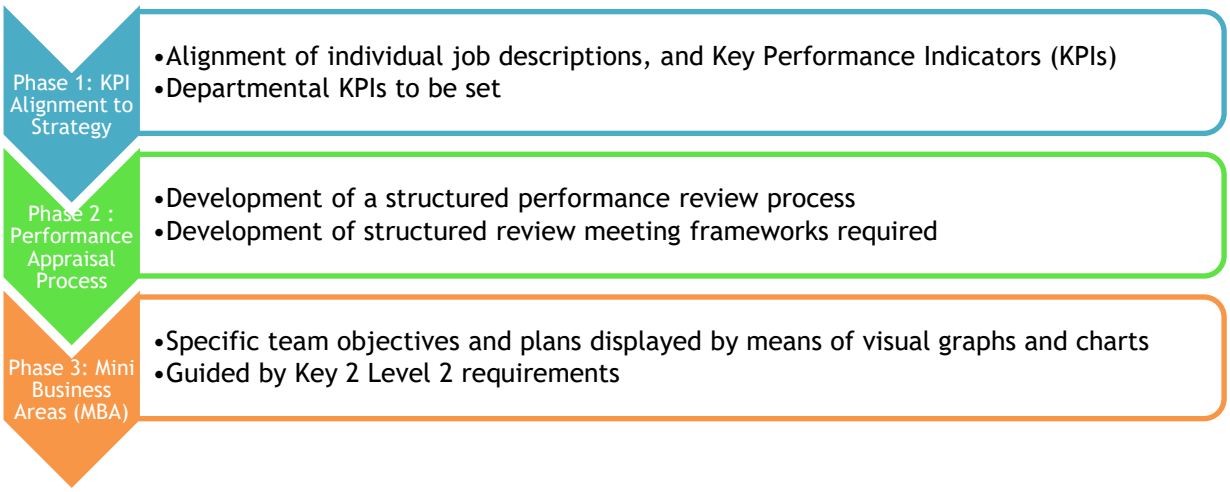

Figure 3: 3 Phase Implementation Plan

The 3 implementation phases reinforce the organisational hierarchy and facilitate the flow of goals from directors to individual employees (Figure 4). This structure ensures strategic alignment and highlights the importance of each role within the organization.

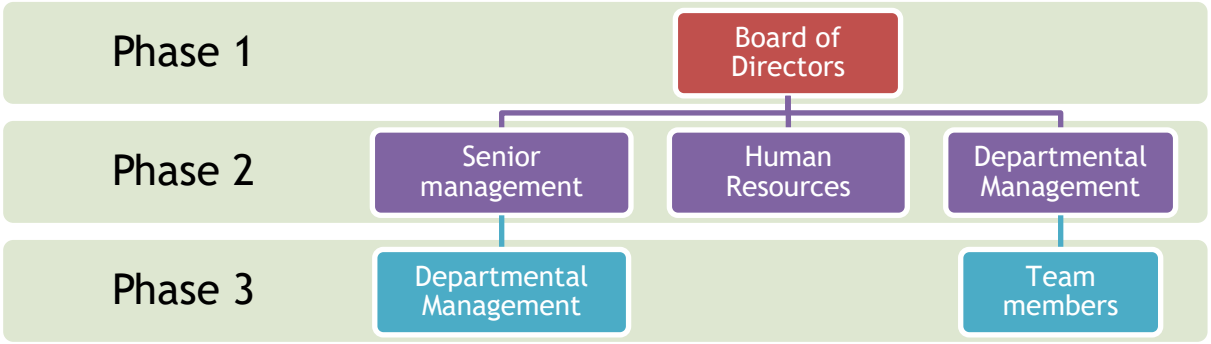

Figure 4: Key Decision Makers Per Phase

5.1.1 Phase 1: Key Performance Indicator Alignment

In this phase, the focus is to be placed on the overall organisational alignment to the strategic objectives and goals. This phase is focused on developing the strategic alignment, leadership commitment, and communication categories.

Within the organisation, the strategic and departmental goals are set, however, the gap lies with linking the strategic goals to departmental KPIs and the definition of individual deliverables. Therefore, the plan (Table 4) is focused on creating the links between individual and departmental KPIs to the organisational strategy that is defined by the Board of Directors.

The benefit of this phase is to ensure that employees understand how specific roles directly impact the overall strategy. This will give individuals clarity so that decisions can be made faster, and focus can be placed on value-adding activities. The alignment will also assist in optimising resource allocations and the adaptability of team members to change as the link between actions and strategy will be defined. The soft benefit of implementing the alignment is that individuals will have a sense of purpose and accountability for actions as they understand the impact of actions within the organisation.

For this phase, the Board of Directors (BoD), senior management (SM), departmental managers (DM), human resources (HR), and individual employees (EM) need to be involved in specific phases of implementation to ensure continuous communication and alignment.

Table 4: Phase 1 Overview Implementation Plan

No	Action Item	Responsible	Proposed Time Frame
1	**Definition of Organisational strategic goals**	**BoD**	**1 Month**
2	**Alignment of departmental KPIs**	**SM, DM**	1 Month
2,1	Draft of proposed KPIs per department	SM, DM	
2,2	Review with Department Leaders	SM, DM	
2,3	Finalisation of Team KPIs	EM, DM	
2,4	Roll out of Departmental KPIs within organisation	DM	
3	**Alignment of individual KPIs and Job descriptions**	**HR, DM**	2 - 3 Months (Depending on department size)
3,1	Draft of proposed KPIs	HR, DM	
3,2	Review of drafted KPIs with individual employees	EM, DM, HR	
3,3	Finalisation of individual KPIs	EM, DM, HR	
3,4	Roll out of Individual KPIs - Initiation of Phase 2	HR, DM	

5.1.2 Phase 2: Performance Appraisal Process

As per the survey results, the organisation has no formal or informal performance review process in place. Therefore phase 2 focuses on developing the necessary structure to develop and roll out a Performance Appraisal Program (PAP). The high-level steps required is detailed in Table 5. Critical communication platforms need to be included in the framework to support the team to meet deliverables and performing without communication blocks. The aim of the phase is to ensure that performance is periodically (monthly) monitored and reviewed within the organisation to ensure overall business success in alignment with the strategy.

This phase will also support development of all five categories evaluated by the survey by ensuring communication platforms, performance development opportunities, feedback loops, and strategic alignment. The formal PAP will allow employees and management to voice concerns and resolve conflict or mediocre performance strategically. Overall performance within the organisation will be improved.

The challenges that could be faced will be related to a resistance to change and misalignment to organisational goals. therefore, it is critical to ensure that phase 1 is implemented correctly. It is also necessary to ensure that all stakeholders are informed of changes and potentially allowed to contribute to development so that the culture of improvement can be initiated from the foundational phases.

Table 5: Phase 2 Overview Implementation Plan

No	Action Item	Responsible	Proposed Time Frame
1	**Industry Benchmarking**	**SM, HR**	1 Month
2	**System Design**	**SM, HR**	2 - 3 Months
2,1	Select the appraisal method based on benchmark	SM, HR	
2,2	Develop and document framework	SM, HR	

2,3	Design forms and tools to be used	SM, HR	
2,4	Create necessary training material	SM, HR	
3	**Pilot testing of system**	**DM, HR**	1 - 2 Months
3,1	Pilot Implementation	DM, HR	
3,2	Evaluation and review of pilot test	DM, HR	
4	**PAP Roll out and implementation**	**SM, DM, HR**	**2 - 3 Months**
5	**Post implementation review**	**HR**	**6 Months Post roll out**

5.1.3 Phase 3: Mini Business Areas (MBA)

The concept of an MBA is for each department to treat its departmental function like a business. In the sense that they focus on key deliverables that will make their "mini business" profitable. This is a concept detailed within the Key 2 guidelines of the 20Ks.

Phase 3 focuses on developing these MBAs by visualising the KPIs developed in Phase 1 and tracking the performance of the team to support Phase 2. These visual management charts can be used to enhance communication, increase transparency, and improve overall performance management by displaying Key team KPIs, opportunities for the continuous improvement project, tracking project progress, and other critical data in a way that is easily understood throughout the organisation (Figure 5). The aim will also be to display time real-time data simply to improve focus areas and quicker decision-making.

Data inaccuracy and resistance to change may be a challenge to be mitigated. Training can be developed to ensure teams are aligned with the goal of the MBA. The guidelines for the development and implementation of an MBA are structured and detailed within the 20Ks program.

Figure 5: Sample of a Mini Business Area at the Logistics Department

6 CONCLUSION AND RECOMMENDATIONS

The 20Ks score of 1.17 revealed by the survey analysis supports the fact that the foundational implementation of the 20Ks has not been completed.

The organisations framework needs to align with the 20Ks in the following ways:

- Key 2: Focus should be placed on leadership visibility and communication. Developing a structured performance appraisal framework will help align individual KPIs with

strategic goals and enhance top-down and bottom-up alignment through development discussions.

- Key 10: The desired workplace standards and culture should be clearly communicated to employees, with their involvement encouraged in shaping a culture of continuous improvement. Positive leadership-employee engagement will foster discipline, while structured development discussions provide a clear platform for communication and workplace discipline management.

It is also recommended that an internal communication strategy be developed to define the rules of engagement within the organization to promote open communication. Transparency should also be practiced by developing Mini Business Areas as recommended by the Key 2 guidelines. This will allow the team to visualize and track the progress of team KPIs and potential continuous improvement opportunities.

The key starting point for implementation is to develop the alignment between individual job descriptions and the strategic alignment. This will lead to the development of:

- Leadership commitment through ensuring structured interactions and accountability for performance discussions with the team.
- Communication with opportunities for employees to engage with the management team and vice versa through multilevel meetings.
- Training and development as performance-based discussions can lead to the identification of skills gaps and opportunities to upskill the teams. This will also aid in the development of a skills matrix for all departments.
- Goal alignment within the organization with each employee understanding their value within the organisation and a holistic picture of the organisation's direction.
- The employee engagement levels will also improve as the team will have a sense of belonging within the organization through the above actions. This will also aid in building a continuous culture as communication channels, team relations, and organizational direction are clearly defined through the development.

It is also recommended that further investigations be completed to test the organisation readiness against the 20Ks Level 1 requirements as to identify the key gaps that need to be closed to build the foundation of continuous improvement that will support the organizational goal of operational excellence.

In conclusion, the research has provided significant direction concerning the gaps within the organisation that are hindering the development and successful implementation of continuous improvement culture using the 20Ks.

ABSTRACT

Armscor, South Africa's defence acquisition agency, provides systems engineering support for the Department of Defence. This study investigates requirements engineering processes at Armscor's Acquisition Organisation, then compares them with the processes of clients and contractors. A mixed-method was employed, and the results of a survey of 30 practitioners were combined with thematic analysis of qualitative inputs. The results show a strong implementation of requirements management tools across all groups, yet specific gaps remain in areas such as stakeholder involvement, iterative reviews, and specification clarity. Clients initiate requirements mostly internally; in contrast, Armscor and contractors attribute them to external stakeholders, which causes asymmetry in visibility and influence. Reviews are milestone-dominated and unresponsive to changes in operational requirements, causing cost and time overruns. The study emphasises that requirements engineering is better conducted with inclusivity, collaboration, and iterative procedures. Improving these processes may result in better project results and augment South Africa's defence acquisition capability.

Keywords: Systems Engineering, Requirement Specification, Acquisition Process, Requirement Management, Systems Life Cycle.

1 INTRODUCTION

According to the South African defence review, Armscor has to acquire defence equipment on behalf of the Department of Defence (DoD), which is its major client, and it is essential to have the necessary armaments to carry out this function as mandated by DoD [1]. The armaments may be acquired or adopted through a comprehensive System Engineering (SE) approach. SE processes are crucial for the Acquisition Organisation (AO) business, and more so from the integrative nature of the company between the client, contractor, and defence industries. These three role players have one common goal: to provide services to the DoD and ensure the success of their mission [1].

SE processes positively benefit the contracting model, referring to the strategies and structure of the contract between the service provider and Armscor, the AO. This contracting strategy may enable a cost-effective system that meets the functional and operational requirements within the given schedule [2]. This paper focuses on requirements management during the conceptual phase of a system's life cycle. The requirement can be defined as a statement that captures the objectives and purpose of the proposed system for the end-user, with which all stakeholders have a mutual agreement [3]. Requirement Engineering (RE) is the reconciliation approach to technical and social challenges [4]. Overlooking the RE process may lead to failures, challenges and consequent risks that may be costly and catastrophic [3].

To reduce project failure risk, capturing and documenting requirements is crucial [3]. Previous research suggests that the three role players in the defence sector apply SE processes [5]. However, the standard SE processes have not been adopted entirely. Therefore, the following gaps exist according to [6]:

- The requirement specification structures lack substantial SE content and often prescribe a solution.
- Interpreting the SE processes creates various understandings among the stakeholders.
- Even though SE practices guide organisations, there is a lack of common adoption of a requirement specification.
- Customised and integrated SE practices and processes are lacking.

This research evaluated the AO's RE (specification and management) processes and their interfaces to the client and contractors. It also reveals how effective the current processes have been and how they could be improved to be effective and efficient. The study further identified gaps that arise from integrating the processes and made recommendations to close the gaps. The outcomes will benefit the stakeholders in utilising standardised RE processes, which may positively impact the deliverables of their projects.

2 LITERATURE REVIEW

2.1 Systems Engineering

This paper uses the definition of SE as provided in the International Council on Systems Engineering (INCOSE) handbook [2]:

> *"An interdisciplinary approach and means to enable the realisation of successful systems. It focuses on defining customer needs and required functionality early in the development cycle, documenting requirements, and then proceeding with design synthesis and system validation while considering the complete problem."*

The definition of SE also depends on the business's application and nature. From this definition, the importance of customer needs or requirements is evident, as it forms part of the process. These are translated into the definition of the functional system. Furthermore, iterative methods are necessary to realise the final product [2]. A project to develop a new system needs to consider the following phases of a system's life cycle, as shown in Figure 1 [7]:

- **Conceptual Design Phase**: This initial phase draws inputs from the operational deficiencies and the technology opportunities. The outputs of this phase will then be the system's functional specification and defined system concept.
- **Engineering Development Phase**: The system concept is translated into a physical system design that meets the end-user requirements: schedule, cost, and operation. Once the formulation and definition of the system concept are realised, the outputs of the concept development stage are fed into this stage.
- **Post Development**: This stage uses engineering development phase outputs to produce the system and support the system's operational, deployment, and retirement stages.

On a high level, these three phases show the stages of a system life cycle and outline high-level activities that give input and outputs until the end, usually a functional system and/or operational and maintenance documents.

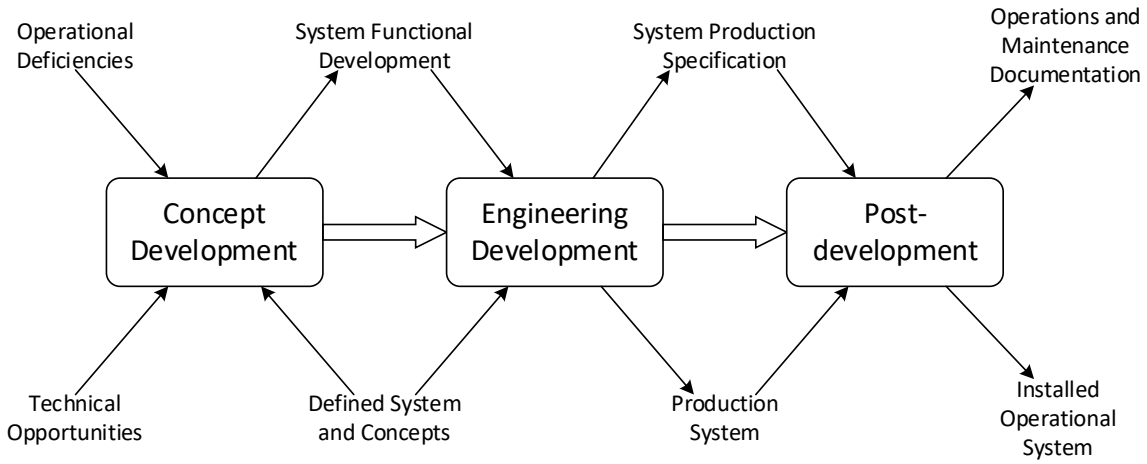

Figure 1: System Life Cycle Stages (adapted from [7])

Standard practice would first be for the client to identify a need or an opportunity. A demand-pull or technology-push method can determine the need or opportunity. Demand-pull opportunities stem from a need or a problem requiring a solution. Technology push, conversely, stems from the solution where the technology capability is combined with other systems to make a cohesive, complete system [8]. Hence, it can be stated that the SE method translates authorised operational demands and requirements into system-building elements suitable for operational use. It can aid in requirement management processes based on requirements or client needs. As a result, system life stages can be used to evaluate RE procedures.

2.2 Acquisition Organisation Management Documents

Management documents in the form of acquisition practices, standards, and policies guide programme managers (PM), SE, and other role-players within the AO. These Management Documents are tailored to close the gap identified as lacking in support of the SE processes as applied by the AO. The acquisition process, as mentioned, does not happen in isolation and has interfaces that link the stakeholders to the external processes, as shown in Figure 2 below.

The AO (Armscor) manages all projects through guidance from practices, standards, and policies. These are found in the organisation's management documentation system. The management documents have been tailored with extractions from some of the international standards mentioned above and customised to suit the organisational goals. These guiding documents are briefly explained in the following subsections. Two standards shall be evaluated according to what is practically being implemented to address the question of interest.

Documentation in the form of acquisition procedures, standards, and rules serves as a reference for PM, SEs, and other AO role-players.

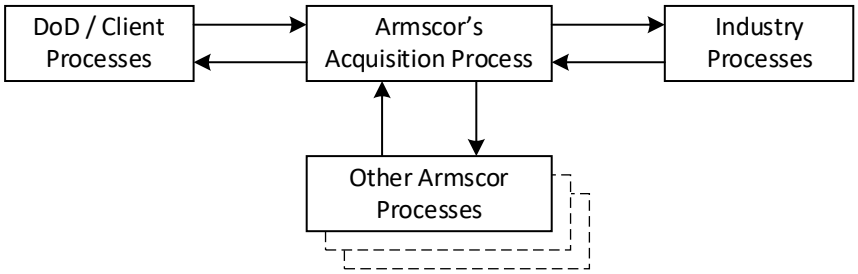

Figure 2: Acquisition Process Context Diagram (A-PRAC-1010)

The Acquisition and Practice (A-PRAC-1010) document was previously called the Systems Acquisition Management Practice (A-PRAC-1024), which, according to the previous analysis, did not address the SE standards of practice [9]. The international standard IEEE-15288 formed a basis for this newly developed A-PRAC-1010, consisting of four high-level processes, as seen in Figure 3.

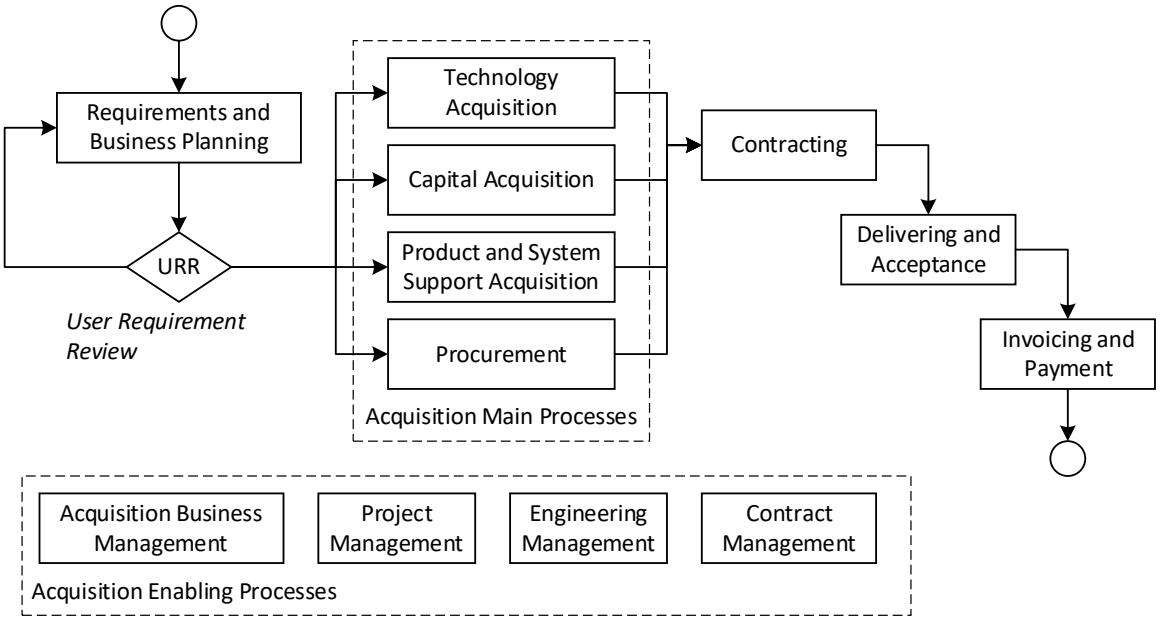

Figure 3: Acquisition Business Process Model (A-PRAC-1010)

The process of interest for this research is how to structure the requirement specifications under the Engineering Management enabling process. The process of acquiring the resources and the set of phases that make up the acquisition process, in which technology is developed and refined into workable concepts based on capital, product, and system acquisitions, is known as the Acquisition Main Process. The output is of primary interest as it is the input to the contractor's environment. The Acquisition Main Process, as shown in Figure 3, is described as follows:

- The Technology Acquisition Process applies to an upgraded or newly invented technology base established to be utilised to acquire equipment. These are referred to as Technology projects.
- The Capital Acquisition Process is applied for Capital Projects, which is translated from acquiring upgraded or new systems funded through a Department of Defence capital

budget. This process stipulates the phases that are applied in the capital acquisition of these projects.
- The Product and System Support Acquisition Process refers to material and services acquisition projects that complement and support existing operational capabilities.
- The Procurement Process aims to acquire already defined systems, support existing/new systems, and make them operational.

The Acquisition Enabling Processes are fed into the Acquisition Main Process (Figure 3), and the interest is in the requirement specification translated from the Engineering Management enabling process. Engineering Management, according to A-PRAC-1010, is aimed to:

- Define system requirements.
- Transform the requirements into an effective product.
- Allow for consistent reproduction of the product where necessary.
- Support the use of the product to facilitate the required services.
- Sustain the provision of services.
- Retire the product when it is no longer in use.

A Requirement Specification (RS) is a list of requirements that the equipment, design, product, or service must meet. The RS process specifies the impending system's network, hardware, software, and functional needs. The author seeks to underpin what standards are applied in implementing each project type and whether the RS processes are applied so that a custom or blanket approach is followed. Capital projects evaluate technology matured under Technology Projects during the Concept and Definition Phases. PSS and Procurement Projects support operational systems acquired under Capital Projects [10].

The Policy, Process and Procedure for the Acquisition of Armaments in the DoD (DAP-1000) is an addition to the A-PRAC-1010. It is a policy framework intended to govern the acquisition of armaments in the DOD and the Organisation. This document is a framework policy that outlines the various functions, interlinking them with the responsible roles. This policy document outlines the system's life cycle. The organisation also uses the RSA-MIL-STD-3 programme, which outlines the baseline requirements over a programme's lifecycle. The advantage of this Standard is that it serves as a guide to managing various baselines in the system development stage, reducing the programme risks. The risk management plan document created for each programme is used by the Department of Defence (DOD) acquisition environment to implement risk management for acquisition projects. A risk management strategy is required during certain acquisition phases, according to the RSA-MIL-STD-3 document. Lastly, the Standards for Technical Contract Condition (A-STD-61) stipulates the requirement for management of technical effort on contract execution. A-STD-61 formulates different sets of technical contract conditions that can be part of the Defence Acquisition Policy.

2.3 External Stakeholder Practices

Since the Acquisition Process does not happen in isolation, the client must know the Acquisition processes within Armscor and the Industry to a certain extent. This discussion aims to analyse the approach followed by the stakeholders to structure their requirements.

2.3.1 Defence Review Guiding Document

A defence review is a high-level document that the Minister of Defence drafts to ensure that the national defence needs are met [1]. This document is generated from a White Paper, a collective effort of all the units that fall under the defence. What stands out the most within this policy framework is that the defence review seeks to eliminate inefficiencies and minimise costs by ensuring the rationale of command and management principles. The concept has historically been frequently associated with considerable reductions to the armed forces and

their equipment programmes. It has come to be seen as little more than a justification for a policy of defence regression.

As stated in this policy framework, the expectation is for the acquisition process of armaments to be comprised of members from Armscor, SANDF, and the Defence Secretary to cope with the number of acquisition functions within the DoD. Therefore, a structured process of authorisation and decision-making is to be followed. Passing the responsibility to AO to make an acquisition translates to the need for risk management. However, the whole team is responsible for risk management and mitigation at the requirement phase and at each level of a system's life cycle where their roles are involved [11].

2.3.2 SEMBASE Model

The Systems Engineering Management Model, also called the SEMBASE model, is more formally structured for critical aspects of systems engineering management [12]. This model accommodates clients and direct stakeholders in the life cycle process design phase. The SEMBASE model addresses the interaction between the life cycle integration and the SE process [13]. The SEMBASE approach verifies requirements at the system level with the design and models at each development phase, and SE processes are applied concurrently to each life cycle phase. The concept model verifies and validates (V&V) the concept requirements. The SEMBASE provides a framework to analyse Armscor's standards application compared to the industry and will form the basis for comparing the findings with those of the client and the contractor [13].

Nyareli and Erasmus [14] bridged the defence industry gap relative to the SEMBASE Model. The SEMBASE model has been derived from the ISO/IEC 26702/IEEE Std 1220. This model emphasises the life cycle integration, which involves clients and stakeholders during the design phase [14]. Comparing the models used in the paper above may be relevant to this study. Here, the relationship of the defence industry SEM to those of the AO is investigated. The gap identified can be used to analyse the relationship between the three role players.

2.3.3 System Engineering Capability Model

The System Engineering Capability Model is promulgated from the EIA-731.1 standard and is intended to guide organisations in assessing the capability of application of SE processes [15]. The relevance of the model to this paper is that the stakeholders' involvement in all the stages of a system life cycle is shown in the early system requirement development activity [15]. The Vee model indicates the phases in the system life cycle using the defence industry as the project management model [16]. When formulating and analysing requirements, the client must share their knowledge. One of the driving forces of requirement statements is achieved through a collaborative process of acceptance and elimination of requirements [17].

2.4 Requirement Engineering Processes

The process for RE includes gathering, articulating, discussing, prioritising, defining, verifying, and maintaining system requirements, which is called requirement engineering. The specific, outlined criteria are the foundation for all future system development work. The organisation can achieve substantial financial benefits by preventing issues before the project's completion during the RE process. RE is typically considered a front-end activity in the creation of software systems. This is generally accurate. However, requirements frequently change during development and after a system has been in operation. As a result, RE is crucial to managing change in the software development process [18]. RE defines the following aspects of a project:

- Defining the constraints.
- Specifying the process involved.

- Documenting the process.
- Ensure that there is an improvement in the problems encountered.
- Identifies client's needs, leading to efficient decision-making.

Figure 4 below describes the requirements engineering process and outlines the relationship between stakeholders and the requirements. Another critical aspect is that the path derived from needs leads to requirements [4].

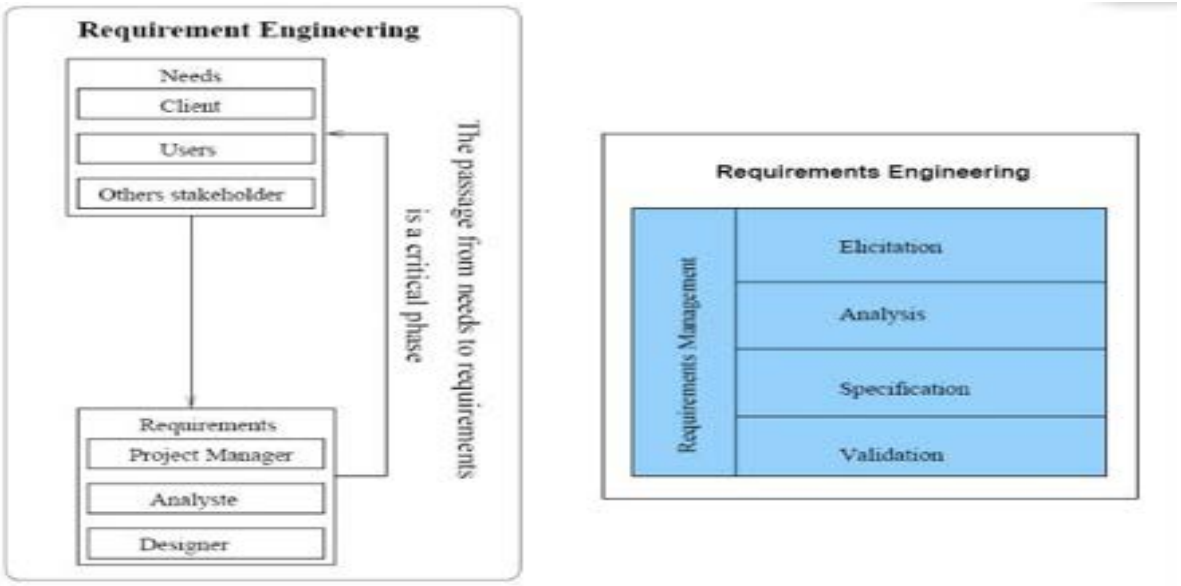

Figure 4: Requirements Engineering Process (adapted from [4])

According to Pandey and Pandey [19], several tasks, including requirements elicitation, requirements analysis, requirements negotiation, and requirements validation, are a part of the RE process. Identifying the needs for the proposed system is a process called requirements elicitation. Interpreting, analysing, modelling, and validating stakeholder information are all parts of elicitation. Problems are resolved, and agreement on requirement revisions is reached through requirements analysis. Every stakeholder has their requirements. Thus, those that address core functions should be given priority. Entity Relationship Diagrams, Data Flow Diagrams, State Transition Diagrams, Activity Diagrams, and Use-Case Diagrams are used in Requirements Documentation to show requirements at different levels of complexity. Once the issue is described, the various parties must confirm its nature through requirements validation and verification.

3 CONCEPTUAL FRAMEWORK

The AO has four enabling processes encapsulated within the Acquisition Process. The process of interest for this research is how to structure the requirement specifications under the engineering management enabling process. The process of acquiring the resources and the set of phases that make up the acquisition process, in which technology is developed and refined into workable concepts based on capital, product, and system acquisitions, is known as the Acquisition Main Process. The output is of paramount interest as it is the input to the contractor's environment. The aspects of interest to this study in the Acquisition Main Process, as shown in Figure 3, are described as follows:

- The Technology Projects are upgraded or newly invented technology bases established to be utilised to acquire equipment. The requirements and specifications of technology-type projects are typically produced via a collective setting based on inputs

from the client, the AO, and the contractor. This requirement type is called the Project definition.

- Capital Projects are translated from acquiring upgraded or new systems funded through a Department of Defence capital budget.
- Product and System Support Projects (PSS) refer to material and services acquisition projects that complement and support existing operational capabilities. An example of a PSS project is maintenance and after-sales support to an existing system.
- The Procurement Projects aim to acquire already defined systems, support existing/new systems, and are operational. These are usually the commercial off-the-shelf systems (COTS) or the military off-the-shelf systems (MOTS).

An A-SPEC is a tool to translate requirements specifications into complete system specifications during the concept phase of a life cycle. The conceptual framework outlined in this study provided a comprehensive understanding of the intricacies involved in requirement specifications of project management, particularly within the context of Engineering Management in the AO organisation. By delving into various types of requirement specifications, stages of the requirements management process, characteristics of good requirement specifications, and requirement specification management, this framework offers valuable insights into the foundation of successful project initiation and execution. Clear and precise requirement specifications are imperative for project success, serving as the blueprint for design, verification, and maintenance processes. The framework emphasises the importance of unambiguous, complete, correct, understandable, verifiable, consistent, achievable, and executable requirement specifications, ensuring alignment with project objectives and stakeholder needs.

In addition, delineating project types within the AO organisation elucidates the diverse contexts in which requirement specifications operate, ranging from technology projects to capital projects, product and system support projects, and procurement projects. Each project type necessitates tailored approaches to requirement specification management, underscoring the significance of flexibility and adaptability in project planning and execution. The conceptual framework provides a roadmap for stakeholders involved in project initiation, offering guidance on formulating robust requirement specifications that lay the groundwork for project success. By incorporating insights from literature, theoretical frameworks, and practical considerations, this framework is valuable for enhancing project management practices and driving organisational effectiveness within the AO and beyond.

4 RESEARCH METHOD

This study adopted a mixed-methods approach to evaluate Armscor's (AO) requirements specification and management processes and their interaction with clients and contractors. The design combined a quantitative survey of role players with qualitative follow-up analysis, ensuring both breadth and depth of insight into current practices and challenges. A comparative case study design was chosen, as the research objective required examining similarities and differences across the three stakeholder groups (AO, clients, and contractors).

4.1 Data Collection

The study population comprised professionals directly involved in acquisition and requirements processes:

- **AO**: project managers, systems engineers, and technical managers.
- **Client representatives**: project officers and systems managers.
- **Contractors**: system engineers, domain or research group leaders, and operations managers.

A total of 30 participants were surveyed, with distribution across groups as follows: AO (n = 13), Clients (n = 7), and Contractors (n = 10). This ensured representation of perspectives from all three primary stakeholders involved in the requirements lifecycle. Data were collected through a structured survey questionnaire and distributed electronically. The survey contained closed-ended questions (quantitative) and open-ended prompts (qualitative). Key focus areas included:

- Initiation and elicitation of requirements.
- Methods of requirements gathering and documentation.
- Tools and processes for tracking, reviewing, and updating specifications.
- Approaches to prioritisation, conflict resolution, and quality assurance.
- Challenges encountered in requirements specification.

Where applicable, the survey provided categorical options (e.g., documentation methods, review frequency) alongside opportunities for free-text responses to capture nuanced practices.

4.2 Data Analysis

Quantitative responses were tabulated and analysed descriptively, with frequency counts and percentages used to highlight trends across stakeholder groups. Comparative analysis was employed to identify points of alignment and divergence among AO, clients, and contractors (e.g., in methods of initiation, documentation, and review). Qualitative data from open-ended responses were examined using thematic analysis, grouping responses into categories to capture recurring patterns and challenges. This enabled richer insights into the contextual issues underlying quantitative trends, such as stakeholder involvement gaps and communication challenges.

To enhance validity, the questionnaire was aligned with established requirements engineering practices as described in prior literature (e.g., INCOSE standards and SEMBASE model). Triangulation was achieved by comparing perspectives across the three stakeholder groups, reducing bias from any source. Reliability was supported by the structured survey format and consistency in data coding during thematic analysis.

5 RESULTS AND ANALYSIS

5.1 Participants' Distribution

This section analyses the data obtained from the 30 survey participants. Most respondents, 43%, were from the AO, followed by 30% from Contractors and 26% from Clients.

5.2 Requirements Specification Process

5.2.1 Initiation of Requirements

Table 1 summarises how requirements are typically initiated in the projects across the AO, Client and Contractor groups. The results reveal some variances in the sourcing of requirements amongst stakeholders. All AOs and 70% of Contractors leverage external stakeholders to identify project requirements. This points to both these groups relying heavily on needs analysis from their outside ecosystem, including partners, vendors, technology firms and other entities. In contrast, only 1 out of 8 Client respondents named external stakeholders as project requirements initiators. It suggests that clients depend predominantly on internal sources to recognise new requirements aligned with their role in managing operational systems for end users.

Further evidence is seen in Client responses; all eight respondents stated that internal stakeholders help initiate requirements, with 50% naming technology capability as a driver. Clients, therefore, mainly identify needs by analysing current solution gaps or emerging

technologies that can address operational demands. On the other hand, no significant gaps exist between groups for internal stakeholder identification.

Table 1: How Requirements are Initiated

	AO (13)	Client (8)	Contractor (10)
Identified by external stakeholders	13	1	7
Identified by internal stakeholders	3	8	2
Technology capabilities	0	4	3

5.2.2 Requirement Gathering Methods

Table 2 presents the methods for gathering stakeholder requirements. Review of documentation was the most popular method used by all three groups overall. Prototyping was also a standard method. Observation and interviews were the least employed. Some participants also noted workshops, use cases, and the study of external vendor artefacts as other helpful methods for requirements gathering.

Table 2: Methods Used in Requirement Gathering

Variables	AO (13)	Client (7)	Contractor (10)	Total
Review of documentation	7	6	8	21
Interviews	2	4	1	7
Observation	2	1	2	5
Prototyping	5	3	5	13

5.2.3 Documentation and Tracking

Table 3 summarises how requirements are documented and tracked across textual documents, requirements management (RM) tools and project management software. Most respondents across the three groups indicated using RM tools (90%) and project software (90%) to manage specifications.

Table 3: How Requirements are Documented and Tracked

Variables	AO (13)	Client (7)	Contractor (10)	Total
Word documents	3	2	6	11
RM tools (e.g., DOORS)	13	8	6	27
Project management software	13	7	7	27

This points to the widespread adoption of systems built explicitly for requirements documentation. Word documents were still used by over one-third of participants, but were considerably lower compared to the dedicated tools. This indicates a need for flexibility where formal tools may be infeasible or unavailable. There should be standardisation in leveraging RM and project management tools for robust specifications tracking. Qualitative insights from some respondents also highlighted the use of Excel for tabulated tracing and architectural models for visualisation.

5.2.4 Review and Update Process

Figure 5 shows requirements review and update frequency across major milestones, continuous tracking and only when requested by stakeholders. The majority of AO participants (6 out of 13) indicated review as per stakeholder requests, while Clients (5 out of 8) and Contractors (4 out of 9) primarily performed updates at project milestones. However, no single approach stands out, reflecting variability in rigour for specifications' upkeep. Regular, extensive reviews are vital for optimising complex systems to meet evolving user, technology

and mission needs. The findings suggest opportunities across groups for more proactive, iterative evaluation compared to discrete milestone tracking.

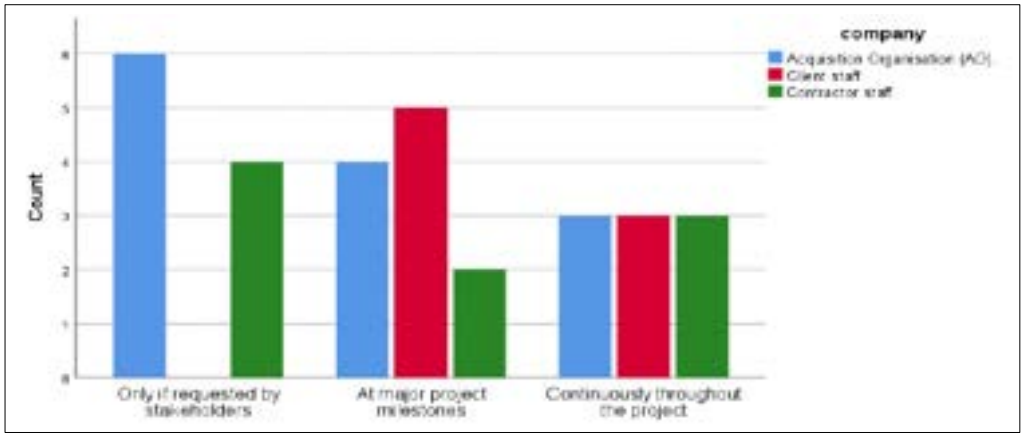

Figure 5: Requirements Reviewed and Updated after Initial Documentation

5.2.5 Prioritisation and Conflict Resolution

Table 4 shows how conflicts between stakeholder requirements are resolved. The most common approach indicated by 40% of respondents was prioritisation based on criticality, ensuring key user functionality is not compromised. 33% preferred negotiation and compromise amongst stakeholders, reflecting collaborative resolution. Only 13% of participants preferred deferring lower priority requirements instead of more decisive steps of elimination or negotiation. This allows less critical capabilities to be revisited later without entirely dropping them. Another 13% chose to eliminate requirements, causing conflicts altogether. This may reflect instances where needs significantly diverge and cannot be reconciled through other steps.

5.2.6 Quality Assessment

Table 5 lists the aspects utilised by the groups to assess the quality of requirements specifications in their projects. Key criteria evaluated by all participants include readability, traceability, completeness and testability of specifications. Alignment is needed in adopting fundamental quality checks, even if teams utilise different proprietary procedures or platforms.

5.2.7 Challenges Faced

Table 6 outlines the key challenges faced by the groups in developing robust requirements specifications compiled from the survey responses. The top challenge indicated by the majority was an incomplete understanding of client/stakeholder needs.

Table 4: How are Conflicts between Stakeholder Requirements Resolved

Responses	Frequency	Percent
Prioritisation based on criticality	12	40.0
Negotiation and compromise	10	33.3
Deferring lower-priority requirements	4	13.3
Elimination of requirements causing conflict	4	13.3
Total	**30**	**100.0**

Table 5: How Organisations Assess the Quality of Requirements Specifications

Variables	AO (13)	Client (7)	Contractor (10)	Total
Readability/clarity	13	8	9	30
Traceability	13	8	9	30
Consistency	9	7	9	25
Completeness	13	8	9	30
Testability	13	7	9	29

Table 6: Challenges Faced in Developing Requirements Specifications

Variables	AO (13)	Client (7)	Contractor (10)	Total
Incomplete understanding of client/stakeholder need	11	7	8	26
Lack of stakeholder involvement and sign-off	8	2	8	18
Insufficient details due to project deadlines	13	3	9	25
Poor communication among the project team	11	6	8	25
Unclear/ambiguous documentation	7	4	6	17

This is closely followed by insufficient specification details due to project deadlines and poor team communication, hampering requirements consensus. Contractors have relatively less autonomy and visibility while adhering to partners' specifications. However, broad challenges like comprehension of user needs, looming deadlines, miscommunication, etc., affect all groups. Participant comments also highlighted other issues, like technologically infeasible requirements and moving targets based on market trends.

5.3 Impacts of Requirements Specification

Table 7 shows the impact of unclear or misunderstood requirements specifications on project outcomes. 19 out of 30 respondents indicated major impacts, including significant delays and cost overruns.

Table 7: Impact of Unclear/Misunderstood Requirements Specifications on a Project

Responses	AO (13)	Client (7)	Contractor (10)	Total
Minor impact	0	0	2	2
Moderate Impact	5	2	2	9
Major Impact	8	6	5	19
Total	13	8	9	30

Table 8 summarises the practices adopted by groups for handling changes in requirements after the initial agreement. The most common techniques include careful requirements review, impact analysis and assessing schedule and cost implications. This highlights that a rigorous change review covers impact assessment and trade-off analysis. Respondents also pointed to negotiations in case of significant changes to establish new timelines and budget impact.

Table 8: Management Process for Changes to Requirements Specification

Responses	AO (13)	Client (7)	Contractor (10)	Total
Careful review and analysis of new/modified requirements	12	4	8	24
Assessment of schedule and budget impacts	9	8	8	25
Negotiation of new timelines and budgets	8	6	7	21
Reduction in project scope to accommodate change	4	1	2	7

5.4 Recommendations for Improvement

Drawing on the comparative analysis of specification processes and observed challenges, Table 9 consolidates suggested enhancements from survey participants across the three groups to elevate requirements engineering effectiveness based on the comparative analysis. The top recommendation chosen by 70% of respondents centred on increased involvement of all stakeholders throughout requirements processes from initial elicitations through change approvals. This indicates that inadequate visibility into user environments frequently undermines requirements fidelity today.

5.5 Discussion of Findings

The comparative analysis of requirements engineering processes amongst the AO, Client and Contractors offered valuable revelations on alignment areas but illuminated gaps needing abridgement [6]. This discussion connects the crucial findings to validate against prior academic work and practitioner perspectives from the field. This indicates recognition of the challenges highlighted in Laureani & Antony [20] regarding the risk of failure from inadequate requirements acquisition. The participatory, multi-modal elicitation aligns with system engineering principles, as Blanchard [10] emphasised, to gain holistic stakeholder inputs for converting to specifications.

Table 9: Management Process for Changes to Requirements Specification

Responses	AO (13)	Client (7)	Contractor (10)	Total
Increased involvement of all stakeholders	9	8	4	21
Better tools for managing and tracking	9	6	6	19
Develop templates for requirement types	10	6	6	22
Improve documentation processes	9	4	7	20
Increase reviews and updates of requirements	7	3	4	14
Enhance change management processes	2	5	3	10
Improve alignment with collaborating organisations	13	5	5	23

The widespread adoption of RM tools reflects the increasing alignment with international standards such as IEEE-15288, which informed the A-PRAC-1010 framework [2], [9]. This finding supports the literature's call for standardisation in AO practices while showing progress since earlier reports of inconsistent adoption. This endorses Armscor's transition from previous technical rigour gaps. Tool unification also facilitates the organisational maturity capability framework [16]. This limited contractor autonomy contrasts with the SEMBASE model, which stresses continuous involvement of all stakeholders throughout the lifecycle [13], [15]. The observed gap reinforces Nyareli & Erasmus's [14] finding that South African defence contractors operate with constrained visibility in requirements development. Integrating more comprehensive access protocols can prevent disjointed execution.

Armscor's challenge of transitioning specifications into complex integrated defence systems can likewise be gained through pilot-driven development. Tracing use case journeys early in prototyping stages reveals hidden, unviable gaps to capture solely via contract-driven specifications documentation. The emphasis on iterative, user-driven corrections aligns with collaborative elicitation approaches described by Konaté et al. [4], underscored by Joseph-Malherbe & Malherbe's [17] call for collaborative change management of requirements.

A glaring challenge raised by the majority was insufficient detailing attributable to project pressures. Trade-off conflicts then arise, as echoed by participant comments on balancing rework versus resources. Unreasonable deadlines suppress requirements, eventually slowing overall outcomes. Alignment is also impacted as changes require extensive negotiations

amongst groups. Project timelines must thus judiciously balance urgency and engineering necessities. While the discussion doesn't delve into some areas extensively, the recommendations from participants pave the way for advancing requirements excellence.

6 CONCLUSIONS AND RECOMMENDATIONS

This study evaluated the requirements engineering (RE) processes within Armscor's Acquisition Organisation (AO) and its interactions with clients and contractors. Applying a mixed-methods comparative case study revealed both areas of alignment and persistent gaps across the three stakeholder groups. While the widespread use of requirements management tools demonstrates progress towards standardisation and alignment with international frameworks such as IEEE-15288 and A-PRAC-1010, shortcomings remain in stakeholder integration, requirements detailing, and the predominance of milestone-driven reviews.

The value of this study lies in providing empirical evidence from the South African defence acquisition context, an area underrepresented in RE literature. It confirms that foundational practices are in place but highlights persistent challenges compromising effectiveness. By directly comparing perspectives from AO, clients, and contractors, the research offers a holistic picture of the requirements landscape, bridging a gap noted in prior studies that often focus on only one group of stakeholders. The findings carry direct implications for all three role players in the defence acquisition ecosystem:

- For Armscor's AO, the evidence underscores the need to strengthen continuous and iterative engagement with stakeholders, moving beyond ad-hoc or milestone-based reviews. Embedding iterative validation throughout the lifecycle would better reflect the evolving operational environment.
- For the Department of Defence as a client, the reliance on internally initiated requirements suggests a missed opportunity to integrate technology-driven and external stakeholder inputs. Broader engagement would ensure specifications remain responsive to emerging defence needs.
- For contractors, the reported lack of autonomy in requirements access highlights the necessity for earlier and more substantive involvement. Enabling contractors to participate meaningfully from the outset would reduce downstream misalignments and costly rework.

At a strategic level, improving requirements specification processes is not merely a technical adjustment but a pathway to enhancing mission readiness, cost efficiency, and timely project delivery. In a resource-constrained defence environment, refining RE practices translates into systems that better meet operational demands, minimise overruns, and strengthen the resilience of acquisition programmes. These improvements directly align with the intent of existing frameworks such as A-PRAC-1010 and SEMBASE, but also reveal where practice continues to diverge from their principles.

The study points to several avenues for further research. First, longitudinal analysis of acquisition projects would help establish how iterative improvements in RE processes affect project outcomes over time. Second, cross-national comparisons with other defence acquisition organisations would benchmark South Africa's progress against international best practice and identify transferable lessons. Finally, intervention-based studies that pilot collaborative and iterative approaches in live projects could provide practical pathways for embedding the study's recommendations.

In conclusion, the study demonstrates that while the South African defence acquisition system has made notable strides in adopting requirements management tools and frameworks, gaps in inclusivity, detailing, and iteration persist. Addressing these challenges requires a cultural and procedural shift that places stakeholder engagement, iterative review, and practical

alignment with operational contexts at the heart of requirements engineering. By doing so, the AO, clients, and contractors alike can contribute to acquisition processes that are more efficient, resilient, and ultimately more effective in delivering mission-critical systems.

POLITICAL INTERFERENCE AND ITS IMPACT ON HEALTHCARE INFRASTRUCTURE PROJECTS IN AFRICA: CONTEXTUAL INSIGHTS FROM GHANA

P.K. Agede[1], G.B. Fanta[2] and S. Grobbelaar[3]

[1,2,3]Department of Engineering and Technology Management,
University of Pretoria, South Africa

ABSTRACT

Political influence affects the execution and sustainability of healthcare infrastructure projects across Africa. Through the lens of principal-agent, cultural risk and institutional theories, this study examines the nature and impact of political interference on government healthcare infrastructure projects in Ghana. Project data on past and ongoing healthcare infrastructure projects was also analysed to help identify patterns of political intervention and project delays. The review found that political interference manifests through partisan prioritisation, manipulation of procurement processes and weaknesses in project governance impacted timelines, financing, quality and sustainability of projects. The review also identified the need for institutional project governance reforms as strategies to manage political interventions. Promoting openness in procurement, fiscal devolution, capacity building and use of project management tools were emphasised as recommendations to tackle this problem. Findings from the review provide relevant insights for developing a contextually relevant risk management framework for government healthcare infrastructure projects in Africa.

Keywords: Healthcare Infrastructure, Political Interference, Ghana

1 INTRODUCTION

The development and sustainability of healthcare infrastructure are fundamental to a robust health system [1], [2], [3] and are crucial for achieving Sustainable Development Goal 3 - Good Health and Well-being [4]. However, across Africa, public healthcare infrastructure projects face systemic challenges, including funding constraints, substandard quality and delays [5], [6], [7], thereby hindering the attainment of this goal. Despite the critical importance of healthcare infrastructure, the evidence observed points to political interference with project prioritisation, procurement, and overall execution, which plays a significant role in exacerbating these challenges [8], [9], [10].

Political interference can be described as actions by politicians or politically affiliated individuals pushing through their will on project decisions, side-stepping or overriding established project processes and administrative procedures [11]. In Ghana, as in many African countries, politicians make policies and decisions relating to public projects [12], [13], [14]. Their decisions shape key project management areas such as financing, scheduling, procurement and quality delivery, which in turn present risks that affect project outcomes [5], [8], [12], [15], [16]. Studies [8], [9], [12] have shown that these interferences significantly affect the effective execution and sustainability of government healthcare infrastructure projects across Africa. Some of the effects of political interference in these projects include project delays [17], [18], a wide design-reality gap [5], resource wastage [8], cost overruns [19], [20], institutional conflicts and project failure [9].

While this phenomenon of political interference is not unique to Ghana, the availability of project data, policies and a centralised project structure provides a compelling case study focus. Insights from this study are, however, transferable to other African countries having similar structures and challenges. This study was conducted to identify the nature of political interference, the consequences of these interferences, institutional and cultural factors moderating this phenomenon, and the strategies implemented to help mitigate these risks. These valuable insights will help in developing a comprehensive and effective risk management framework that will improve the outcomes of government healthcare infrastructure projects on the African continent.

This study also draws on the Principal-Agent Theory, Institutional Theory and Cultural Risk Theories to analyse the dynamics of political interference in healthcare infrastructure projects. The relationship between a party (the principal) that delegates authority to perform activities to another party (the agent) on their behalf [21], [22], [23], [24] can be beneficial or detrimental to projects [25], [26], while institutional structures and cultural risk perceptions may foster or hinder political risks in these project environments [27], [28], [29], [30]. Incorporating these theories helps to provide nuanced insights into how political interference arises and affects project outcomes.

A review of relevant literature is presented in the next section. A detailed explanation of the method used for the study follows this. The analysis of the scoping review is subsequently presented and discussed. Conclusions from the study are then made in the final section.

2 LITERATURE REVIEW

2.1 Healthcare Infrastructure Gap

Africa accounts for about 24% of the world's disease burden and contributes about half of the world's mortality due to communicable diseases [31]. It is projected that over 6000 new health facilities must be constructed to meet universal health care accessibility targets for Africa by 2030 [32]. Ghana, with over 60% of its healthcare facilities being government-run [33], is currently unable to meet the health needs in critical areas, including disease diagnosis [34], [35], surgical capacity, trauma care [35] and natal care [36]. This situation is attributed to

inadequate investments in healthcare infrastructure [35]. There is, therefore, a need to provide sustainable healthcare infrastructure [37], including physical buildings and structures, supply and waste management systems, medical devices, digital health systems and ancillary healthcare support systems [38] to help bridge this gap. However, Ghana has experienced many stalled projects in the healthcare infrastructure sector [37], [39].

2.1.1 Healthcare Infrastructure Project Structure in Ghana

The Ministry of Health is the state institution responsible for policy formulation and running the health system in Ghana [33]. The Infrastructure Directorate of the Ministry is in charge of initiating and overseeing health infrastructure projects [40]. The Ghana Health Service and Teaching Hospitals are agencies under the Ministry that run the health facilities [33], [41].

The legislation guiding the procurement of public goods and services, including health infrastructure in Ghana, is the Public Procurement Act, which was passed in 2003 and further amended in 2016 [42].

These structures have been established to ensure the efficient execution of health projects in the country. However, political considerations [41] have hampered the realisation of these ideals.

2.2 Political Interference in Healthcare Infrastructure

Politicians and politically affiliated persons are known to interfere with projects with acts such as influencing the selection of contractors and providers of goods and services [15], [16], [43], side-stepping cost-benefit analysis and impact assessment processes [10], by-passing project governance procedures [44], acts of corruption [9], [45] and even suspending projects [46]. Political commitment and competing interests largely influence the direction of public health policy in Africa [14]. Political interference with government projects in Ghana is usually carried out for the politician's gain or electoral advantage [15], [47]. These disruptions by politicians may not align with the project objectives and processes, thereby exposing projects to conflicts and causing undue delays [17].

Some classic cases of political interference in healthcare infrastructure projects in Ghana are the Ashanti Regional Hospital project in Sewua, which resulted in a tussle between the government and the project contractor [48] and the University of Ghana Medical Center project, where there was a conflict between the University and the Ministry of Health over the authority to manage the facility [49].

The political dynamics in Africa, typified by instability, corruption and governance challenges, distinctly impact healthcare systems [13], [50]. These dynamics make it important to develop context-specific strategies to mitigate political risks and enhance opportunities to ensure the successful delivery of healthcare infrastructure projects on the continent.

2.3 Effects of Political Cycles on Projects

Political cycles often influence infrastructure project development [51], [52]. In Africa, incumbents may prioritise projects for electoral gains, whereas government transitions risk altering project priorities, thereby undermining continuity and stalling essential healthcare infrastructure developments during and after election periods [51], [52]. In Ghana, a change in government presents a huge risk to projects commenced by the previous government. For example, the Fomena Hospital, Abetifi Hospital and Afari Military Hospital projects were all stalled once there was a change in government in 2017 [46]. There is, therefore, a need to understand the link between political cycles and projects and then develop project governance mechanisms to ensure the continuity and completion of critical healthcare infrastructure.

2.4 Contributing and Moderating Factors to Political Interference

2.4.1 Principal-Agent Theory

This theory explores the relationship between the politicians and the project executors. Principal-agent conflicts usually affect project scheduling [23], [26]. Conversely, a good principal-agent relationship may contribute to cost savings [23], better communication and collaboration [26] and meeting project schedules [25]. Dick-Sagoe [9] proposes that further research be conducted to investigate the role this relationship plays in contributing to project failure.

2.4.2 Institutional Theory

Institutional theory examines how institutional structures within organisations enable and shape political risks. It examines how rules, norms and practices at organisations promote or mitigate political interference [27], [28]. Institutional theory helps to understand the dynamics at public institutions that can be used to provide insights to help curb interference with these projects.

2.4.3 Cultural Risk Theory

Cultural perceptions of risk influence the management of political risks in the healthcare infrastructure space. Cultural Risk Theory examines the role cultural attitudes play in dictating how stakeholders identify, assess and respond to political interference [29], [30]. Such attitudes can amplify or downplay the likelihood of political interference in these projects. It is important to provide context-sensitive strategies that align with local dynamics to mitigate political interference.

3 METHODOLOGY

This research undertook a scoping review of the literature on political intervention in health infrastructure projects and an analysis of health infrastructure project data from the Ministry of Health in Ghana. Only journal and conference papers indexed in SCOPUS and Web of Science (WoS) were used for the review. The method used for this study was adopted from similar studies [9], [14], [15], [16], [17].

3.1 Scoping Review

A scoping review was conducted to compile and evaluate existing findings [53], [54], [55] on the nature of political interference, the effects of these interferences, institutional and cultural factors moderating this phenomenon, and the strategies implemented to help mitigate these risks. Given the limited academic literature on the subject in Ghana, relevant studies from other countries were included to enrich the insights and provide contexts applicable to Ghana and Africa. The review, relying on the PRISMA guideline, was conducted using the following procedure:

1. Search terms and phrases were used to find relevant literature. These terms and phrases included the following words: “political”, “politics”, “interference”, “influence”, “corruption”, “hospital”, “health facility”, “health infrastructure”, “health construction”, “ministry health”, “health department”, “health infrastructure project”, “public project”, “sustainability”, “project management”, “health governance”, “health policy”, “ehealth”, “health information system”, “digital health”, “project delay”, “procurement”, “failure”, “success”, “principal-agent”, “institutional structure”, “culture”, “Ghana”, “Africa”, “sub-Sahara”.
2. Search terms and phrases were used from 15th to 21st May, 2025.
3. The initial search resulted in 1214 papers – 917 from SCOPUS and 297 from WoS.

4. Duplicate papers were identified and removed.
5. The selection of papers for the review was based on the inclusion and exclusion criteria outlined in Table 1.
6. A review and screening to identify relevant papers for the study was conducted. A backwards and forward search was also carried out from relevant papers to identify other relevant studies not seen from the original search.
7. After screening and reviewing relevant papers, 28 papers were selected for the review.
8. A concept frequency cloud was developed using the ATLAS.ti (version 25) software tools to visualise the frequently identified concepts in the papers.
9. The ATLAS.ti software was also used to identify, group and evaluate theories and themes relevant to the study.

Table 1: Inclusion and exclusion criteria

Criterion	*Inclusion*	*Exclusion*
Project type	Public sector healthcare infrastructure projects, including public-private partnership projects	Sole private sector healthcare infrastructure projects or non-healthcare infrastructure projects
Study focus	Studies on political interference or project governance	Studies unrelated to political interference or project governance
Study period	All publication years	Not applicable
Study location	All publication locations	Not applicable
Publication type	Peer-reviewed literature	Unreviewed or grey literature
Language	English language publications	Non-english language publications

3.2 Project Data Analysis

A review of project data on government healthcare infrastructure in Ghana was conducted to complement the scoping review findings. The study accessed project data from the Ministry of Health in Ghana on the 23rd April, 2025. The data covers projects initiated from 2017 to 2024. This enabled the development of a regional distribution of projects, showing the areas prioritised by the government. The analysis of the documents captured the number of projects initiated and uncompleted, while linking them to political cycles. This provided empirical evidence on the effect of elections on healthcare infrastructure projects in Ghana.

4 RESULTS

This section presents the results from the scoping review and project data analysis.

4.1 Scoping Review

4.1.1 Publication Analysis

A total of 28 papers were included for the scoping review. The highest frequency of papers published was recorded in 2023, with 8 research papers. No publications were recorded for 2015, 2017 and 2019. No publications before 2014 were recorded for this study. The annual publication trend is shown in Figure 1. Some key journals where relevant papers for this study were published are listed in Table 2. Country-specific studies included in this review were

conducted in 13 different countries. 11 papers were included from Ghana, 2 from South Africa and Cameroon. Lesotho, Ethiopia, Kenya, Uganda, Nigeria, Libya, Brazil, India, Norway and the United States had 1 paper each. 3 studies were conducted in multiple countries.

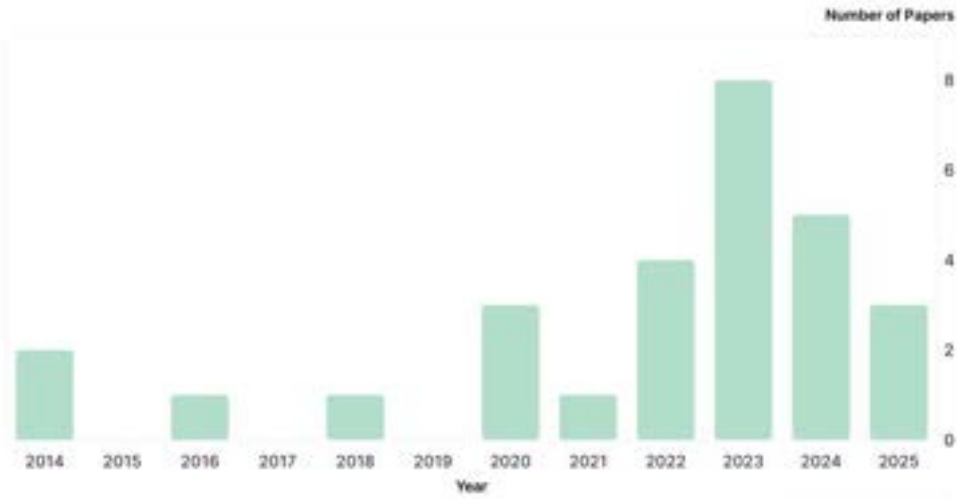

Figure 1: Annual publication trend

Table 2: Key journals

Title	*CiteScore*
Politics and Policy	2.5
Health Policy and Planning	6.0
Global Public Health	6.5
International Journal of Managing Projects in Business	7.0
JMIR Medical Informatics	7.9
Frontiers in Public Health	4.8
Health Research Policy and Systems	7.5
BMJ Open	4.4

Research studies included in the review used different research methods. These studies employed qualitative, quantitative and mixed-methods approaches. The summary of the research methods used and their frequency is presented in Table 3.

Table 3: Research methods used in studies

Method	*Number of Papers*	*Occurrences*
Systematic Literature Review	2	[33], [56]
Document Review/Analysis	8	[12], [57], [58], [59], [60], [61], [62], [63]
Interview	14	[41], [47], [60], [61], [64], [65], [66], [67], [68], [69], [70], [71], [72], [73]
Focus Group Discussion	2	[60], [72]
Survey	7	[9], [64], [66], [74], [75], [76], [77]
Model Testing	1	[78]

The concept frequency cloud, which was developed with ATLASti.25 software is presented in Figure 2. It illustrates that the papers included in the review focused on concepts relating to public health projects, which is relevant to the study.

Figure 2: Concept frequency cloud

4.1.2 Nature of Political Interference

Political interference in healthcare infrastructure manifests through a plethora of practices and conditions. The review identified the nature of political interference as presented in the various studies. These include politicised project prioritisation, changes in political leadership, procurement breaches, collusion and political appointments. These tend to undermine project planning, disrupt project continuity, endanger project quality, increase project costs and foster corruption. The areas and forms of political interference are grouped into thematic areas and presented in Table 4.

Table 4: Categorisation of Political Interference in Healthcare Infrastructure Projects

Theme	*Description*	*Occurrences*
Prioritisation and Policy Direction	Project priority, policy direction and decision-making based on political agenda.	[33], [41], [61], [62]
Political Transitions	Halted or abandoned projects after changes in political leadership.	[47], [65], [70]
Procurement	Undue influence over project procurement processes.	[47], [57], [59], [64], [74]
Collusion and Clientelism	Politicians collude with contractors and government officials for political or financial benefits through kickbacks, bribery and fraudulent payments.	[47], [74]
Misappropriation and Misallocation of Resources	Redirecting project funds for personal or political gains.	[61], [65]
Political Appointments	Favouritism in leadership appointments usually involves unqualified persons or persons with partisan affiliations.	[60]
Political Commitment	Lack of political leadership to ensure long-term health infrastructure development.	[56], [69], [74]
Technical Undermining	Disregarding or overriding technical recommendations, while prioritising personal or political gains.	[71]

General Corruption	Broad and unspecified references to corruption by politicians in the project cycle.	[63], [72], [78]

Focusing on Ghana, the Ministry of Health holds sole control over policy formulation and capital project execution, marginalising local managements, who lack real control over project budgets and execution [33]. Also, where there is no formalised prioritisation system, decision-making on projects becomes susceptible to political influence, as highlighted by Sandhu [61]. The absence of public participation in project selection and budgeting also creates room for projects to be inspired and championed solely by political considerations [47], [63]. These weaknesses in governance and accountability structures in the healthcare infrastructure system foster political interference.

4.1.3 Contributing and Moderating Factors to Political Interference

The scoping review encompassed papers that examined political interference in health systems through the lens of principal-agent theory, institutional theory or cultural risk theory. The review of the principal-agent problems is presented in Table 5. The results indicate a persistent misalignment in goals between political authority (the principal) and technical agents. It also indicates that political actors heavily influence project executors' autonomy in decision-making. This is as a result of the imbalance in power, poor oversight and a politicised resource allocation system. These conflicts are further exacerbated by conflicting authority structures and weak coordination channels.

Table 5: Principal-Agent factors to political interference

Theme	*Description*	*Occurrences*
Power Imbalance	Political leadership imposes their decisions or sidelines expert advice due to the disproportionate power it wields over project implementers.	[33], [41]
Communication and Coordination	Limited interaction between policymakers and the project implementers leads to mistrust and poor coordination.	[33]
Conflicting Authority and Roles	Overlapping mandates between political authority and technical agencies cause conflicts and inefficiencies.	[33]
Oversight Gaps	Agency oversight gaps, fostering manipulation of reports, costing and politicised contractor selection.	[64]

The review of papers that covered the moderating role institutional structure plays in fostering political interference is presented in Table 6. The results show that a rigid top-down hierarchical structure, unclear project roles at the local level, and inadequate project management capacity within institutions promote political interference in health systems. Additionally, the lack of continuity at local institutions hampers institutional memory and resilience, creating a conducive environment for political interference.

Table 6: Institutional factors to political interference

Theme	*Description*	*Occurrences*
Power Structure	The top-down hierarchical structure of the health system hinders lower-level discretion on decisions.	[41], [47]
Undefined Project Governance Roles	Undefined roles and weak institutional continuity at the local project level make projects vulnerable to political influence.	[33]
Technical and Financial Capacity	Weak project management capabilities reduce resistance to political influence.	[63], [69]

Cultural norms and practices play a moderating role in political interference in health projects. These cultural risk factors, which promote political interference, are summarised in Table 7. Cultural norms such as political and familial loyalty, along with deference to authority, fuel tolerance for political interference in project processes. Additionally, a lax public service discourages due diligence and whistleblowing, thus impeding objective project

governance. Furthermore, a culture that rewards political alignment over technical competence normalises political interference in projects. A system characterised by deep mistrust among technical authorities may lean towards political authority. A society exhibiting these features will be susceptible to political interference in public projects.

Table 7: Cultural risk factors to political interference

Theme	*Description*	*Occurrences*
Politicised Loyalty	Lack of objectivity and weakened professional conduct due to allegiance to and expectations of loyalty to the ruling party.	[47]
Distrust	Distrust among leadership in the health sector.	[33]
Deference to Authority	The cultural norm of deference to authority fosters political dominance over professional advice and practices.	[41], [66]
Public Work Ethics	The passive view of public work, low accountability and complacency promote interference.	[47], [66]

4.1.4 Impact of Political Interference

The review revealed the multidimensional impact that political interference has on healthcare projects. These impacts have been grouped into themes relating to key project management areas – schedule, quality, cost and procurement. There is an additional theme of state capture, which indicates the lasting effect of interference. These themes are presented in Table 8.

Table 8: Impact of political interference

Thematic Area	*Description*	*Occurrences*
Schedule Management and Project Disruptions	Poor planning, unmeritorious project schedule extensions and project abandonments.	[9], [74]
Project Quality	Substandard work, delivery of inferior goods and services, leading to unsustainable projects.	[74]
Financial and Cost Management	Overcommitment of state resources, misapplication of funds and inflated costs.	[9], [47], [64], [65], [74]
Procurement and Contracts	Biased tendering process, contracts being awarded to partisan affiliates, insider sub-contracting and bribery.	[64], [74]
State Capture	Weak project monitoring, bypassing regulations and collusion between political actors and officials.	[69], [74]

Financial and budgetary mismanagement significantly results from political interference. Politicians tend to start more projects than there are available funds for [47]. In other instances, funds are misdirected from ongoing projects to new, politically motivated projects [65]. This stems from the highly politicised procurement process in public projects [64], [74]. Contracts for public projects that are awarded based on affiliation with the ruling party tend to have severe effects on these projects [74]. These politicised procurements and contracts tend to lead to issues such as weak project monitoring and bypass of regulations, which culminate in compromised quality and delivery of substandard goods and services [9], [74]. These practices of interference also often lead to project schedule delays and even result in project abandonment in instances of change in political leadership [9], [74]. The challenge of collusion among political actors, technical persons and contractors compromises the sustainability of projects in public health systems. Ultimately, the interference by politicians reflects deep systemic challenges in health systems.

4.1.5 Mitigation Strategies

This review identified an array of strategies for mitigating the challenge of political interference in healthcare infrastructure projects. These recommendations and strategies have been clustered into the seven thematic areas in Table 9.

Governance and Institutional Reforms were widely emphasised as essential to combating the problem of political interference in the health projects. Recommendations, including creating independent institutions to oversee projects [47], enacting legislation to protect technocrats and separating political and administrative roles [66] were made. These recommendations are to ensure professionalism and independence in managing these projects. Additionally, assigning clear project roles and building the capacity of project executors [12], [70], [77] was identified as a mechanism for mitigating the influence of politicians in health projects. The literature advocated for the involvement of academics and experts in planning and executing projects [75]. It was also highlighted that empowering authorities and communities at the local level could help manage this problem. It was recommended that reducing the directive powers of centralised authorities, promoting the involvement of grassroots and actively promoting fiscal decentralisation [65], [78] can enhance project performance and accountability.

Table 9: Proposed mitigation strategies

Thematic Area	*Description*	*Occurrences*
Governance and Institutional Reforms	1. Establish independent institutions to oversee projects. 2. Develop legal frameworks for institutions that empower technical personnel and separate administrative power from political power in institutions.	[12], [33], [47], [60], [66], [70], [73]
Clear Project Roles and Capacity Building	1. Assign well-defined project roles to qualified persons. 2. Promote professional skills development and engage academic or professional institutions for technical support.	[47], [60], [65], [68], [70], [75], [77]
Financial Management	Ensure the availability and disbursement of funds before projects commence.	[47]
Local Ownership and Decentralisation	1. Promote fiscal and political devolution to local authorities and communities to enhance local project planning and implementation. 2. Centralised bodies should play advisory roles.	[47], [65], [73], [78]
Transparency and Accountability	1. Open and digitalised procurement systems that allow for stakeholder and public oversight. 2. Guaranteeing whistleblower protection	[63], [64], [67], [74]
National Development Plan and Policy	Alignment of projects to a national development plan instead of political manifesto promises or arbitrary plans.	[47], [56], [69]
Project Planning and Risk Management	Promote the use of project management and data gathering tools and processes such as cost-benefit analysis, feasibility studies, review workshops and risk management tools.	[12], [58], [61], [70], [75]
Public Engagement and Oversight	Promote the involvement of citizens, the media and civil society organisations in project processes.	[57], [68], [74]

Promoting a transparent and accountable procurement process also emerged as a strategy to manage the influence of politicians in health projects. Papers stressed the importance of a fair tendering process, public monitoring of the procurement process, protection of whistleblowers, and the use of digital procurement systems to help enhance trust and eliminate favouritism [64], [67], [74]. Studies also highlighted the need for establishing a national development plan and aligning health projects with this plan [47], [56]. These studies argue that projects should stem from a well-developed national plan rather than from political

manifestos and promises. This will ensure the continuity of projects which are geared towards a common nationalistic vision.

The review found studies that underscored the importance of using project management and data gathering tools to help eliminate the occurrence of political interference. These studies [58], [61], [70], [75] recommend the use of risk management tools, cost-benefit analysis, feasibility studies and review workshops to aid in an evidence-based decision-making process. Other papers advocated for the need to empower and involve the public in project processes [57], [68], [74]. They contend that citizen and civil society participation will promote accountability and help reduce the prevalence of interference by political actors in these projects.

Findings from this review form a strong foundation for developing a contextually relevant risk management framework that will strengthen the effective delivery and sustainability of health infrastructure projects while reducing the undue influence of politicians.

4.2 Project Data

4.2.1 State of Health Infrastructure Projects from 2017 to 2024

A total of eighty-six (86) projects were initiated by the government between 2017 to 2024. These included the construction and rehabilitation of health centres, district and regional hospitals. Also included were Community-based Health Planning and Services (CHPS) compounds and specialised health facilities. These projects were financed through government budget allocations, loans and grants from international partners. Contracts for executing these projects were awarded to either local or international contractors, with varying timelines.

Many of these projects faced implementation challenges, which led to a significant number (69.77%) remaining uncompleted. Table 10 shows that these projects were unable to meet their completion schedules, irrespective of their planned completion timelines. For example, 80.95% of projects scheduled for completion within one year remained uncompleted. This trend continued for projects scheduled for completion between four to five years and five to six years, where 77.14% and 75.00% non-completion rates were recorded, respectively. Projects scheduled to be completed between two to three years saw a 40.91% non-completion rate. However, all projects that were initiated without defined timelines remained uncompleted.

Table 10: Uncompleted projects based on planned completion timeline

Planned Completion (Years)	*Uncompleted Projects*	*Total Number of Projects*	*Percentage of Projects Uncompleted (%)*
0-1	17	21	80.95
2-3	9	22	40.91
4-5	27	35	77.14
5-6	3	4	75.00
No defined timeline	4	4	100.00

As reported in Table 11, this phenomenon of non-completion showed itself when categorising these health facility projects by their bed capacity. High-bed-capacity projects (201+ beds) recorded a 100% non-completion rate, whereas moderately low-bed-capacity projects (11-50 beds) recorded a 42.86% non-completion rate. Low-bed-capacity projects (0-10 beds) had an 81.82% non-completion rate. 51-200 bed-capacity projects recorded an 85.71% non-completion rate.

Table 11: Uncompleted projects based on bed capacity

Bed Capacity	*Uncompleted Projects*	*Total Number of Projects*	*Percentage of Projects Uncompleted (%)*
0-10	27	33	81.82
11-50	12	28	42.86
51-200	6	7	85.71
201+	5	5	100.00

4.2.2 Regional Distribution of Projects

The study examined the regional distribution of projects and generated a regional heat map, Figure 3, which shows the spatial location of the projects. The Ashanti, Greater Accra and Eastern regions had the highest concentration of projects. In contrast, regions such as Upper West, Savannah, Northern and Oti were heavily underrepresented. This uneven distribution of projects, prioritising regions of electoral strategic importance to the ruling government [79] and neglecting regions with a comparatively low access to healthcare infrastructure [80] aligns with the findings from the scoping review. Technical needs assessments [81] seem not to be the primary determinant of health infrastructure project siting, but rather political considerations.

Figure 3: Regional heat map of projects

4.2.3 Effect of Political Cycles on Projects

The study further analysed data based on political cycles. This was done to investigate the link between political electoral cycles and project initiation. As presented in Figure 4, 82.93% of projects that were initiated a year before elections (pre-election) remained uncompleted. A 76.00% non-completion rate was recorded for projects initiated during election years. Non-completion rates dropped significantly to 35.00% after election years (post-election). No

project was initiated during non-election years. This pattern suggests that healthcare infrastructure projects, despite their critical need, are used as a political tool.

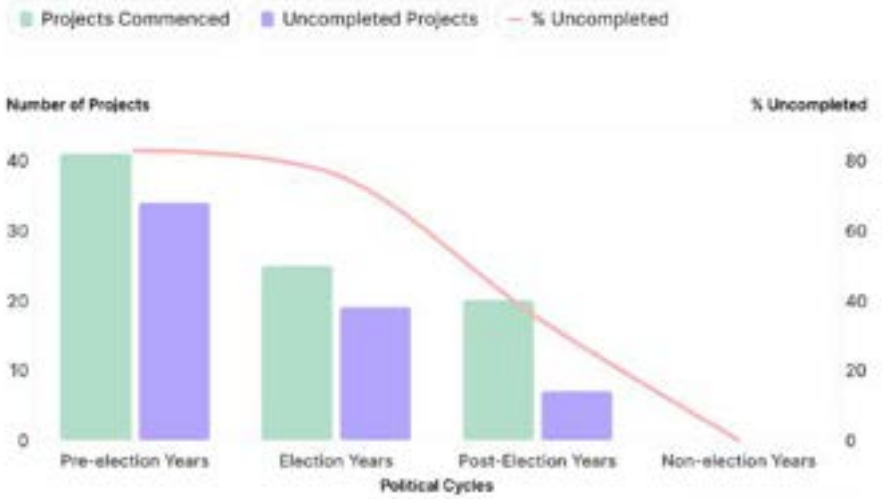

Figure 4: Distribution of projects initiated and uncompleted by political cycle

5 DISCUSSION

The scoping review identified the ways political actors interfere with public healthcare infrastructure projects. Interference is often carried out in project selection or prioritisation, contract awards and procurement selection, which leads to undesirable outcomes such as low-quality delivery, cost inflation, project delays and state capture of public projects. The review revealed that political interference typically occurs due to technical undermining, weak project governance structure, collusion between political actors and project stakeholders, and other forms of corruption. The review revealed that the enablers of political interference in health systems include power imbalances between political authorities and project implementers, weak institutional structures, and sociocultural attitudes prevalent in society. It is, therefore, essential to consider these enabling factors when developing effective solutions to this problem.

Focusing on Ghana, the health infrastructure project data analysis revealed that about 70% of projects initiated between 2017 and 2024 remained uncompleted. Official reasons for this high non-completion rate included delays in end-user training, delays in the supply of goods and services, project scope variations and land disputes. Other reasons included project relocation, project cancellations and reactivation, contract termination and government pause on project funding due to debt restructuring. Whereas factors such as natural disasters and COVID-19 may play a role in supply chain challenges [82], [83], [84] , these were not recorded as official causes for project non-completion.

The skewed distribution of projects seen in the regional project heat map developed from the project data affirms claims made in literature that it is political rather than technical considerations made when selecting and prioritising projects [71]. This confirms that political interference in these projects is deeply embedded in the project implementation process. The effect is a compromised health system with poor public health outcomes in underrepresented locations, which politicians deem less strategic.

Additionally, the analysis showed that projects typically commenced one year before (2019 and 2023) or during the year of a national election (2020 and 2024), whereas no healthcare infrastructure projects were initiated during non-election years (2018 and 2022). It can be argued that these projects were initiated as a political tool to garner

votes. Not surprisingly, projects initiated during political election periods recorded the highest rates of non-completion. This pattern, which aligns with findings from the scoping review, undermines the continuity and long-term sustainability of healthcare infrastructure in any health system, as elected governments may suspend, relocate or cancel projects [47], [65], [70].

The convergence of insights from the scoping review and project data thus provides triangulated evidence that political authorities interfere with healthcare infrastructure projects. Both sources identified the influence of political considerations in project implementation, specifically in the selection and siting of projects, as well as the use of projects as an electoral tool.

The scoping review identified useful strategies and recommendations that can help eliminate or reduce the occurrence of political interference in health projects. Key among them is separating political and administrative roles, developing open contracting systems, setting up independent bodies to oversee projects, encouraging public project involvement, fiscal devolution and utilising project management and data gathering tools. These measures are strongly believed to promote transparency and accountability and ensure evidence-based project decision-making devoid of the whims of political authority.

Insights from this review lay a strong foundation for developing an effective and relevant risk management framework tailored to the unique nature of the political environments in Africa.

6 CONCLUSION

This study examined the cause, moderating factors and mitigation strategies of political interference in public healthcare infrastructure projects. Relying on a scoping review and analysis of project data from Ghana, the study was able to identify that there is a systemic interference across the various stages of the project cycle. The procurement stage came out as the stage where political manipulation is most prevalent. It also emerged from the study that political cycles, cultural attitudes, and weak institutional structures play major roles in reinforcing this phenomenon.

The scoping review demonstrated the roles principal-agent theory, institutional theory and cultural risk theory play in driving political interference in these projects. It is, therefore, important to look at this subject matter through these lenses to provide holistic insights to tackle this problem. This study brought up meaningful strategies for tackling political interference in these critical projects. Separating politicians from administrative and project decisions, opening up the procurement process, as well as active citizen participation in projects, came out strongly as strategies to help mitigate the undue influence of political actors.

The limitation of this study was the unavailability of financial and contractor performance data, which could have enhanced the depth of the analysis. Another limitation was that publications made in only English-language texts were selected for the scoping review. This prevented the inclusion of useful insights from non-English publications.

Future studies should be widened to capture insights from more African countries to enhance the generalisability of findings. Studies incorporating project implementers, policymakers, end-users, public service workers and other relevant stakeholders will deepen the understanding and gather more useful mitigation insights. Further studies on developing and conducting empirical tests on a political risk management framework based on insights from this study may also be beneficial for improving healthcare infrastructure project delivery.

This study presents useful insights that can guide the development of a transparent and resilient project governance system to help mitigate political interference in health systems in Africa.

7 ACKNOWLEDGEMENT

The authors acknowledge the Infrastructure Department of the Ministry of Health, Ghana, for providing access to the project data utilised in this study.

A REVIEW OF STRATEGIC DRIFT: UNDERSTANDING THE CONTRIBUTING FACTORS AND RECOVERY EFFORTS

D. Mahadeo[1] and S. Grobbelaar[2*]

ABSTRACT

Strategic drift is a challenge organisations face when their strategy is misaligned with the external environment, leading to potential underperformance or failure. A systematic review of 54 research articles identified internal key factors: complacency, culture, decision-making, and misalignment, as well as external key factors, external environment, competition, politics, and economic pressures, which contribute to strategic drift. This scoping review aimed to analyse and synthesise the existing literature on strategic drift, focusing on understanding the primary internal and external factors and outlining how organisations attempt to recover from strategic drift through strategic realignment, management changes, innovation, and restructuring. The findings suggested that the external factors need to be understood, and the internal factors need to be aligned for recovery from strategic drift through proactive leadership, organisational flexibility and continuous innovation. Further research could include industry-specific factors and recovery strategies in a South African context.

Keywords: Strategic Drift, Strategic Management, Organisational Culture, Scoping Review

1 INTRODUCTION

Literature defines strategic drift or inertia in various ways; Laird [1] defined the term as a mismatch between the organisation's environment and strategy in 1988. Based on this initial definition, Bonnici [2] further explained that it is when an organisation's strategic responses fall behind in the ever-changing environment due to internal dynamics. While strategic drift is not a new topic in organisational theory, it is noteworthy that many organisations still experience it to their detriment [3]. Existing literature will be reviewed, which will aim to answer the following two questions:

1. What are the key internal and external factors which contribute to strategic drift?
2. How do organisations recover from strategic drift?

This review is particularly relevant in rapidly changing organisations and industries, where external factors significantly influence strategic decisions. There is limited literature applicable to the South African context and manufacturing. Therefore, this review will look at the global perspective. The findings will be used to identify gaps and further research topics within the South African context to assist organisations experiencing strategic drift.

2 REVIEW METHOD

2.1. Inclusion criteria

A scoping review was chosen to review the literature to identify knowledge gaps [4]. The inclusion criteria encompassed a broad spectrum of studies using the PCC (participants, concept and context) framework to capture a holistic view of strategic drift and recovery. The organisations that have experienced strategic drift were considered participants; the concept was the internal and external factors contributing to strategic drift, and the context was defined as organisations struggling to keep up with a changing environment. A specific time frame was excluded as the topic has, to date, remained unchanged in its foundational theory [5].

2.2. Search strategy and evidence selection

The scoping review was conducted according to the JBI methodology recommended by Aromataris et al. [6]. The electronic databases Scopus and Web of Science were chosen for the preliminary search. Scopus has the most extensive database, and Web of Science has a broad range of literature [7]. The search string: ("strategic drift" OR "strategy drift" OR "strategic misalignment" OR "strategic inertia" OR "strategy deviation") AND ("strategy") AND ("organisation" OR "organisation" OR "corporate" OR "industry" OR "company" OR "corporation" OR "firm") was used in the databases. This initial search yielded 595 documents in Scopus, to which the following conditions were applied:

1. Conceptual Focus
2. Applicable to the research questions
3. Peer-reviewed journal articles
4. Written in English
5. Available electronically

2.3. Data extraction

Based on the above conditions, 107 articles were available for review. The abstracts of these articles were exported in CSV format to Excel. The abstracts were further reviewed, and 54 remained, which were found to be relevant to the research questions. These articles were then downloaded and encoded into ATLAS.ti, a qualitative data analysis software capable of classifying, organising and analysing large quantities of data to obtain insights and relevant

information. ATLAS.ti facilitated the articles' systematic analysis, ensuring no pertinent information was overlooked.

2.4. Limitations

The original search parameter of not having a publication year constraint remained, as it was confirmed that literature from 1988 to 2024 was relevant to the topic. However, more recent articles were focused on capturing the relevant developments and findings. The review did not consider any articles that were not written in English to ensure consistency in the analysis and data interpretation. Only published articles and textbooks available to the public were considered, not pending, confidential or unpublished works.

2.5. Publication Sources

Figure 1 depicts that the UK published the most articles (17) about strategic drift compared to the other 21 countries. Articles from various regions were reviewed to have a holistic view of the topic and to ensure that the research would be relevant to stakeholders, regardless of location.

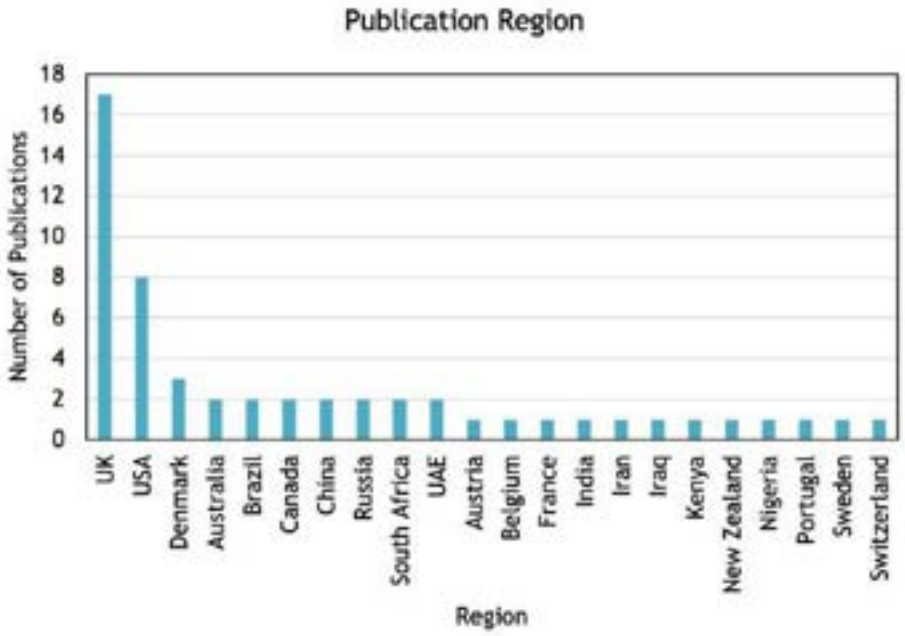

Figure 1: Graphic depicting the regions from which the reviewed articles were published.

From the reviewed articles, 42 mentioned internal factors, and 32 mentioned external factors which affect strategic drift. Many articles mentioned internal and external factors, which often influence each other.

3 RESULTS

3.1. Internal Factors

Internal factors are the contributing elements within an organisation that influence its strategic drift, as they hinder the organisation's ability to recognise or respond to changes in the internal environment [8]. As can be seen in Figure 2, there are a few internal factors which were identified as contributors to strategic drift. It was noted that these factors often overlap

and are interrelated. The findings of all internal factors are summarised in Table 1, and key internal factors are discussed below.

3.2. Complacency

Organisations and leaders become complacent due to successes in the past, which leads to failure in recognising and adapting to the changes that occur in the external environment [9]. The external environment moves rapidly for most industries where innovation is a central focus. Being complacent in this environment is detrimental to organisations as they resist change due to deeply ingrained practices and routines used during organisational success [3]. This is often referred to as organisational inertia [3]. Complacent organisations tend not to take as many risks, and the management of these organisations frequently has a defensive attitude about the organisation's performance [10]. However, organisations that don't take risks may face a higher risk of falling into strategic drift. On the other hand, successful organisations' management often has a cognitive bias through overconfidence, which may also lead to strategic drift [11]. This cognitive bias may hinder the drive to innovate and quickly adapt to counteract the changes in the external environment [10].

3.3. Culture

Complacency opens the gateway to many other internal factors, such as a culture that is resistant to change. Edwards [5] describes an organisation with a culture that did not learn from failure. This organisation adhered to traditional approaches, which caused a failure to adapt to new technologies, eventually resulting in organisational decline. Organisations cannot successfully adhere to strategies if there is a culture of teams operating in isolation and lacking communication [12]. Poor communication due to internal divisions makes ensuring the organisation is aligned with the strategy at all levels challenging, leading to strategic inertia [12]. Ness [13] recommends that the strategy align with the organisation's culture to avoid future clashes when necessary changes occur. Culture is a key internal factor as it affects an organisation's ability to be aligned with its external environment through strategy. When an organisation's culture does not promote innovation and change, it will foster conditions conducive to strategic drift [14].

3.3.1. Decision Making

Complacency and cultural misfits often lead an organisation to make poor strategic decisions. Effective decision-making is critical for strategic success as it determines an organisation's responses to the external environment [15]. In a fast-paced environment, fast and adequate decision-making is required to respond to change [16]. When management takes too long to make decisions due to hesitancy or cognitive biases, responses will be delayed, and the organisation will fall behind [16]. Poor decisions are often made due to a lack of data, such as market intelligence or consumer preferences, which causes organisations to be led astray from their strategic objectives [17]. The decision-making processes continuously require both internal and external feedback. When management takes too long to make decisions due to hesitancy or cognitive biases, responses will be delayed, and early signs of strategic misalignment or drift will not be recognised [2].

3.3.2. Misalignment

One primary form of misalignment leading to strategic drift is the disparity between the strategy set out by management and the execution [9]. This misalignment occurs due to poor communication, uncertainty, and lack of resources, ultimately leading to a strategic drift [18]. External environments are growing increasingly complex, which brings uncertainty, exacerbating the misalignment between internal capabilities and external demands [19] The misalignment between internal goals and external demands is a key internal factor as these

inefficiencies, which are caused by other internal factors, lead to missed opportunities and responses to changes in the external environment [20].

3.3.3. Management

The management of an organisation plays a vital role in strategic success; from the previous factors, it is evident that if there is no management support, strategic drift is inevitable. When management neglects certain parts of the strategic objectives and focuses on others, there is an increased risk of strategic drift [17]. Management needs to foster an environment conducive to innovation and adaptation, so there will not be resistance when external factors come into effect [21]. If the environment is not conducive to innovation, there will be significant hindrances to the responses to the external environment, once again causing strategic drift. Without management support, an organisation will eventually find its misalignment with its strategic objectives, with little hope of recovering unless drastic changes are made.

Table 1: Summary of internal factors found in literature.

Key factor	Findings	Reference
Complacency	Unable to meet supply and demand	[22]
	Resistance to take risks	[23]
	Core competencies which do not promote change	[24]
	Cognitive bias	[5]
Culture	Resistance to change causes a reluctance to enter thriving markets or leave declining markets	[25]
	Poor communication and working in silos	[12]
	Inflexible hierarchy which leads to cultural rigidity	[12]
Decision Making	High Capital Expenditure – decision made to expend capital to meet high demands which caused debt and financial fragility	[20], [26]
	Labour Disputes due to employees unhappy with the organisations decisons	
	Defensive attitude of managers causing ineffective decision making	[10]
	Slow Innovation and adaptation to changes in the external environment	[2]
	Rash decisions leading to high-risk situations with no pay-off	[16]
	Uncertainty of situations due to lack of data	[9]
Misalignment	Process Disparity	[27]
	Poor strategic execution	[28]
	Inappropriate strategy	[11]
Management	Dysfunctional leadership	[9]
	No management support	[29]
	Lack of strategic oversight	[17]
	Failure to foster an adaptable culture	[14]

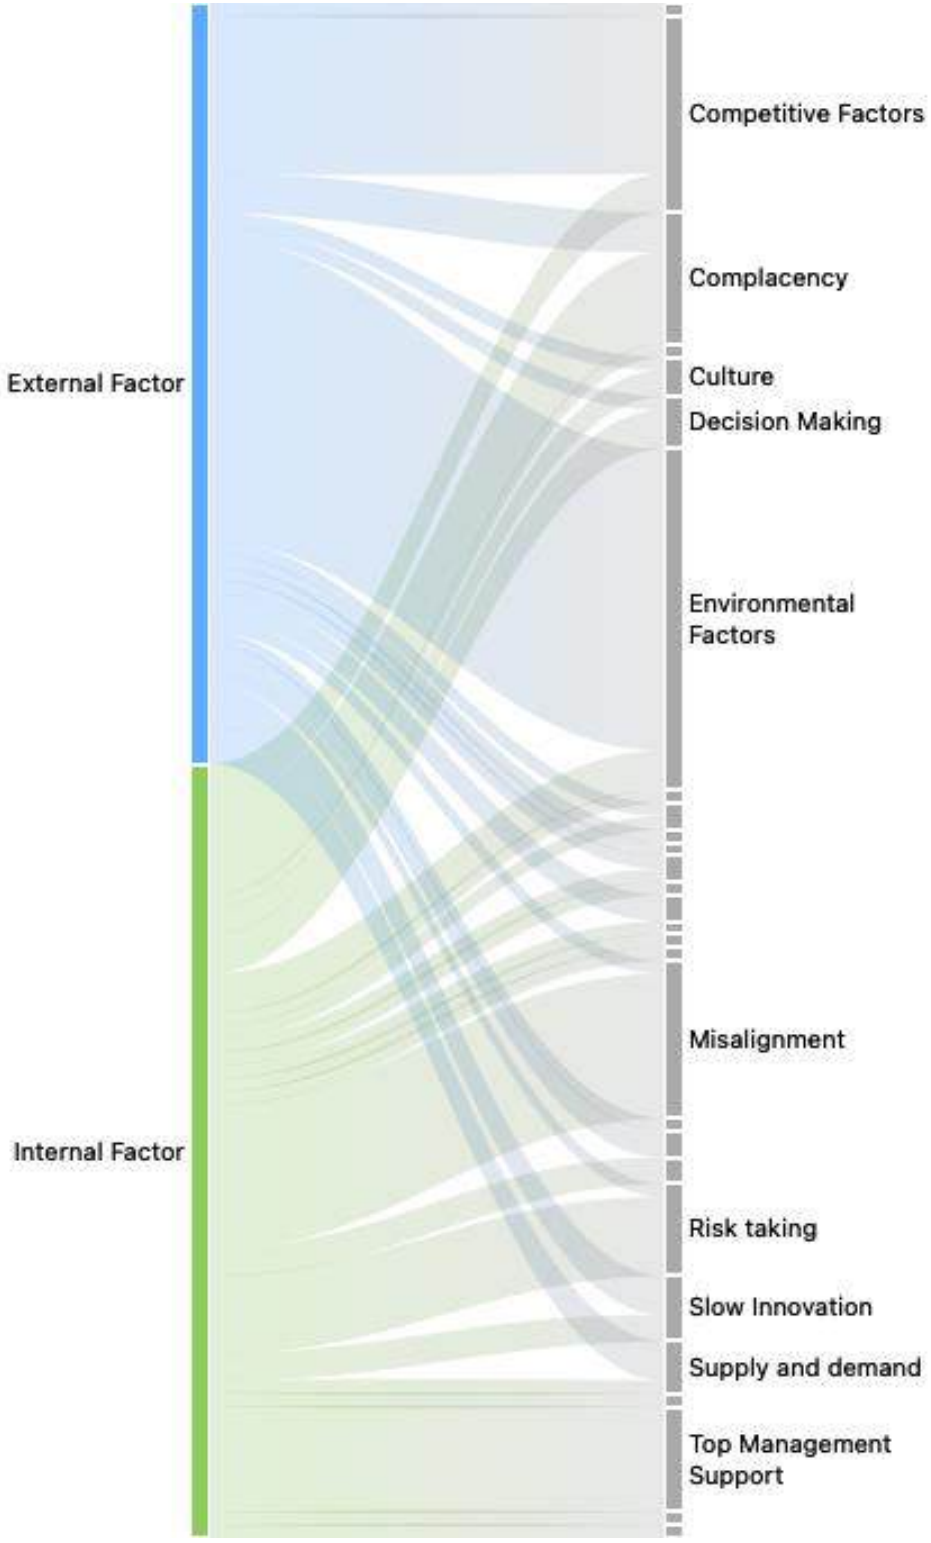

Figure 2: Key Internal and External Factors.

3.4. External Factors

External factors occur outside the organisation, such as the political, economic, technological, legal, global and social environment [8]. For most organisations, this environment rapidly changes, and it is necessary to understand and adapt to the changes to ensure that strategic

objectives are realised and that the organisation does not drift into failure. Numerous factors pose risks to the strategic objectives. However, it is impossible to predict and identify all of these factors, so it is necessary to clearly understand what the organisation can do to mitigate the risks posed [25]. Figure 2 depicts the key internal and external factors. From this figure, the most relevant factors are seen. The findings of all external factors are summarised in

Table 2, and key internal factors are discussed below.

3.4.1. Environmental Factors

This broad term has been used to group changes in the overall external environment, such as technological advancements, industry disruptions and regulatory changes [25]. Rapid environmental changes are generally caused by technological advancements that render existing products or services irrelevant to the market; this requires organisations to continuously adapt their strategies to ensure they do not fall behind in the industry [17]. The further breakdown of these factors is discussed below.

3.4.2. Competitive Factors

With the advancement of technology, globalisation has become an increasing threat to organisations [12]. There is an increase in competition as new markets are opened and available on a global scale; organisations who do not respond to this external factor by entering new markets will be at risk for strategic drift as the competitiveness of the organisation will drop compared to organisations who adapt their strategies to take advantage of globalisation [30]. Rapid technological advancements render existing products irrelevant or processes obsolete; organisations must adopt new technology to stay relevant and aligned with their strategy [17].

3.4.3. Political

Political instability, regulatory changes, and changes in government policy create challenges for organisations to remain aligned with their strategies. When the external environment is politically volatile, organisations may face disruptions that affect their operations [26]. If the strategy is adapted to the disruptive environment, organisations will be aligned and avoid the risk of strategic drift [17]. As the environment changes, new or changing regulations come into play to account for industry changes; organisations that do not modify their operations and strategies to comply with these regulations will find it difficult to operate in the environment [5].

3.4.4. Economic

The economy plays a significant role in how strategies are formed. Recessions, inflation and changes in supply and demand all significantly impact the strategy [31]. Failing to adapt to these changing conditions may result in strategic drift [32]. Economic recessions are a significant factor leading to strategic drift as organisations do not recognise the need for changes in time, leading to the strategic models being misaligned with the reduced consumer demand [18]. Another factor which reduces consumer demands, as well as operational costs, is inflation and cost pressures. The rise in costs and decline in demand result in operational inefficiencies and a drift from the strategic objectives [29]. Reduced consumer demand leads to performance declines. When this is unexpected, organisations find it challenging to return

to usual performance levels and achieve their strategic objectives, leading them to strategic drift.

Table 2: Summary of external factors found in literature.

Key factor	Findings	Reference
Competitive	Technological Advancements by competitors rendering existing products/services obsolete.	[33]
	New market entrants which floods the market	[20]
	Price competition	[18]
	Product Differentiation from competitors	[9]
	Innovation fatigue for organisations who cannot innovate as fast as competitors	[10]
Political	Political instability which cause disruptions to operations	[31]
	Labour disputes	[26]
	Government policies	[34]
	Foreign policy shifts which can limit the trade which happens with foreign markets	[23]
Economic	Reduced consumer demand	[12]
	Inflation	[35]
	Consumer spending patterns	[23]
	Currency Fluctuations	[8]

3.5. Recovery

Once an organisation recognises that it has drifted from its strategy, recovery to realign the strategy to the external environment begins. Realigning the strategy involves identifying the misalignment, which factors influenced the drift and then strategic realignment.

3.5.1. Strategic Realignment

Organisations recovering from strategic drift often begin by realigning their strategy by evaluating their core competencies, understanding their external environment, and adjusting their focus to better fit the external environment. Smith [12] identified an organisation which had fallen into a strategic drift but recovered successfully by determining that its outdated models and culture did not promote innovation. They embraced new business models that better suited the market and adjusted their culture, allowing the organisation to recover from the strategic drift [12]. To realign the strategy, organisations need to understand their strengths and weaknesses and the external threats and opportunities to take advantage of the market and recover by regaining market share and achieving strategic objectives [28].

3.5.2. Management Change

As mentioned, management is one of the key internal factors which cause strategic drift. Strong and visionary management plays a crucial role in recovering from strategic drift, as it is necessary to make bold changes to realign the organisational strategy with the external environment [19]. Transformational management is required to encourage a culture shift and promote innovation to overcome the inertia from strategic drift, as seen in the case study by Gajere [17].

3.5.3. Innovation

Driving innovation and adopting new technologies will assist declining organisations in keeping up with competitors in their industry. Lucas Industries failed to innovate as fast as its

competitors, leading them into a strategic drift; innovation was embraced to recover from this [5]. GKN recovered from its strategic drift by investing in new technologies, which assisted it in staying ahead of competitors through technological trends [36]. Organisations need innovation to recover from strategic drift and maintain their position in the marketplace.

3.5.4. Organisational Restructuring and External Market Analysis

Depending on the organisation and industry, it is often necessary to restructure the operations and processes to better align with the strategy. Anglo American Platinum restructured its operations to focus on core competencies to recover from strategic drift [26]. The effective recovery of strategy requires organisations to thoroughly understand their environment and external factors to restructure themselves internally.

4 SUMMARY OF RESULTS

This ScR identified primary internal and external factors as key contributors to strategic drift. Internal factors were identified as complacency, culture, inadequate decision-making and misalignment. Complacency, which is prevalent in previously successful organisations, happens due to resistance to change, risk aversion, and cognitive biases. Cultural elements, included resistance to innovation, poor cross-functional communication, and rigid hierarchical structures, created internal barriers to strategic adaptation. Decision-making deficiencies from management hesitancy, cognitive limitations, and inadequate data analysis hindered organisational responsiveness. Misalignment between strategy and execution occurred through process inconsistencies, resource allocation issues, and fundamental differences between strategy and the organisational environment. Primary external factors were identified as competitiveness, political, and economic pressures. Competitive factors included technological advancements making existing products obsolete, disruptive new market entrants, aggressive price competition, and innovation challenges. Political pressures emanated from regulatory shifts, labour disputes, and government policy changes. Economic pressures frequently resulted from demand fluctuations, inflationary environments, shifting consumer behaviours, and currency volatility.

The literature demonstrated that recovery from strategic drift necessitates addressing both internal dynamics and external pressures. Organisations began recovery by critically assessing their core competencies regarding environmental demands, subsequently modifying their business approaches and strategic focus. Transformation at the management level emerged as crucial, with leadership changes being necessary for cultural evolution and strategic redirection. Adopting innovative practices, particularly technological implementation, facilitated a new competitive advantage. Operational restructuring centred on core organisational strengths contributed significantly to successful recovery trajectories across multiple case studies.

The findings demonstrate that strategic drift represents a complex organisational phenomenon involving cognitive, cultural, structural, and environmental elements. Organisations that recovered successfully demonstrated the capacity to understand their external environment, realign their internal factors to match environmental demands, and implement changes in leadership, innovation approaches, and organisational structure. These interconnected recovery mechanisms suggest that addressing strategic drift requires a holistic organisational response rather than isolated strategic adjustments.

5 CONCLUSIONS

Through a systematic review of the literature, the aim was to answer the following research questions:

1. What are the primary internal and external factors which contribute to strategic drift?

2. How do organisations recover from strategic drift?

A review of literature databases revealed 54 papers relevant to the research topic. The review highlights that strategic drift results from a complex interplay between internal organisational dynamics (complacency, culture, decision-making processes, and strategic misalignment) and external pressures (environmental changes, competitive forces, political instability, and economic factors). This perspective advances understanding beyond the traditional view of strategic drift as a mismatch between strategy and environment. Recovery strategies were highlighted through strategic realignment, management changes, innovation, and restructuring.

This review offers several important insights for organisational leaders and strategic managers aiming to make waves. Proactive monitoring of internal and external factors is essential for early detection of strategic drift. Organisational culture serves as either a catalyst or a barrier to strategic alignment, making culture management a critical skill for leadership. Recovery from strategic drift requires a multifaceted approach involving strategic realignment, leadership changes, innovation adoption, and organisational restructuring. Successful organisations can be particularly vulnerable to complacency and cognitive biases, requiring deliberate efforts to maintain strategic vigilance.

This review highlights the limitations in the literature of insufficient industry-specific studies, empirical data on successful organisational recovery strategies, and how innovation and technology adaptation influence strategic drift in the South African context. Future research should address the following gaps identified in this review. Industry-specific studies examining how strategic drift manifests in different sectors, particularly South African contexts, would provide valuable contextualised insights. Empirical studies tracking organisations through the complete strategic drift and recovery cycle could provide valuable insights. Comparative analyses of recovery strategies would help identify which approaches are most effective under different conditions. Investigating how emerging technologies and digital transformation influence strategic drift dynamics is relevant in today's rapidly changing business environment. Developing practical diagnostic tools would help organisations identify early signs of strategic drift, enabling proactive intervention before significant performance decline occurs. The findings of this review provide valuable insights for both researchers seeking to address existing gaps in the literature and practitioners working to maintain strategic alignment in increasingly dynamic environments. By understanding the complex interplay of factors contributing to strategic drift, organisations can better position themselves to recognise early warning signs and implement appropriate recovery strategies when misalignment occurs.

THE FIFTH INDUSTRIAL WAVE: SYNCHRONISING INDUSTRY 5.0 AND RENEWABLE ENERGY

G.D. Bezuidenhout[1*] and M. Mangaroo-Pillay[2]

[1,2]Department of Industrial Engineering
Stellenbosch University, South Africa

ABSTRACT

Harnessing the synergy between human-centric automation and clean energy, this paper explores how Industry 5.0 (I5.0) is not just riding the renewable revolution - but amplifying its waves. Grounded on the pillars of a human-centric approach, sustainability and resilience, I5.0 provides a well-developed structure that can be integrated with the continuous research and development of renewable energy. This study makes use of a systematic literature review (SLR) to explore the overlap of I5.0 and renewable energy that includes the scope, benefits, challenges and enablers. It was found that there is substantial overlap and shared concepts between I5.0 and renewable energy. The findings highlight the potential of the transformation of renewable energy with the overlap of I5.0, fostering a more resilient and sustainable future. I5.0 not only complements renewable energy but also strengthens the impact it has on the renewable energy innovations.

Keywords: Industry 5.0, Renewable Energy, SLR, Sustainability, Resilience

1 INTRODUCTION

The growing urgency of climate change, rising energy demands, and the depletion of fossil fuels have catalysed global efforts toward adopting renewable energy sources such as solar, wind, hydro, and bioenergy [1]. These technologies form the cornerstone of the green energy transition, aiming to reduce carbon emissions, enhance energy security, and support sustainable development. However, despite significant advancements, challenges remain in optimising efficiency, integration, and scalability across various energy systems [2].

Parallel to this evolution, the industrial world is undergoing a transformation beyond the automation and interconnectivity of Industry 4.0. Industry 5.0 (I5.0) [3] emerges not as a replacement but as an enhancement, one that brings humans back into the loop, emphasizing a human-centric approach, resilience, and sustainability. Unlike its predecessor, which focused heavily on efficiency through cyber-physical systems and the Internet of Things (IoT), I5.0 promotes collaboration between humans and intelligent machines to address broader societal goals, including environmental stewardship [4].

The intersection of renewable energy and Industry 5.0 opens new avenues for innovation, particularly in how clean energy systems are designed, managed, and scaled. Integrating I5.0 principles into the renewable energy sector could lead to more adaptable, intelligent, and resilient energy infrastructures that align with societal and environmental needs. However, the extent to which these two paradigms complement and reinforce each other remains underexplored in academic literature.

This paper seeks to bridge that gap by conducting a systematic literature review (SLR) to investigate the overlap between Industry 5.0 and renewable energy. Specifically, it examines the scope of integration, key benefits, existing challenges, and potential enablers that arise from this intersection.

The central research question that is used as the backbone of this study is:

How does the integration of Industry 5.0 concepts enhance the development, deployment and impact of renewable energy systems?

The research question provides the opportunity to define the research aim: Conduct a Systematic Literature Review (SLR) to investigate the overlap between renewable energy and Industry 5.0 concepts and to what extent the overlapping concepts can be used to design an implementation framework.

2 RESEARCH METHODOLOGY

This study followed the SLR method. A SLR is a structured, unbiased method for identifying and synthesising existing research. It was used in this study to ensure a rigorous, evidence-based understanding of the overlap between Industry 5.0 and renewable energy, providing a credible foundation for the framework. The method consists of three phases: Planning, conducting and documenting. [5] The steps within these phases are detailed as follows:

A) Planning the review

- **Step 1 – Research purpose and objective**: Clearly set the purpose of the SLR
- **Step 2 – Develop research protocol:** Create the research protocol, which must include the inclusion criteria, exclusion criteria, databases to be searched, keywords and quality assessment criteria

B) Conducting the review

- **Step 3 – Establish relevance criteria**: Establish which types of studies are relevant to the study (Update the inclusion and exclusion criterion)

- **Step 4 – Search and retrieve the literature**: Search the selected electronic databases for literature
- **Step 5 – Selection of studies**: Select literature based on the inclusion and exclusion criteria
- **Step 6 – Quality assessment for relevant studies**: Assess the literature for quality
- **Step 7 – Data extraction**: Extract data from the selected literature
- **Step 8 – Synthesis of studies (analysis)**: Extract facts and conclusions from the selected literature

C) Documenting the review

- **Step 9 – Reporting:** Report on the SLR in detail
- **Step 10 – Dissemination**: Publish the SLR findings in an academic source

2.1 Step 1 - Develop a research purpose

The purpose and objectives of the SLR are captured in both section 1 and section 2 of this research paper: To investigate literature on the overlap between Industry 5.0 and renewable energy. The aim was divided into four categories: the scope of integration, key benefits, existing challenges and potential enablers.

2.2 Step 2 - Develop a research protocol

The review protocol was developed and can be viewed in Table 1.

Table 1: Research protocol

Purpose of the study	Explore the overlap between Industry 5.0 and renewable energy to identify how their integration can enhance sustainability, resilience, and human-centric innovation in energy systems.
Inclusion criteria	- Literature including "Renewable energy" or "Industry 5.0" in their title, abstract or keywords
Exclusion criteria	- Literature older than 2020 - Non-English literature - Literature that focuses on the development of Industry 4.0 - Case study specific papers (i.e. Studies that do not contain any information regarding I5.0 or renewable energy, but rather how it is applied to a case study) - Literature that uses AI technology
Search databases	Searches were conducted on the following databases, namely: - ScienceDirect - Scopus - Web of Science - Emerald Insight Journals - IEEE Xplore
Keywords	The following keywords were used to search the databases: - **"Renewable energy" and "Industry 5.0"**
Quality assessment criteria	- Literature will be checked for relevance: any evidence of the scope of integration, key benefits, existing challenges, and potential enablers regarding I5.0 and/or renewable energy - Scientific and peer-reviewed literature was considered

2.3 Step 3 - Establish relevance criteria

To elaborate on what is mentioned in table 1, here is a breakdown of the criteria that wat used to assess the literature:

- **Direct Discussion of Industry 5.0 Concepts**: The paper must discuss key principles of Industry 5.0, such as human-centric design, collaboration between humans and machines, sustainability, resilience, and advanced digital technologies (e.g., AI, IoT, digital twins) in an I5.0 context.

- **Focus on Renewable Energy Systems**: The paper should address renewable energy types (e.g., solar, wind, hydro, bioenergy) or related infrastructure, integration strategies, or supply chain issues relevant to the renewable energy transition.
- **Conceptual or Strategic Integration**: The study must go beyond technical application and explore or propose conceptual frameworks, challenges, benefits, or enabling technologies that highlight how I5.0 principles intersect with renewable energy development.
- **Non-case-specific Generalisability**: Preference was given to papers offering generalizable insights over isolated case studies, ensuring broader applicability of the findings for framework development.
- **Alignment with Research Aim**: The content should contribute to the goal of identifying overlapping themes, synergies, or enablers between I5.0 and renewable energy to inform the design of an implementation framework.
- **Current Literature:** Only literature from 2020 onwards was included to capture the most recent advancements and policy directions, as Industry 5.0 emerged formally in 2021, and renewable energy technologies have rapidly evolved in the past few years. This ensures the review reflects current socio-economic, technological, and sustainability contexts.

2.4 Step 4 to 6 – Search, Selection and Quality Assessment of the resources

The literature selection process followed the PRISMA statement. The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement is a standardised framework designed to enhance the transparency, rigor, and reproducibility of systematic literature reviews. It provides a structured process for identifying, screening, and selecting studies, typically illustrated through a flow diagram that outlines the number of records identified, included, and excluded, along with reasons for exclusions. The PRISMA approach ensures that literature selection is methodical and unbiased by clearly documenting each stage of the review process, from initial database searches and duplicate removal to full-text assessment and final inclusion, thus improving the overall quality and credibility of the review findings.

The literature selection process is illustrated in Figure 1. The initial search resulted in 133 resources from five databases. After screening the 133 resources based on the research protocol, a total of 17 were selected for the quality check. Resources were rejected due to the following reasons:

- Several sources were case-specific and did not have relevant literature
- Multiple sources solely focused on I5.0 and did not mention renewable energy
- Few sources were in the context of Industry 4.0 and focused on Industry 4.0 technologies

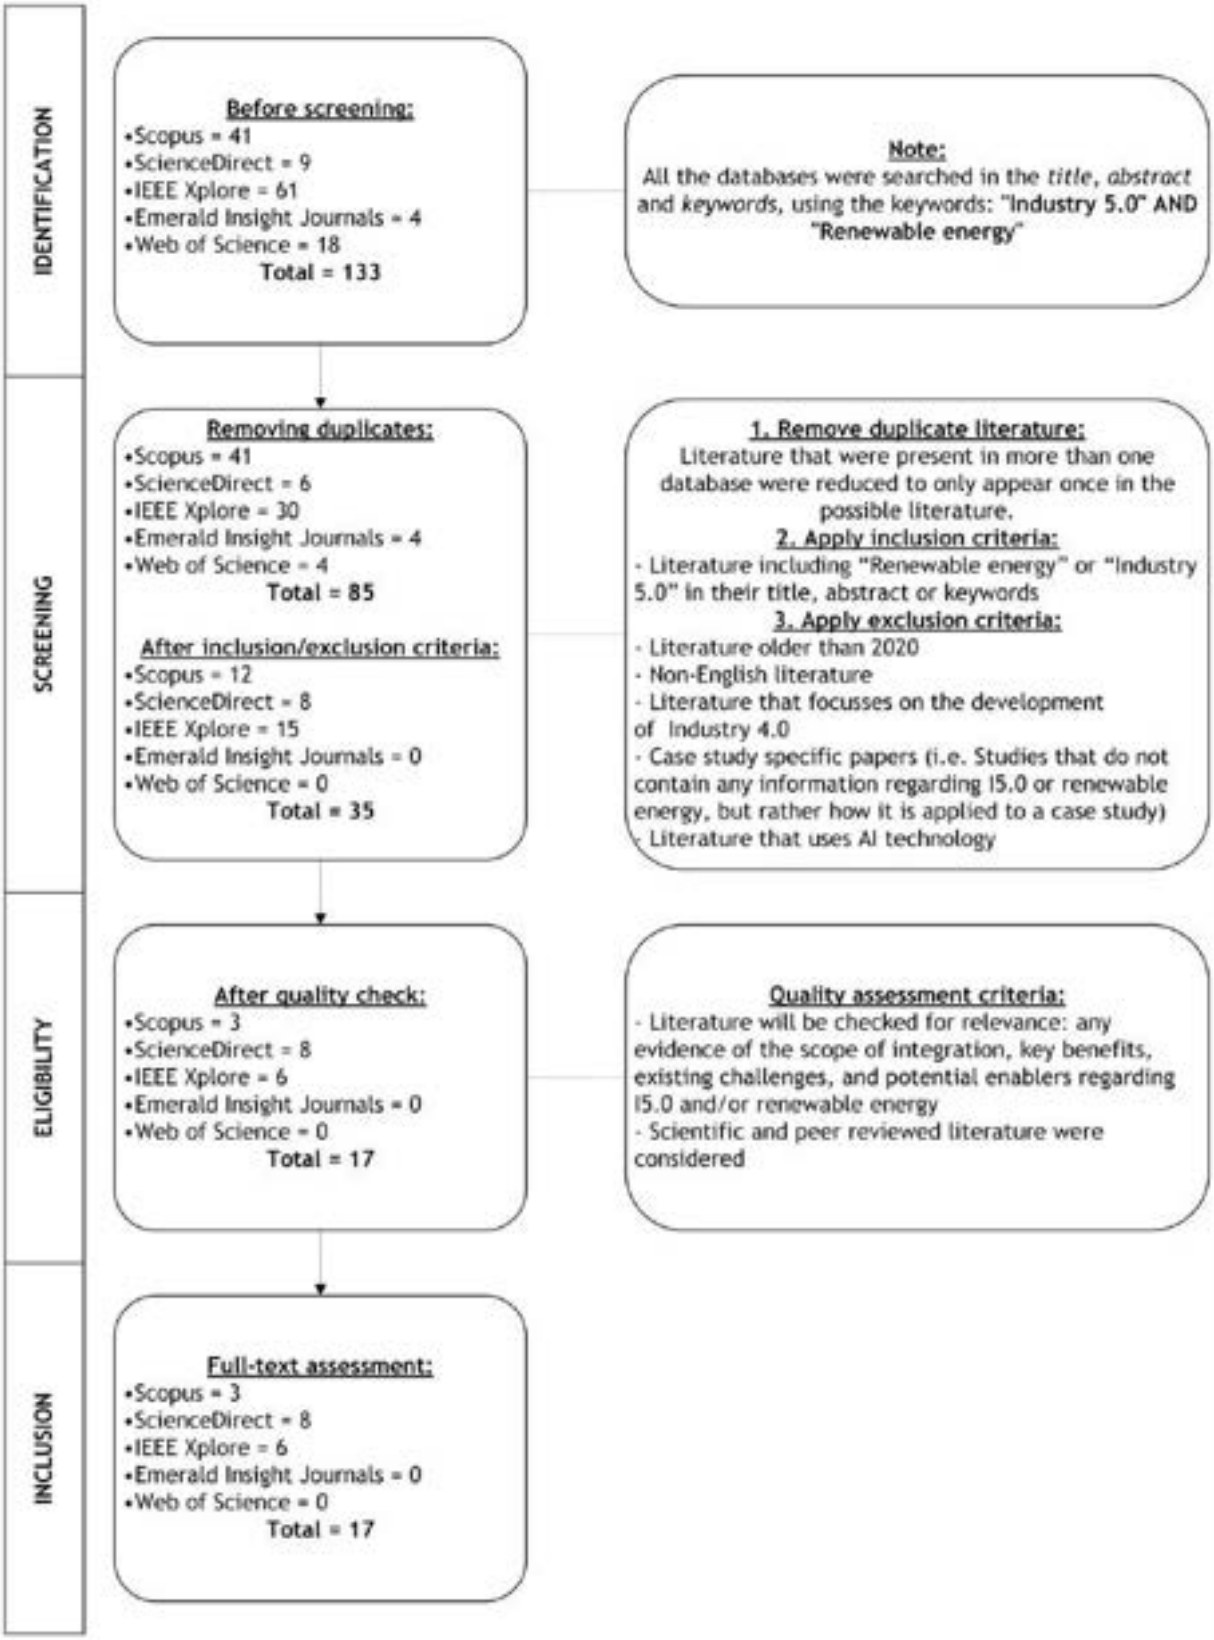

Figure 1: Literature selection process

After the selection process, these 17 resources passed the quality check and were included for full-text assessment. The final resources that were selected are detailed in Table 2, including the authors, year, title and the type of resource.

Table 2: Resources found

#	Author(s) and year	Title	Type of source

3 FINDINGS

3.1 Step 7: Data extraction

Following the selection process, data was systematically extracted from the 17 chosen resources. For each paper, key information pertaining to Industry 5.0 and renewable energy was identified and categorised according to the research objectives: scope of integration, key benefits, existing challenges, and potential enablers. This extraction involved a detailed reading of the abstracts, introductions, discussion sections, and conclusions to pinpoint explicit and implicit connections between the two domains. The extracted data formed the basis for the subsequent comparative analysis, ensuring that all relevant insights from the selected literature were captured for synthesis. Figure 2 shows the information that has been extracted from the relevant sources. The 'x' marks the category that has been extracted from the respective resource.

Findings / Author(s)	Industry 5.0				Renewable Energy			
	Scope	Benefits	Challenges	Enablers	Scope	Benefits	Challenges	Enablers
(Chaikovska et al., 2024)	x							
(Onile et al., 2023)	x			x				
(Chaudhari et al., 2021)	x	x	x	x				
(Habash, 2022)	x	x	x	x				
(Szeredi et al., 2024)	x				x			
(Wilkening et al., 2024)					x	x	x	x
(Khazaei et al., 2025)	x	x	x		x	x	x	
(Sharma et al., 2025)	x			x

(Hu et al., 2025)	x							
(Tyagi et al., 2024)	x	x	x	x				

Figure 2: Breakdown of categories found in resources

3.2 Step 8: Analysis and synthesis of findings

The intersection of Industry 5.0 and renewable energy represents a significant opportunity to reimagine sustainable development by aligning technological advancement with environmental and human-centric goals. Drawing from current literature, a comparison of these two domains across their scope of integration, benefits, challenges, and enabling conditions reveals both distinct trajectories and shared synergies.

A. Scope of Integration

The scope of integration for Industry 5.0 is largely defined by its focus on human-centricity[16] and the use of advanced digital technologies such as Artificial Intelligence (AI), Internet of Things (IoT), digital twins, and cyber-physical systems to create intelligent, adaptive, and collaborative manufacturing environments[6], [7]. This approach redefines productivity through personalisation[17] and social responsibility[21]. In contrast, renewable energy integration prioritises decentralised, sustainable energy systems, leveraging diverse sources like solar, wind, hydro, and hydrogen to reduce carbon emissions and fossil fuel dependency, particularly in developing countries[12]. Both domains share a reliance on digital tools and smart systems to improve performance, while collectively supporting resilient infrastructure, resource efficiency, and socio-technical innovation on a global scale[14].

B. Key Benefits

Industry 5.0 and renewable energy offer complementary yet distinct benefits. Industry 5.0 facilitates mass customization, increased adaptability, and enhanced worker satisfaction through human-machine collaboration and lifelong learning [14]. It also supports workforce resilience in the face of technological disruption [8]. Conversely, renewable energy provides environmental protection, energy security, and economic diversification, including job creation in emerging green sectors[20]. Shared benefits include improvements in system efficiency, operational resilience, and the advancement of sustainable development goals, indicating a natural synergy between the two [13].

C. Existing Challenges

Despite their promise, both fields face notable challenges. Industry 5.0 suffers from limited awareness, skills mismatches[18], and the difficulty of integrating cutting-edge technologies into traditional systems [8], [9]. There is also a gap in ethical and regulatory frameworks for managing human-machine interfaces. Renewable energy struggles with intermittency issues, market barriers, and the continued dominance of fossil fuel infrastructures in many regions, notably in Latin America [20]. Common challenges include investment gaps, fragmented policy environments, and institutional inertia, which together hinder cross-sector transformation [19].

D. Potential Enablers

Several enablers can facilitate the convergence of Industry 5.0 and renewable energy systems. For Industry 5.0, advanced simulation tools (e.g., digital twins)[11], collaborative robotics (cobots), and intelligent production platforms are critical drivers of innovation [22]. Renewable energy is enabled by technologies like smart grids, distributed storage, and community-driven models, which increase adoption and grid stability [15]. Both systems benefit from investment in digital education, public-private partnerships, and regulatory support that incentivize clean technologies and promote inclusive transformation[14]. A shared emphasis on collaborative governance and capacity building is crucial for bridging technological potential and societal readiness.

3.3 Step 9: Reporting

The conceptual framework derived from the systematic literature review is presented through a set of four Venn diagrams, each addressing a critical dimension of the integration between Industry 5.0 and renewable energy. These dimensions are Scope of Integration, Key Benefits, Existing Challenges, and Potential Enablers. Each diagram juxtaposes the defining features of Industry 5.0 and renewable energy, while highlighting areas of convergence at their intersection. The Scope of Integration (Figure 3) outlines overlapping trends such as the integration of AI, IoT, and digital twins into physical systems, as well as shared sustainability goals. Key Benefits (Figure 4) emphasizes the mutual advantages of adopting both paradigms, including increased efficiency, job creation, and reduced emissions. Existing Challenges (Figure 5) identifies common hurdles such as high capital investment requirements and infrastructure limitations. Finally, Potential Enablers (Figure 6) illustrates the strategic interventions needed to align policy, workforce development, and innovation to support this integration. This visual framework serves as both an analytical lens and a strategic guide for stakeholders aiming to harness the synergies between Industry 5.0 and renewable energy systems.

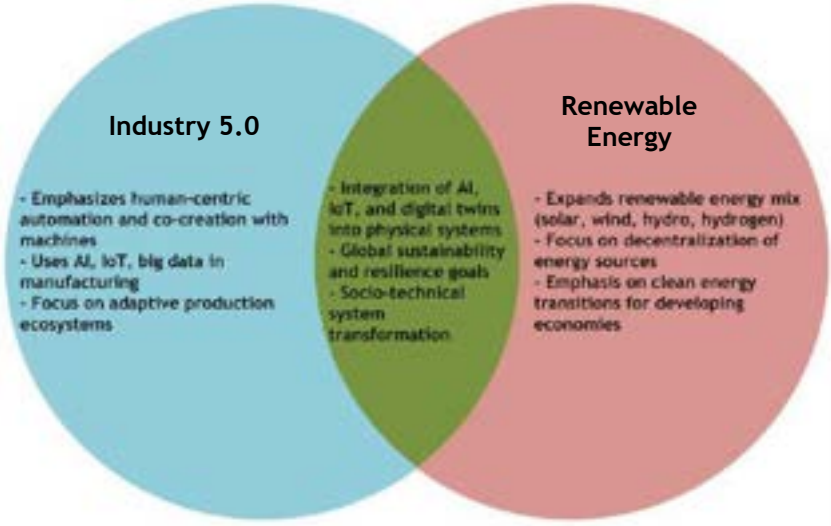

Figure 3: Scope of integration

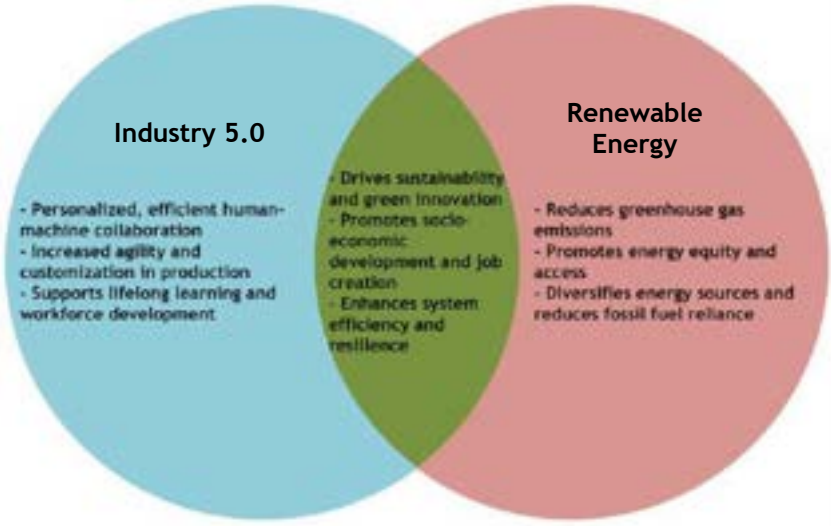

Figure 4: Key benefits

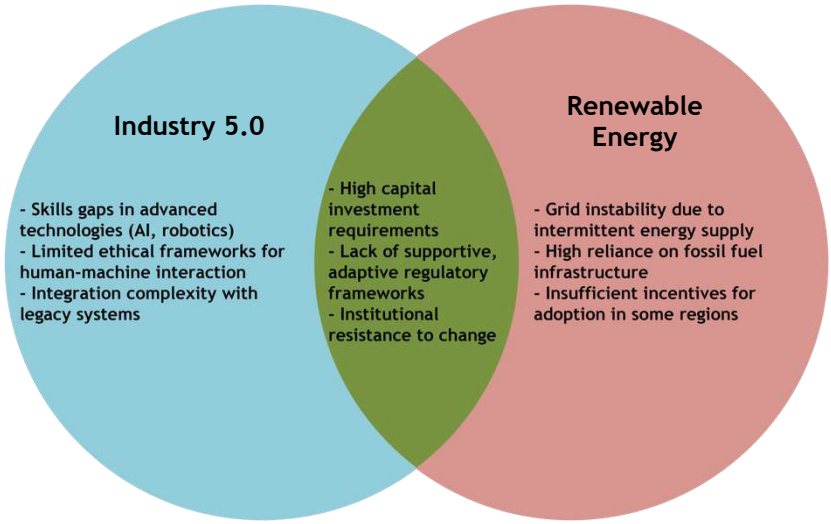

Figure 5: Existing challenges

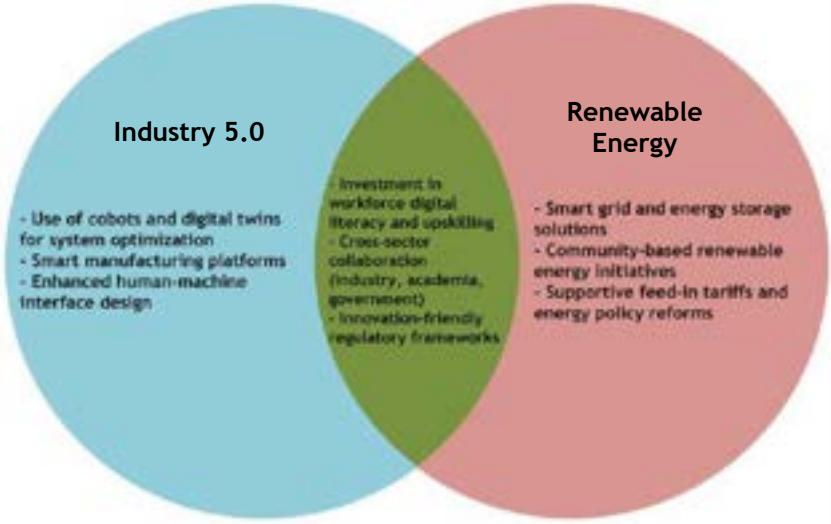

Figure 6: Potential enablers

4 CONCLUSION

The systematic literature review, visually represented through a series of Venn diagrams for each comparative component, vividly illustrates the substantial and strategic overlap between Industry 5.0 and renewable energy. This framework effectively highlights not only the distinct characteristics of each domain but, more importantly, the critical points of intersection where profound synergies can be harnessed.

The developed framework, illustrated through four Venn diagrams, offers significant insights into the integration of Industry 5.0 and renewable energy. One of the key implications is the clarity on a shared vision, especially evident in the Scope of Integration diagram. This visual highlights how both domains are aligned in their pursuit of a sustainable and resilient future, with common reliance on digital technologies such as AI, IoT, and digital twins, and a mutual emphasis on socio-technical innovation. These are not parallel developments but rather deeply interconnected movements. Additionally, the Key Benefits diagram identifies clear growth areas, revealing how the integration of these two paradigms can lead to

enhanced system efficiency, improved operational resilience, and accelerated progress toward sustainable development goals. These intersections suggest rich potential for future research, policymaking, and investment that leverages the strengths of both fields.

The Existing Challenges diagram further provides value by enabling targeted problem-solving. It outlines shared impediments such as high capital investment requirements, fragmented policy environments, and institutional resistance, indicating that overcoming these barriers requires coordinated efforts across industrial and energy sectors. Perhaps the most actionable insights come from the Potential Enablers diagram, which offers a strategic lens into how these challenges can be addressed. It emphasises strategic enablement through shared interventions such as digital education, public-private partnerships, and innovation-friendly regulation, clear areas where policy and practice can work together to facilitate progress.

The usefulness of this visual framework lies in its ability to enhance comprehension of complex interrelationships through the intuitive format of Venn diagrams. This makes it accessible to a wide range of stakeholders including policymakers, industry leaders, and academic researchers. Moreover, by clearly delineating overlaps and distinctions, the framework supports strategic decision-making related to resource allocation, technology development, and policy formulation. It also aids in the identification of research gaps, particularly in the non-overlapping sections, which may indicate underexplored areas ripe for investigation. Lastly, the overlapping zones highlight collaborative opportunities, encouraging joint initiatives among the manufacturing, technology, and renewable energy sectors to realise shared sustainability goals.

In essence, the Venn diagram framework not only synthesises the findings of this systematic literature review but also serves as a powerful tool for conceptualising and advancing the integration of Industry 5.0 and renewable energy. It visually confirms that Industry 5.0 is not merely riding the renewable revolution, but actively shaping and strengthening its impact, thereby fostering a truly resilient, human-centric, and sustainable energy future.

5 FUTURE RESEARCH

Future research should explore how Industry 5.0's human-centric and sustainable principles can transform rural areas in developing nations through renewable energy deployment.

Several critical areas warrant further research to deepen the understanding and effectiveness of integrating Industry 5.0 with renewable energy, particularly in rural and under-resourced contexts. One key avenue is the development of context-specific Industry 5.0 models—exploring how these concepts can be adapted to the unique cultural, economic, and infrastructural realities of diverse rural communities to encourage local ownership and ensure long-term sustainability. Another vital area is the human-centric integration of technology, which stands as one of the primary differentiating factors between Industry 4.0 and Industry 5.0. While Industry 4.0 largely emphasised automation and efficiency, Industry 5.0 recognises humans not as peripheral operators but as central actors who collaborate with advanced systems. Future research should therefore explore strategies to upskill rural workforces, equipping them with both the technical competence and the confidence to manage, maintain, and co-create smart renewable energy systems. This includes designing intuitive, culturally relevant interfaces, embedding local knowledge into system design, and ensuring that technology adapts to the people rather than forcing communities to adapt to technology. Another critical focus is on the economic and social impacts, where research should aim to quantify the socio-economic benefits such as job creation, income generation, and community resilience, while also assessing how Industry 5.0-enabled renewable solutions can alleviate energy poverty and promote circular economy principles. Finally, the investigation must extend to supportive policy and governance, identifying effective frameworks and fostering

public-private partnerships that can mobilize resources, expertise, and investment for scalable rural development initiatives.

ABSTRACT

The global expansion of Lean Manufacturing (LM) literature has significantly contributed to implementing conventional techniques effectively in the automotive industry. However, the domain of lean principles beyond production processes presents an avenue to explore lean principles in engineering functions that encompass organisational structures, leadership and processes. The implementation of Lean Engineering (LE) represents an innovative approach that integrates lean principles with lean manufacturing techniques to enhance the operational efficiency of engineering functions. While LE is underpinned by the foundational principles of LM, it broadly emphasises the importance of effective planning practices. These practices are crucial for ensuring predictability and responsiveness within engineering functions and projects. Therefore, this study conducted a systematised scoping review to identify the planning tools that enabled the implementation of LE within project-based environments, particularly, for the automotive industry. The study's findings supported the adaptation of planning tools used in LE.

Keywords: lean engineering, waterfall, agile, Scrum, Kanban, hybrid, Toyota Kata

1 INTRODUCTION

Lean Engineering (LE) is the systematic approach that ensures engineering organisations or departments have well-defined project management planning processes to reduce waste, enhance team productivity and achieve on-time project delivery [1]. Kämpf [2] conducted a comparative multi-case study that explored the application of lean practices within white-collar work environments, extending beyond the traditional industrial contexts. The results emphasised successful strategies towards cultivating autonomous, empowered and efficient teams in non-manufacturing environments [2]. This study further contended that the application of industrialisation principles, such as lean methodology, in white-collar jobs had the potential to foster a unified and goal-driven organisation of labour. As a result, Kämpf's [2] study expanded the understanding of lean thinking beyond conventional manufacturing environments to other professional fields. These principles redefine non-manufacturing labour through standardised processes, tools and metrics, reducing reliance on individual discretion and experience as well as fostering consistency in daily task execution [2].

However, the extensive literature continues to emphasise that, although these strategies change office-based roles, a gap remains regarding their adoption in specialised engineering work [1-7]. Additionally, insufficient project planning remains a pervasive concern across various sectors, project types and organisational scales. Heagney [8] asserts that numerous project managers emphasise swift execution at the expense of comprehensive planning, while businesses often allocate insufficient time to this essential phase. Consequently, this lack of planning frequently causes project teams to address errors to alleviate stakeholder dissatisfaction and manage delays; ultimately, making poor planning a key contributor to project failure [8]. In parallel to LE advancement, agile methodologies have gained popularity in software development owing to their flexibility and responsiveness to changing requirements [9]. However, their effectiveness in engineering tasks within the automotive sector remains uncertain [9].

Notwithstanding the presence of numerous project management methodologies, traditional approaches are often challenging to integrate and adapt within complex engineering environments, such as the automotive sector [2]. Traditional approaches, such as the waterfall method, tend to be inflexible owing to their repetitive nature, which constricts continuous improvement in professional settings where knowledge work requires evolving goals [3]. In contrast, agile frameworks often lack the necessary structure for engineering workflows in the automotive industry that are grounded in cross-functional collaboration and sequential task dependencies [3].

While attempts to bridge the limitations of these approaches have been attempted through hybridisation in conventional manufacturing, there is still a theory-practice divide in LE settings [5], particularly, the automotive industry, even when employing Advanced Product Quality Planning (APQP) [3]. APQP is a structured support tool for lean principles, which is intended to assure product quality assurance and process reliability [3]. Additionally, planning tools are often used in isolation without a clear understanding of how they can collectively support lean principles such as waste reduction, standardisation, team empowerment and productivity improvement [8]. As a result, there is a need to explore a range of project management methodologies, including waterfall, agile, Scrum, Kanban and hybrid approaches, incorporating APQP. This study sought to explore and integrate these tools into a unified approach that supported LE practices.

This study aims to contribute to the development of a unified framework by identifying and integrating key project management tools intended to support LE departments, thereby improving project team performance. To achieve this aim, the study conducted a systematised scoping review, following the methodology by Arksey and O'Malley [10]. For the study, this

systematised scoping review was used to identify relevant planning tools and extract core themes from existing literature that would inform the development of a conceptual framework that supported the adaptation and integration of lean principles in white-collar contexts to establish and foster the evolution of structured LE practices. While this approach provided a solid conceptual foundation, it is limited by its reliance primarily on existing literature and the absence of empirical validation. In doing so, the study further laid the foundation for the development of context-sensitive tools that could be tailored to the specific needs of LE teams.

2 RESEARCH METHOD: SYSTEMATISED SCOPING REVIEW

This study employed a qualitative research methodology, specifically a systematised scoping review, to comprehensively identify and analyse relevant literature. Following Arksey and O'Malley's [10] definition, the systematised scoping review serves as a "*methodological framework*" for systematically mapping key concepts and evidence in the field. Figure 1 illustrates the process, which involved several stages: defining the research problem and objectives (outlined in the Introduction); conducting systematic database searches to locate relevant studies; screening titles and abstracts to select studies (documented via a PRISMA flow diagram); charting data from included full-text articles (summarised in a data charting table); and collating and reporting the findings [10].

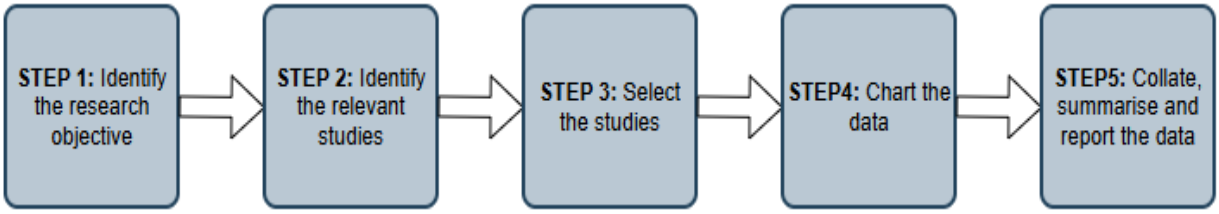

Figure 1: Scoping review approach (*adapted Arksey and O'Malley [10]*).

2.1. Identification of the research objective

The objective of this study is to identify and integrate planning tools from traditional, agile and hybrid methodologies into a conceptual framework that supports effective planning practices within LE environments.

2.2. Identification and selection of relevant studies

The relevant studies were identified by searching databases such as PubMed, Science Direct, and Springer using the appropriate keywords, including *lean engineering, agile project management, waterfall project management, traditional project management, hybrid project management* and *Toyota Kata*. A total of 327 reports were identified during the initial search and uploaded to Rayyan.ai, where the screening and selection processes were carried out. After the studies were identified, 19 duplicate records were removed before the in-depth screening of abstracts.

The relevant studies were selected based on four inclusion criteria. For example, studies had to (i) be published between 2010 and 2025 to allow for a wider capture of the development and growth of LE, (ii) contain at least one relevant keyword in the title, (iii) be written in English and (iv) focus on business or corporate-related contexts. Moreover, only studies that had open access were included. As a result, 279 records were excluded during the screening process, with an additional 15 records not having full-text articles available. As a result, the initial screening process yielded 13 articles for the full-text analysis. Additional sources, including grey literature such as conference proceedings, were identified through snowballing. These sources included the Systems Engineering Body of Knowledge (SEBoK), Google Scholar, and ResearchGate. From this search, 27 records were screened and included in the full-text

analysis, resulting in a final sample of 40 records in the scoping review. Figure 2 shows a summary of this process in the PRISMA diagram.

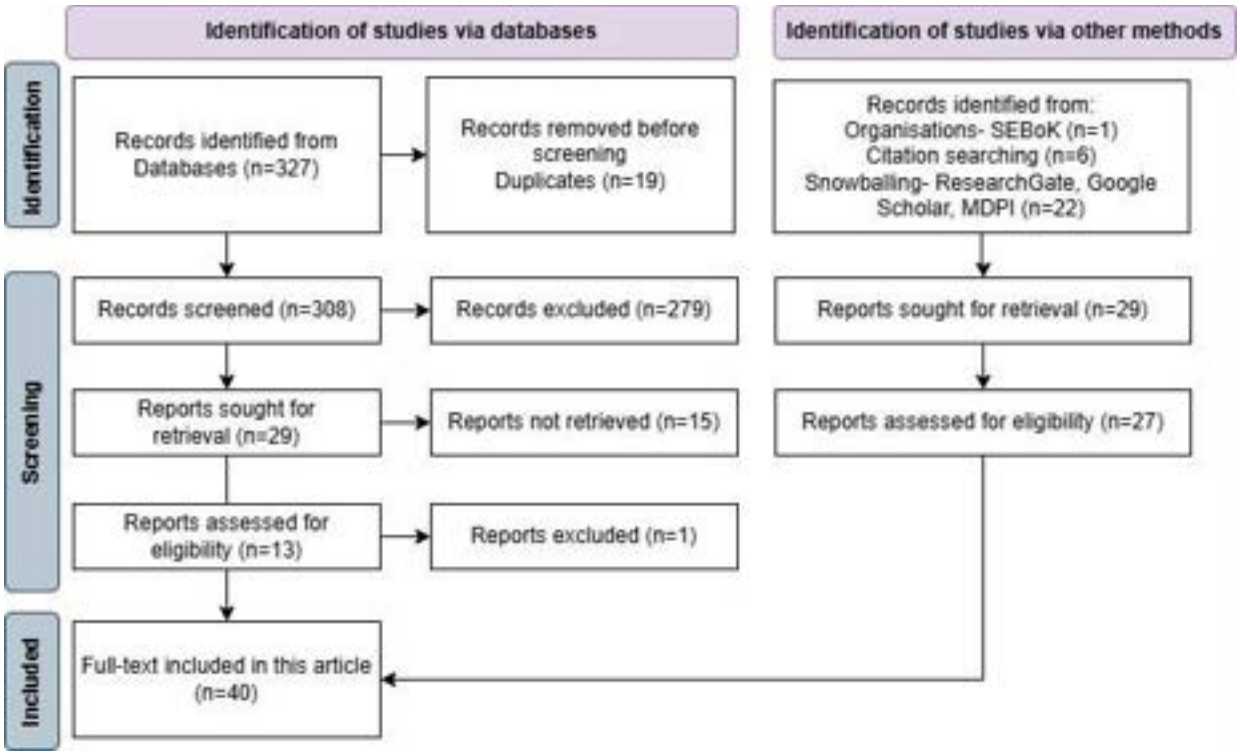

Figure 2: PRISMA diagram *(adapted from [10])*

2.3. Charting the data

Charting entails synthesising and sifting through qualitative data to extract and categorise it into meaningful concepts [10]. The concepts presented in the charting table were derived through a manual systematic coding process applied to the reviewed literature. Initial analysis of studies [1-7] revealed recurring themes related to the application of both waterfall and agile methodologies. These dominant themes guided subsequent citation searches and deeper analysis, which led to the identification of hybrid methodologies that integrated elements of both approaches. Similarly, the tools associated with each methodological approach were identified through thematic analysis, reflecting their repeated mention across the sources. This iterative process of coding allowed for the emergence of consistent patterns and concepts that formed the basis of the charting table.

As a result, in this study, the charting process was used to map key elements from the literature, which are visually represented in Table 1. This table highlights major themes relevant to the research, outlines the core concepts underpinning each theme, and identifies influencing factors within those concepts. It also demonstrates how these factors are supported by the literature, providing a clear linkage between findings and the conceptual framework being developed [10]. Overall, the charting process structured the data and enhanced understanding of how project management tools and methodologies interact within LE contexts.

Table 1: Data charting table (adapted from [10])

Concepts	Sub-concepts	Factors of influence	Literature to support

Lean engineering	Lean manufacturing and lean engineering	• Lean principles • Productivity improvement • On-time project delivery	[1-7]
Waterfall Project management	Planning phases	• Traditional and waterfall phases • Tools: Work breakdown structures, network diagrams, Gantt charts and resource planning	[8, 12-15, 17-19]
Agile project management	Overview of agile project management types	• Difference between agile project management and waterfall/traditional project management • Background of agile manifesto and methodologies	[20-24]
	Scrum agile project management methodology	• Scrum roles • Scrum ceremonies	[20, 25, 26, 43]
	Kanban agile project management methodology	• Concept of Kanban • Kanban board	[20, 27-29, 30]
Automotive project management governance	APQP	• Concept of APQP • Gates of APQP	[16]
Toyota Kata	Background	• Toyota Kata improvement and coaching • Tool for sprint retrospectives	[33-36]
Developing country context	Challenges	• Leadership commitment, infrastructure, resource constraints and risks when implementing agile methodologies	[37, 38, 40]

3 FINDINGS: SYSTEMATISED SCOPING REVIEW

The majority of the studies (75%) were published between 2015 and 2025, indicating a substantial focus on recent advancements in LE and agile methodologies. A limited number of studies were published between 2010 and 2014 (22.5%), providing foundational perspectives to LE and project management. Furthermore, a solitary study published in 1996 was included as it served as a fundamental reference for the development of lean principles.

3.1. Lean engineering background

As introduced by Womack and Jones in 1996, lean thinking proposes a broader scope of lean use, starting with removing waste and then applying the idea of a "value stream" to improve how products or services are delivered to the market more efficiently [11]. Building on this foundation, several studies [1-7] identify that Lean Systems Engineering (LSE) and Lean Engineering (LE) involve applying lean principles, methods and tools to engineering as well as related activities to maximise value and minimise waste. Its objective is to achieve optimal lifecycle value for projects using minimal resources, with value defined as the efficient delivery of successful project or product outcomes without waste [3].

Japanese projects were often viewed as “heavyweight” owing to the centralised leadership of program managers who exercised full control over budgets and staffing, which resulted in more structured project planning and control [4]. Interestingly, the study *Commentaries on ‘The lenses of lean’* [4] presents multiple perspectives on project management approaches. While some companies adopted heavyweight methods, Toyota considered these heavyweight methods, including waterfall methods, inefficient and contrary to lean thinking [4]. Toyota rejected these inefficient heavyweight approaches owing to the company’s emphasis on flexibility and continuous improvement [4]. As a result, Toyota aims to create a responsive production system, which aligns with an iterative approach [4].

In contrast, lean principles and Toyota-style production emphasise small teams, early defect detection through daily builds and continuous integration as well as flexible, overlapping workflows instead of rigid sequences [1, 4, 6]. This supports a more "lightweight" approach, which is a method that is streamlined, flexible and adaptable, such as agile methods [4]. Agile methods are lightweight, however, without attention to systematic components like early planning and design, even agile projects risk wasting engineering effort and may become inefficient at the portfolio level [4].

The lightweight approach translates to specific agile practices in many modern agile teams, where development is guided by a backlog of user stories and epics created by product owners or subject matter experts trained in story writing and acceptance criteria [5]. Durham and Michel [5] argue that this practice influences engineering design by encouraging iterative development, early validation of design assumptions, and incorporating stakeholder feedback into the design requirements. These stories are prioritised into sprints, where developers select tasks, build features and submit codes for testing and review [5]. While common, this workflow often suffers from communication gaps and limited shared understanding between stakeholders and developers [5].

Ultimately, agile alone does not guarantee a lean engineering process; nor do heavyweight, waterfall-based approaches [1-4]. Accordingly, this study's scoping review examined planning tools from both methods to inform a hybrid model that combines systematic planning with iterative delivery, supporting team productivity, minimising waste and ensuring on-time project completion to create a conceptual framework that supports planning in LE environments.

3.2. Traditional and waterfall project management

Traditional project management methodologies are defined by their structured and predictable nature, emphasising comprehensive planning. Despite evolving practices, many organisations persist in embedding these methods within their operational frameworks [12]. The five phases of project management include initiation, planning, execution, monitoring and control, and closing [13]. The waterfall project management model, named for its downward, uninterrupted flow like a waterfall, does not allow revisiting previous phases [14]. It is a type of traditional project management method that follows a strict, step-by-step sequence where each phase, namely, planning, design, implementation, testing and maintenance, must be completed before the next begins [13]. Although originally adapted for software development in the 1970s, waterfall project management mirrors traditional project management principles [14]. However, Heagney [8] emphasises that the planning phase is critical to project success. Accordingly, this review examined key planning tools used in traditional project management and waterfall project management methodologies, namely, Work Breakdown Structures (WBS), Network Diagrams, Gantt charts and resource planners [8, 13].

3.2.1. Work breakdown structure and APQP

A Work Breakdown Structure (WBS) organises all project work based on deliverables, outlining the complete project scope. It further divides the overall work into distinct tasks and arranges them in a structured, hierarchical format [15]. A WBS is a complete breakdown of all the work involved in a project, covering every task from start to finish [15]. Several studies show that a WBS is essential to project planning and can be used as a communication tool [14-17]. The studies by Sirsha *et al.* [14] as well as Devi and Reddy [17] emphasise that the WBS tool is aligned with waterfall approaches as the project scope and deliverables are defined upfront. Burghate [17] also argues that the WBS is a universal simplification tool that improves project clarity regardless of which methodology is used, hence, it can be utilised in agile projects as well.

Advanced Product Quality Planning (APQP) is a structured framework consisting of methods and procedures designed to guide product development, especially within the automotive sector [16]. Initially, implemented by General Motors, Ford, Chrysler and their suppliers, APQP provides a systematic approach for outlining and organising the steps involved in product development [16]. For Deshpande and Ekabote [16], APQP's primary goal is to ensure that both product design and quality planning align with the expectations of internal and external customers [16].

Figure 3 illustrates both the phases of APQP and the application of a WBS as guided by Deshpande and Ekabote [16] as well as Devi and Reddy [17]. Level 1 includes the entire projects scope, level 2 divides the scope into deliverables, and level 3 illustrates the work packages (smaller tasks) [17].

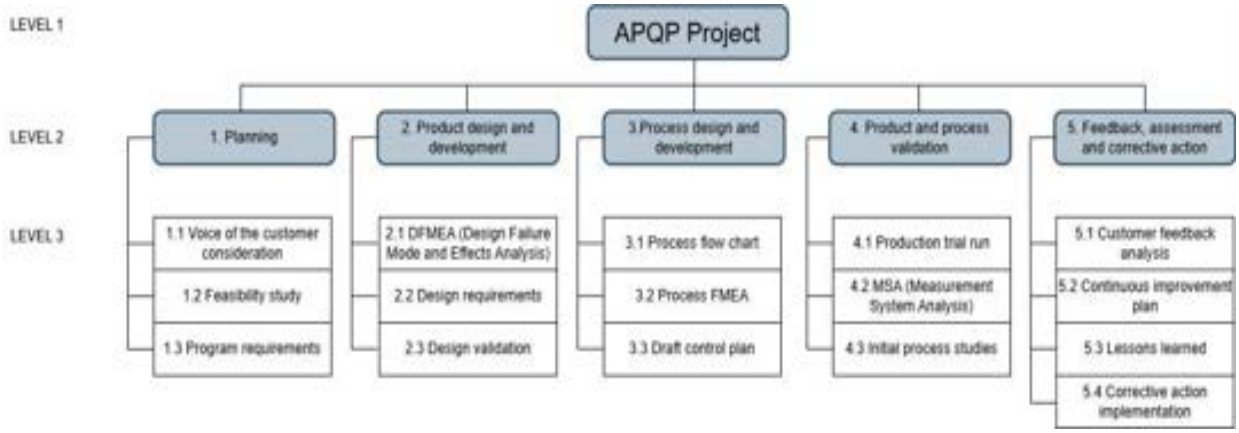

Figure 3: WBS of generic APQP project (as outlined *by Deshpande and Ekabote [16])*

3.2.2. Network diagram

A network diagram illustrates the sequence in which project activities are performed. It typically uses either activity-on-arrow notation, where arrows represent tasks and nodes; circles or boxes represent events or activity-on-node notation, where nodes represent tasks and arrows show the sequence of activities [8]. Two primary techniques used to construct network diagrams are the Critical Path Method (CPM) and the Program Evaluation and Review Technique (PERT) [8]. According to Heagney [8], network diagrams are an effective scheduling tool. As a result, when these network diagramming tools are applied in the LE context, they can be utilised as collaborative project planning tools that lay the foundation for aligning the workflow with stakeholder expectations [6, 8].

3.2.3. Gantt chart and resource planner

A Gantt chart is a project management tool used to represent a project schedule visually. Predecessors, which illustrate task duration and interdependencies, thereby form a visual representation of the project timeline [8]. Deshpande and Ekabote [16] suggest that this tool has been used in APQP projects, however, with some challenges such as its rigidity, it contradicts the dynamic interdependencies in cross-functional teams. This affects the design phase, which often experiences delays [8] and shifts customer requirements [8]; consequently, hindering task sequencing and process variability, which is essential in LE [1]. Oppenheim *et al*. [1] contend that Gantt charts are limited to scheduling and sequencing; however, to support the planning phase effectively, resource planning offers an additional layer of integration that can enable LE practices in both agile and traditional environments.

For Ojo *et al*. [18], resource planning is used to compare the hours required per project with the available hours of each resource or team member, improving visibility of capacity utilisation and task demands. This can enable project managers to optimise the allocation of

human resources across multiple projects [18]. Moreover, Mayer and Bertoncelli [19] report that the Theory of Inventive Problem Solving (TRIZ) resource checklist can further support resource utilisation by helping teams leverage available resources. Mayer and Bartoncelli [19] emphasise the importance of resource planning when budgets are minimal. On the other hand, Ojo *et al*. [18] provide a guideline for calculating the optimal allocation of resources to a portfolio of projects at a strategic level. However, the Gantt chart remains the most effective low-level resource planning tool as it is project-specific [8]. While the findings from the three studies [8, 18, 19] focus on planning tools in isolation, their combined application could provide a foundation for LE by reducing waste related to human resource inefficiencies [6, 8 18, 19].

3.3. Agile project management

Agile promotes a mind-set focused on flexibility and responsiveness. As a lightweight approach, it is well-suited for managing evolving requirements and delivering functional software through incremental and iterative development [20]. Most software development life cycle models incorporate loops, as shown in Figure 4, where specific steps are repeated, known as iterations. Iterative models enable early feedback, which helps reduce project risks [21]. Agile design and architecture have also enhanced global software development through practices such as diagramming, prototyping and real-time communication [22].

In contrast, the waterfall model follows a linear, plan-driven approach, which is illustrated in Figure 4 [20]. Its primary limitations include inflexibility, and the high cost and time required to make changes. Agile, by comparison, is value-driven and emphasises continuous feedback through iterative cycles known as sprints. However, it also presents challenges, such as difficulty in estimating costs and timelines for large-scale projects, the need for experienced cross-functional teams, and the potential for insufficient documentation [20].

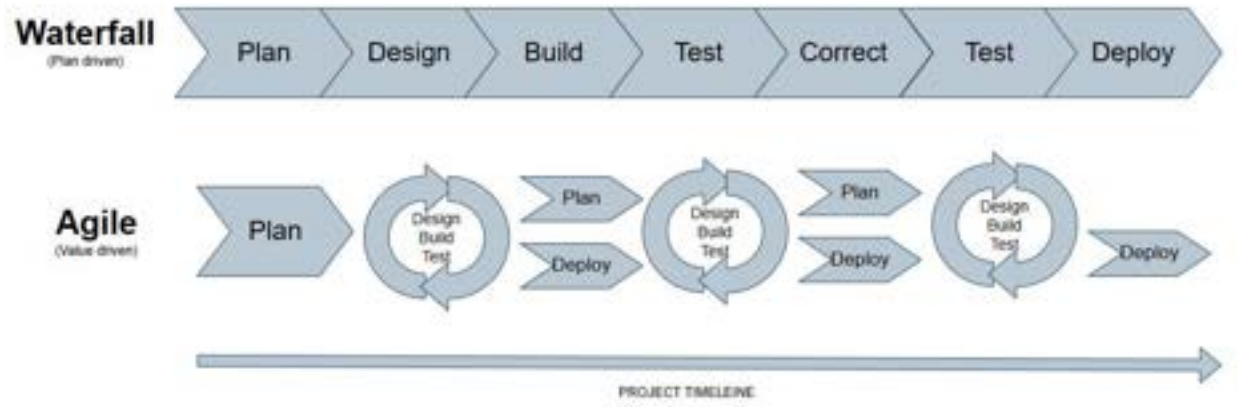

Figure 4: Comparison of waterfall and agile project management (a*dapted from [20])*

The agile manifesto is based on the values of people over rigid processes, a working product over extensive documentation, customer collaboration over strict contracts, and adapting to change over sticking to plans [20]. Common agile approaches include Scrum, Kanban, Extreme Programming (XP), Lean Software Development, Crystal, Feature-Driven Development (FDD), Dynamic Systems Development Method (DSDM), and Agile Unified Process (AUP) [23].

Four studies highlight the significance of agile principles such as iterative development, stakeholder communication and responsiveness to change [20, 21, 22, 23]. Boral [20], Kneuper [21] and Ferdiana *et al*. [22] illustrate the application of agile in software development environments, while Omonije [23] explores the broader impact of agile beyond software development. Omonije [23] illustrates that if agile is applied in engineering environments, it will enable the organisation to respond to changes swiftly, which will improve the productivity

of engineering teams to support LE. Of the four common agile approaches identified, Sunder and Deepalakshmi [24] highlight Scrum and Kanban as the most widely adopted and recognised. These two approaches were, therefore, the focus of further investigation in this study.

3.3.1. Scrum

Scrum is a widely used agile methodology that emphasises iterative and incremental software development. Its creators compared it to the game of rugby, where team members work closely together and continuously pass responsibility; just as they would pass a ball, to maintain momentum and competitiveness [20]. Boral [20], Sassa *et al.* [25] as well as Stettina and Smit [26] highlight that Scrum enables the rapid and continuous delivery of tasks in cycles of two to four weeks, known as sprints. A sprint, or iteration, is a time-boxed period that serves as the fundamental unit of development in Scrum [20, 25, 26]. Its duration is defined before the project begins and remains consistent throughout [20]. Three studies define three core roles in Scrum, namely, the product owner, who collaborates with stakeholders to gather requirements and manages the product backlog; the scrum master, who facilitates daily stand-ups and ensures adherence to Scrum principles by coaching the team; and the scrum team, a cross-functional group responsible for developing the product [20, 25, 26].

According to Stettina and Smit [26], key practices, also referred to as Scrum ceremonies, include portfolio reviews, project planning sessions, sprint backlog planning, sprint planning, daily stand-up meetings (daily Scrum), and sprint retrospectives. During sprint planning, the team and product owner select tasks from the product backlog to prioritise for the upcoming sprint [20, 25]. In daily stand-ups, team members discuss completed tasks, current work, and raise any blockers or *ad hoc* activities that may impact progress [20, 25]. Sprint retrospectives focus on reflection and improvement; the team discusses what went well, what did not, identifies potential causes of issues, reviews blockers, and creates an action plan for continuous improvement [20, 25]. The Scrum methodology, including its ceremonies, is illustrated in Figure 5.

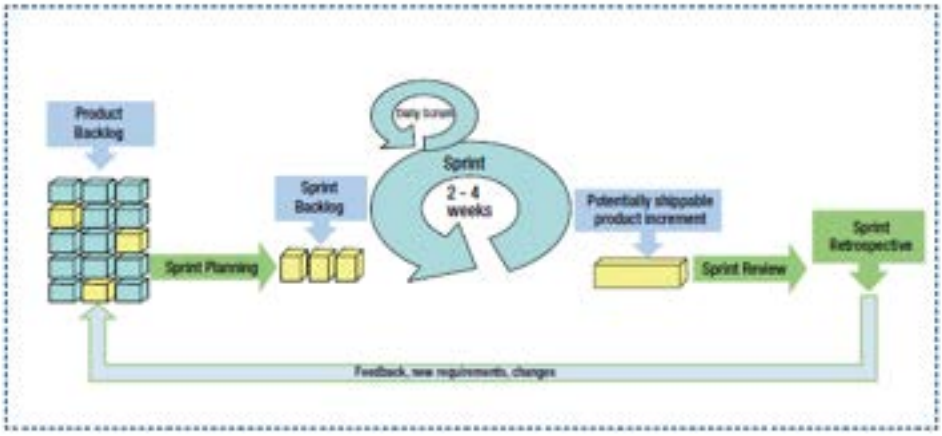

Figure 5: Scrum methodology [20]

While Boral [20] and Sassa *et al.* [25] present Scrum as an effective framework, Stettina and Smit [26] reveal potential drawbacks when Scrum is applied to multi-project environments, such as increased overhead and reduced efficiency owing to multitasking. This suggests that while Scrum can support lean engineering principles, its effectiveness may depend on flexible application rather than strict adherence to all its prescribed rules and resource requirements.

3.3.2. Kanban

Kanban is an agile methodology that visualises work using Kanban boards [20]. These boards typically display cards or sticky notes arranged in columns such as “Planned”, “In Progress” and “Done”, making it easy to track work in progress and identify bottlenecks [27]. A study by Parsons and MacCallum [28] explored the use of lean and agile in education by implementing the lean principles of pull and flow through Kanban boards and story cards, respectively [28]. Boral [20], Zasornova *et al*. [27] as well as Parsons and MacCallum [28] suggest that Kanban is guided by six key principles, namely:

1. Visualising the workflow: Using a board where cards move through stages (for example, from development to testing, as shown in Figure 6).
2. Limiting work in progress (WIP): Improving flow and minimising delays that can block tasks.
3. Managing flow: Focusing on just-in-time planning and quick issue resolution (for example, using an expedite row (as shown in Figure 6).
4. Making process policies explicit: Defining clear criteria for moving tasks between stages.
5. Implementing feedback loops: Using regular retrospectives.
6. Improving collaboratively and evolving experimentally: Adjusting WIP limits to meet project demands.

Figure 6 illustrates the workflow and principles of the Kanban methodology [20].

Figure 6: Kanban methodology [20]

For Mood [29], traditional Kanban applications often face workflow inefficiencies, task misalignment and bottlenecks caused by static configurations. Kanban works best when integrated with other agile methodologies. For example, both digital and physical boards promote collaboration; however, physical boards with sticky notes require less effort to update during meetings [30]. The Kanban approach aligns well with lean principles such as flow, pull and just-in-time, making it a valuable tool for implementing lean engineering. As potential workflow inefficiencies may arise if Kanban is used in isolation, it should be complemented with other methods or practices to ensure effective implementation of LE [5, 29].

3.4. Hybrid project management

Hybrid project management combines traditional and agile techniques to leverage the strengths of both while minimising their weaknesses [31]. Four common hybrid types include Water-Scrum-Fall, Waterfall-Agile, Hybrid V-Model, and Agile-Stage-Gate [31]. Water-Scrum-Fall integrates a traditional planning phase, a Scrum-based iterative development phase, as well as traditional implementation and closing phases. The Waterfall-Agile uses a waterfall approach for planning only, with agile methods applied during development and final phases. The Hybrid V-Model resembles Water-Scrum-Fall but replaces the waterfall method with the V-Model for the traditional phases. Agile-Stage-Gate divides the development process into stages combined with agile sprints, foregoing traditional tools like network diagrams and Gantt charts [31]. Since teams operate within traditional organisational structures, this often results in "agile islands in a waterfall", where agile and conventional development coexist [32].

Both studies by Reiff and Schlegel [31] and Kasauli et al. [32] suggest that neither waterfall or agile alone is sufficient for all contexts. A hybrid Waterfall-Agile model is well-suited for APQP projects, as it allows the structured planning phases to be executed using the waterfall approach, while agile methodologies can be applied to the iterative development and deployment stages. Furthermore, neither Scrum nor Kanban alone is sufficient to fully support LE implementation; therefore, a combined agile approach that integrates both frameworks is recommended to maximise flexibility, efficiency and continuous improvement [26, 29, 31, 32].

3.5. Toyota Kata

Reflection occurs during sprint retrospectives, where the team reviews its current state, defines improvement goals, and develops a plan to achieve them [33]. This process closely aligns with Deming's Plan-Do-Check-Act (PDCA) cycle and Mike Rother's Toyota Kata. In a study by Özcan-Top and McCaffery [34], agile was implemented at a medical device company operating under regulatory constraints. During this study, value stream mapping was used in the prioritisation phase to identify bottlenecks [34]. The prioritised recommendations were then executed using the Improvement Kata, which supported iterative implementation until each recommendation was completed [34].

Various studies define Toyota Kata as a management and improvement methodology that embeds continuous improvement as a mind-set and habit [33- 36]. Rother [35], the originator of the concept, states that it is implemented through the Improvement Kata and taught using the Coaching Kata. With repeated use, these routines become second nature [36]. Although developed for manufacturing, the psychology behind the Improvement Kata is considered universal, with the methodology applicable across various domains. While the content may vary, the structured approach remains consistent [36]. Across four studies, the Improvement Kata involves these common four steps, namely, establishing a target condition or vision, understanding the current condition, identifying obstacles, and defining the next condition [33-36]. During sprint retrospectives, this approach could help teams plan and achieve their goals through its iterative and experimental nature. However, this would require amending the rules of the Scrum retrospective ceremony.

4 DISCUSSION

Several studies [37–40] argue that applying lean practices in developing countries requires adaptation to local economic realities, infrastructural limitations and cultural differences. For instance, Olu-Lawal *et al*. [37], in a comparative study between the USA and Africa, demonstrate that leadership commitment, organisational culture and workforce engagement are critical for successful implementation. However, these factors are often undermined by limited resources and weak infrastructure [37]. Similarly, agile methodologies such as Scrum and Kanban encounter contextual barriers in developing settings. Resource constraints may

prevent the appointment of dedicated roles like Scrum Masters or the allocation of separate spaces for tools such as Kanban boards [26]. Additionally, agile teams often rely on digital tools for workflow management, but technological immaturity in many developing countries makes this reliance challenging, particularly, in the automotive sector [37].

In response to these challenges, agile implementation must be tailored to local capacities through low-cost and accessible practices that maintain core agile values such as collaboration and transparency. Rahayu *et al.* [38], in their study of agile practices in Indonesia, identify frequent issues such as unclear requirements, poor documentation, unstructured teams, undefined roles, inadequate sprint planning, as well as the inconsistent use of daily stand-ups and retrospectives. These findings reinforce the need to customise agile methods and invest in capacity-building initiatives to improve adoption in resource-constrained environments.

To achieve effective implementation, a hybrid framework that balances structure with flexibility is essential. While agile promotes adaptability, certain structured planning tools from the waterfall model remain valuable [20, 26, 29]. For example, stakeholder engagement and documentation can follow the Advanced Product Quality Planning (APQP) framework, which aligns well with the planning stages of waterfall without compromising agility. To address spatial constraints, teams can place physical Kanban boards in existing workspaces such as boardrooms. Rotating the Scrum Master role among team members offers a practical solution to staff shortages. These adaptations reflect the findings of Stettina and Smit [26], who support multitasking and cross-functional roles to improve execution. Incorporating resource planning into routine Scrum activities further strengthens project management efficiency [8, 18, 19].

Moreover, a robust lean engineering framework must incorporate well-established lean principles. Studies on Lean Enablers [1, 3, 6] demonstrate consensus around six foundational principles, namely, respect for people, stakeholder value definition, waste elimination, process flow, customer-driven value delivery, and continuous improvement. Embedding these into the framework enhances its applicability. For instance, respect for people can be demonstrated through active participation and punctuality in daily stand-ups [20, 25]. Mapping stakeholder value across the project lifecycle aligns with agile values [21-23]. Waste can be identified through retrospectives that capture *ad hoc* and non-value-adding activities [20, 25]. Process flow improves through Kanban boards, and customer alignment is sustained through iterative feedback [27, 28]. Furthermore, applying practices such as Toyota Kata supports ongoing improvement across cycles [33-36].

In highly regulated environments, agile alone may prove insufficient. Hybrid models that blend agile and traditional project management have yielded better outcomes [39]. While agile typically uses a bottom-up approach, lean employs a top-down structure [39], and combining both offers a balanced solution. Omoruyi *et al.* [40] report that 71.7% of organisations in Nigeria use Scrum as their main agile framework, with 13.3% adopting Kanban. These figures provide a relevant benchmark for similar developing economies, reinforcing the framework's broader relevance. As shown in Figure 7, the proposed model accounts for these patterns by integrating both frameworks with contextual modifications.

Finally, incorporating design thinking further enhances the framework's effectiveness. Reiff and Schlegel [31] propose a Waterfall–Agile hybrid that uses traditional planning tools in conjunction with agile execution. Complementary studies [5, 28, 41] highlight the benefits of user story mapping, which bridges customer empathy with backlog prioritisation to guide development. Based on this evidence, the proposed framework introduces story mapping during the initial waterfall phase and continues its use through agile iterations. This integration ensures consistent customer involvement and helps teams create solutions that address real user needs. As illustrated in Figure 7, the framework brings together lean

principles, agile adaptability, and design thinking to form a context-sensitive approach tailored to the unique constraints of developing countries.

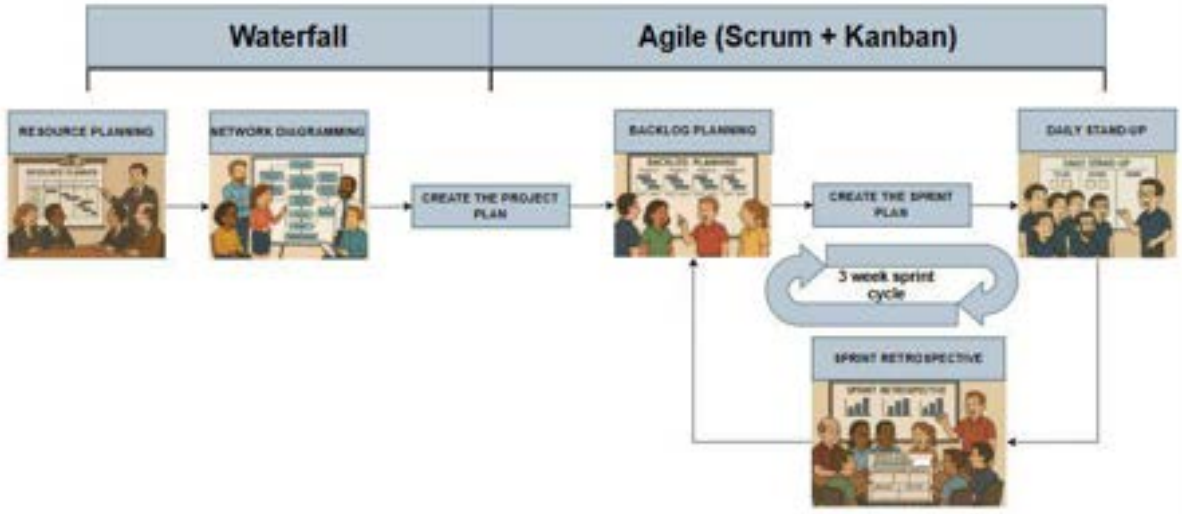

Figure 7: Conceptual framework (images generated from [42])

Figure 7 illustrates that the conceptual framework initiates with resource planning, where management evaluates team capacity in relation to project requirements. This step ensures the appropriate allocation of skills and availability prior to project initiation, aligning with the findings of previous studies [18, 19]. Following this, the team, comprising the product owner and cross-disciplinary engineers, conducts collaborative project planning. During this phase, a Work Breakdown Structure (WBS) and a network diagram are developed. These planning tools lay the foundation for a detailed Gantt chart and a formal project plan, both of which structure the project's timeline and dependencies [8, 14-17]. Stenholm *et al*. [3] and Heagney [8] suggest that the integration of the network diagram supports lean engineering principles by maximising planning lifecycle value and minimising waste.

Once the project plan is finalised, tasks are transferred to a backlog board, where they are refined into smaller, manageable tasks. These tasks are then grouped into at least four sprints to promote structured execution [20]. The team begins sprint planning by selecting tasks from the backlog and assigning them to the “Planned” column on a Kanban board, which includes the columns “To-Do”, “Doing”, and “Done” [20, 27, 28]. This visual workflow facilitates real-time tracking of progress. Task allocation considers individual capacity, with junior engineers often absorbing more tasks owing to their lighter involvement in strategic meetings compared to senior engineers. A key metric at this stage is the comparison between planned and actual hours worked, which informs team capacity and project efficiency.

Daily stand-up meetings, lasting fifteen minutes and facilitated by a rotating Scrum master, occur at the Kanban board [20, 28]. These meetings help the team track progress, identify blockers, and log time spent on *ad hoc* tasks. By ensuring rapid feedback loops and quick resolution of issues, these practices contribute to improved productivity compared to traditional waterfall approaches, where delays in communication and problem identification can hinder progress [20, 28]. The team reviews these metrics, planned versus actual hours and planned versus *ad hoc* effort, during sprint retrospectives, where performance is evaluated, and continuous improvement opportunities are discussed [25]. If performance falls short of targets, the Toyota Improvement Kata guides structured problem-solving through its iterative process, reinforcing the lean principle of continuous improvement [43].

Despite these benefits, the framework has certain drawbacks. Its implementation relies on a top-down approach, which can create challenges in securing senior leadership buy-in, particularly given its relatively recent emergence [20]. Furthermore, teams may initially resist participating in daily stand-ups and sprint planning sessions, as these practices introduce unfamiliar routines and ways of thinking [20].

Industry examples validate the practical application of variations of this framework. For instance, Ford's implementation of Lean Product Development (LPD) and their customised approach to lean engineering, achieved a 40% reduction in die construction lead times, a 50% reduction in tooling costs, and a 35% improvement in quality, while also enhancing employee morale by 30% [7]. These outcomes provide a valuable benchmark for automotive suppliers seeking to adopt lean engineering practices. By applying the proposed framework, organisations can align their project planning and execution strategies with proven lean methodologies to enhance performance, reduce waste and support sustainable development.

5 CONCLUSION

This study conducted a systematised scoping review to identify planning tools relevant to the implementation of LE. By examining existing literature, new insights were revealed that contributed to the advancement of LE practices. Key findings highlighted the integration of planning tools from both waterfall project management, such as Work Breakdown Structures (WBS), network diagrams and Gantt charts as well as and agile methodologies, including Scrum and Kanban. The investigation of hybrid project management approaches revealed the value of combining waterfall's structured planning with agile's iterative development, particularly through the waterfall-agile model.

Based on these insights, the study proposes a conceptual framework for LE that merges elements of waterfall, Scrum and Kanban. This model aligned well with the automotive industry's stage-gate process (APQP), where planning is traditionally based on waterfall methods, while implementation could benefit from agile practices. The analysis underscores the importance of this integration, as it offers a practical pathway for industries to transition towards more flexible and adaptive project management without abandoning the rigour of established processes. This contribution is significant as it bridges a gap in existing project management planning approaches by applying lean principles beyond the manufacturing environment. If adopted, the proposed approach is expected to enhance team productivity, reduce defects, shorten project delivery times and, ultimately, increase stakeholder satisfaction.

Future research should validate this framework across sectors through targeted case studies, evaluating its adaptability and long-term impact. Demonstrating its application in real-world contexts will reveal sector-specific challenges and opportunities, strengthening its practical relevance. In doing so, this study lays the groundwork for more adaptive, efficient and stakeholder-aligned engineering project management practices.

ABSTRACT

Business Intelligence (BI) solutions occasionally fail to drive decisions and actions. This study identifies key factors that bridge the gap between BI insights and strategic decisions and actions, investigating how to ensure BI leads to decision-making and action. The research examines the influence of BI insights through five theoretical models: Decision Theory, Technology Acceptance Model, Unified Theory of Acceptance and Use of Technology, The Value of Real-Time Data Model, and the Perception-Cognition-Action (PCA) regulation process. A thematic clustering approach using ATLAS.ti and manual mind mapping, supported by Python and OpenAI, was used to analyse critical success factors. The study introduces a theoretical framework based on the PCA framework, integrating additional data processes to enhance the impact of BI insights. The critical success factors clustered findings contribute to improving data-driven decision-making by strengthening the generation and utilisation of actionable insights.

Keywords: Business Intelligence, BI, Decision-making, Actionable insight, Action

* Corresponding Author

1 INTRODUCTION

Business Intelligence (BI) has been widely adopted across various sectors to support data-driven decision-making and action. However, there remains considerable confusion and inconsistency in how BI is defined and interpreted. A review of existing studies reveals several common themes and emerging concepts in the definitions of BI.

*"BI is a broad category of applications, **technologies**, and processes for gathering, storing, accessing, and **analysing data** to help business users make better **decisions**." [1, p. 491]*

*"BI is a general category of applications and **technologies** used for collecting, accessing, and **analysing data to assist decision-makers in making** informed **decisions**." [2, p. 43]*

*"BI is a process driven by **technology** that **analyses** business **data** to provide information that can be **actioned** so that executives and managers can make better-informed business **decisions**." [3]*

The above definitions highlight three core concepts of BI: technology to analyse data, provide actionable insights, and make business decisions. It is important to note that recent literature has introduced the notion of "that can be actioned" in the definition. There has been an evolution of thinking that BI should incorporate actions. In this research, action is seen as physical bodily movements as well as digital workflows performed by computers.

Supply chains use BI for various reasons, such as to track, predict and optimise costs, monitor utilisation of assets and resources, and assess compliance with processes. BI helps executives understand what is happening in the operations of the supply chains and helps them make more strategic decisions and plans to act on.

Observations in the Supply Chain Industry suggest that BI solutions can occasionally fail to drive decisions and actions, and the full maturity of the solutions is not reached. BI-driven insights do not always translate into effective actions within the organisation. There is a gap between the insights resulting from BI systems and the organisation's response actions [4].

This study seeks to examine the key factors that affect the ability of BI solutions to effectively translate insights into organisational action. Given the general objective, the research questions are:

- Why do dashboards, on occasion, fail to drive action?
- What factors contribute to action being taken based on BI insights?
- How can the effectiveness of dashboards in driving action be improved?
- What technological features in BI tools enhance effective action based on insights?

The remaining sections of the article are structured as follows: first, the review methodology is presented, followed by the findings from the literature review. Next, a theoretical framework is discussed, and finally, the strengths and limitations of the research are examined, and concluding remarks are given.

2 REVIEW METHODOLOGY

This section discusses the literature review approach, guided by the research questions, along with the methodology used for selecting and analysing relevant sources.

2.1 Search Protocol

A comprehensive literature search was conducted across multiple academic databases, including Scopus, ResearchGate, SpringerLink, ScienceDirect, and Google Scholar, covering the entire period. The search strategy employed a combination of relevant keywords and phrases aligned with the research objectives. These search terms included: "Business Intelligence Action", "Business Intelligence", "Driving Action", "Reason for Action",

"Transforming Data into Action", "Business Intelligence Theories", "Business Intelligence History", "Business Intelligence Tools", "Dashboard", and "Business Process". Boolean operators and truncations were applied where appropriate to broaden the search scope and capture variations in terminology. Additionally, the derivative and prior works cited in reference [1] were reviewed. This source was identified as a foundational article with direct relevance to the research objectives of the present study and was therefore used to trace additional scholarly contributions within its citation network.

2.2 Selection Process

A total of 74 sources were initially identified through the database search. Following a structured screening process, 41 publications were selected for inclusion in the final review. The selection criteria were based on relevance to the research objectives and adherence to academic standards (Table 1). Specifically, only articles published in peer-reviewed journals or reputable conference proceedings were included.

Table 1: Selection criteria

Inclusion Criteria	Exclusion Criteria
Relevance to the research objectives	Not freely available
Academic publications	Not written in English
Seminal Work	Only possible to find abstract
	Reports and news articles

2.3 Data analysis

A thematic analysis was conducted using ATLAS.ti to systematically examine the selected articles in accordance with the research objectives. The coding process focused on key themes, including "BI Failure Reasons", "Critical Success Factors", "Improvement Strategies", and "BI Technologies". To facilitate thematic organisation, ChatGPT was employed to assist in structuring the coded data within a predefined thematic framework, reflecting the stages of the BI lifecycle. For enhanced visualisation, the output was mapped using MyMap, an AI-based mind-mapping tool.

3 LITERATURE REVIEW

The literature content is extracted and analysed in alignment with the research objectives and questions. An assessment of decision-making gaps and dashboard failures is presented. Next, the factors leading to action based on BI insights and improving the effectiveness of BI reports are addressed. The technological features of BI tools are discussed, and finally, models linked to BI are presented. In this way, a comprehensive review clearly addresses the research problem, objectives, and questions to gain a broad understanding of BI and its challenges and technological solutions that align with the study goals.

3.1 Overview of Reviewed Literature

The articles originate from 24 different countries, with the United States (8) and Australia (7) contributing the highest number of publications. Overall, Asia stands out as the most represented continent, with 15 articles originating from 12 countries, followed by North America with 10 articles. In contrast, South America (1) and Africa (2) are the least represented, which may reflect limited BI-related research activity in these regions. The exclusion of non-English publications may have contributed to the underrepresentation of South American research outputs. As shown in Figure 1, the selected articles are drawn from all the major continents.

Figure 1: Literature Source Countries

Most of the reviewed literature was published after 2005, with a noticeable increase in scholarly output in recent years (Figure 2). This upward trend indicates growing academic interest in the concept of BI as a driver of data-driven decision-making and action.

Figure 2: Number of Publications by Year of Publication

The selected articles were retrieved from five distinct academic databases. Most sources originated from ResearchGate, followed by Scopus, which contributed a substantial portion of the reviewed literature (Figure 3).

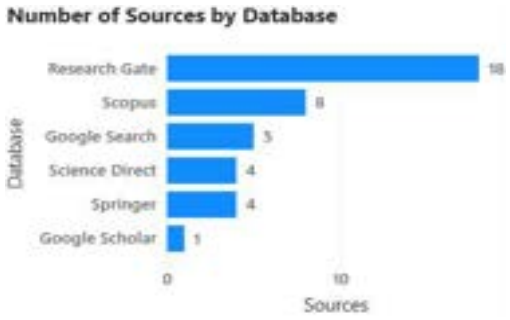

Figure 3: Number of Sources by Database

Most of the sources are peer-reviewed journal articles (31 of 42); however, the selection also includes six conference proceedings, two book chapters, as well as one book and one doctoral thesis, as illustrated in Figure 4.

Many literature studies explored various aspects of BI. A study in 2008 highlighted that theory formulation and literature review remained the most employed research strategies in the field [5]. A systematic literature review published in 2020 examined 84 studies from the period 2011 to 2020, further mapping methodological trends in BI research [6]. Jourdan [5] noted that the survey research strategy had been infrequently employed in BI. However, recent

research demonstrates an increased use of survey methodologies within the BI domain, indicating a shift toward more empirical studies [7], [8], [9], and [10].

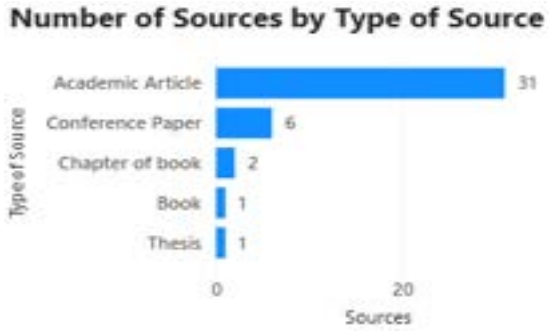

Figure 4: Number of Sources by Type of Source

3.2 Decision-Making Gaps and Dashboard Failures

In this study, the success of BI systems is evaluated based on their ability to drive actionable insights that lead to improved organisational efficiency. Any factor that impedes or disrupts this process is classified as a failure of the BI system. Based on the thematic analysis of the selected literature, BI system failures can be categorised into four primary themes (Figure 5):

- Lack of strategic alignment and analytical talent: The absence of a clear BI strategy, combined with a shortage of skilled personnel and ineffective data presentation, can undermine the successful implementation of BI systems [11], [12].
- Governance and adoption issues: Insufficient stakeholder buy-in, lack of governance structures, and unregulated system usage may lead to inconsistent application of BI tools, limiting their effectiveness [11], [13].
- Data Quality: Poor data quality issues, such as inaccuracies and inconsistencies across source systems [11], [13], [14]. Additionally, information overload also contributes to system failure [15].
- Integration and user-related challenges: Technical integration issues, limited user accessibility, and disconnects between developers and end-users can hinder BI from driving analytical insights into action [12], [16], [17], [18].

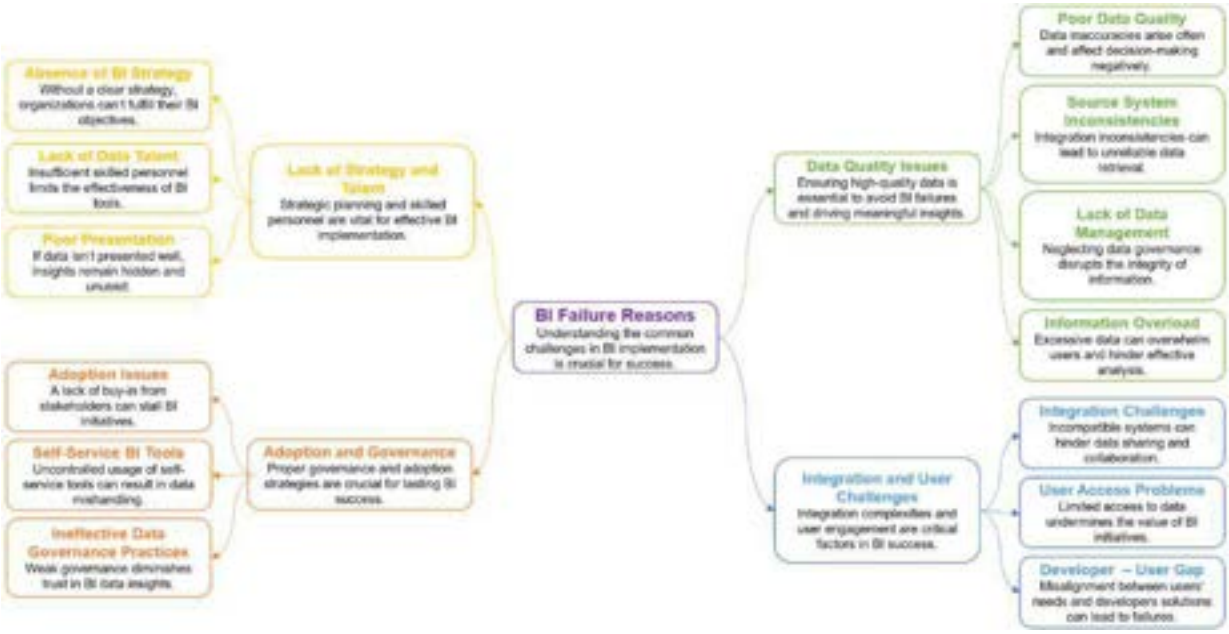

Figure 5: BI Failure Reasons Mind Map

3.3 Success Factors

Many studies have identified the Critical Success Factors (CSFs) for BI, and some of these could be considered action drivers within BI processes. Some studies have categorised CSFs [19], and others have ranked them by relative importance [20].

In this study, CSFs were systematically coded, and their quotations were extracted using ATLAS.ti. These quotations were then processed using ChatGPT, which was instructed to organise the CSFs into a sequential framework aligned with the typical BI process flow: from data capture, storage, analysis, and visualisation, interpretation and ultimately action. Additionally, the prompt directed the model to identify factors that are critical across all stages of the BI lifecycle. The result was then used to create the cycle in Figure 6. It is observed that different Critical Success Factors (CSFs) play distinct and pivotal roles at various stages of BI solution development, while certain foundational factors remain essential throughout the entire process.

Figure 6: Cycle with CSFs at Each Stage

The CSFs for successful BI implementation were also initially clustered using a Python script and OpenAI API and further refined through manual thematic grouping using ATLAS.ti and mind mapping to ensure alignment with the research context. The resulting common themes and categories are summarised in Table 2. The Python script will be made available upon request.

3.4 Improving the Effectiveness of BI Dashboards

This section discusses the strategies for improving a BI dashboard's effectiveness in driving action. Based on the reviewed literature, the ten best practices for BI dashboard design and implementation were identified and are presented and discussed in detail.

Table 2: CFS Themes and Codes

CFS Theme	CSF Codes
Strategy	Well-established business case, clear vision, business strategy link, well-defined vision, clear goals and objectives, strategic plan
Top Management Support	Executive buy-in, management support and commitment and sponsorship
Team and their skills	Developer skills, the team possess the right mix of skills, teamwork & composition, knowledge and technical capabilities of the BI team
Project Related Factors	Project management skills, Project planning, Project team competencies, Project scope is clearly defined and managed
Data Related Factors	Data quality, high quality of data at source systems, sustainable data quality, precision, consistency, data efficiency, and effective data management
Training	Education, formal education, training and support are in place for business vision, training users, and competency development
Ease of interpretation and usability	Easy to interpret, easy to implement insights, ease of use
Perception	Perceived ease of use, perceived enjoyment, perceived incentives, perceived usefulness, perceived value

External Factors	External environment, third-party interactions
Project Champion	Project leader/champion, a high-level champion from the business side
Development approach, incremental & iterative	Adaptive, evolutionary development approach, business-driven and iterative development approaches, flexibility, and design must adapt
Trust and Habit	Trust, habit, human factors like information behaviours, and hope for performance
User	Self-efficacy, user buy-in, user-oriented and friendly technologies, user expectations, user satisfaction, user support, user training, user participation
System Related Factors	Stable source systems are in place, appropriate technology, system integrity, system quality, alerts and notifications, IT infrastructure, ability to integrate with other systems
Change Management	Ability to manage change, attitude towards change, and user-oriented change management
Communication	Effective communication, the communication strength of the bi team, and communicating change management
Organisational Factors	Organisational size, organisational acceptance, organisational structure, organisational learning, and organisational competence
Culture	Organisational culture, subjective norms
Resources	Adequate resources, human resources, and technology experience
Cognitive Fit	Cognitive loads induced by the content of the dashboard, psychological state or 'mindset', creativity and original thinking, the sociotechnical fit and the cognitive fit
Speed of implementation, access and response	Rapid implementation, prototype is used as proof of concept, speed, timely response, timely access, user access, access to organisation data

1. **Define clear objectives and key performance indicators (KPIs).** By starting with specific goals for what you aim to achieve with BI, you provide the criteria to filter information based on data relevance [5]. You are also able to track progress and success.
2. **Engage stakeholders early.** "Business Intelligence solutions must be built with end users in mind, as they need to use it" [6, p. 75]. It's important to include end-users in the planning and design phases. This ensures that BI tools meet user needs and that reports, and dashboards are actionable and understandable.
3. **Ensure data quality and integrity.** Based on the BI failure reasons and the success factors discussed in the previous two sections, the topic of data quality came up. It is important to ensure data quality right from the point of data capture. As the famous saying goes, "Garbage in, Garbage out" [7, p. 28]. BI insights are only as good as the data they rely on. Regularly cleanse, validate, and standardise data to prevent inaccurate analysis and to build user trust in BI outputs.
4. **Use self-service BI Tools.** "Self-service BI equips business users with the flexibility and tools to explore their own data and, through a prototyping approach, express their information requirements" [8, p. 23]. You empower non-technical users to explore data independently. Self-service tools allow business units to run analyses without relying entirely on IT, fostering data-driven decision-making across the organisation.
5. **Foster a data-driven culture.** This emphasises the fourth level of sense-making in knowledge management [9]. "Knowledge embedded in organisational culture is usually implicit, assumed and taken for granted" [10, p. 4]. Data-driven culture supports the use of BI systems and fosters it by emphasising their economic and operational benefits [11]. Promoting the value of data-driven decisions through training and regular communication is important.
6. **Prioritise real-time or near-real-time data.** This is further discussed in the next section, which discusses the technological features of BI tools. It is important to deliver information at the right time, location, and form [12]. This enables faster decision-making and a more agile response to changes in the business environment.

7. **Focus on effective data visualisation.** Use clear, intuitive visualisations to present insights. Visualisations assist users in creating progressive visual representations of information. The capacity to imagine the information in a graphical set-up (rather than words or numbers) assists users with comprehending information in an insightful manner [13]. Complex data sets become easier to understand with effective visualisations, which increases user adoption and actionability.
8. **Implement role-based access and security.** According to [14], database security is one of the top 10 database features to have, and security is one of the top 5 dimensions in BI, according to [15]. Managing access to BI tools and data by roles to maintain security and ensure that users only see information relevant to the drivers of the problem is good practice.
9. **Enable mobile access to BI Tools.** Users require the freedom to access information anywhere and anytime. "Digitalised platforms such as mobiles and tablets have led to ease of data delivery in the business intelligence sector" [5, p. 34]. Mobile-friendly BI allows users to access insights on the go, improving accessibility and responsiveness. It is good practice to make BI dashboards mobile-friendly.
10. **Invest in training and support.** [14] mentions training as one of the five key factors in implementing BI solutions. [15] rank training as the 5th most important process for BI implementation, and [11] have training as their 4th critical success factor, to mention 3 out of the 28 sources that reference training. Comprehensive training ensures that users can fully leverage BI tools. Ongoing support and resources help users troubleshoot issues and maximise their productivity.

3.5 Technological Features of BI Tools

This section explores the key technological enablers of BI identified through the analysis of the selected literature. The discussion begins with an overview of Online Analytical Processing (OLAP), followed by an examination of various BI tools and platforms. The role of predictive analytics is then explored, alongside the emergence of embedded BI capabilities. The analysis continues with the development of Real-Time BI (RTBI) and the use of automated alerts to support timely decision-making. Finally, the section concludes with a discussion on design indicators for managing information load, which aim to improve user comprehension and actionability.

Online Analytical Processing (OLAP): A total of seventeen sources reviewed in this study mentioned OLAP as an important technological feature in BI systems. As described by Bataweel [21], "OLAP is a cube-like structure called a hypercube. It has facts that are numerical in nature and that are categorical in dimensions. The specific data and design of the cube are obtained from tables where measures are obtained from records in the fact table and its dimensions from the specific dimension tables". OLAP makes it possible for clients to inspect multidimensional data with speed and from **multiple perspectives** [13]. Similarly, OLAP is used to analyse data from different angles and distil it into actionable information [29].

BI Tools: Tripathi and Bagga [13] evaluated several BI tool solutions in 2020 and concluded Microsoft Power BI, Tableau and Qlik as the leaders among all. According to Google Trends, Power BI has been on the rise since 2015 (**Error! Reference source not found.**7). Price has a big influence on the choice of BI tools. While Tableau requires a substantial annual platform fee, Power BI offers more flexible monthly licensing options tailored to different user needs, making it a more cost-effective solution for many organisations.

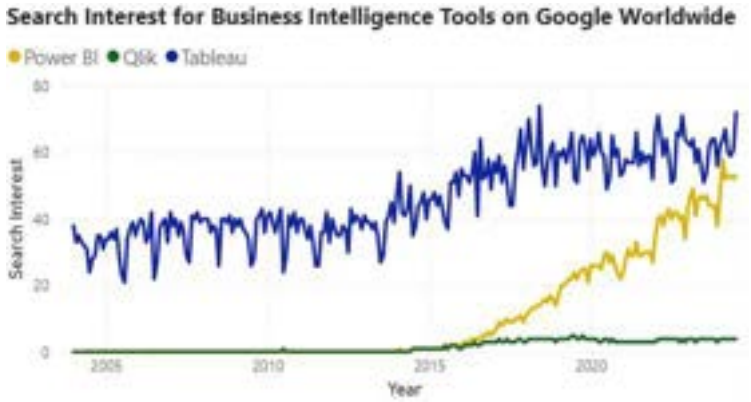

Figure 7: Google Trends Industry Leading BI Tools [16]

Predictive analytics: Eight literature sources within the reviewed literature highlight predictive analytics. It is broadly defined as "A group of analytical techniques and processes for finding relationships in data and using these discovered relationships to predict future outcomes" [1]. Predictive analytics involves investigating historical and current data to identify patterns, assess potential risks, and uncover emerging opportunities [13]. In the supply chain sectors, predictive analytics can be used to forecast logistic costs depending on volumes expected to be shipped using linear regression.

Real-Time BI (RTBI): Twenty-one (21) of the sources refer to real-time data, which shows its importance. "RTBI operates on operational data with zero delays and gives real-time modelling, data analysis and action based on insights" [17], [18]. The latency between the data capture and action significantly decreases the value of the data. The fundamental objective of RTBI is to remove this latency to get maximum value from the data. However, implementing RTBI poses technical and financial challenges. Based on the researcher's professional experience, most conventional BI tools, such as Power BI and Tableau, rely on scheduled refresh intervals, making true real-time functionality difficult to achieve. Achieving near real-time updates in Power BI through push datasets requires specialised configuration by data engineers and often incurs increased infrastructure and processing costs. Consequently, many RTBI solutions are built directly on web-based platforms, without using tools like Power BI and Tableau.

Embedded BI: Embedded BI is identified as a key future development in the evolution of Business Intelligence systems [16], [31]. This observation aligns with the researcher's professional experience: in 2022, the organisation where the researcher was employed began embedding dashboards directly into web-based applications. This integration significantly reduces context switching, allowing users to transition seamlessly from insight to action within the same application.

Automated alerts: Bijker and Hart [8] highlight alerts and notifications, which align with the third proposition of this research (Alerts are a crucial feature to drive action from a BI dashboard). Watson (2009) states: "Designing business processes with BI embedded in them (e.g., business activity monitoring (BAM) dashboards, alerts) makes BI part of the work system." Otherwise, not many people in the literature discuss alerts linked to BI. The researcher found this interesting as alerts are a key selling point for the company the researcher works for. Many BI Tools can send alerts based on the data presented in the dashboard. Interestingly, this capability was not highlighted as a critical success factor or future development in any literature reviewed. This could be seen as a gap in the literature.

Burnay et al. [19] state that it would be valuable to study the design of indicators for informational loads. This point is agreed with, as the researcher is a designer using BI tools,

and finds that it would be helpful to indicate the information load being conveyed to the user, depending on the design.

3.6 Models Linked to BI

In this section, some of the models linked to BI found in the literature are presented. The decision-making model and theory, Technology Acceptance Model (TAM), Unified Theory of Acceptance and Use of Technology (UTAUT), then the Real-time value model and Perception-Cognition-Action regulation process are discussed.

Researchers have proposed the use of decision theory to guide BI system adoption [6], while others have explored how individual decision-making styles influence the use of BI tools [32]. These findings suggest that organisations may need to implement differentiated strategies to promote effective BI utilisation among users with diverse cognitive and behavioural decision-making preferences.

The TAM is widely used to comprehend new information systems' acceptance, adoption, and usage [6]. This article proposes that the successful adoption of the dashboard must ensure continued use and subsequent action. An advantage of the TAM is its simplicity and effectiveness in predicting user acceptance and behaviour; however, it doesn't take external factors into consideration and may be influenced by cultural bias.

The UTAUT2 has been applied to verify the factors affecting the implementation of BI tools [18]. The UTAUT2 (Figure 8) identifies the most important variable that influences both the behavioural intention and the actual usage [18]. The advantages of the UTAUT are the comprehensive nature of the framework and its strong predictive power in behavioural intention to use technology. However, its complexity is due to numerous constructs and moderating variables that can sometimes complicate analysis and interpretation.

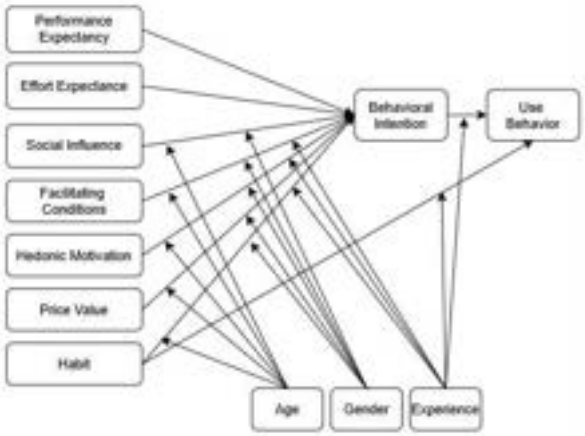

Figure 8: Unified Theory of Acceptance and Use of Technology (UTAUT2) [20]

Figure 9 shows how the value of real-time data decreases exponentially with time until action is taken. There is a latency between the occurrence of a business event and when action is taken in response to the event. This research focuses on the latency between information delivered and action taken, the decision-making latency. It is important to understand why delays occur in decision-making, or why action is sometimes not taken at all, despite the availability of relevant information. A key advantage of the real-time data value model is its emphasis on decision-making latency, which aligns closely with the objectives of this research. However, a limitation of the model is its narrow focus, as it considers only temporal delay as the source of data value loss, without accounting for other contextual or cognitive factors.

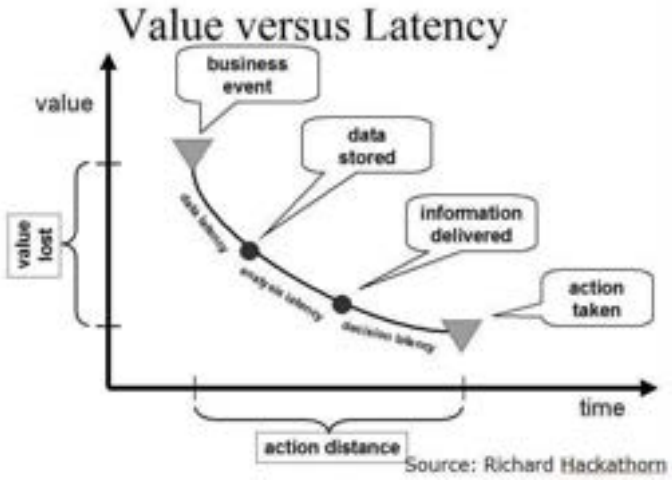

Figure 9: The Value of Real-Time Data [1]

The Perception-Cognition-Action (PCA) regulation process describes driving behaviour, involving a sequence of core mental activities that can also be applied to BI dashboard usage [33]. Users must first perceive the information displayed on the dashboard, followed by cognitive processing in which the data is interpreted and evaluated to support decision-making. This leads to a corresponding action. Subsequently, the impact of that action influences what is displayed on the dashboard, and the resulting insight becomes the new input to be perceived, creating a continuous PCA feedback loop (Figure 10).

This process has not been explicitly applied as a dominant framework in the context of BI. The advantages of the process are that it brings to the forefront the cognition steps required to translate perception into action. The model is simple, intuitive, and relatable, making it accessible to both researchers and practitioners. It is relatable. However, it may not naturally incorporate foresight or proactive strategies.

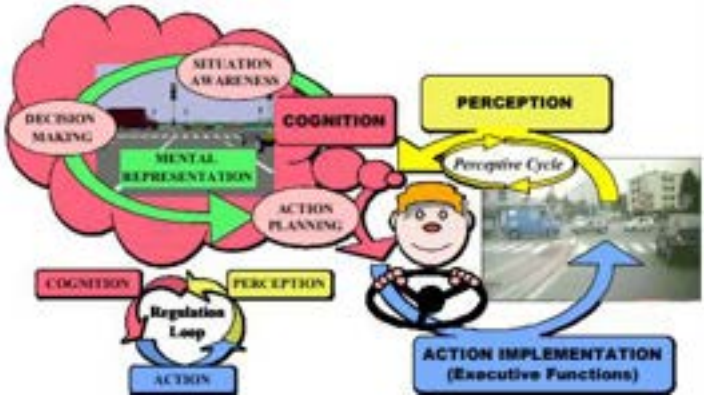

Figure 60: Perception-Cognition-Action regulation process [21]

4 THEORETICAL FRAMEWORK

The theoretical framework developed in this research adapts the PCA regulation process [21],

tailored to the context of BI. While PCA has not been explicitly applied within BI research, its core components and underlying principles align well with BI, particularly in the context of organisational decision-making processes

Figure 11 presents the adapted PCA model within the BI context. Although the framework retains the foundational PCA functions, it incorporates additional data processes to close the

loop between action and perception through BI processes. The three data processes introduced to bridge this gap include: data sensing or capturing, data storage, and data analysis and updated visualisation. While data processing is not the primary focus of the model, it plays a critical intermediary role in enabling continuous feedback and adaptation between action and perception.

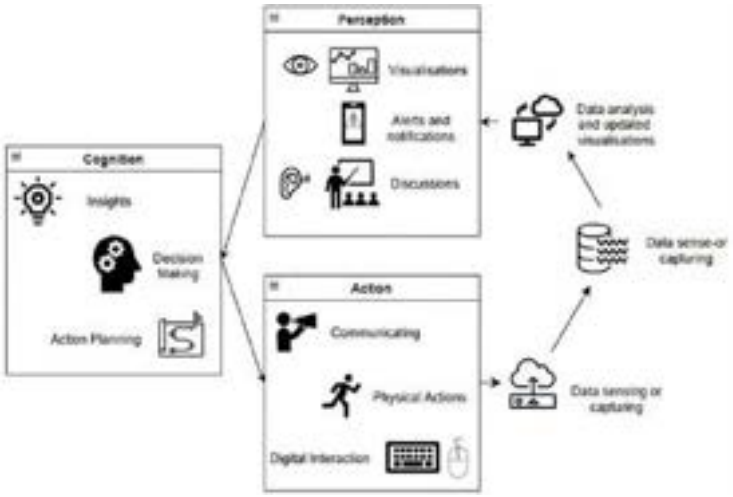

Figure 71: Theoretical Framework of BI-Guided PCA Loop (Adopted from Bellet et al. [33])

4.1 Perception

Once a BI dashboard is developed, the visualisation of data becomes the primary medium through which users perceive insights. The developer validates the content and structure of the dashboard involves iterative sessions with end-users to confirm that the dashboard can be trusted as an accurate source of insight to create a correct perception. Visualisations can be presented in various formats, but effective dashboards typically adhere to three core principles [22]:

- Directing user attention to key visuals: The most important visuals should be clearly highlighted, ensuring that users are not distracted by irrelevant or extraneous information.
- Minimising time to information: The time required for a user to look at the visuals to gain insight, referred to as perception latency, should be reduced. Lower latency enhances the efficiency and value of data-driven decision-making.
- Providing contextual information: Visuals should include relevant context, such as performance targets, historical benchmarks, or thresholds. This enables users to evaluate whether current performance indicators reflect desirable or problematic conditions.

The use of alerts and notifications from dashboards can also be perceived. Alerts can reduce the lag between data updates and user awareness, thereby increasing the timeliness and value of data. Alerts should be triggered when predefined thresholds or benchmarks are exceeded. It's important not to overwhelm people with excessive notifications and ensure that the appropriate audience is reached. Notably, positive alerts, such as those celebrating goal achievement, can be as impactful as warnings of underperformance [23].

Moreover, interpretive discussions that occur while viewing dashboards further enrich the perception process. For example, a user observing an upward trend in Turnaround Times might learn through conversation that the increase is due to a specific operational issue. This context

adds depth to the visualisation and enhances the insight derived from it. Such discussions linked to the visuals provide essential context, shaping how visuals are perceived and informing the subsequent cognitive phase of realisation.

4.2 Cognition

Following perception, the next cognitive phase in the decision-making process is cognition, wherein one of the key subprocesses is the generation of insights. In this context, insights refer to meaningful realisations derived from the interpretation of perceived data [24]. Individuals rely on internal mental models to make sense of information, and these models can change to new insights when a dashboard is perceived as a credible and accurate source of truth.

A course of action must be determined once the perceived information is understood and meaningful insight into the situation has been gained. Decision-making often involves time lags, which can diminish the value of data [1]. Striking a balance between thoughtful deliberation and timely action is essential. While decision-makers frequently seek additional data, statistics, and figures to enhance the quality of their choices, there are instances where time constraints necessitate rapid decisions based on the best available information.

Once a decision has been reached, it must be followed by the formulation of an action plan [21]. This may involve devising a strategy or, in simpler cases, outlining specific tasks in the form of an action list. For instance, an individual monitoring a weight-tracking dashboard may notice their weight exceeding a specific threshold, leading to the development of an exercise or behavioural plan.

4.3 Action

The cognition function is followed by action, the phase in which a tangible impact is realised, and the true value of data is ultimately extracted [1]. Once a strategy or task has been formulated, it must be effectively communicated and executed. The communication function, often delivered through instructions, is one of the CSFs for effective BI implementation.

Actions may take the form of digital interactions and physical activities. For example, a digital interaction could involve cancelling a planned load in a Transport Management System due to vehicle underutilisation and replanning to optimise capacity. A physical action might involve increasing the number of vehicles scanned at a facility to enhance compliance monitoring and collect more accurate turnaround time data.

4.4 Data Processing

Actions often generate new data points, either sensed automatically by electronic sensors or captured manually through operational activities. For example, vehicle movements can be monitored using telematics systems, which continuously collect location and usage data. Ensuring the accuracy of data sensing and capture is critical for maintaining high data quality, one of the most frequently mentioned CSFs in the literature.

The capability to expand efficiently as more data is accumulated is required for a sustainable system. Data can be stored in many different formats and data types. The data visualisation tools cater for ingesting data from these many different data storage locations. The security of the data storage locations is also essential to ensure that data is accessed and used for ethical means. Security is also vital so that the data doesn’t just get deleted.

After data is captured, it must be stored in appropriate repositories such as databases, data warehouses, or data lakes [37]. To support a sustainable and scalable system, these storage solutions must be capable of efficiently expanding as data volumes increase. Given the diversity of data formats and types, storage infrastructures must accommodate structured, semi-structured, and unstructured data [37]. Data visualisation tools are designed to interface

with a wide range of storage systems, allowing for flexible, integrated analysis across diverse data sources. Ensuring the security of data storage environments is critical to prevent unauthorised access, promote ethical data use, and protect against accidental or malicious data loss.

Data must be processed, analysed, and visualised to extract meaningful insights and ensure that the dashboard reflects updated information. Real-time updates are particularly valuable, as they eliminate the lag between an action and the perception of its results, enabling faster decision-making [1]. However, real-time data processing often demands significant computational resources, making batch processing with scheduled refreshes a more practical approach in many scenarios. In such cases, it is important to align refresh schedules with typical user access patterns to ensure that the most current data is available when dashboards are typically viewed.

5 STRENGTHS AND LIMITATIONS

This study is conceptual in nature, grounded in an extensive literature review and built upon an adapted PCA model that has not often been associated with BI implementation. The research offers a novel contribution by exploring the often-overlooked action phase within BI processes. Additionally, it advances the theoretical landscape by closing the PCA loop through the integration of critical BI components such as data capture, data storage, data analysis, and visualisation.

However, a key limitation of this study lies in the absence of empirical validation. The proposed theoretical framework has not yet been tested in practical settings, which restricts the ability to confirm its applicability and effectiveness. Future research should therefore focus on empirically testing the framework across diverse organisational contexts to evaluate its utility and generalisability. Further investigations could also explore specific elements of the framework, such as the factors influencing the perception of dashboard visualisations, as well as enablers and barriers related to cognitive processes within BI environments.

6 CONCLUSION

This research presents a conceptual framework that integrates the PCA process into the context of BI, offering a structured approach to enhance the impact of dashboards in driving organisational action. Through a comprehensive literature review and thematic analysis, the research identifies CSFs, common failure points, and best practices for dashboard design and implementation. By explicitly addressing the often-overlooked “action” phase, the study closes the loop between data perception and action, incorporating essential BI processes such as data capture, storage, analysis, and visualisation. This research provides practical guidance for professionals working in the field of BI on how to design dashboards that are more actionable and elicit effective user responses. By enhancing the capacity of dashboards to facilitate informed decision-making and prompt effective action, this study contributes to strengthening organisational performance and operational efficiency.

ABSTRACT

This review (SLR) explores the integration and production of 3D printed assembly models in smart factories to enhance the learning capabilities of learning factories. The study delves into the characteristics of 3D printed objects that enable them to withstand repeated assembly and disassembly. Through a comprehensive review protocol, search strategies, data extraction criteria, and quality assessments, the research identifies the correlation between learning and smart factories within the Industry 4.0 landscape. The findings highlight the value of education and insights in supporting Industry 4.0 initiatives and fostering new research endeavours. Parameters are identified for the most durable parts to be made, identifying snap fit joints and PLA and ABS materials as viable options. By highlighting the potential of 3D-printing technologies in learning farm environments inside industrial settings and methods to produce quality equipment to reach the end goal, this article adds to the growing conversation around Industry 4.0 and its multifaceted sector.

Keywords: Smart factories, Learning factories, 3D printing, Interlocking parts, FDM (Fused Deposition Modelling)

* Corresponding Author

1 INTRODUCTION

Industry 4.0 technologies are driving a new manufacturing revolution, marking the dawn of the next industrial era [1]. This fresh viewpoint focuses on how manufacturing may combine technological advancements in digitalization to achieve optimum production with the least number of resources. With the rise of Industry 4.0 and all its possibilities comes challenges. As organizations move toward implementing and operating smart factories, they must equip their workforce with new and specialized skills to fully leverage the transformative potential of Industry 4.0 [2].

Personnel in this sector can be trained in learning factories, which are defined as industrial facilities created to duplicate I4.0 technology for educational gain [3]. Smart factories mimic the industry and thus have the potential to educate users more on how the industry would possibly work, leading to more well-rounded and knowledgeable students [4]. An assembly model, like a 3D puzzle, is one of the tools that will be utilized in the learning factory described in this study. The model ties into the concept of a learning farm in the sense that students will be provided with hands-on work, giving them the necessary practical experience. The part must be durable as it will be assembled and disassembled repeatedly.

We will perform an SLR to identify literature that will define and highlight the importance of learning factories and their correlation with smart factories. The study will additionally aim to explore methods for successful 3D manufacturing of a durable assembly model through printing parameters, materials used, and design concepts.

2 A SYSTEMATIC LITERATURE REVIEW: REVIEW PROTOCOL

A variety of review methods can be used to perform an SLR; in this study, Xiao & Watson's protocol is utilized [3]. Table 3 shows the steps and the phases that they fall into.

Table 1: Xiao & Watson's protocol

Phase	Nr.	Step
(Phase 1) Planning the Review	1.	The formulation of the research questions
	2.	Develop a review protocol
(Phase 2) Conducting the review	3.	Search for literature
	4.	Screen for Inclusion
	5.	Assess quality
	6.	Extract Data
	7.	Data analysis
(Phase 3) Reporting the Review	8.	Report Findings

2.1 Research Question Formulation

Developing research questions is an essential stage in every investigation. A strong research question serves as the cornerstone of critical thinking and the problem-based approach to science. It guides the investigation's path and encourages a deeper comprehension of the topic at hand[5].

The following Research Questions were formulated.

1. *Research Question 1 (RQ1):* What defines a learning farm and what makes them valuable?
2. *Research Question 2 (RQ2):* What is the correlation between learning farms and smart factories?
3. *Research Question 3 (RQ3):* What characteristic of 3D printed models allows them to be robust and withstand repeated assembly and disassembly?

2.2 Review Protocol development

The review protocol is a predetermined approach describing the procedures used in carrying out the review. For thorough systematic reviews, the review procedure is essential. It reduces researcher bias in data analysis and selection, therefore increasing the standards of the paper. The

goal of the study, research questions, inclusion criteria, search tactics, quality evaluation standards and screening processes, and methods for data extraction, synthesis, and reporting should all be covered in the review protocol[6].

2.3 Search of Literature

To search for relevant literature in databases, key keywords were derived from the research questions [6].

2.3.1 Key words:

Set 1: smart factories, learning factories, 3D printing.

Set 2: interlocking parts, Materials.

Set 3: Printing Parameters, Mechanical Properties, Fused Deposition Modelling (FDM)

Search Phrase 1: "Smart factories" AND ("Learning farm" OR "learning Factories") AND "3D Printing".

Search Phrase 2: "Printing 3D objects" AND interlocking parts

Search Phrase 3: "Printing parameters" AND "affecting mechanical properties" AND materials AND FDM.

Databases: Scopus, ScienceDirect, IEEE Explore, Emerald Insight, Web of Science.

2.3.2 Yield of Searches

The following table shows the search phrase along with the yield in each database.

Table 2: Identified literature.

Database	Yield Search Phrase 1	Yield Search Phrase 2	Yield search phrase 3
Scopus	1	1	1
Science Direct	33	4	8
IEEE Explore	0	0	0
Emerald Insight	25	4	17
Web of Science	0	1	0
Total	59	10	26

2.4 Inclusion screening

It's crucial to use suitable literature as further limits were included to better refine the search results.

Table 3: Inclusion and exclusion criteria

Inclusion criteria	Exclusion criteria
Published Articles.	Non-English Articles.
Articles published in the years 2014-2024.	Literature that did not focus on how Smart factories and smart farms work in collaboration.
Articles containing the three search phrases	Articles that are not open source

Duplicates were removed, and abstracts were read through to identify if they suited the research questions that were asked.

2.5 Data Extraction Criteria

(Data Extraction is done separately for phrases 1 and 2). The data that were extracted from each study are: Year Published, Authors, Title, Database the article was found in, and basic principles found in the literature.

2.6 Data Analysis Criteria

(Data Analysis is done separately for phases 1 and 2). The Data from Table 5 was summarised and provides the following information: title of each study, the database in which the study was published and publication reference.

2.7 Quality Assessment Process

The prescribed Quality assessment process as per Xiao and Watson can be found in the table for along with a description and application thereof[6].

Table 4: Yield of Search Phrases with steps

Step	Description	Yield Phrase 1	Yield Phrase 2	Yield Phrase 3
Literature identification	The first stage, as stated by the article, is to search for literature using the keywords identified from the Research Questions in select Databases. Only published articles are used.	Only open Access English articles were chosen.) • Scopus=0 • Science Direct=33 • IEEE Explore=0 • Emerald Insight=24 • Web of Science=0 **Total: 57**	Only open Access English articles were chosen. • Scopus=0 • Science Direct=3 • IEEE Explore=0 • Emerald Insight=4 • Web of Science=0 **Total: 7**	Only open Access English articles were chosen. • Scopus=0 • Science Direct=8 • IEEE Explore=0 • Emerald Insight=16 • Web of Science=0 **Total: 24**
Screening for inclusion	The abstract of the included literature is then scanned to decide if the articles are fitting. Normally, two researchers perform this step, but in this case, only one will. Duplicates are merged. Articles that are not suitable are removed.	Literature with unsuitable abstracts were removed. • Science Direct=16 • Emerald Insight=13 **Total: 29**	Literature with unsuitable abstracts were removed. • Science Direct= 3 • Emerald Insight=2 **Total: 5**	Literature with unsuitable abstracts were removed. • Science Direct= 3 • Emerald Insight=7 **Total: 5**
Quality and Eligibility Assessment	In this step, the full text of the remaining articles is briefly examined to determine the relevance. Articles found to be unfit are removed.	• Science Direct=7 • Emerald Insight= 3 **Total: 10**	• Science Direct= 3 • Emerald Insight=0 **Total: 3**	• Science Direct=1 • Emerald Insight=1 **Total: 2**
Iterations	This phase involves a thorough analysis to investigate the methodology each paper uses. To gather the data	A full text review was performed on the 10 papers to acquire the needed literature	A full text review was performed on the 3 papers to acquire the needed literature	A full text review was performed on the 6 papers to acquire the needed literature

3 A SYSTEMATIC LITERATURE REVIEW: RESEARCH RESULTS

The results of the three different search phrases are placed in tables 5-8. The title, study type, a summary, and publication reference are displayed in the tables.

3.1 Search Results for search phrase 1:

Table 5: Results keywords set 1

#	Title	Item Type	Database	Summary of Study Applicable to the Objectives of SLR	Reference
1	SEPT Approaches for Education and Training using a Learning Factory	journal Article	ScienceDirect	The document discusses the development of a modern learning factory, referred to as the School of Engineering Practice and Technology (SEPT) learning Factory, which integrates Industry 4.0 technologies and emphasizes practical learning. It focuses on educational methodologies for teaching undergraduate as well as graduate students. Learning factories are defined as specialized labs for education, training, and research in the document.	[7]
2	Integrated Product / System Design and Planning for New Product Family in a Changeable Learning Factory	journal Article	ScienceDirect	A case study on introducing belt tensioners to a learning factory is detailed, emphasizing hands-on experience. The integrated product design method involves steps like product assessment and 3D modelling. Educating engineering students on changeable manufacturing systems is advocated and highlighted. It showcases various learning factories and stresses the importance of training in manufacturing systems. In summary, the document provides insights into managing product variety challenges through changeable manufacturing, illustrated by a case study in a learning factory.	[8]
3	Learning Factory: The Path to Industry 4.0	journal Article	ScienceDirect	The document specifically focuses on the potential impacts that smart factories may have on education for Engineers and their approach to competency development. It also sets up three pillars for a successful Learning factory, which include didactic, integration, and engineering. Research conducted identified relevant aspects that developed a four-phase model to direct the shift in production engineering methods toward a learning factory. Further, characteristics for engineering and educational objectives are identified in the context of learning farms.	[9]

4	Tangible Industry 4.0: A Scenario-Based Approach to Learning for the Future of Production	journal Article	ScienceDirect	The study focuses on learning factories, which are described as educational platforms offering hands-on training in production management. It integrates smart manufacturing and Industry 4.0 concepts, providing practical experience in advanced manufacturing technologies. According to the document, learning factories use equipment that mimics real-world complexities to prepare students for the challenges of modern production.	[4]
5	Towards a proactive vision of the training for the 4.0 Industry: From the required skills diagnostic to the training of employees	journal Article	ScienceDirect	The document emphasizes the significance of training in the context of Industry 4.0. It highlights the impact of digitalization on industrial processes and the need for companies to adapt to remain competitive within the market. A potential problem identified is a lack of training in Industry 4.0, and the impact that it may have on the quality of work is discussed. Three tools developed at Strasbourg to support the training are introduced. These tools include a diagnostic tool to assess the maturity level of companies, grids to design adapted learning paths, and a Learning Factory to facilitate a learning-by-doing approach	[10]
6	"Digital literacy": Shaping industry 4.0 engineering curricula via factory pilot-demonstrators	journal Article	ScienceDirect	The document introduces what learning factories are and identifies 4 main conditions a factory must fulfil to qualify as a smart factory. It identifies the scarcity of skilled labour in the UK and India. Methods are then discussed wherein this gap of skilled labour can be filled in reference to smart factories. Overall, the paper identifies how curricula can be developed.	[3]
7	Industry 4.0: A Technologically Oriented Definition Based on Bibliometric Analysis and Literature Review	journal Article	ScienceDirect	The study discusses the concept of learning factories, which are said to be designed to transfer theoretical knowledge into practical training for employees. Learning factories are seen as a promising approach to competence development and knowledge transfer in the context of Industry 4.0. Learning farms are tied to the concept of smart factories and are intended to prepare employees for the challenges posed by Industry 4.0. Education in learning factories is expected to be complex, focusing on the latest trends in manufacturing, research, and education in various engineering areas. Complexity is necessary to ensure that employees are adequately prepared for the changes brought about by Industry 4.0.	[11]
8	Organizational learning and Industry 4.0: findings from a systematic literature review and research agenda	journal Article	Emerald Insight	The study highlights 9 dimensions to tie organisational management of I4.0, including the significance of continuous learning and skill development, particularly in the framework of a learning factory within Industry. With learning factories as a tool, operations can become more efficient in the context of an industrial setting through improving knowledge and skills regarding technologies and procedures used in Industry 4.0.	[12]

9	Essential ingredients for the implementation of Quality 4.0: A narrative review of literature and future directions for research	journal Article	Emerald Insight	This study proposes eight key ingredients for the effective implementation of I4.0, which include handling big data, improving prescriptive analytics, using I4.0 for effective integration, strategic advantage, leadership, training, organizational culture, and top management support. Learning factory's concept is discussed, which is defined as a physical or virtual environment where students, professionals, and researchers can gain practical experience in a real-world industrial setting. Learning factories are tied to smart factories as they provide a platform for education and research in the context of Industry 4.0.	[1]
10	Integration of Industry 4.0 technologies with Education 4.0: advantages for improvements in learning	journal Article	Emerald Insight	This study makes a connection and states that just like there is an Industry 4.0, education 4.0 exists. The level of education at which training should take place falls to 70 % in higher education, indicating that the methods used in learning factories should not be too simple.	[13]

3.2 Search Results for search phrase 2:

Table 6: Results keywords set 2

#	Title	Item Type	Data Base	Summary of Study Applicable to the Objectives of SLR.	Reference
1	Printing 3D objects with interlocking parts	journal Article	ScienceDirect	To create robust 3D printed models, the document discusses breaking apart large models into smaller pieces, with an emphasis on using interlocking parts instead of gluing or other types of connectors. To prove the method's effectiveness, several models, including a 22-piece interlocking ring puzzle, a 6-part Duck, a 12-part Bunny, and a 10-part vase, were made. The designs produced were determined to be acceptable.	[14]
2	Methodology for the design process of a snap-fit joint made by additive manufacturing	journal Article	ScienceDirect	To create durable 3D printed models, the article discussed snap-fit joints as a possible solution. Methodology used includes design validation stage, feature deformation analysis, ergonomics check, and retention feature evaluation. Performance conditions under which the model is designed involve additive manufacturing technology, printing material, model geometry, and snap-fit performance. A 6-piece 1-gallon plastic container was used to prove the effectiveness of the methodology. ABS (Acrylonitrile Butadiene Styrene) plastic was used with MultiJet technology. The container quality was found to be satisfactory.	[15]

3	Detailed design process and assembly considerations for snap-fit joints using additive manufacturing	journal Article	ScienceDirect	The paper divides the process of designing a model into five steps: • Design specifications • Conceptual design • Detailed design • Design Validation • Manufacturing Additionally, the paper contains instructions on mathematics to develop deflection and retention mechanisms for snap-fit joints. Results from the text suggest that the snap-fit system design equations now in use can forecast feature strain behaviour to some extent and that adhering to design principles can prevent deflection failure related to material overstraining.	[16]

3.3 Search Results for search phrase 3:

Table 7: Search results for phrase 3

#	Title	Item Type	Database Used	Summary of Study Applicable to the Objectives of SLR.	Reference
1	Investigating the large-strain compression properties of PLA parts manufactured by FDM using experiments and constitutive modelling	Journal Article	Emerald Insight	PLA (Polylactic Acid) parts' compression characteristics are examined in this study through investigating the effect of infill density and strain rate. Compression testing was done where different strain rates and infill densities were used to analyse the scale of deformation. It was discovered that the yield stress of PLA increased with increasing strain rate and infill density. From testing, three damage mechanisms were identified: matrix crazing, twisting, and filament breaking. Matrix crazing was found to be the main deformation mechanism at increased infill density (95%), whereas filament breaking and twisting were found to be the damage processes for higher strain rates.	[17]
2	Printing parameters and materials affecting mechanical properties of FDM-3D printed Parts: Perspective and prospects	Journal Article	ScienceDirect	In the article, FDM processes are discussed, as well as the impact that they have on the mechanical properties of the produced parts. The influence of printing parameters and materials on tensile strength, flexural strength, and Young's modulus is identified. Common materials used in FDM are discussed, such as ABS, PLA, and Nylon, and their effects on the mechanical properties of the printed objects. Important information about how variables such as infill density, infill speed, printing temperature, printing orientation and raster angle are analysed.	[18]

3.4 Evaluating Statistics of Articles

Before addressing the research questions, an assessment of the 15 recognized studies will be conducted concerning the publication years and journals in which the articles are found. The scatter plots will be used to look at each search term independently. To determine which journals the articles are published in, a pie chart will be utilized.

3.4.1 Search phrase 1:

The scatterplot in Figure 1 displays the number of articles published per year for search phrase 1.

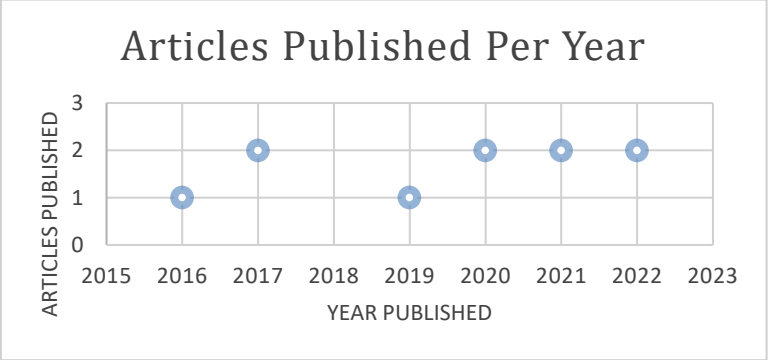

Figure 1: Articles published per year search phrase 1.

The graph in Figure 1 reaches a constant peak of 2 articles between the years 2020 and 2022. This possibly proposes that in this period, there was a growing interest in the concept of learning factories and smart factories. The fact that there were no studies relevant to the definition of learning farms and smart factories after 2022 could suggest the articles got more specialized, as it was already defined in previous years (2016-2022), and there was no need for further similar literature.

3.4.2 Search phrase 2:

The scatterplot in Figure 2 displays the number of articles published per year for search phrase 2.

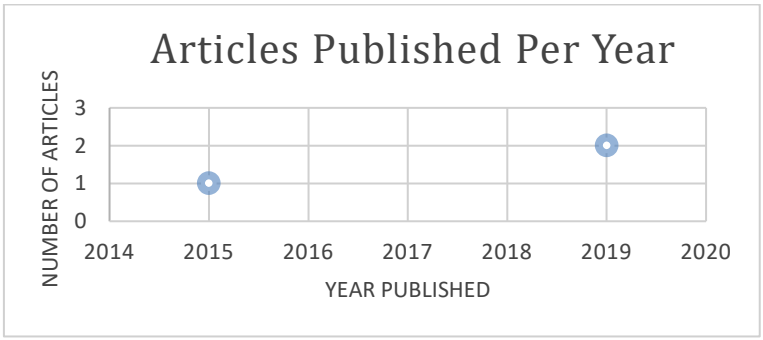

Figure 2: Articles published per year search phrase 2.

As there are only two points in the plot from figure 2, a definitive conclusion cannot be drawn, however an increase in the number of publications could be associated with the developing concept of learning and smart farms.

3.4.3 Search phrase 3:

The scatterplot in Figure 3 displays the number of articles published per year for search phrase 3.

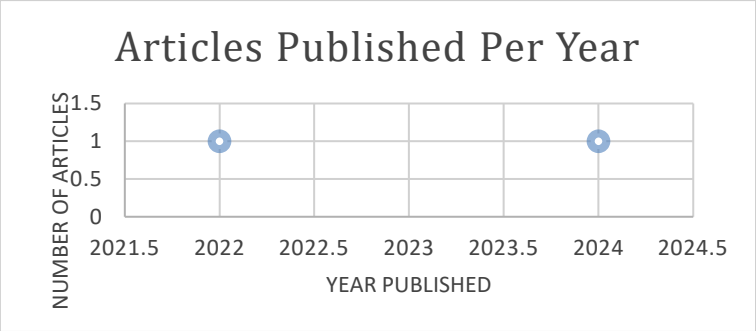

Figure 3: Articles published per year search phrase 3.

From the scatterplot in Figure 3, in both 2022 and 2024, only 1 relevant study was published per year. Since the studies are not older than 2 years, we can deduce that the theories are relatively new. We cannot make any assumptions with certainty, as there are too few points on the plot. The available data could possibly suggest that in the time period between 2022 and 2024, there was no rise in interest in the concepts of durable 3D printing parameters.

3.4.4 Overview:

The pie chart in Figure 4 displays the percentage of articles per publication title/journal:

similar issues are located. From Figure 4, the top three journals used were those of Procedia Manufacturing and Procedia CIRP at 20 %. The rest of the titles, like the Rapid Prototyping Journal, range between 6 and 7 percent. Researchers can use the pie chart to determine the primary regions where studies were published.

3.5 Research Question 1: What defines a learning farm, and what makes them valuable?

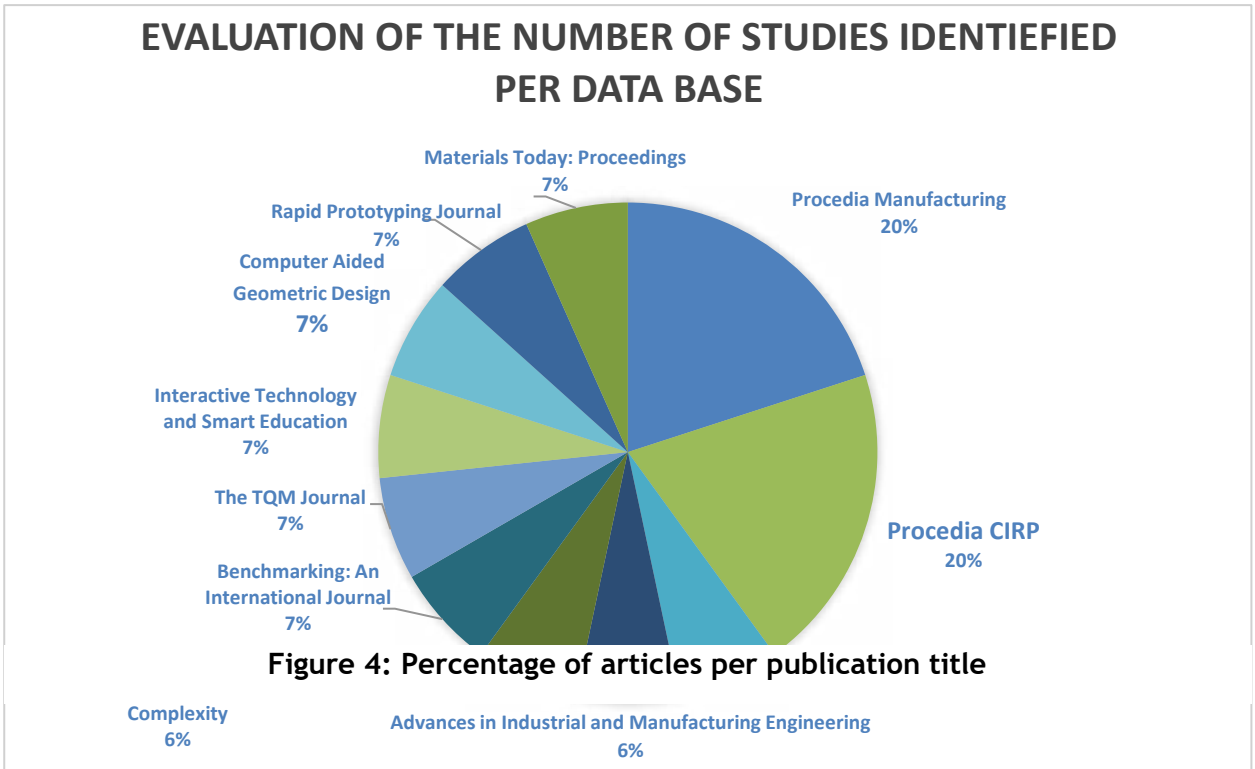

Figure 4: Percentage of articles per publication title

Learning farms, as defined by Nithyanandam et al. [3], are educational facilities within academic institutions that replicate industrial setups, specifically focusing on technologies associated with

Industry 4.0, like robotics, automation, and additive manufacturing. A learning factory, as outlined by Sony et al. [1], serves as a simulated environment, either physical or virtual, wherein professionals, researchers, and students can acquire practical knowledge applicable to the industry.

To understand the importance of learning farms, we turn to the insights provided by 10 articles in Table 6 that highlight the significance of skill development, its impact on industry 4.0, and that learning farms play a crucial role in competence development, leading to better employees/students in the industry. A consistent theme across these articles underscores the significance of Industry 4.0 as a transformative era, demanding a specialized skill set for effective engagement. Moraes et al. [13] conceptualize this shift as Education 4.0. To make the most of Industry 4.0, we need skilled people. Learning farms play a crucial role by providing the necessary training in:

- Simulation of real-world processes
- Interdisciplinary learnership
- Technology integration
- Decision making and problem solving.
- Practical application of theory
- Industry collaboration

Learning factories contribute significantly to preparing students and employees for the I4.0 environment by providing a practical understanding of manufacturing processes and skills essential for the industry.

3.6 Research Question 2: What is the correlation between learning and smart factories?

According to et al Nosalska (2019) the most important technology component of I4.0 is that of smart factories[19]. They put ideas into practice in the real world. Although they consist of a considerable amount of automation and machines, scientists agree that research indicates that human labour will remain a crucial component of the organization and the connection between physical and digital assets. Smart factories still require humans as primary operators; they are not going to become autonomous, unmanned factories [11].

When people are involved in processes, the skills and education to operate the systems need to be cultivated, and this is where Learning farms and smart factories come together. The goal of smart factories is to prepare employees and students by bringing the knowledge of theoretical studies to the factory floor. Learning factories present a promising solution for knowledge transfer and competency development in the context of Industry 4.0. Research focuses on identifying suitable learning tactics and developing training programs based on current developments in engineering education, research, and production, in this scenario, being smart factories [11].

3.7 Research Question 3: What characteristics of 3D printed objects allow them to be robust and withstand repeated assembly and disassembly?

The durability of 3D printed models and their resilience during assembly and disassembly hinge on various factors, including the design of the snap-fit system, material selection, and printing parameters [15] [18].

Careful consideration must be given to the design of the snap-fit system, ensuring proper dimensioning and orientation to distribute stresses effectively. Utilizing 3D interlocking enhances structural strength and stability, enabling repeated disassembly and reassembly without compromising integrity [14].

Material choice is critical, with Acrylonitrile Butadiene Styrene (ABS) and Polylactic Acid (PLA) commonly used due to accessibility and cost-effectiveness. ABS offers good impact strength and abrasion resistance, but is not suitable for high heat applications, while PLA, although

biodegradable, is brittle and has low heat distortion temperatures [18]. ABS exhibits less variation between samples and higher wear resistance compared to PLA [18].

Additionally, printing parameters such as layer thickness and building chamber dimensions affect model partitioning and snap-fit system features, necessitating careful evaluation to optimize durability [15].

Table 10 compares the influences of various printing parameters and materials to provide a comprehensive understanding [18].

Table 8: Printing Parameters and materials effect on mechanical properties

Material used	Print Orientation	Layer Thickness	Raster Angle and print temperature	Print Speed	Infill Density and Pattern
PLA	Low print speed and layer thickness lead to increased flexural and tensile strength. Flatwise-oriented objects containing maximum layer thickness had the best bond between layers. Edgewise orientation with minimum layer thickness contained the best bond between layers	A decrease in Layer thickness increases tensile strength. This lower layer thickness leads to more layers being needed, therefore leading to higher printing times. Thus, the correct combination of tensile strength and time consumption should be assessed on one's own discretion.	0 degrees raster angle proved to demonstrate the best mechanical properties for FDM printing. At a temperature of 215 C, the best tensile performance was attained.	It was recommended to keep printing speeds below 90 mm/s as polymers are poor thermal conductors and the materials will not be able to bond effectively.	To increase tensile strength, 100 % infill densities were found to be more effective for PLA along with a honeycomb structure. Additionally, under constant strain rate, increased infill density led to higher yield stress. In higher strain compression testing, matrix crazing was seen in cases with higher infill densities (95%), while fibre splitting and twisting were seen in cases with lower infill densities (55%). [17].
ABS	0 Degrees (parallel to tensile force) orientation was found to lead to maximum tensile strength.	Decrease in Layer thickness increases tensile strength. This lower layer thickness leads to more layers being needed, therefore leading to higher printing times. Thus, the correct combination of tensile strength and time consumptions should be assessed on own discretion.	0 degrees raster angle proved to demonstrate the best mechanical properties for FDM printing.	It was recommended to keep printing speeds below 90 mm/s as polymers are poor thermal conductors and the materials will not be able to bond effectively	Higher infill densities along with concentric pattern led to higher tensile strength and mechanical properties.

It is evident from the data in Table 10 and the text that ABS will be a better fit for the project. It is more durable than PLA and can tolerate the wear and tear that frequent assembly and disassembly will cause. Thus, from the reviewed literature, it is concluded that ABS demonstrates greater consistency in achieving optimal mechanical properties, as its best performance is consistently obtained at 0° print orientation, reduced layer thickness, and 0° raster angle. These parameters reliably enhance tensile strength without significant variation between orientations. Furthermore, ABS maintains its strength benefits across higher infill densities and concentric patterns, making its mechanical performance more predictable and less dependent on complex

trade-offs between layer thickness, speed, and infill design, unlike PLA which shows more variation based on print orientation and density.

4 CONCLUSION

In conclusion, learning farms can be defined as real-world training grounds enabling students and employees to obtain practical experience in relevant areas of Industry 4.0, leading to more complete workers and more effective utilization of the relevant technologies. Learning farms are valuable for the industry as they replicate an industrial setting and technologies used in I4.0. In this case, learning factories serve as learning platforms; they teach employees how to effectively operate a smart factory, providing them with training in problem solving, industry correlation, practical experience, and interdisciplinary collaboration, therefore making them crucial for educational purposes.

The vital role that individuals play in the operation of smart factories, and the fact that learning farms train the involved humans to operate the systems efficiently, form a link that connects learning farms and smart factories. Automation and mechanical systems are key in smart manufacturing, but human skills are still necessary for successful operation. The development of the competence required for productive interaction of humans with technologies like additive manufacturing, robotics, and automation is significantly facilitated by learning farms, which combine theory and application, enabling workers to better operate in smart factories, solidifying the correlation between learning farms and smart factories.

Although the complexity of the model created is not explicitly discussed, we can conclude that, because smart factories are complex, containing multiple automated systems, the assembly model should be of a higher complexity level. The model should challenge a university-level student without being overwhelming.

For a durable 3D printed model, careful design, material selection, and attention to the printing process are necessary to ensure that printed models are durable, especially when it comes to their capacity to survive repeated assembly and disassembly. Interlocking snap-fit joints that can withstand repeated assembly and disassembly with ease. Therefore, it is an efficient way in which a durable assembly model is produced. As discussed throughout the document, ABS and PLA are both widely used materials, with ABS edging PLA in terms of better variation as well as possessing better resistance to wear, therefore, making ABS a better option for this scenario. Increased robustness can thus be attributed to decreased layer thickness, printing orientation parallel to tensile force, 0 degrees raster angle, printing speeds below 90 mm/s, and higher infill densities combined with concentric pattern. In conclusion, 3D printed model quality is thus a direct result of the iterative design process, the use of 3D interlocking, and careful consideration of material and printing parameters.

5 FUTURE RECOMMENDATIONS

From the research done on the study, there was a lack of articles that could correlate work difficulty performed in learning farms to the level of study. In the future, research could be done on the complexity of the educational tools utilized in learning farms and how this is matched to the study level. More specifically, research can be done on the complexity of assembly models that can be used at a certain level of education.

Additionally, only 2 studies were found to be relevant for search phrase 3. More research can be done comparing different materials used for 3D printing, exploring the advantages and disadvantages. Each material should be discussed to printing parameters and correlation to mechanical properties. The attributes of the materials can also be compared.

Possible research questions that could be used for future studies are:

1. What complexity of assembly models can be used at a certain level of education?

2. How do 3D printing materials compare in printing parameters and attributes for maximum mechanical properties?

ABSTRACT

This systematic review navigates the integration of adaptive manufacturing paradigms within smart factories. Design implementations and emerging technologies are prioritized while examining diverse manufacturing system designs and the corresponding efficiency within a smart environment. This review aims to identify the most suitable key manufacturing designs for smart manufacturing regarding adaptability, space efficiency, and dynamic production capabilities. It emphasizes the shift from mass production to mass customization due to dynamic market demands and Industry 4.0 innovations. Upon comparing diverse manufacturing systems, it is evident that Matrix Structured Manufacturing Systems (MMS) and Cyber-Physical Production Systems (CPPS) offer optimal solutions for smart factories by providing scalability, adaptability, and efficient integration with emerging technology. Lastly, the review underlines the importance of ongoing research to remain competitive in the dynamic manufacturing sector and navigate the rapid evolution of technology.

Keywords: Manufacturing system, Smart Factory, Performance Evaluation, Design, Industry 4.0

1 INTRODUCTION

In today's swiftly evolving markets, manufacturing industries are compelled to transition from their conventional, static modes of operation to more dynamic, adaptive methodologies. This shift is largely propelled by the emergence of Industry 4.0, which signifies a major transformation, introducing cutting-edge technologies like the Internet of Things (IoT), artificial intelligence (AI), and robotics. These technologies are the cornerstone of smart factories, where the synergy of interconnected machines and sophisticated systems fosters a remarkable enhancement in production efficiency and flexibility.

Yet, the journey to embracing smart factories is overloaded with complexities. It demands a deep understanding of the design principles and operational mechanics of the manufacturing systems in question. Before these systems are integrated into a smart factory setting, it is important to investigate every aspect of their functionality and interaction within such an advanced environment. This strategic foresight is vital to ensure that the system aligns with the factory's objectives, exhibits resilience against rapid market fluctuations, and operates efficiently.

This Systematic Literature Review (SLR) aims to explore the evolution of manufacturing systems, aligning them not only with the pace of market dynamics but also with the groundbreaking technological advancements of Industry 4.0. The complexities of these systems within the context of smart factories are unraveled, providing a detailed examination and offering significant insights. The goal is to equip industry professionals with a comprehensive understanding and effective strategies to navigate and excel in this new, transformative era of manufacturing.

2 METHODOLOGY

This study follows a systematic literature review (SLR) methodology to evaluate and compare adaptive manufacturing paradigms applicable to smart factories. The objective was to identify the key design characteristics, benefits, and limitations of each paradigm within the context of Industry 4.0.

A comprehensive search was conducted across major academic databases, including IEEE Xplore, ScienceDirect, SpringerLink, and Google Scholar. Keywords used in the search included: “adaptive manufacturing,” “smart factories,” “flexible manufacturing systems,” “reconfigurable manufacturing,” “cyber-physical systems,” “matrix production,” and “Industry 4.0 manufacturing.”. There are multiple combinations that can be used for the search strings to get the necessary literature used below for the SLR. Two examples of these search strings are as follows: ("Factory layout" OR "Factory design”) AND "paradigm" AND ("Reconfiguration" OR "Layout transformation") , ("Smart factories" AND "planning" AND "optimal" AND "layout") .The search focused on peer-reviewed journal articles and conference proceedings published between 2010 and 2024 and a manual search has also been conducted.

The following inclusion criteria was followed:

1. Only published journal articles were included in the search process.
2. Journal articles containing the specified keywords within the title, abstract, or keywords. These studies may include any review study or studies that refer to other studies containing the relevant keywords.
3. Journal articles that were published between 2014 and 2024 were included, excluding backward search journal articles, to ensure only relevant paradigms regarding the present or future manufacturing trends were selected.

The following studies were excluded from the search process:

1. Non-English articles

Table 1: Quality Assessment

Phases	Description
Literature Identification	The quality assessment process starts with identifying the literature. Typically, a more broad search is conducted, followed by adjusting the keywords accordingly to narrow down the results. Keywords set one: 58 Keywords set two= 18 Total = 76
Screening for inclusion	During this phase the remaining studies are screened by reading the abstracts to ensure all studies are relevant and all inclusion and exclusion criteria is adhered. Keywords set one = 19 Keywords set two = 7 Total = 22
Quality and eligibility assessment	This phase consists of skimming through the full text of all remaining studies to ensure relevancy and discarding all duplicate studies. Keywords set one = 7 Keywords set two = 4 Total = 11 No duplicates were found
Iterations	The last stage consists of conducting a detailed and thorough evaluation of all remaining studies. This will aid in identifying all relevant information required to achieve the aim of the review. A backward search was also conducted and 4 relevant studies were included. Total = 15 A full text assessment was done on these 15 studies to collect required information regarding research questions.

The quality assessment process can be seen in Table 1 below. Each manufacturing paradigm was analyzed for its design specifications, adaptability, space efficiency, scalability, and integration potential with emerging technologies. This enabled a structured comparison to identify paradigms most suitable for smart factory implementation, particularly in dynamic production environments.

3 MANUFACTURING PARADIGMS

Henry Ford's introduction of the moving assembly line in 1913 marked the initiation of the mass production paradigm, notably facilitated by dedicated machining lines producing essential automobile components. These lines were highly efficient for large-scale production of specific parts, proving profitable until the mid-1990s [9]. However, evolving consumer demands, increased global competition, technological advancements, and environmental regulations have led to a shift from standardized to personalized products. Manufacturing systems are now challenged to transition from mass production to mass customization and personalized production [8].

This shift has resulted in a rise in product variety, shorter life cycles, uncertain demands, and cost pressures. Traditional manufacturing systems, like sequential assembly lines or cellular job shop layouts, are grappling with challenges in handling diverse product varieties, fluctuating demands, or high production volumes in the face of this evolving paradigm [15].

Assembly systems face several challenges in the contemporary manufacturing landscape. These challenges encompass integrating new processes or altering process sequences, ensuring the efficient use of assembly resources amid significant variations in processing times for different product variants, minimizing the effort required for system reconfiguration due to physical changes resulting from the addition or removal of assembly stations, and addressing fixed points—referring to equipment that cannot be relocated due to physical constraints [8].

In the contemporary global manufacturing landscape, diverse manufacturing paradigms grapple with the shared challenges outlined earlier, each addressing these concerns with unique approaches. As these paradigms navigate the integration of new processes, variable processing times, reconfiguration demands, and the presence of fixed points, they expose distinctive strategies to ensure competitiveness in today's dynamic market. Whether adopting lean manufacturing, agile production, or other innovative paradigms, each approach brings its own implications when applied to manufacturing environments. This diversity reflects the evolving nature of modern manufacturing, where flexibility and responsiveness are essential for staying competitive and meeting the demands of a rapidly changing market.

3.1 Flexible Manufacturing Systems (FMS)

The Flexible Manufacturing System (FMS) represents a rapidly evolving paradigm within the manufacturing domain, now recognized as an integral component of intelligent manufacturing systems and a cornerstone for digital manufacturing. This paradigm involves the integration of intelligent machine tools and industrial robots into flexible production systems, supported by advanced software for simulation, monitoring, and control of production processes. The strategic decision to implement an FMS is driven by the complex requirements of modern industrial environments, aiming to increase production capacity amidst product diversification, shorter product life cycles, and heightened competitiveness. Positioned as a fundamental component of Industry 4.0, the FMS connects machines, workstations, and logistics equipment in a coordinated manufacturing process driven by computer systems.

This advanced manufacturing system is designed to handle diverse tasks, accommodate high complexity, ensure timely delivery, and minimize manufacturing costs. It particularly excels in scenarios where production is unpredictable, organized in small batches, and subject to frequent changes. The key elements encompass intelligent machine tools, industrial robots, sophisticated software for simulation and control, and seamless interconnectivity of various components within the manufacturing process.

The Flexible Manufacturing System (FMS) experienced significant development in the mid-1990s, spurred by heightened globalization and intensified worldwide competition. However, it became evident that while FMS offered a partial economic solution in competitive markets, its typical serial structure, commonly used in industry (excluding job shops), had limitations. The serial structure facilitated changes in the manufactured products but resulted in a relatively slow production rate. Moreover, it lacked the volume flexibility needed to respond effectively to unexpected changes in demand arising from global competition [9]. This recognition prompted further reflections on the role and adaptability of FMS within the evolving landscape of manufacturing paradigms.

3.2 Reconfigurable Manufacturing Systems (RMS)

Reconfigurable Manufacturing Systems (RMS) emerged as a solution to overcome the constraints associated with both dedicated and flexible manufacturing systems [9]. RMS embodies six key reconfigurable characteristics:

- Convertibility: which involves designing for functionality changes, enabling the transformation of existing systems and machines to suit new production requirements.
- Scalability: focusing on designing for capacity changes, facilitating the modification of production capacity by adjusting manufacturing resources or changing system components.
- Customization: where flexibility is confined to a specific product family, ensuring customized flexibility for that family.
- Modularity: emphasizing the compartmentalization of operational functions into manipulable units for optimal arrangement between alternate production schemes.
- Integrability: showcasing interfaces for rapid integration, allowing the rapid and precise integration of modules through mechanical, informational, and control interfaces.
- Diagnosability: designed for easy diagnostics, enabling the automatic reading of the current system state to detect and diagnose the root causes of output product defects and swiftly correct operational defects.

These characteristics collectively aim to enhance system responsiveness, reduce reconfiguration time and effort, and enable continuous adaptation throughout the system's lifetime, aligning with the goal of creating a "living factory" capable of adjusting production capacity swiftly while maintaining high-quality standards. Implementing a Reconfigurable Manufacturing System (RMS) design involves several considerations [9]. Firstly, there's the significant initial investment cost, with RMS systems, like machining systems for engine blocks, requiring substantial capital. While minimizing investment is crucial, it's equally important to weigh the implications for productivity and product quality, as these factors affect operating costs.

The design and configuration of RMS play a vital role in product quality and reliability. For instance, in a two-stage RMS setup, variations and misalignment can impact the final assembled product's dimensional distribution, potentially affecting quality. Additionally, the reliability of the RMS material handling system and machine downtime can influence overall productivity. Despite scalability advantages, the complexity of material handling systems in RMS, such as cell gantries, introduces reliability and productivity trade-offs. Balancing cell-gantry reliability and machine reliability is crucial in RMS configurations. Lastly, considering market volatility and forecasting challenges is essential when planning new RMS systems. Designing systems with an adjustable structure to facilitate scalability in response to market changes becomes a critical consideration in this context

3.3 Line-less Mobile Assembly Systems (LMAS)

LMAS operates based on three key principles: the clean floor approach, mobilization of all assembly resources, and unrestricted assignment of resources and products [8]. The clean floor approach emphasizes a factory design with a spacious, obstacle- free shop floor to facilitate reconfiguration and resource movements. Mobilization involves ensuring that all assembly resources within the factory are mobile and adaptable. Unrestricted assignment pertains to the system's capacity to handle varying processing times and scale production volume without disrupting the existing setup. LMAS aims for significant automation, reacting autonomously to changes in the production program. Its design spans control at individual resource levels to overall routing and scheduling within the factory. Reconfiguration in LMAS occurs on both medium and short-term scales to optimize resource utilization. Practical implementations may adopt hybrid approaches, combining mobilized resource areas with fixed machinery zones to achieve an effective balance.

3.4 Matrix Structured Manufacturing System (MMS)

The Matrix Structured Manufacturing System (MMS) prioritizes key principles for enhanced operational flexibility and scalability in the work environment [15]. Firstly, MMS enables a dynamic material flow, allowing products to be intelligently routed through the system, leading to varied lead times and enabling real-time decisions on workstations. Individual cycle times at workstations are a feature of MMS, avoiding a constant cycle time and ensuring balanced product flow by allowing workstations to forward products as soon as related process steps are completed. MMS also provides redundancy in workstations for processing specific work packages, minimizing the risk of workstation blocking and enhancing availability.

Workstations in MMS can handle multiple work packages, reducing the total number of workstations and promoting efficiency. The primary goal of MMS is high utilization achieved by minimizing waiting times and non-productive periods at workstations, thereby enhancing efficiency and production rates. Despite its advantages, challenges include implementing physical flexible material flow between workstations and developing logistic concepts for material supply, especially for large products like cars. MMS is particularly well-suited for diverse product components, such as automotive parts or electronic devices.

Augmented reality (AR) and virtual reality (VR) increases flexibility and accuracy of manufacturing systems [4]. AR allows experts to overlay virtual models of production spaces onto the actual shop floor, enabling real-time validation and simulation for different scenarios. This ensures that each facility's functions are optimal, improves material flow, and enhances ergonomics and safety in human-robot collaboration systems. On the other hand, VR technology is useful for training workers in handling complex tasks, enhancing their skills and contributing to increased precision and efficiency in manufacturing. These immersive technologies, including AR and VR, offer valuable support to workers, aiding them in challenging tasks and improving industrial processes even before implementation. This, in turn, reduces the need for costly adjustments and rework in real- time production.

3.5 Swarm Production System (SPS)

The Swarm Production System (SPS) is developed to tackle the challenges of frequently changing factory layouts and the execution plan for a fleet of autonomous robots. Its goal is to facilitate agile, reconfigurable, and flexible production by using mobile robot platforms for both workstations and material transport [1]. SPS differs from traditional production systems in keyways, including the use of Autonomous Mobile Robots (AMRs), a dense population of robots on a confined shop floor area displaying coherence and coordination, high flexibility in the shop floor layout that can adapt to current product demand in real-time, and a multi-agent framework for autonomous robots.

The system's interoperable management, known as the Swarm Manager (SM), handles task planning, allocation, and scheduling for both process and product transport robots. These features empower SPS to achieve agile, reconfigurable, and flexible production, responding quickly to market needs, adapting to new product families with efficient throughput, and producing a product family with multiple variants, capabilities not achievable with traditional production systems.

3.6 Biologicalisation

Biologicalisation in Manufacturing is emerging as a new frontier in the context of Industry 4.0 and digitalization [2]. It involves integrating principles, materials, functions, structures, and resources from biology and bio-inspired sources into manufacturing technologies and systems. This integration is anticipated to progress through advancements in computer science, information technologies, biotechnology, and manufacturing science. The

incorporation of biological processes is expected to bring about intelligent behavior and flexibility in manufacturing, aligning with the goals of Industry 4.0 for smart, automated, connected, and flexible factories. However, there are challenges to address. Natural systems may differ in life cycles or operating envelopes from artificial ones, making it complex to apply natural principles to technical systems. Additionally, interdisciplinary approaches are needed for product and system design, posing difficulties with traditional factory layouts. The use of biological materials may demand new and potentially costly manufacturing techniques, and ethical and environmental concerns about the impact on ecosystems and biodiversity need consideration. Despite these challenges, Biologicalisation in Manufacturing holds promise for innovative and sustainable advancements in the manufacturing sector.

3.7 Cyber-Physical Production Systems (CPPS)

The modular system design approach for Cyber-Physical Production Systems (CPPS) involves incorporating modularity to enable the addition or removal of modules, allowing flexibility in system capabilities concerning product features and production volume [6]. However, this approach comes with certain drawbacks. Firstly, managing a modular system introduces complexities in coordinating and maintaining interactions between different modules. Additionally, integrating diverse modules and ensuring seamless operation may be challenging, especially when dealing with legacy systems or components from various vendors. Lastly, designing and implementing a modular system architecture may require additional development effort and resources compared to traditional monolithic systems. Despite these challenges, the modular approach offers adaptability and changeability in CPPS, contributing to enhanced flexibility in manufacturing systems.

3.8 Fluid Manufacturing System (FLMS)

The Fluid Manufacturing System (FLMS) is a flexible production system that prioritizes resource allocation and reconfiguration of resources to individual process modules, aiming for optimized manufacturing performance [7]. FLMS is built to be modular and mobile, allowing process modules to be assembled from single resources to create advanced manufacturing systems. Manufacturers adopting FLMS face challenges in adapting to changing market demands, navigating increased environmental complexity, and coping with heightened competitive pressures focusing on customer needs. Traditional production systems have technical limitations that hinder adaptability, leading to the development of novel approaches like FLMS. While FLMS offers promise in supporting required changeability, its implementation comes with challenges such as complex planning and control, high equipment costs, and intricate material flow dynamics. Addressing these challenges calls for innovative solutions to successfully implement fluid manufacturing systems.

Table 2: Manufacturing System Characteristics

Manufacturing System	Design Specifications	Benefits	Drawbacks
FMS	Integrates intelligent machine tools and industrial robots, advanced software for monitoring and control	High adaptability to product changes, suitable for small batch sizes	Limited volume flexibility, relatively slow production rate
RMS	Six key characteristics: Convertibility, Scalability, Customization, Modularity, Integrability, Diagnosability	Rapid adaptation to changes, enhances system responsiveness	High initial investment, complexity in balancing reliability and productivity
LMAS	Principles: Clean floor approach, mobilization of resources, unrestricted resource and product assignment	Facilitates significant automation and reconfiguration, adaptable to varying production volumes	Requires spacious, obstacle-free shop floor, complex balance between fixed machinery and mobilized resources
MMS	Dynamic material flow, individual cycle times at workstations, redundancy in workstations	Enables real-time decision-making, minimizes waiting times, enhances efficiency and production rates	Complexity in implementing flexible material flow, logistic challenges for large products
SPS	Fleet of AMRs for workstations and material transport, agile and reconfigurable production	High flexibility in shop floor layout, quick adaptation to market needs, efficient throughput	Management complexity, ensuring coordination among dense robot population
Biologicalisation	Integration of principles, materials, functions, structures from biology into manufacturing	Promotes intelligent behaviour and flexibility, innovative and sustainable advancements	Complexity in applying natural principles, ethical and environmental concerns
CPPS (Modular)	Incorporates modularity, allowing flexibility in system capabilities concerning product features and volume	Adaptability and changeability, allows for scalability in response to demands	Complexities in coordinating modules, additional development effort required
FLMS	Focuses on resource allocation and reconfiguration to individual process modules, modular and mobile design	Optimized manufacturing performance, supports required changeability	Complex planning and control, high equipment costs, intricate material flow dynamics

4 A COMPARATIVE ANALYSIS OF MATRIX STRUCTURED AND CYBER-PHYSICAL PRODUCTION SYSTEMS

In the fast-paced and ever-evolving arena of smart manufacturing, the architectural foundation of a smart factory must be rooted in systems that are not just technologically advanced but also inherently adaptable, scalable, and efficient. The pursuit of these ideals brings to the forefront two contemporary manufacturing systems: the Matrix Structured Manufacturing System (MMS) and Cyber-Physical Production Systems (CPPS).

The MMS stands out as an exemplary model for dynamic smart factories, characterized by its adaptability and scalability. It adopts a matrix layout that introduces redundancy in work cells, ensuring robustness and resilience in the manufacturing process. Automated Guided Vehicles (AGVs) are integral to this layout, providing a flexible material handling mechanism that facilitates an uninterrupted flow of materials and components. This configuration proves especially beneficial in mass customization scenarios where the production line must swiftly adapt to varied product specifications without compromising efficiency.

Emphasizing scalability, the MMS allows a smart factory to pivot and grow according to market demands and technological developments. It ensures that a smart factory based on this system is not just equipped to handle the manufacturing needs of today but is also primed for the challenges and opportunities of tomorrow.

On the other hand, CPPS heralds a modular approach to smart factory design. Its modular nature is the cornerstone of a system that is not only flexible but also capable of integrating a myriad of components and technologies. This versatility is crucial in environments where product features and production volumes are not static but prone to change. The CPPS's ability to integrate seamlessly across various technological platforms makes it an ideal candidate for smart factories aiming to maintain a cutting-edge position in a competitive marketplace.

Both MMS and CPPS systems underscore the importance of dynamic production capabilities. Thus, a critical element for smart factories that must respond with agility to the ebb and flow of industrial demands. By incorporating these systems, a smart factory positions itself to not just respond to current manufacturing challenges but also to anticipate and adapt to future trends.

Following this discussion, it becomes apparent that the decision to implement either MMS or CPPS should be made with a strategic foresight that aligns with the core objectives of the smart factory. The detailed comparison of these systems is elucidated in the table below, which encapsulates their respective strengths and potential limitations within the context of smart factory design.

Table 3: Manufacturing System in Smart Factory Context

Manufacturing system:	Adaptability	Space Efficiency	Dynamic Production Capabilities	Maturity
FMS	High	Moderate	High	Mature (Widely Used)
RMS	Very High	High	Very High	Mature
LMAS	High	Low (requires spacious area)	High	Emerging
MMS	High	Moderate	High	Mature

SPS	Very High	Moderate (complexity in dense robot population)	Very High	Emerging to Mature
Biologicalisation	Moderate	Moderate	Moderate (depends on implementation)	Early Stage
CPPS (modular)	High	High	High	Mature
FLMS	High	Moderate	High	Emerging to Mature

The information provided in the table serves as a critical guidepost for decision-makers in the manufacturing sector. By considering adaptability, space efficiency, dynamic production capabilities, and the maturity of each system, industry leaders can make informed choices that resonate with their vision of industrial innovation and sustainability.

5 CONCLUSION

The evolving landscape of modern manufacturing demands diverse designs of manufacturing systems to ensure competitiveness. The transition from mass production to mass customization and personalized production necessitates innovative approaches to address challenges such as diverse product varieties, fluctuating demands, and cost pressures. Various manufacturing paradigms have emerged, each with its unique strategies to ensure competitiveness in today's dynamic market. Ultimately the choice of a manufacturing paradigm depends on the specific operational needs of the smart factory. MMS and CPPS emerge as strong contenders, offering optimal solutions in terms of adaptability, space efficiency, and dynamic production capabilities. MMS excels in scenarios requiring efficient material flow and scalability, while CPPS provides modularity and integration for rapidly changing production needs. The adoption of these paradigms will play a crucial role in shaping the future of smart factories, ensuring they remain competitive and responsive to evolving market demands and technological advancements.

Amoss@armscor.co.za

ABSTRACT

The Mobile Air Defence System (MobADS), developed by Denel for the South African National Defence Force (SANDF), is a short-range, mobile system designed to counter UAVs, cruise missiles, and helicopters. It integrates the Local Warning Radar System (120 km range, <10 min deployment), the 35 mm Mk 5A/7 Integrated Gun Firing Unit, the ADA HQ Mobile Vehicle, and the Air Defence Operations Centre for decentralised command and rapid response. This desktop-based, qualitative study offers the first open-source, system-level analysis of MobADS within SANDF's mobility doctrine. It includes subsystem evaluation, benchmarking against Türkiye's Steel Dome, and global trends in air defence, with a focus on AI, EW resilience, and interoperability. Key findings highlight MobADS's strong mobility and autonomy but note limitations in long-range interception, allied interoperability, and AI capability. The study also identifies priorities for future upgrades, including layered missile integration, EW resilience, and automation, especially in the African operational context.

Keywords: The Mobile Air Defence System (MobADS), Air Defence Operations Centre (ADOC), Tactical Command and Control System (TCCS).

1 INTRODUCTION

The evolving nature of modern aerial threats, including unmanned aerial systems, low-observable cruise missiles, and precision-guided munitions, demands agile, layered, and modular air defence solutions, particularly for countries with vast and varied operational terrains such as South Africa. To meet this requirement, the South African National Defence Force (SANDF), in collaboration with Denel, developed the Mobile Air Defence System (MobADS): a highly mobile, decentralised platform designed to protect critical assets. MobADS aligns with the SANDF's mobility doctrine, integrating the Local Warning Radar System (LWRS), Integrated Gun Firing Unit (IGFU), ADA Mobile Headquarters Vehicle, and Air Defence Operations Centre (ADOC), networked through the Tactical Command and Control System (TCCS) to enable coordinated target acquisition, engagement, and real-time situational awareness under combat conditions [1]. Its containerised configuration ensures survivability and consistent performance in challenging terrains and infrastructure-limited environments, although only the HQ vehicle provides limited armour protection.

This paper assesses MobADS from a combined technical-operational perspective, defining the research question in Section II and outlining objectives and methodology, which include subsystem analysis and international benchmarking. Section III reviews literature on Ground-Based Air Defence Systems (GBADS), Integrated Air Defence Systems (IADS), and mobile tactical air defence technologies, drawing on comparative studies by Matejček, Bansal, Dodge, and Youvan [2], [3], [4].Section IV details system architecture and integration, while Section V evaluates operational performance in varied deployment scenarios. Section VI addresses key limitations such as the absence of long-range missile intercept capability, constrained artificial intelligence integration, and limited resilience against electronic warfare. Section VII presents a comparative analysis with Türkiye's Steel Dome, highlighting both convergences and divergences in design and doctrine. Finally, Section VIII synthesises findings and offers recommendations to ensure MobADS' continued relevance within national and regional defence frameworks.

2 PROBLEM STATEMENT

The South African National Defence Force (SANDF) faces a growing spectrum of low- and medium-altitude aerial threats, including unmanned aerial vehicles (UAVs), cruise missiles, rotary-wing aircraft, and precision-guided munitions. The Mobile Air Defence System (MobADS), developed by Denel, provides a mobile, short-range defensive capability aligned with the SANDF's mobility doctrine. However, its current configuration is constrained by limited long-range interception capacity, minimal artificial intelligence (AI) integration, modest interoperability, and vulnerability to advanced electronic warfare tactics. These limitations reduce its operational flexibility, especially in multi-domain threat environments and joint regional operations. Without targeted capability enhancements such as layered missile defence, AI-enabled command-and-control, and hardened electronic warfare resilience, MobADS risks diminished effectiveness in safeguarding South Africa's strategic assets and fulfilling its regional defence commitments.

3 RESEARCH QUESTION

How does the MobADS system deliver mobile air defence capability, and what opportunities exist to enhance its role in supporting the SANDF's operational requirements?

4 RESEARCH OBJECTIVES

The objectives of this paper are to:

- **Describe the architecture and operational subsystems** of the Mobile Air Defence System (MobADS), including the Local Warning Radar System (LWRS), Integrated Gun

Firing Unit (IGFU), ADA HQ Mobile Vehicle, and Air Defence Operations Centre (ADOC), within the context of the SANDF's mobility doctrine.

- **Evaluate the performance of MobADS** against the operational requirements of the South African National Defence Force, using metrics such as detection range, deployment time, integration capacity, survivability, and mobility.
- **Benchmark MobADS against comparable international mobile air defence systems**, with a focus on Türkiye's Steel Dome, across key parameters including threat engagement envelope, artificial intelligence integration, command-and-control architecture, interoperability, and electronic warfare resilience

5 RESEARCH METHODOLOGY

This study followed a desktop-based qualitative research approach to evaluate the Mobile Air Defence Systems (MobADS) operational effectiveness and strategic potential within the South African and regional defence environment. The combination of methods was chosen to ensure triangulation: the systematic literature review (SLR) establishes the state of the art in mobile air defence; the technical subsystem analysis assesses current capability; and the comparative benchmarking identifies performance gaps and potential enhancements. This approach ensures technical insights are contextualised within both global trends and SANDF operational realities.

Systematic Literature Review (SLR)

The SLR was conducted on 3 March 2025 using an adapted PRISMA-style screening process to ensure transparency and reproducibility. Searches were performed in academic and defence-focused databases, including Google Scholar, IEEE Xplore, and Scopus. Boolean search strings included:

- "Mobile Air Defence System" AND "South African National Defence Force"
- "MobADS" AND "short-range air defence" OR "SHORAD"
- "Mobile air defence" AND "comparative analysis" AND "Türkiye"
- "Ground-Based Air Defence Systems" AND "command-and-control" AND "integration"

The review was limited to English-language publications from 2022 to 2025 to maintain relevance to contemporary trends, technological developments, and doctrinal shifts. In addition to automated searches, manual screening of technical reports, defence white papers, and operational case documentation was conducted from sources including the Armaments Corporation of South Africa (Armscor), Denel, the African Defence Review, NATO, and UN peacekeeping reports. Reference mining identified additional grey literature and industry technical papers.

Technical Subsystem Analysis

The technical analysis focused on four primary MobADS subsystems: the Local Warning Radar System (LWRS), the Integrated Gun Firing Unit (IGFU), the ADA HQ Mobile Vehicle, and the Air Defence Operations Centre (ADOC). Subsystem performance was evaluated against five criteria: detection range, deployment time, integration capability, survivability, and mobility rating. Metrics were derived from open-source technical specifications, manufacturer data, SANDF documentation, and corroborated field reports.

Comparative Benchmarking

A structured matrix comparison was applied to benchmark MobADS against Türkiye's Steel Dome system. Seven attributes, derived from NATO air defence capability guidelines and

emerging technology benchmarks, were used: threat engagement range, AI integration, command-and-control (C2) architecture, interoperability, mobility, electronic warfare (EW) resilience, and export readiness. Each attribute was scored using available open-source data, supplemented by the researcher's operational experience and case studies of mobile air defence deployment.

Limitations and Assumptions

Due to national defence classification protocols, detailed operational performance data could not be disclosed. The analysis, therefore, relied on declassified reports, open-source defence publications, and manufacturer technical briefs. This may limit insights into classified C2 resilience, software vulnerabilities, and live-fire performance under operational conditions. These constraints were mitigated through data triangulation and the use of multiple corroborating sources for incomplete specifications.

Replicability

To facilitate replicability, the methodological steps are summarised in Table 1 below, while Figure 1 presents the PRISMA flow diagram for literature selection.

Table 1: Methodological Overview

Step	Method	Purpose	Key Outputs
1	Subsystem Selection	Identify core MobADS components	LWRS, IGFU, ADA HQ, ADOC
2	Technical Analysis	Assess Performance against five criteria	Subsystem Capability Scores
3	Comparative Benchmarking	Matrix Scoring vs Steel Dome	Capability Gaps and Upgrade Opportunities
4	Literature Review	Contextualise within Global trends	Doctrinal and Technological Insights

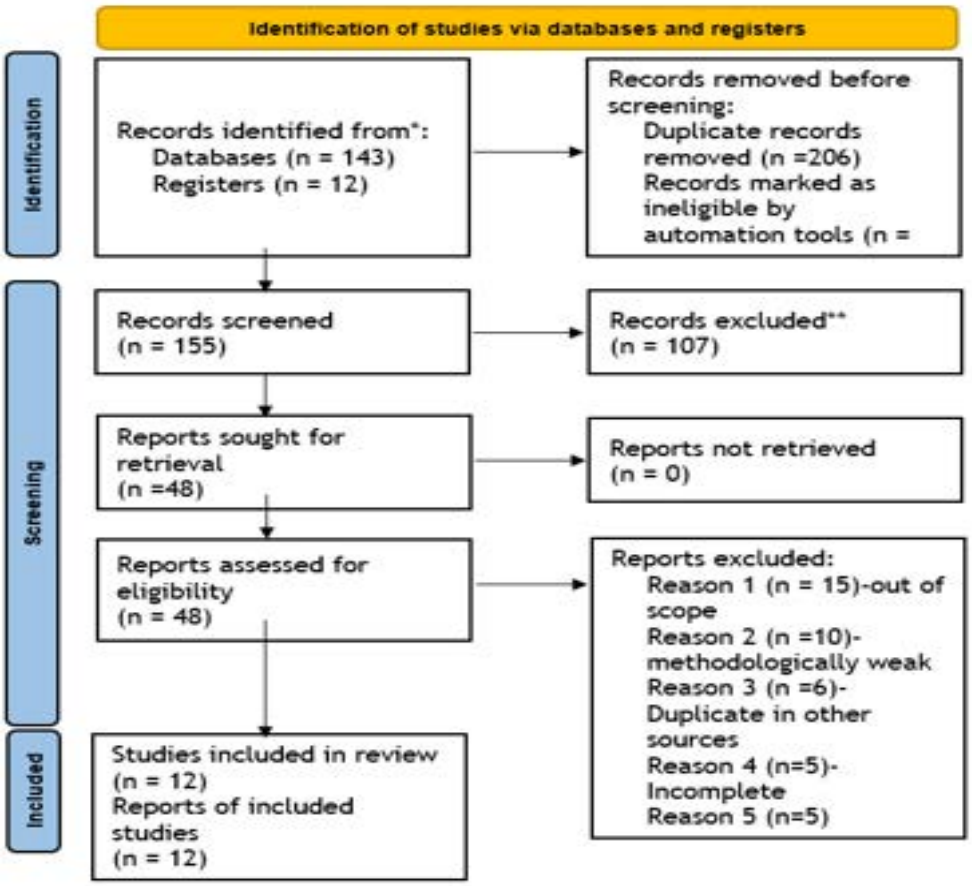

Figure 1: PRISMA flow diagram of the study selection process

6 LITERATURE REVIEW

The following literature presents a comprehensive examination of global developments in modern air defence systems, with a particular focus on Ground-Based Air Defence Systems (GBADS), Integrated Air Defence Systems (IADS), and Mobile Air Defence Systems (MobADS). It explores the evolving operational, technological, and doctrinal imperatives driven by increasingly complex aerial threats, including drones, stealth aircraft, cruise missiles, and hypersonic weapons. By analysing studies from diverse geopolitical contexts, the literature highlights key advancements in radar technology, missile guidance, interoperability, mobility, and command-and-control integration, offering a global perspective on the transformation of air defence capabilities in the 21st century.

6.1 Ground-Based Air Defence Systems (GBADS)

In their 2023 study, Matejček and Šostronek provide a comprehensive technical assessment of Ground-Based Air Defence Systems (GBADS), urging the modernisation of existing capabilities in response to the increasing complexity of aerial threats. They classify GBADS into four tiers: Very Short Range (VSHORAD), Short Range (SHORAD), Medium Range (MRAD), and Long Range (LRAD) based on engagement envelopes ranging from 5 km to over 120 km, each contributing to a layered air defence architecture that enhances redundancy and coverage. The study identifies critical limitations in legacy systems, particularly Soviet-era GBADS, citing their vulnerability to modern threats such as high-speed precision-guided munitions, low-observable cruise missiles, and loitering drones. Modern GBADS, the authors argue, must integrate advanced radar technologies (e.g., AESA, Doppler, frequency-hopping), multimodal guidance

systems (RF, IR, laser), and diagnostic tools like Built-In Test Equipment (BITE). They model radar acquisition zones using variables such as radar range, missile flight time, and target velocity, and employ probabilistic models reflecting saturation engagement doctrines. Case studies of systems such as the RBS-70 NG, NASAMS II, IRIS-T SL, and BARAK 8 illustrate the operational diversity of modern GBADS across tiers.

The study emphasises the importance of interoperability within command structures like NATO's NATINAMDS, highlighting command nodes from the Joint Force Air Component to national Fire Units, interconnected through data protocols like LINK-16 and JREAP. Complementing this analysis, Bansal's 2019 work expands on Integrated Air Defence Systems (IADS) as multi-layered, network-centric architectures designed to neutralise diverse threats ranging from fifth-generation aircraft to ballistic missiles. His model includes long-range surveillance platforms (e.g., AEW&C, UAV-based radars), strategic SAMs (S-300, S-400), medium-range interceptors (Barak-8), and inner-layer defences such as MANPADS and CIWS. A key feature of IADS is its kill chain integration from detection to destruction, facilitated by C4ISR frameworks, EMCON protocols, and multi-backbone communications, including satellite and fibre links. Both studies converge on the necessity for modular, scalable, and digitally networked air defence systems capable of withstanding electronic warfare and cyber-attacks while remaining interoperable with allied assets. They conclude that modern GBADS and IADS form the backbone of future Integrated Air and Missile Defence (IAMD), ensuring survivability and operational resilience in contemporary and future combat theatres [5].

6.2 Mobile Air Defence Systems (MobADS)

In a 2024 assessment compiled by the Heritage Foundation, Dodge articulates a systematic overview of the operational functionality and strategic posture of mobile air defence systems (MobADS) within the broader framework of U.S. missile defence capabilities. The assessment identifies MobADS as a critical component in countering evolving aerial threats, including cruise missiles, drones, and hypersonic systems, particularly in dispersed and contested operational environments. Dodge's report underscores the integral role of mobility and modularity in enhancing battlefield resilience. These systems are not confined to fixed installations but are instead deployed on tactical ground platforms such as trucks or armoured vehicles capable of repositioning in response to shifting threat dynamics. The operational construct revolves around a triad of interconnected subsystems: surveillance radars, command-and-control (C2) nodes, and interceptor launch platforms. Each component is designed to function autonomously when required, but is more effective when networked into an integrated battle management architecture.

The author further details that the radar systems used in MobADS are optimised for rapid detection and target acquisition, while the C2 infrastructure manages threat classification and prioritisation, enabling a dynamic and timely engagement decision. Interceptor systems, whether missile or gun-based, are guided through real-time data relays between radar and C2 nodes, a synergy that enhances both precision and operational tempo. Notably, the study critiques legacy missile defence doctrines for their over-reliance on static, theatre-based platforms ill-suited to modern asymmetric threats. MobADS, in contrast, is depicted as adaptable and capable of functioning within multi-domain operations, often in coordination with air, naval, and cyber elements. Dodge's analysis also highlights future imperatives, including increased integration of AI-assisted target recognition and autonomous kill-chain execution, which are already emerging as technological trends within next-generation MobADS frameworks. In conclusion, Dodge’s 2024 military strength index provides not just a technical dissection of mobile air defence mechanisms, but also a strategic rationale for their prioritisation within modern force structure planning. His findings affirm MobADS as indispensable to contemporary deterrence and defence postures, especially under conditions of contested logistics, decentralised command, and high-threat proliferation [3].

While international IADS literature provides valuable benchmarks, much of it is grounded in NATO, Israeli, or Asia-Pacific operational frameworks. These models often assume access to high-budget, networked infrastructure, which may not align with the SANDF's logistical and doctrinal environment. The absence of peer-reviewed studies on African air defence systems poses a challenge for region-specific benchmarking and underlines the need for frameworks tailored to the strategic and budgetary realities of African states.

6.3 Global Trends

In a 2024 study by Youvan titled *Global Missile Defence Systems: Comparative Analysis and Strategic Implications*, the author undertakes a comprehensive comparative analysis of contemporary missile defence architectures, exploring the interplay between technical capabilities, geopolitical dynamics, and emerging technologies. The research systematically evaluates global systems such as the S-400 Triumf, Iron Dome, THAAD, Patriot PAC-3, HQ-9, Aster 30, David's Sling, and Arrow 3, examining their operational range, engagement strategies, and regional deployment patterns. Through a layered analytical approach, Youvan underscores the dual role of missile defence systems as both protective mechanisms and strategic instruments influencing deterrence postures, alliance politics, and regional security balances. The study highlights technological trends like artificial intelligence and directed energy weapons (e.g., lasers) as transformative forces poised to enhance interception efficiency, automate threat response, and reshape battlefield doctrines. Furthermore, it delves into critical vulnerabilities, including cyber threats, system integration challenges, and the limitations of kinetic kill vehicles, while also evaluating strategic implications such as arms races, crisis instability, and the erosion of arms control frameworks. Ultimately, the research advocates for integrated, multi-layered, and ethically governed missile defence strategies as indispensable tools for safeguarding national security while maintaining international stability amidst rapidly evolving threat landscapes [4].

The literature review explores global advancements in air defence, focusing on Ground-Based Air Defence Systems (GBADS), Integrated Air Defence Systems (IADS), and Mobile Air Defence Systems (MobADS). Key studies highlight the increasing threat posed by UAVs, stealth aircraft, cruise missiles, and hypersonic weapons, which necessitate modular, layered, and network-centric responses. Matejček and Šostronek [2] emphasise the modernisation of GBADS through advanced radar and missile guidance technologies. Bansal [5] presents IADS as a digitally integrated framework for comprehensive threat detection and engagement. Dodge [3] examines the strategic role of MobADS in dispersed, high-threat environments, identifying artificial intelligence as a key enabler for future capabilities. Youvan [4] provides a comparative evaluation of global missile defence architectures, noting their strategic and technological implications. Collectively, the literature underscores a shift towards interoperable, AI-assisted, and mobile air defence systems suited to complex and evolving operational theatres.

7 SYSTEM OVERVIEW

7.1 Description of MobADS components

This section offers a focused overview of selected subsystems within the Mobile Air Defence System (MobADS), chosen by the authors for their direct relevance to the study's objectives. Due to space limitations set by the conference, only a few key functional elements are discussed, namely the Local Warning Radar System (LWRS), Integrated Gun Firing Unit (IGFU), ADA HQ Mobile Vehicle, and Air Defence Operations Centre (ADOC). While MobADS comprises additional components and capabilities, the authors have limited the scope to these subsystems for the purpose of this paper, examining their structure, roles, and contributions to the system's mobile and integrated air defence functionality.

7.1.1 A Local Warning Radar System (LWRS)

The ESR 220 Thutlwa forms a vital node within the South African Army's Ground-Based Air Defence System (GBADS), delivering a highly mobile, autonomous, and resilient solution for tactical air surveillance and fire control. Engineered around a solid-state, L-band 2D radar, the Thutlwa is capable of tracking up to 100 airborne targets within a 120-kilometre range, providing early warning and real-time air picture generation for low to medium-altitude threats. Mounted on a Kynos Aljaba 8×8 armoured chassis, the system is self-contained with its power generation, enabling rapid deployment and operational readiness within ten minutes of arrival, regardless of external support infrastructure. It integrates Identification Friend or Foe (IFF) capabilities, enhancing situational awareness and mitigating the risk of fratricide through the fusion of primary radar and IFF data into a consolidated Recognised Air Picture (RAP). Its command and control architecture is interoperable with broader GBADS elements, enabling seamless coordination with weapon systems like the GDF 05 L90 twin 35 mm cannons for integrated local warning, engagement planning, and fire control. The vehicle platform affords high cross-country mobility and protection for the crew and mission-critical systems, ensuring survivability and sustained operations within high-threat or rapidly changing operational theatres [6], [7]. Figure 1 below shows the LWRS mounted on its mobile platform.

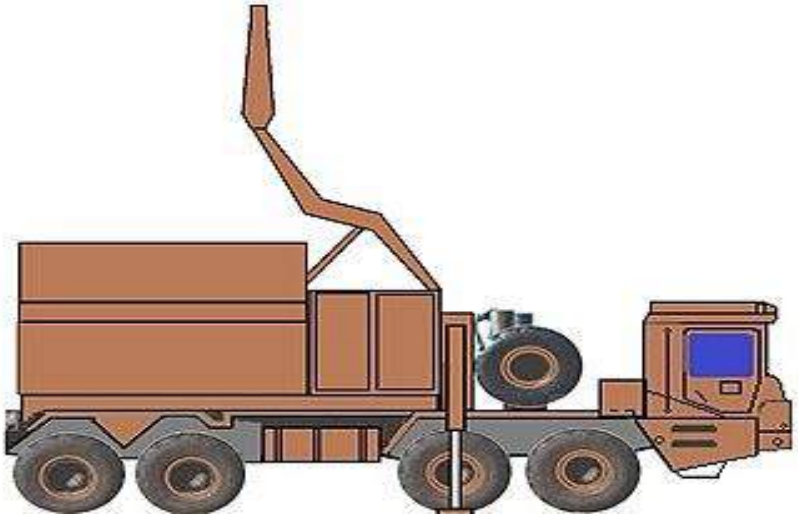

Figure 2: Local Warning Radar System (LWRS)

7.1.2 Integrated Gun Firing Unit

The Gun Fire Unit (FU) is engineered to deliver protection for stationary, high-value assets such as airfields, bridges, command-and-control centres, and key industrial installations. It is capable of defending against conventional airborne threats through the deployment of gun systems situated within the inner defensive layer. Central to this capability is the Integrated Gun Fire Unit (IGFU), which, in conjunction with its Sensor Unit (SU), provides uninterrupted air surveillance across the designated protection zone. The gun systems, specifically the 35 mm Mk 5A or Mk 7 variants, are employed to neutralise close-range aerial threats. The IGFU comprises several critical system components, including a containerised shelter that houses both the Gun Air Defence Control System Interface (GAI) and the Control Unit (CU). The CU is responsible for managing both the sensor and gun systems, enabling seamless target acquisition and engagement.

The shelter further includes the Power Supply Unit (PSU) and the human-machine interface (HMI) operator consoles. These consoles facilitate a range of core functions: selecting primary modes for the sensor system; displaying search radar and Track-While-Scan (TWS) data; selecting and prioritising targets for engagement; managing setup tasks; detecting and

localising system faults; visualising outputs from electro-optical sensors; monitoring gun status and ammunition levels; and issuing fire commands to the gun systems. The Sensor System, which encompasses the SU and CU, provides essential air surveillance, target acquisition, and tracking capabilities, while also controlling the guns in real-time. The GAI extends air defence control functions and provides a data interface between the CU and the broader system architecture. Together, these components form a cohesive, highly responsive air defence platform capable of operating in high-threat environments [8], [9]. Figure 2 below shows an Integrated Gun Firing Unit for the MobADS.

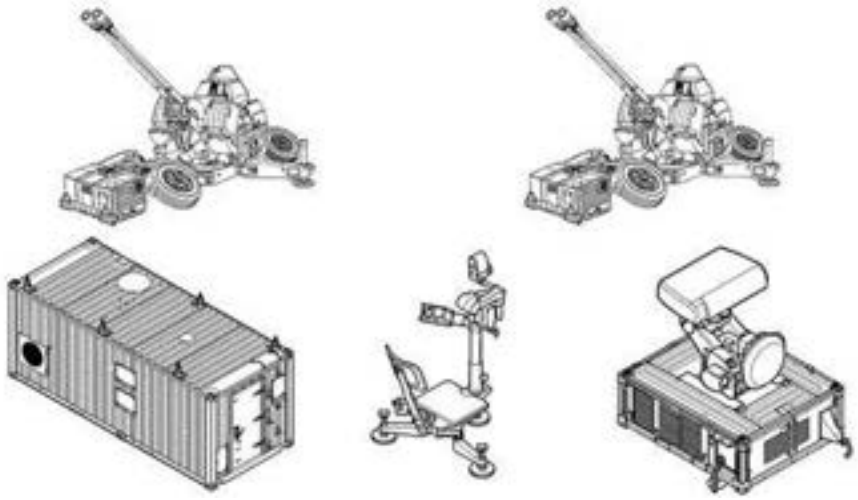

Figure 3: Integrated Gun Firing Unit

7.1.3 ADA HQ Mobile Vehicle

The Headquarters (HQ) Vehicle System is defined as the HQ platform that integrates the essential command and communications systems. It is equipped with the required interfaces and supporting subsystems, including power supply, internal lighting, and auxiliary components, enabling it to perform various command functions within the Mobile Air Defence System (MobADS) Regiment and Batteries. The ADA Mobile HQ Vehicle serves as a high-mobility, tactical command-and-control centre, purpose-built for both on-road and off-road operational environments. Built on the combat-proven chassis of the Ratel 60 mm Mortar ICV and 12.7 mm Command Vehicle variants, the ADA Mobile HQ incorporates a range of modifications tailored to meet Air Defence Artillery (ADA) operational requirements. The configuration consists of the standard vehicle hull coupled with a rotating turret, armed with either a 60 mm mortar or a 12.7 mm machine gun. The vehicle variant is not specifically selected on mission needs, but on what is available as CFE for allocation to the project for modification. Designed with crew survivability as a priority, the ADA Mobile HQ is capable of accommodating a team of four personnel. The vehicle offers ballistic protection against small arms fire at close quarters and against projectile threats up to 12.7 mm calibre at medium-range engagements [1]. Figure 3 below depicts the ADA HQ MOBILE VEHICLE used by the South African National Defence Force.

Figure 4: ADA HQ MOBILE VEHICLE

7.1.4 Air Defence Control System

The Air Defence Control System (ADCS) serves as a Functional Element (FE) within the broader Mobile Air Defence System (MobADS), with the primary objective of supporting and enabling the Air Defence (AD) Control function. As a product system, the ADCS is classified as a Computer Software Configuration Item (CSCI), comprising multiple distinct modules and functional components. These modules are deployed across various levels of control within the system architecture, tailored to their specific operational roles. The ADCS software is installed on operator terminals situated at different command levels, including the Regiment Air Defence Operations Centre (RADOC), Battery Air Defence Operations Centre (BADOC), Local Warning Radar System (LWRS), Integrated Gun Fire Unit (IGFU), and future developments such as the Short-Range Local Warning System (SRLWS) and Short-Range Air Defence Fire Units (SHORAD FUs). The system is fully scalable according to the operational role and level of employment, ensuring adaptability and mission-specific performance. At the core of its functionality, the ADCS software governs the flow, processing, and presentation of critical information. This includes the detection and tracking of airborne targets, accurate classification of these tracks, threat evaluation, and the assignment of appropriate weapon systems, ultimately facilitating the successful engagement and neutralisation of hostile aerial threats.

The ADCS is seamlessly integrated with the MobADS Tactical Command and Control System (TCCS) and the associated communications infrastructure, enabling real-time situational awareness and coordinated response. An essential feature of the ADCS is its capacity to coordinate MobADS firepower with precision, thereby reducing the risk of fratricide (unintended engagement of neutral or friendly forces) while enhancing the cost-effectiveness and operational efficiency of threat responses. Furthermore, the ADCS interfaces with the Sector Command Centre (SCC) within the Joint Air Defence (JAD) organisational structure, reinforcing interoperability across defence layers. The Central Air Defence Authority (CAD) is implemented at the Battery level, enabling direct control over Fire Units (FUs) to streamline command pathways and significantly reduce system reaction times. ADCS control is realised via dedicated ADCS nodes at both Battery and FU levels. In support of system resilience, a fallback mechanism has been integrated, allowing for graceful degradation of the CAA's functions in the event of equipment failure, ensuring continued operational capability under degraded conditions [1], [10]. Figure 4 shows the inside of the Air Defence Operation Centre.

Figure 5: Air Defence Operation Centre

7.1.5 Subsystem Integration Summary

The Mobile Air Defence System (MobADS) comprises several key subsystems that operate in an integrated manner to deliver layered, mobile, and responsive air defence capabilities across tactical environments. These components include the Local Warning Radar System (LWRS), Integrated Gun Firing Unit (IGFU), ADA Mobile Headquarters Vehicle, and the Air Defence Operations Centre (ADOC).

- The LWRS, based on the ESR 220 Thutlwa radar, provides rapid-deployment, L-band 2D air surveillance from a mobile 8×8 platform. It supports early warning, real-time tracking of up to 100 aerial targets, and seamless integration with Identification Friend or Foe (IFF) and command-and-control systems. Its robust mobility and autonomous operation make it ideal for expeditionary and high-threat environments [6], [7].
- The IGFU delivers close-range defence for critical fixed infrastructure using either 35 mm Mk 5A or Mk 7 gun systems. It is equipped with a comprehensive sensor suite, Gun Air Defence Control System Interface (GAI), and operator consoles within a containerised shelter. The system allows for real-time air surveillance, threat engagement, and full command over gun operations through the Control Unit (CU), ensuring precision and responsiveness under combat conditions [8], [9].
- The ADA Mobile HQ Vehicle serves as a mobile command-and-control centre tailored for on- and off-road deployment. Based on the Ratel 60 mm Mortar and 12.7 mm Command Infantry Combat Vehicle platforms, the vehicle integrates communications systems, mission support electronics, and modular subsystems. It provides command roles at the Regiment and Battery level and offers protection for a crew against small arms and medium-calibre threats [1].
- Lastly, the Air Defence Control System (ADCS) acts as the centralised software backbone of MobADS, classified as a Computer Software Configuration Item (CSCI). It is deployed across various control nodes such as RADOC, BADOC, LWRS, and IGFU and is adaptable for future SHORAD and surveillance developments. The ADCS manages critical data processing, target classification, threat evaluation, and firepower coordination. Fully integrated with MobADS TCCS and communications systems, it ensures accurate engagement, minimised fratricide, and operational continuity. It also

interfaces with the Joint Air Defence (JAD) command architecture through the Sector Command Centre (SCC), with resilience supported by a fallback mechanism for degraded operation [1], [10].

8 COMPARATIVE ANALYSIS OF THE SANDF MOBADS AND TÜRKİYE'S STEEL DOME SYSTEMS

The modernisation of air defence capabilities is a pressing imperative for middle powers seeking to respond to evolving aerial threats in complex operational environments. Both South Africa's Mobile Air Defence System (MobADS) and Türkiye's Steel Dome (Çelik Kubbe**)** represent sovereign attempts to craft adaptable, layered, and responsive air defence architectures. While each system is grounded in different threat perceptions, geopolitical realities, and industrial capacities, they converge around the principles of mobility, modularity, and digital integration. A comparative analysis highlights both shared strengths and divergent trajectories in the design and deployment of these two systems.

8.1 Contrasting Doctrinal Foundations: South Africa's MobADS vs. Türkiye's Steel Dome

MobADS emerges from South Africa's need for a tactical, expeditionary air defence solution suitable for both domestic protection and regional peacekeeping missions. It is structured around the SANDF's mobility doctrine, protecting against low and medium-altitude threats in complex terrain with high levels of autonomy. In contrast, Türkiye's Steel Dome is conceived within a national strategic deterrence paradigm, designed to establish a sovereign, integrated air and missile defence shield over a vast and geopolitically sensitive airspace. It reflects Ankara's post-Cold War doctrinal shift from fighter-centric offensive power to indigenous, layered defensive autonomy [6], [8].

8.2 System Architecture and Network Integration

MobADS is composed of a collection of subsystems such as the Local Warning Radar System (LWRS), Integrated Gun Firing Unit (IGFU), ADA Mobile HQ Vehicle, and Air Defence Operations Centre (ADOC), all networked through the Tactical Command and Control System (TCCS). The design facilitates decentralised command and real-time engagement, particularly against close-range threats. While robust, MobADS still largely operates within a conventional command hierarchy and is optimised for short-range and inner-layer defence. Steel Dome, however, features a more complex and vertically integrated architecture, with Artificial Intelligence-assisted (AI) C5ISR (Command, Control, Communications, Computers, Combat Systems, Intelligence, Surveillance, and Reconnaissance) at its core. It's HAKİM Command and Control system, together with RADNET and HERİKKS, enables full-spectrum integration from radar surveillance to interceptor launch, including space-based sensors and electronic warfare modules. This **deep integration** allows Türkiye to execute multi-domain, multi-layered operations and anticipate emerging hypersonic and stealth threats [1].

8.3 Layered Defence and Threat Engagement Envelopes

MobADS' future development plans are expected to include the integration and enhancement of its VSHORAD and SHORAD capabilities, aimed at improving adaptability and providing a more robust, layered air defence posture against evolving aerial threats. It excels in protecting stationary assets and responding to low-altitude, fast-moving threats such as UAVs and rotary aircraft. Steel Dome employs a multi-layered missile defence framework, with intercept ranges of 4 km (Korkut), 10 km (Gürz), 40 km (Hisar-O), and up to 200 km in its forthcoming Super variant. This configuration provides Türkiye with low-, medium-, and high-altitude coverage and positions it closer to integrated air and missile defence (IAMD) capabilities seen in NATO and Israeli doctrines. It also enables simultaneous engagement of multiple aerial threats at varying altitudes and ranges [11].

8.4 Technological Sophistication and Artificial Intelligence (AI) Integration

MobADS features containerised sensor suites, fault detection systems, electro-optical tracking, and centralised fire control, providing a high level of situational awareness and engagement efficiency. However, it lacks deep artificial intelligence integration and relies primarily on operator inputs and semi-automated systems. Conversely, Steel Dome incorporates AI for threat detection, trajectory prediction, and kill-chain optimisation, drastically reducing response time. The AI component ensures a dynamic adaptation to evolving tactics such as swarm drones and loitering munitions. It also supports integration with **space-based early warning systems** and offers autonomous kill-chain execution, reflecting next-generation AD system evolution [11].

8.5 Mobility and Deployment Flexibility

Both systems are mobile, but in different contexts. MobADS, built on rugged 8×8 and Ratel combat platforms, is suited for high mobility in regional terrains, enabling agile deployment in both national and peacekeeping missions. It prioritises tactical mobility and autonomous operation. Steel Dome, while including mobile launchers and gun systems, is designed for strategic mobility, capable of being repositioned across Türkiye's vast geography depending on threat concentration. It is more static at the higher layers but provides operational reach through long-range radar and missile platforms [1], [11].

8.6 Interoperability and Alliance Integration

MobADS is interoperable within the SANDF and African regional frameworks but does not support NATO-standard communication protocols or joint operational doctrines. Its integration with the Joint Air Defence (JAD) architecture reflects a limited regional scope. Steel Dome, however, is being engineered for NATO interoperability, with future integration into the European Sky Shield Initiative and command interoperability through the HERİKKS system. This enhances Türkiye's role in collective defence while retaining full sovereignty over system deployment and control [1], [11].

8.7 Exportability and Industrial Base

MobADS represents a niche domestic capability developed by Denel and related SANDF stakeholders. While technically proficient, its export potential is currently limited due to budgetary constraints, geopolitical alignment, and production scale. Steel Dome is positioned as a flagship export platform, particularly attractive to Gulf countries seeking holistic air defence solutions. Türkiye's vertically integrated defence sector, supported by the Presidency of Defence Industries (SSB), underpins its ambition to become a global supplier of advanced AD systems, building on the success of TB2 and Akıncı drone exports [1], [11].

8.8 Limitations and Development Challenges

MobADS' main limitations include its lack of long-range intercept capability, limited integration with emerging AI technologies, and constraints in countering saturation attacks involving multiple aerial vectors. Upgrades are needed in areas such as electronic warfare resilience, command redundancy, and expanded engagement envelopes. The absence of long-range intercept capability has been recognised and is included in the system's planned future developments. Steel Dome's challenges lie in integration complexity, cybersecurity vulnerabilities, and cost overruns. Unlike Israel's Iron Dome, it is not yet battle-tested, and its anti-ballistic missile (ABM) capability remains underdeveloped. Ensuring resilience under contested electronic and cyber environments will be critical to its long-term viability [1], [11]. Below is Table 2, a comparative table summarising MobADS vs **the Türkiye** Steel dome.

Table 2: A comparison table summarising MobADS vs Steel Dome

Attribute	MobADS (South Africa)	Steel Dome (Türkiye)
Primary Role	Tactical, short-range mobile air defence	Integrated national air & missile defence
Threat Engagement Range	Up to 120 km detection (radar), gun intercept within 4 km	4–200 km layered missile & gun coverage
Core Subsystems	LWRS, IGFU, ADA HQ Vehicle, ADOC	Korkut, Gürz, Hisar-O, Super variant missiles
AI Integration	Limited, operator-driven with semi-automation	AI-assisted detection, trajectory prediction, and autonomous kill-chain
Command Architecture	Decentralised via TCCS, regional scope	AI-enabled C5ISR, NATO interoperability
Mobility	High tactical mobility (8×8 and Ratel platforms)	Strategic mobility across national theatre
EW Resilience	Moderate improvements planned	Integrated EW modules & cyber resilience features
Export Readiness	Limited	High-marketed to Gulf and NATO-aligned states
Deployment Time	<10 min (LWRS)	Variable – dependent on the asset layer
Interoperability	SANDF/JAD framework	NATO-standard, multi-domain capable

9 DISCUSSION

The MobADS represents a critical advancement in the SANDF's pursuit of tactical, modular, and mobile air defence capabilities tailored for sub-Saharan operational conditions. By integrating the Local Warning Radar System (LWRS), Integrated Gun Firing Unit (IGFU), ADA HQ Vehicle, and Air Defence Operations Centre (ADOC) into a decentralised Tactical Command and Control System (TCCS), MobADS delivers high mobility, rapid deployment (<10 minutes), and situational awareness suitable for both domestic and regional deployments [1]. However, limitations persist. The absence of a missile-based intercept capability constrains its layered defence posture, especially against medium- and high-altitude threats. Additionally, while MobADS supports semi-automated operations, it lacks advanced artificial intelligence for autonomous target recognition or kill-chain execution, a shortfall given the global trend toward AI-assisted systems [11]. Electronic warfare resilience remains moderate, with future upgrades needed to improve performance under contested conditions. Compared to Türkiye's Steel Dome, which offers integrated AI, multi-layered intercept ranges (4–200 km), and NATO interoperability, MobADS remains focused on short-range defence within SANDF's regional framework. Still, its modularity, rugged mobility, and integration of legacy platforms offer a sovereign, adaptable solution in resource-constrained environments [11]. For MobADS to remain operationally competitive, enhancements should include long-range missile integration, AI-enabled command automation, improved EW defences, and expanded interoperability with regional and allied forces.

10 CONCLUSION

The Mobile Air Defence System (MobADS) is a key part of the SANDF's short-range air defence, designed to counter UAVs, cruise missiles, and helicopters. This study used subsystem analysis, benchmarking against Türkiye's Steel Dome, and a global literature review to assess MobADS' strengths, gaps, and upgrade needs. It confirms strong mobility, fast deployment, and effective autonomous function. However, weaknesses remain in long-range interception, AI-driven decision support, and joint-force interoperability. Upgrades in layered missiles, EW resilience, and AI-enabled C2 would boost its strategic value. This is the first open-source,

system-level review of MobADS in Africa, offering a clear roadmap for future planning and operational relevance.

ABSTRACT

Quality 4.0 (Q4.0) provides a solution by eliminating process inefficiencies and boosting quality, which promotes organisational and economic growth. However, transitioning to Q4.0 in developing nations such as South Africa (SA) remains challenging since generic frameworks frequently overlook adoption challenges specific to developing countries. Poorly managed migrations might result in adverse outcomes from which businesses may struggle to recover. This study integrates the technology-task-fit, fit-viable and people-process-technology models to create a framework for addressing Quality 4.0 adoption challenges in SA. Using an online survey of 44 manufacturing stakeholders identified through snowballing, the framework provides guidance for successful Q4.0 transitions. The outcome of this paper aligns with the national strategy to leverage technological innovation by 2030 to combat unemployment, poverty, and inequality in South Africa.

Keywords: Quality 4.0, South African manufacturing, Industry 4.0, Technology Migration

1 INTRODUCTION

In global economies, manufacturing serves as a fundamental driver of growth and development. In the African continent, the South African manufacturing sector is known to be the most industrialised economy, ranked among the top third global manufacturing economies based on its capacity to produce and export goods, it's technological innovations and global influence in manufacturing activities [1]. Moreover, this sector has played a pivotal role in job creation, offering employment opportunities to a substantial portion of the population and driving economic growth [2], [3].

Nevertheless, the manufacturing industry in South Africa has faced various challenges, including job losses due to factors like automation, global competition, economic instability, and quality issues [3]. Product recalls have also been a recurring concern, arising when products are deemed unsafe, defective, or non-compliant with regulatory standards [3], [4]. The impact of these challenges is seen in numerous factors including the decline of its total revenue by 2.53% and net profit by 145.66% in 2024 [1].

Maharaj [5] found that adopting digital technologies and reshaping production processes has potential to enhance efficiency, reduce costs and improve product quality thereby redefining the sector to be great again. Other researchers corroborated this and suggested the use of Industry 4.0 technologies to improve manufacturing processes, and subsequently improve quality [3], [6].

As a reinforcement, the president of South Africa, Cyril Ramaphosa presented the national strategy which underscores the goal of fully tapping into technological innovation by 2030 [2], [7], he further urged that South Africa adopt the Fourth Industrial Revolution to address the persistent socio-economic issues such as inequality, unemployment, and poverty in the nation. This also supports the goal set out by the United Nations to fully adopt resilient infrastructure, promote sustainable industrialization and foster innovation to realise global economic growth, particularly in developing nations by 2030 [8], [9].

The fourth industrial revolution occurred because of the integration of several devices into a wireless communication system for more efficient data collecting and analysis through Cyber-Physical Systems [10]. Big data and analytics, internet of things, artificial intelligence, autonomous robotics and mixed realities are some of the technologies that enable this revolution [4], [11], [12]. As a result, companies began to alter their business processes digitally [13]. As a subset of Industry 4.0, Quality 4.0 focuses on the digitization of quality processes and the effects of digital tools on people, processes, and technology [14], [15]. As organisational changes brought on by digitalization occur, additional attention must be paid to quality work to investigate new data sources for analysis and improve the performance of employees, suppliers, and clients. Adopting Quality 4.0 could enable firms to improve resource allocation and cost management.

The need for a comprehensive understanding of Quality 4.0 has ignited interest among corporations, yet a knowledge gap persists, particularly on the best transition strategies [16], [17]. This gap is more pronounced in developing states with limited resources and understanding. Without a tailored transitioning plan, the risk of challenges oversight arises, leading to potential delays, increased costs, or even project failure, to which organisations in emerging economies may not recover from.

This research closes a gap that exist in literature, with an aim to develop a Quality 4.0 transitioning framework for manufacturing organisations in South Africa. This framework is designed to address adoption challenges that are unique to firms in developing countries, often overlooked by generic frameworks. A smooth transitioning plan ensures a successful implementation and reaps full benefits of an initiative. This will ensure firms produce defect

free products, ensuring they maximize profits, remain competitive in the global scale, and boost the nation's economy.

The main aim of this study is supported by the following objectives:

a) To examine the level of preparedness among manufacturers in South Africa for Quality 4.0.
b) To propose a Quality 4.0 transitioning framework.

The developed framework serves as a strategic guide for organisations embarking on their Quality 4.0 journey, ensuring a comprehensive understanding of the essential components for a successful transition, key motivators driving the change, and the capability for organisations to assess their readiness prior to migration. This approach guarantees a smooth, efficient, sustainable and socially responsible transition to Quality 4.0.

2 LITERATURE REVIEW

2.1. Quality 4.0

The Fourth Industrial Revolution and technology advancements have changed the emphasis on quality management, giving rise to the concept of "Quality 4.0." Although it is still in its early stages and lacks established criteria, several academics have begun examining its effects in the context of manufacturing and service sectors [3], [12]. Quality 4.0 is based on Total Quality Management, but it goes beyond TQM by embracing all stakeholders and the crucial technologies for efficient data flow, as it can be seen on Figure 1.

The term "quality" has a broader definition in the context of Industry 4.0, which places an emphasis on value creation, organisational learning, innovation, sustainability, and the use of data to produce fresh insights [16], [17]. To support this perspective, Javaid *et al.* [18] suggest that Quality 4.0 involves crucial elements such as the swift and accurate collection of data from multiple sources, enabling prompt and well-informed decision-making.

Figure 1 Quality 4.0 conceptual framework [14], [15]

According to Sader *et al.* [19], Quality 4.0 is an expanded way of quality management that seamlessly combines contemporary technology with tried-and-true quality techniques like Total Quality Management, Quality Control, and Quality Assurance. This integration results in a broader range of quality management practices and enhances overall quality operations. To achieve previously unheard-of levels of performance, efficiency, and innovation, [16], [19], [20], as referenced by Santos *et al.* [21], emphasises further that Quality 4.0 entails the seamless fusion of cutting-edge technologies with conventional quality methods. This innovative concept aims to include established quality management principles. Maganga *et al.* [17] then conceptualised Quality 4.0 as an integration of modern and cutting-edge technologies into traditional quality management approaches to realise real-time quality management and big data management as illustrated on Figure 2.

Figure 2 Conceptual Framework as adapted from Maganga et al. [17]

By involving suppliers, customers, and society as active co-creators of goods and services, organisations can more quickly gather crucial data and extract meaningful insights. Empirical learning, knowledge discovery through real-time data collection, gathering, and analysis are some of the core tenets of Quality 4.0, all of which promote sensible operational decision-making [14], [17], [19]. As it can be seen on presented literature- as seen on Figure 1 and Figure 2, scholars have conceptualised Quality 4.0 [14], [19], however this study did not find a transitioning framework that shows a step-by-step approach of how firms in South Africa, a developing country need to migrate to this conceptualised quality management regime.

2.2. Frameworks

An outline or conceptual structure known as a framework serves as a foundation for organizing, comprehending, and approaching a certain problem, endeavour, or field of study [16], [22]. Frameworks act as models or guides that people or organisations can use to think systematically and coherently about difficult problems. They often include crucial elements, guiding principles, ideas, and connections that are pertinent to the topic.

2.2.1. Critiquing existing frameworks

Although authors have developed Quality 4.0 frameworks, these frameworks possess limitations and cannot be applied directly to the South African manufacturing setting due to the manufacturing sector's level of complexity and the challenges unique to it and other developing countries due to unique economic, socioeconomic and infrastructure settings.

Organisations in developed counterparts adopt Quality 4.0 for competitive advantage against each other, while those in South Africa, an emphasis is placed on strengthening the sector and the economy by ensuring that organisations learn from each other and are competitive against global counterparts [23], seeing that the sector's output has been declining, with consumers choosing international alternatives [3]. A framework for transitioning firms to Quality 4.0, or any Industry 4.0 initiative, in South Africa should reflect this.

The economic and socioeconomic problems in developing nations are not met by generic transitioning frameworks such as those created by Armani et al. [24], Carvalho et al. [14], Jacob [20], and Zulqarnain et al. [25]. They highlight the adoption of technology in developing economies, but they don't offer guidance to firms on how to rank the technologies that would help them with their present quality management problems. This is a disadvantage since businesses in underdeveloped nations, like South Africa, are strapped for cash and cannot afford to implement all the industry 4.0 technology. Instead, they must determine which will be most effective for them. This strategy should be emphasised in developing country transitioning frameworks.

These frameworks also disregarded collaborating among the organisations, which highlights their pursuit for competitiveness against each other first, which is not the case yet in the South African context as the main aim is still to grow the sector by sharing lessons learnt during migration to be competitive against international rivals [4], [11].

Stakeholder integration in the migration process is mentioned in models by Armani et al. [24], Carvalho et al. [14], Jacob [20], Zulqarnain et al. [25], and the American Society for Quality (ASQ) [26]. A thorough examination of these stakeholders, however, indicates that these models solely consider consumers, the government, and trade associations. This does not include community leaders and workers' unions, which are required to consult in the South African context [2], [27]. Despite being created to serve underdeveloped countries, the frameworks of Maganga et al. [16] and Olaitan et al. [23] did not address the ways in which social ills that impede the adoption of technology could be addressed. Additionally, the government's role in speeding up the adoption of technology in nations where the economy is in survival mode was not discussed.

Frameworks like Gonzalez Santacruz et al. [28] and the American Society for Quality's Quality 4.0 model, which Watson [26] explains in detail, were established for more developed states. Their disregard for budgetary restraints, governmental actions, and economic inclusion is indicative of this. Furthermore, they do not account for testing readiness before fully migrating which may lead to hasty migrations. All these frameworks assumed that local schools and universities were prepared to provide the skills necessary to quickly incorporate individuals into Quality 4.0. As discussed in the introduction, where scholars like Alexander [29] and Maisiri et al. [7] critiqued the South African educational system, this isn't always the case in developing countries.

The models critiqued above omit addressing a lot of the challenges that are found in developing countries like South Africa, which makes them unsuitable for direct application. Technological developments should prioritize enhancing people's lives rather than just increasing competitiveness, and transitioning frameworks should not ignore the local socioeconomic and cultural settings of the nations in which they will be implemented. These models, though they have shortcomings, provide a foundation on which to build models for developing countries.

3 METHODOLOGY

The framework is built using a top-down approach, developed on an integration of People-Process-Technology and Fit-Viable theorems as seen on Figure 3. The People-Process-technology theory stipulates that a technology initiative needs to ensure that all the aspects of an organisation are catered for, including the people and the processes, not just the technology aspect [4], [16], [30]. The Fit-Viable theorem ensures that before the initiative is adopted by an organisation it is fit to resolve their unique issues, and that the organisation has the necessary resources to prepare for a smooth transition to the initiative [23]. An organisation should only transition or implement a new technology once all the factors are met.

Framework Development Process

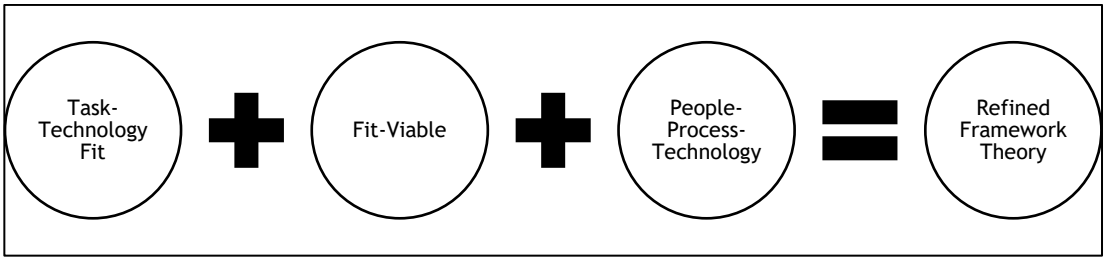

Figure 3 Refined framework theory

To gather the framework components, the study collects opinions from the employees in the manufacturing sector who are involved in quality management activities using an online survey tool.

a. Survey Instrument

The survey instrument was developed based on themes identified through thematic clustering, incorporating questions designed to assess readiness and maturity for new technologies. These questions were informed and refined by insights from experienced researchers in Quality 4.0 and Industry 4.0. For example, Antony et al. [31] and Dias et al. [15] proposed that adopting new technologies and ensuring that they can interface with legacy systems is critical to a smooth transition. Saihi et al. [32] proposed that top managers should embrace Quality 4.0 and provide resources to guarantee a successful transition. Sony et al. [33] and Watson [26] claimed that essential ingredients for Quality 4.0 include skilled and aware human resources, as well as a clear vision and scope, whereas Olaitan et al. [23] and Maisiri et al. [2] discovered that in developing countries, general infrastructure, local government support and data governance, and socioeconomic ills may impede successful adoption of new technologies.

Therefore, the survey had questions based on awareness, management support, infrastructure, technology, skills and resources, education and government support factors.

The main aim of the survey was to gather evidence regarding the status of quality 4.0 readiness in South African manufacturing organisations based on the latent readiness factors identified. From this survey, the challenges of these organisations in respect to Quality 4.0 readiness will be gathered in preparation for the transitioning framework, to ensure that the developed framework is evidence driven.

b. Population and Sampling

The questionnaire was sent to 8 personnel in the manufacturing sector who were known to the researchers as they are also involved in manufacturing and quality activities in different manufacturing clusters. These people were then asked to distribute the survey to their colleagues in the manufacturing sector who had knowledge of quality processes in manufacturing (Snowballing approach) so it can reach a wider audience. Moreover, the snowballing approach can foster a sense of confidentiality and trust, as individuals are more likely to share information with someone in their social circles [34], [35]. The survey ended up with 44 respondents.

Although the survey was anonymous, participants had to meet this criterion:

a) Work for the manufacturing sector.

b) Have knowledge of quality management regimes and industry 4.0.

c) Be willing to participate in the study.

d) Be involved in quality management planning and/or research activities.

c. Data Collection and Analysis

The survey was sent electronically via Microsoft Forms, with clear instructions on how to complete it. The survey questions followed a 5-point Likert scale (1 indicating 'extremely poorly prepared' and 5 indicating 'extremely well prepared') and data collected from the survey was analysed quantitatively using mode to aggregate each item in the themes on Excel packages. This study chose this as the mode is not influenced by extremely high values. Outliers can greatly distort the mean, and the standard deviation is sensitive to them and may give them greater weight, as well as assuming a normal distribution, which may not always be the case in real-world data [36]. The framework was then developed based to combat the weaknesses identified in the survey and ensure a smooth and sustainable transition to Quality 4.0.

4 RESULTS AND DISCUSSIONS

The section below presents the study findings in preparation to developing the transitioning framework for Quality 4.0.

4.1. Survey Results

This section presents the survey findings. The survey received a total of 44 participants. It is crucial to ascertain the items' Cronbach's alpha before analysing the questionnaire results to guarantee internal consistency [4]. The computed Cronbach's alpha for the survey in the current study was 0.83, demonstrating excellent correlation and enabling further analysis of the gathered data.

4.1.1. Demographics

Figure 4 shows the level of education of the respondents. This item was to test if the respondents had some formal training and thus were fit to participate in the study and perform their duties.

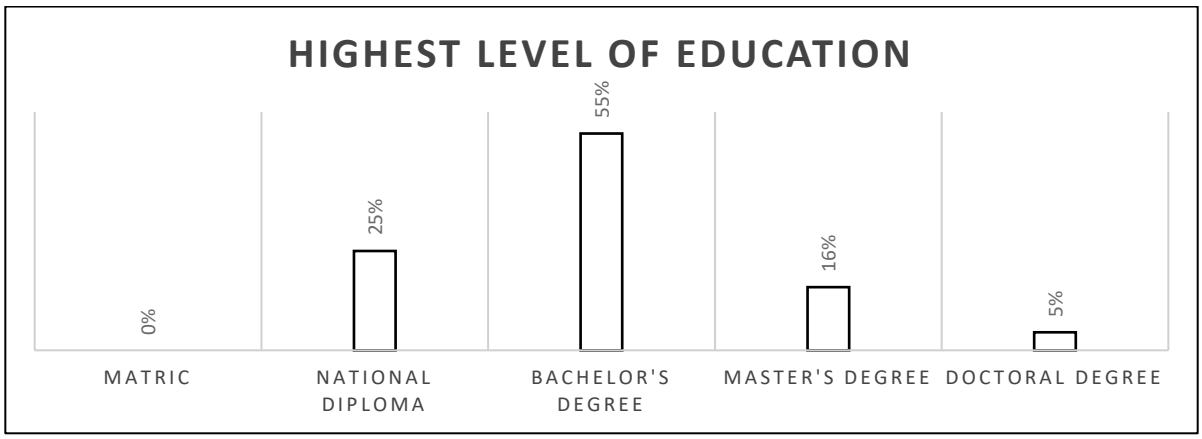

Figure 4 Level of Education

Majority (55%) respondents indicated that they had a bachelor's degree. The next highest number of respondents (25%) had a National Diploma. 16% of the respondents had a master's degree and only 5% hold a Doctoral degree.

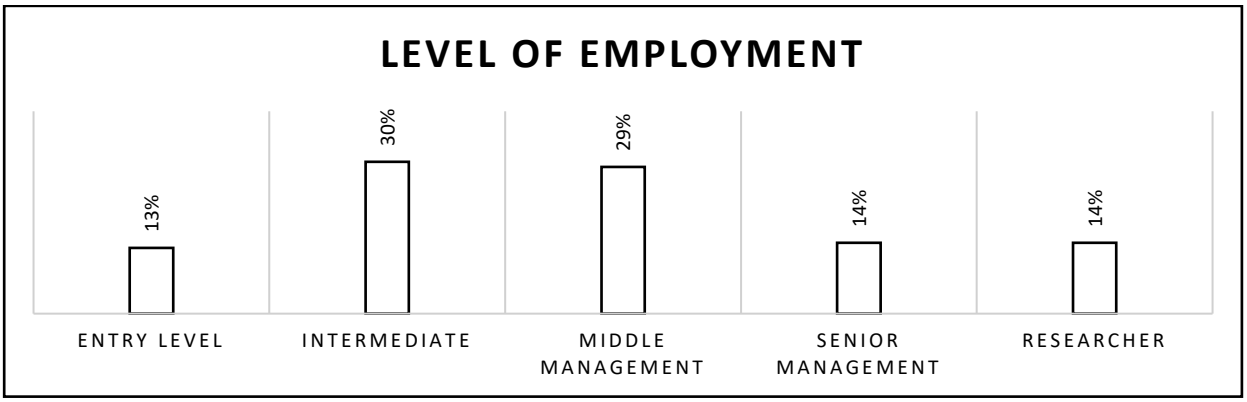

Figure 5 Level of employment

Figure 5 shows the level of employment of the respondents. The figure shows that majority of respondents (30%) were in intermediate positions, followed closely by 29% being in middle management positions. Respondents in senior positions and those in research each accounted for 14% of the respondents, while only 13% of the respondents were in entry level positions.

4.1.2. South African manufacturing readiness for Quality 4.0

The survey analysed the preparedness perception according to industry expects to draw a conclusion on challenges, strengths and weakness of the South African Manufacturing sector leading to Quality 4.0.

Figure 6 presents the aggregate results of current Quality 4.0 readiness in manufacturing sectors in South Africa. This aggregated histogram is skewed to the 'poorly prepared' measure for themes such as the technology adoption, the availability of a clear quality 4.0 vision and strategy, reliable infrastructure, adequate skills and quality 4.0 awareness, collaboration between industry bodies, firms, and institutions of higher learning, change management processes and government support.

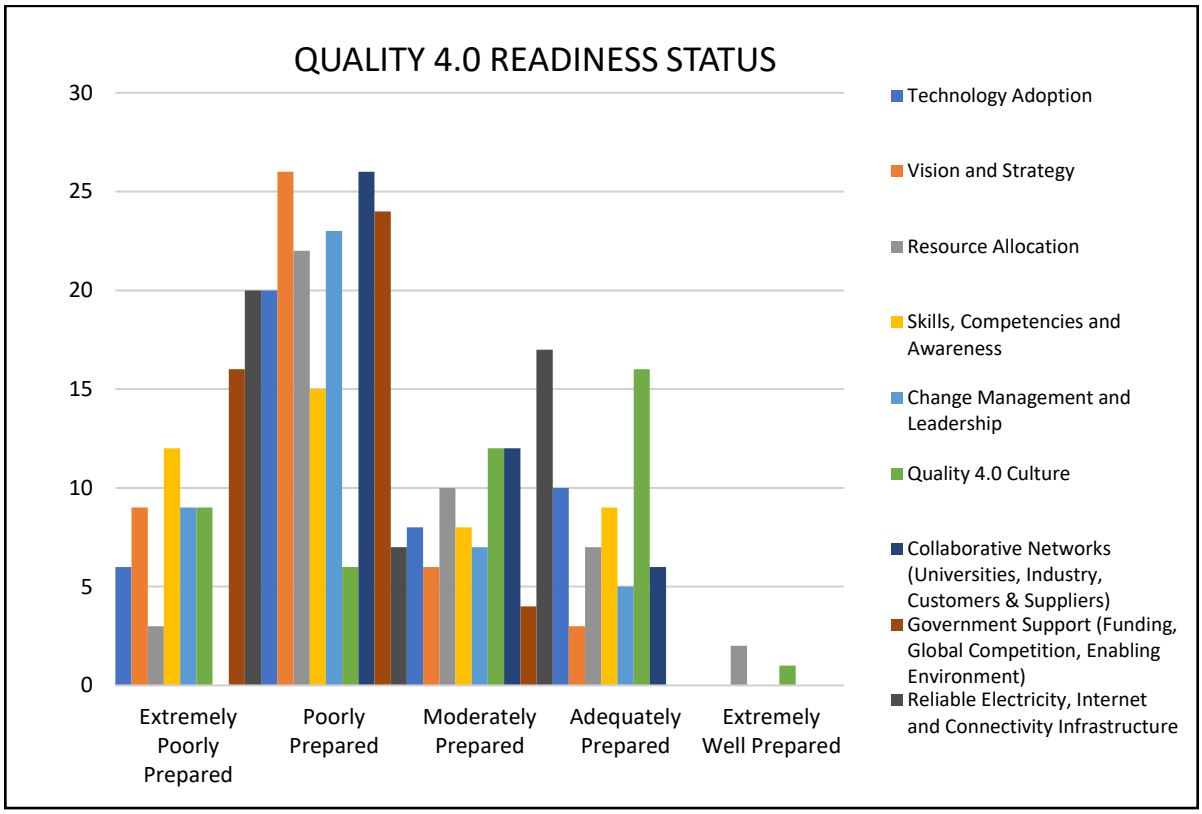

Figure 6 Overall Readiness Status

The findings reveal that while the South African industry possesses certain strengths, it is predominantly affected by several systemic challenges and weaknesses. These barriers highlight the urgent need for a robust, context-specific framework to facilitate a responsible and seamless transition to Quality 4.0. As illustrated in the Pareto diagram on Figure 7, the most significant obstacles to readiness for Quality 4.0 adoption include inadequate technology integration, unreliable electricity and connectivity infrastructure, education and skills mismatches, lack of government support, absence of a clear Quality 4.0 vision and strategy, and constrained financial resources.

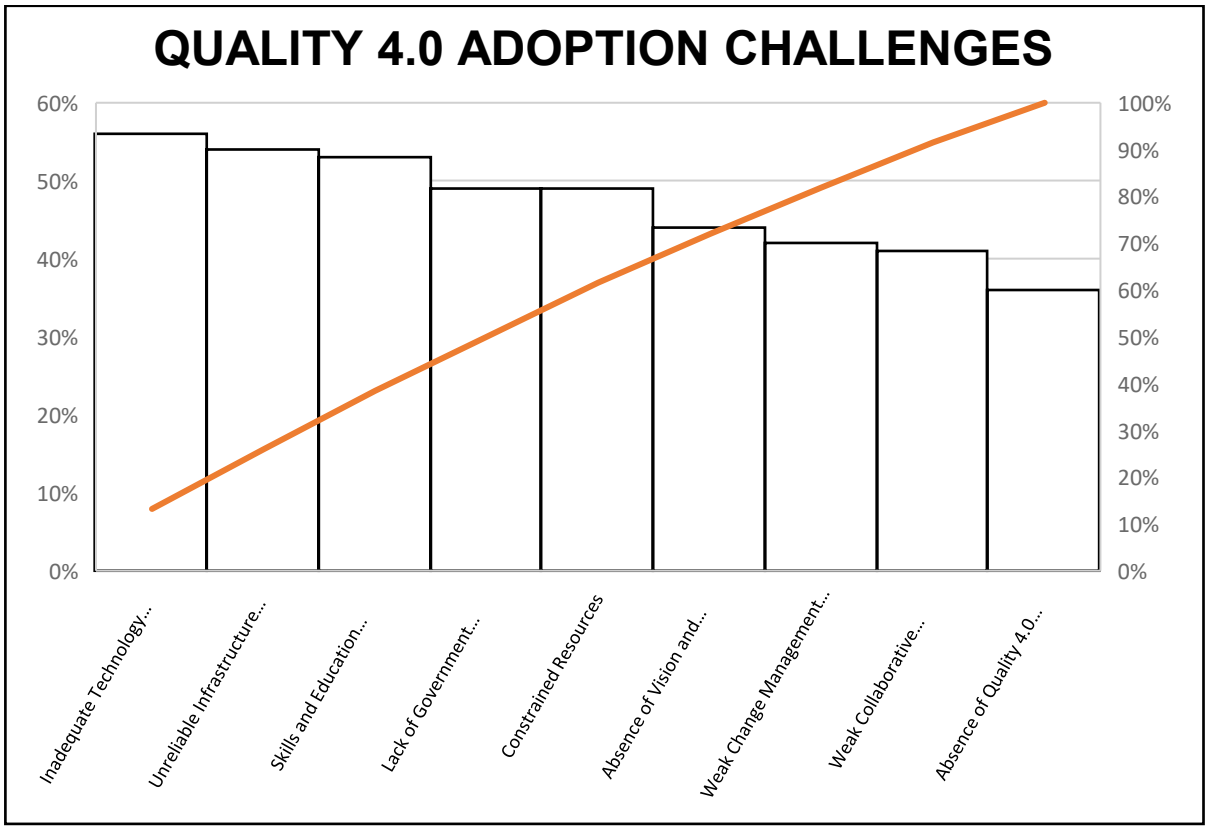

Figure 7 Adoption Challenges

These findings are consistent with literature. For instance, a study by Maisiri et al. [2] emphasised that mismatches in local education and skills required by the industry represent a critical barrier to technological adoption and must be addressed to enable effective transition. Similarly, Alexander [29] and Olaitan et al. [23] identify crime-induced loadshedding as a significant impediment to Industry 4.0 implementation in the country.

The current study reinforces these claims, revealing how energy insecurity and social instability affect organisational readiness. The role of crime and weak local government support was also evident in the study, aligning with findings by Maisiri et al. [2] and Alexander [29], who warned that poor infrastructure and the lack of protective policy frameworks render firms vulnerable to global competition and environmental instability. Compared to other nations, South Africa appears to lack the necessary policy structures and incentives that support sustainable technology adoption—an issue highlighted by Serumaga-Zake et al.[37], who found that countries with such support systems have experienced more successful digital transitions and economic growth. Ropes and Gray [38] also identified operational inefficiencies in South African ports (critical infrastructure) as a critical issue that causes supply chain delays, hindering the timely adoption of modern technologies.

Furthermore, resistance to technology adoption, as reported in this study, supports observations by Maharaj [5] and Maisiri et al. [2], who found that both employees and broader communities often lack understanding of technological initiatives and fear job losses due to automation. This contributes to widespread resistance. Ropes and Gray [38] further noted that misinformation and lack of awareness frequently fuel community-led civil unrest, which in turn disrupts the progress of technology-driven projects.

Additionally, to corroborate findings about resource constraints, a study by Mhlongo and Nyembwe [11] indicated that many firms in South Africa continue to experience financial

constraints—an issue compounded by the economic aftershocks of the COVID-19 pandemic and the ongoing recession.

These results strengthen the justification for this research that a transitioning framework tailored to South African specific challenges is required, as generic framework will not address certain challenges that are peculiar to developing countries. This will ensure a successful implementation and the full benefits of Quality 4.0 for South African manufacturing sectors.

4.2. Quality 4.0 transitioning framework

To address the challenges revealed by the survey results and ensure that manufacturing firms are ready to reap the rewards of Quality 4.0, the transitioning framework is developed and presented in Figure 8. The developed framework for Quality 4.0 adopts a top-down approach, integrating three key models: Technology-Task-Fit, Viability, and People-Process-Technology. These theorems form the basis for an 11-step process designed to guide organisations through the transition to Quality 4.0.

The People-Process-Technology theorem underscores the importance of having factors related to people, processes, and technology ready for transition. Technology-Task-Fit emphasises that the new technology must align with anticipated tasks, ensuring a seamless adoption process. Viability focuses on organisational capabilities, including technology, infrastructure, and financial indicators, to determine if the organisation is ready for the transition.

The research that informed the framework identified Industry 4.0 features such as big data and analytics, cyber-physical systems, additive manufacturing, and the Internet of Things as driving technologies for Quality 4.0. These technologies form the core of the framework's Technology associated with Quality 4.0.

The impact of Industry 4.0 on quality management was identified as rapid process adjustments, reduced downtime, advanced maintenance prognostication, and enhanced connectivity between shop floors, business units, and customers, and a growing economy. These factors form the core Tasks associated with Quality 4.0.

Essential ingredients for preparing to adopt Quality 4.0 were identified, including top management support, infrastructure availability, quality 4.0 leadership, and workforce development. Testing against South African firms revealed room for improvement, with challenges such as unreliable infrastructure, unskilled personnel, lack of government support, socio economic ills and a lack of awareness hindering progress. These challenges were integrated into the framework under building capabilities.

During this stage, South African organisations must address local, social, and cultural concerns that may impede successful Quality 4.0 implementation. Collaboration among industry experts, policymakers, the government, and institutions of higher learning is critical at this point. This ensures that everyone understands their part in making the transition a success. The government and policymakers can also help organisations adopt Quality 4.0 with the goal of boosting the economy by providing incentives or tax breaks as they transition to Quality 4.0, protecting them from global competition, and putting in place structures to combat crime and strengthen national ports to support supply chains.

Higher education institutions must re-engineer education solutions to align with industrial skills requirements. During this stage, organisations must identify the steps of their processes where Quality 4.0 will be most effective and allocate resources accordingly. Organisations must hire, train, and reskill their human resources to be Quality 4.0 ready. This includes involving and elevating community members to ensure they benefit from the transition and promote technological adoption. This not only creates job prospects but also ensures sustainable and socially responsible technology adoption.

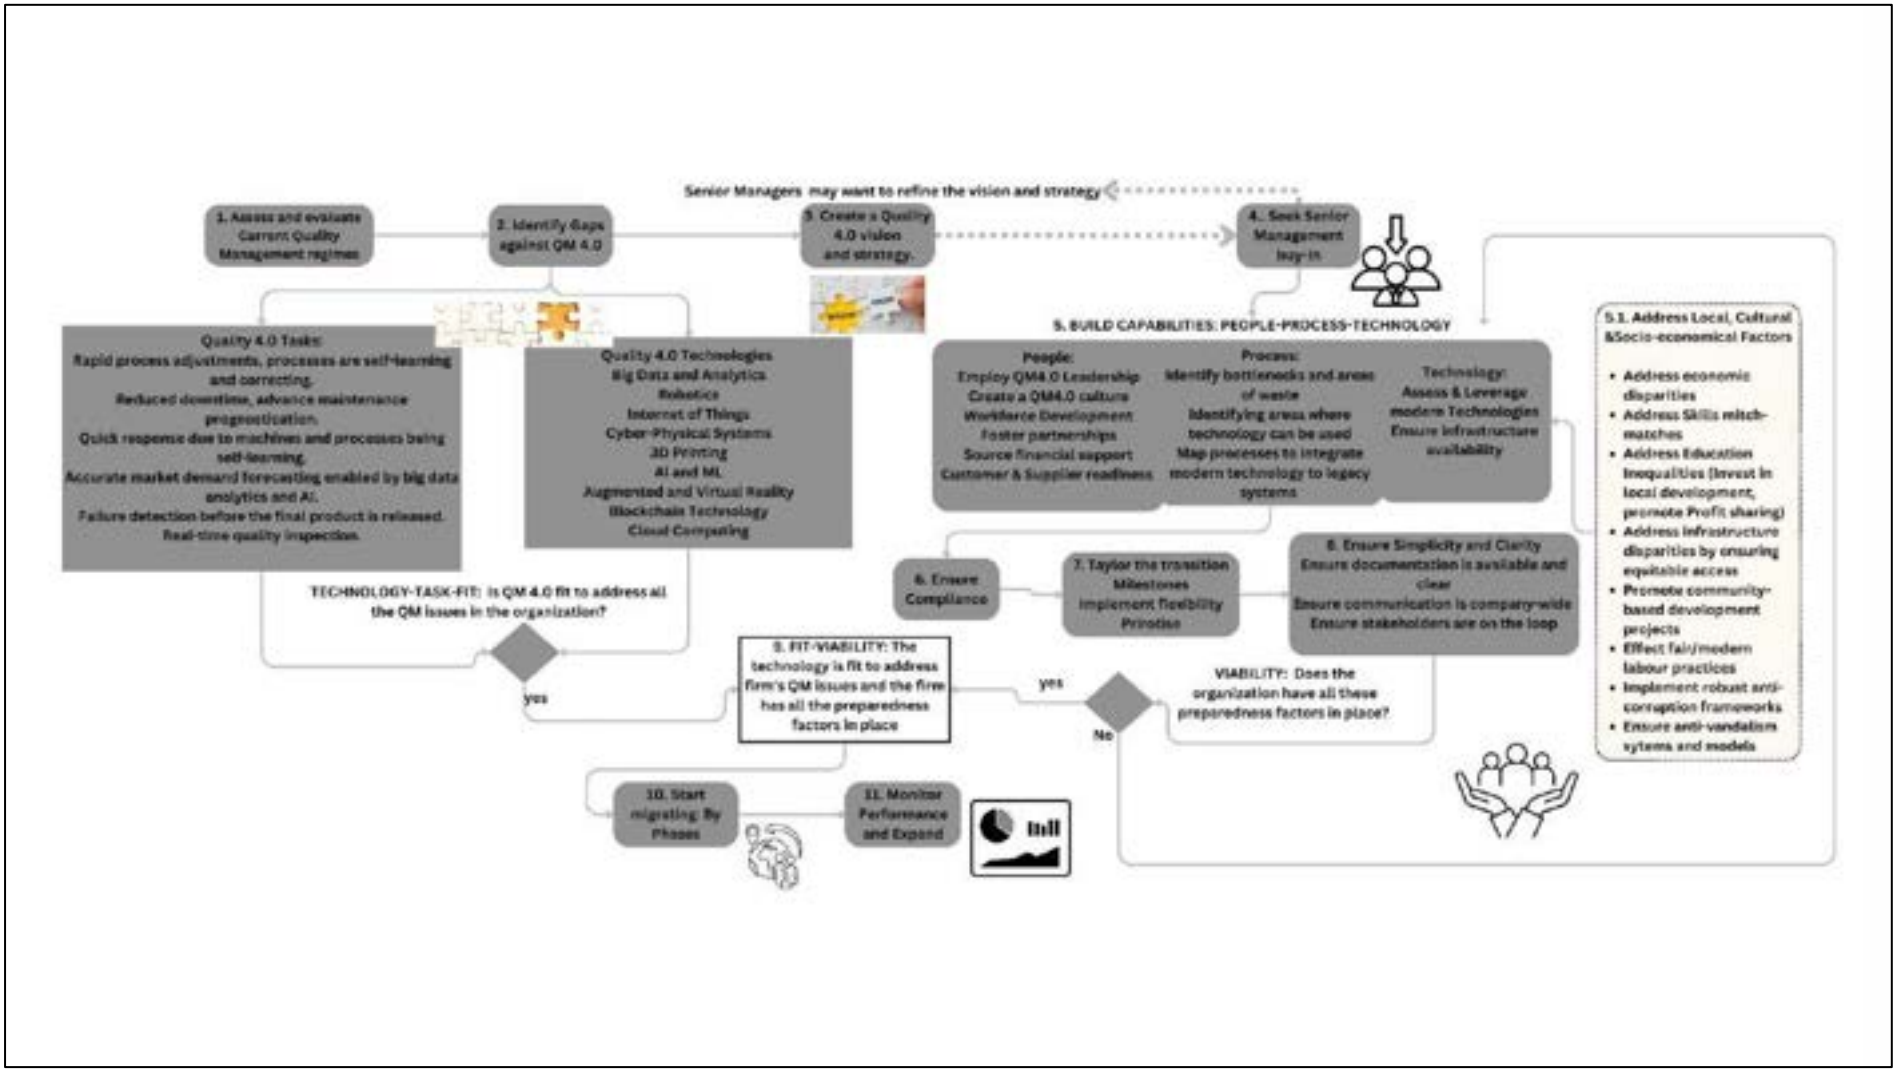

Figure 8 Final Transitioning Framework.

Table 1 provides a summary of the drawbacks of existing frameworks, as stated in section 2.2.1, and how the created framework addresses them. This represents that the framework has bridged the literature gap by building a context-specific Quality 4.0 framework that addresses transitional challenges unique to a developing country like South Africa.

Table 1 Summary of limitations addressed by developed framework

Existing Frameworks	General limitations of existing frameworks	Remedial actions by the developed framework
Sader et al. [19] and Fonseca et al. [39]	These frameworks offer building blocks and benefits of Quality 4.0 but do not offer implementation/migration steps.	The developed framework addressed the limitation by providing 11 transitioning steps that expressly support organisations as they transition to Quality 4.0, ensuring that they do not make rapid migrations.
Jacob [20]	This framework offers capability building blocks but not steps to transition or to test readiness before implementation/migration. Even in capability building, the framework does not cater for issues peculiar to developing economies with social ills that impede technology adoption.	The developed framework caters for socio-economic issues and economic constraints seen in developing countries such as South Africa. Step 5.1 guarantees that capability building is fair and inclusive, ensuring that Quality 4.0 initiatives do not benefit a select few while displacing the majority of the workforce.
Maganga et al. [16]	This model offers steps for building capabilities but does not offer steps to test readiness and assumes capability building in a perfect or developed economy. It does not have measures in place to tackle issues unique to the South African operating context.	In the developed framework, step 9 tests for fit and viability. This step ensures that organisations have assessed the need for Quality 4.0 in their processes and have built the capacity to transition successfully looking at the people, process and plant aspects.
Armani et al. [24], Olaitan et al. [23] and Zulqarnain et al. [25]	These frameworks focus solely on assessing maturity when implementing Quality 4.0, they do not prepare organisations that have not started transitioning nor do they offer steps to deal with organisations in developing countries with social ills that tend to disturb successful adoption of technologies.	This framework was developed with the understanding that many organisations in South Africa do not have the capacity to adopt current technology, as driven by the data in Figures 6 and 7. As a result, before fully transitioning, they must take extra precautions to ensure that they understand the required ingredients, how to prepare them, and how to assess their own preparedness.
Carvalho et al. [14]	This model offers steps for building capabilities but does not offer steps to test readiness and assumes capability building in a perfect economy. It does not have measures in place to tackle issues unique to the South African operating context.	Step 5.1 of the developed framework provides context-specific recommendations, ensuring that capacity building promotes inclusivity and equality. Furthermore, step 9 tests for fit and viability addressing the limitations of the frameworks cited.
Gonzalez Santacruz et al. [28]	This model offers steps for building capabilities but does not offer steps to test readiness and assumes capability building in a perfect economy where adopting advanced technologies is a norm. This model also does not have measures in place to tackle issues unique to the South African operating context.	Step 5.1 of the developed framework provides recommendations on context-specific elements to consider when building capacity in a developing country. Step 9 guarantees that organisations are prepared based on critical readiness aspects to ensure that the transition is smooth and required.

During the framework development process, continuous feedback was solicited from industry experts to ensure its relevance and applicability within the South African context. This

feedback, obtained through a consensus-based approach, informed iterative refinements to the framework until its finalisation. The panel of experts affirmed that the framework was both appropriate and reliable for the current South African manufacturing environment and expressed confidence that it would gain acceptance among industry bodies and deliver the intended benefits for which it was designed.

5 CONCLUSION

This study aimed to develop a framework facilitating the smooth transition of South African manufacturing firms to Quality 4.0 by addressing local technology adoption challenges. The research identified key prerequisites for readiness, including a Quality 4.0 culture, technology integration, skills and competencies, government support, resource allocation, and top management support from research previously conducted by quality and Industry 4.0 researchers. The study revealed that the South African manufacturing industry lacks preparedness for Quality 4.0, motivating the framework's creation. The study used a Pareto analysis to identify challenges hampering a smooth transition to Quality 4.0 and found the top 80% to be: unreliable infrastructure, inadequate technology integration, lack of government support, inadequate education and skills mismatches, constrained financial resources, absence of government support and absence of a clear Quality 4.0 vision and strategy.

This validated the motivation for a transitioning framework tailored for the South African setting. The proposed transitioning framework addresses the challenges and provides a strategic plan, fostering continuous improvement in the Fourth Industrial Revolution. This research's strength is in advocating the implementation of measures to address challenges faced by South Africa, a developing country with unique government structures and policies, socioeconomic challenges and major economic constraints, which existing Quality 4.0 models do not; so that this initiative does not worsen our current economic issues. Applying this framework in the manufacturing sector will enhance competitiveness against international rivals and aligns with national strategies ensuring that the sector's growth combats poverty, unemployment, and inequality.

6 RECOMMENDATIONS AND FUTURE RESEARCH

This study aimed to assess the preparedness for Quality 4.0 adoption in South Africa, focusing on awareness, financial resources, skills, managerial support, technology, infrastructure, and socio-economic aspects. This was done with the intention of using the findings to develop a transitional framework customized to these challenges and ensuring that South African organisations effectively transition to Quality 4.0 in a sustainable and socially responsible manner.

This study emphasised that, unlike in developed countries, adopting Quality 4.0 in South Africa is important not only for competitiveness, but also for inclusive economic growth, and that any framework for Quality 4.0 in SA must include measures to promote education and awareness, equality, inclusive employment, and poverty alleviation.

As the quest for sustainable technology adoption continues, this study contributes to the body of knowledge. Future work could include integrating the framework in South African organisations and increasing its application globally to promote economic growth and sector sustainability. Furthermore, future research could also focus on cost-benefit analyses for Quality 4.0 in developing countries.

Lastly, the study utilised the snowballing sampling approach, which, while recognized to have advantages such as reaching a larger audience because people are often open and secure in sharing their expertise and information with someone in their social networks, also has disadvantages due to potential biases. The authors then recommend that future research should look into larger sampling techniques to improve and validate the findings of this study.

APPENDIX

Table 2 List of Questions

Theme	Item ID	5-Point Likert Scale Questions
Technology	Item 1	To what extent does the organisation's current technological infrastructure support the implementation of Quality 4.0?
	Item 2	How well-integrated are the existing software and hardware systems to support Quality 4.0 practices?
	Item 3	How prepared is the organisation to invest in upgrading the technological infrastructure to align with Quality 4.0 requirements?
Vision and Strategy	Item 4	How articulated is the organisation's digital transformation strategy that includes quality management?
	Item 5	Are the goals and objectives of the organisation's digital transformation strategy related to quality management?
	Item 6	To what extent does the strategy align with industry best practices and emerging trends in Quality 4.0?
	Item 7	How well-communicated is the strategy to employees and stakeholders?

Resource Allocation	Item 8	To what extent has the organisation allocated financial resources for implementing Quality 4.0 initiatives?
	Item 9	How well does the organisation prioritize and allocate resources for employee training and development in the context of Quality 4.0?
	Item 10	How proactive is the organisation in seeking external funding or grants to support the implementation of Quality 4.0 initiatives?
	Item 11	How are employees of the key concepts and benefits of Quality 4.0?
Skills and Competencies	Item 12	To what extent does the organisation provide training programs or initiatives to develop digital skills and competencies required for Quality 4.0?
	Item 13	How open are employees to embracing new technologies and learning new skills related to Quality 4.0?
	Item 14	How fair and inclusive are the recruitment processes in your organisation?
Change Management and Leadership	Item 15	To what extent does the organisation have effective change management processes and strong leadership support for the transition to Quality 4.0?
	Item 16	To what extent are employees involved and engaged in the decision-making and implementation processes related to Quality 4.0?
	Item 17	How well does the organisation support employees in adapting to and embracing changes associated with Quality 4.0?
Data Governance and Security	Item 18	How well-prepared is the organisation to handle data governance and security concerns associated with Quality 4.0?
	Item 19	How well-defined are the data governance policies and protocols in place to ensure data integrity, privacy, and security within the organisation?
	Item 20	To what extent does the organisation have mechanisms to identify and address potential cybersecurity risks related to Quality 4.0?
	Item 21	How prepared is the organisation to comply with relevant data protection regulations and standards in the context of Quality 4.0?
Collaborative Networks	Item 22	To what extent does the organisation engage in collaborations and partnerships with industry associations, research institutions, or government bodies to support the implementation?
	Item 23	How actively does the organisation participate in industry associations or networks that promote knowledge sharing and best practices related to Quality 4.0?
	Item 24	How well does the industry collaborate with institutions of higher learning to help re-engineer the curriculum to meet industry requirements?
Government Support	Item 25	To what extent does the government ensure an enabling environment for organisations?
	Item 26	How would you describe the government's effort to protect organisations from global competition?
	Item 27	How well does the government support technological initiatives and their efforts to alleviate the triple threat in South Africa?
Connectivity Infrastructure (Reliable Electricity & Internet)	Item 28	Do you have reliable and high-speed internet connectivity?
	Item 29	Is the infrastructure capable of supporting the integration of digital technologies and data analytics for quality management?
	Item 30	Do you have reliable electricity supply?

PREFERRED TECHNIQUES FOR NEW PRODUCT DEVELOPMENT: A STUDY OF THE INFORMATION TECHNOLOGY INDUSTRY

S. Varghese[1*], E. van der Lingen[2] and M. Bagherpour[3]

[1,2,3]Department of Engineering and Technology Management
University of Pretoria, South Africa
[1]u22963822@tuks.co.za, [2]elma.vanderlingen@up.ac.za, [3]morteza.bagherpour@up.ac.za

ABSTRACT

Organisations must prioritise innovation to meet evolving customer needs and remain competitive. Successful new product development (NPD) relies on effective NPD techniques to drive innovation. This study explores various NPD techniques and identifies the most favoured ones in the NPD process within an information technology department. Using a qualitative approach, the research collects and analyses non-numerical data through questionnaires. Findings show that techniques like Focus Groups, Concept Testing, and Limited Roll-Out (LRO) are widely used across multiple stages, while Morphological Analysis and Synectics are the least used. The most favoured techniques include Concept Testing, Brainstorming, LRO, and Focus Groups, while Metaphorical Analysis and Synectics are the least favoured. The study highlights a subtle link between usage and preference, which could overlook the value or purpose of NPD techniques. The study offers valuable insights for organisations to refine their NPD strategies.

Keywords: New product development; NPD; Information technology

1 INTRODUCTION & BACKGROUND

The evolving expectations of new-age customers within South Africa's financial services sector, driven by global exposure, social media, and changing mindsets, have led to a growing emphasis on Corporate Entrepreneurship (CE) to drive innovation, business growth, and the development of new products and services. CE is seen as a remedy for organisational stagnation and lack of innovation, fostering transformation and strategic renewal within large companies [1]. New Product Development (NPD) plays a central role in this process, improving customer value and enhancing competitive advantage.

As organisations increasingly recognise the limitations of traditional NPD approaches, they rely on effective NPD techniques to maintain their competitive edge [2]. Consequently, successful NPD has become a crucial competency for businesses aiming to remain relevant in today's marketplace. Implementing effective NPD techniques is essential for improving NPD outcomes, facilitating better decision-making, fostering collaboration, and ensuring a clearer understanding of requirements at various stages of the NPD process, all of which contribute to higher success rates [3].

This study aims to investigate the use of NPD techniques throughout each step of the NPD process and identify the most favoured NPD techniques. The insights gained from this research will provide a vital foundation for businesses seeking to benchmark the use of NPD techniques within their IT departments and develop strategies to enhance outcomes from the NPD process.

2 LITERATURE REVIEW

NPD is a pivotal process in modern business strategy, critical for organisations striving to maintain competitiveness in dynamic markets [4]. The NPD process, along with the various techniques employed, serves as the foundation for this study. Consequently, the NPD process and the range of NPD techniques will be unpacked in detail.

2.1 NPD Process

In 2024, the NPD process is still evolving in response to technological breakthroughs, changes in customer behaviour, and adjustments in market dynamics [3]. The NPD process comprises several stages and gates used to create, improve, and introduce new products into the market. A stage is a phase in which the product is matured, while a gate is a checkpoint at which the product's readiness is assessed [5]. The decision taken at the gate either sends the product back to the existing stage for further improvement or provides the go-ahead to proceed to the next stage of the process. The steps in the NPD process below (Figure 1) were presented by [6] and used in a similar study conducted by [7].

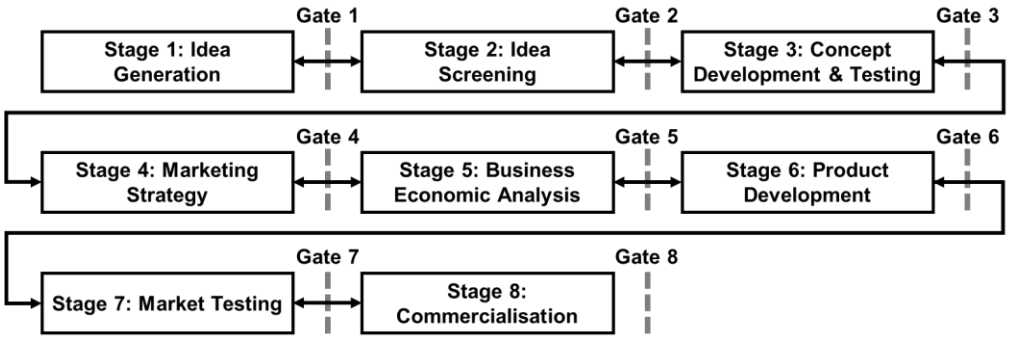

Figure 1: NPD process by [6], [8]

The NPD process outlined above comprises several stages and gates, each crucial for the successful development of new products. A high-level overview of the stages is discussed below:

1. Idea Generation: The stage involves the creation of new ideas for products or services to meet the organisation's strategic objectives [9].
2. Idea Screening: The stage involves assessing the ideas generated and filtering them based on key priorities to identify the ones with the highest levels of product development success [10].
3. Concept Development and Testing: The stage involves unpacking the selected idea by identifying customer needs and translating this into technical terms, which feed into the concept development [11].
4. Marketing Strategy: This stage involves identifying the target market, product positioning, and creating clear communication for going to market [12].
5. Business Economic Analysis: This stage involves the analysis of the financial feasibility of the new product or service [13].
6. Product Development: This stage involves the creation of the product that ensures the customer requirements are met, perceived technical superiority is achieved, development is within budget, and launch timelines are on track [14].
7. Market Testing: This stage involves analysing market information and testing a new product or service in a real-world setting [15].
8. Commercialisation: This stage involves launching the new product to market as per a commercialisation strategy to generate sales [16].

2.2 NPD Techniques

NPD techniques are employed within each stage to achieve efficient and effective outcomes across the NPD process. The NPD techniques discussed in this study were selected for a similar survey conducted by [8].

A high-level overview of the eleven NPD techniques is discussed below:

- Brainstorming: The technique fosters collective creativity by encouraging team members to share diverse ideas, regardless of their expertise [17]. This inclusive approach enhances the likelihood of generating innovative solutions, leading to products and services that better meet evolving customer needs.
- Concept Testing: The technique assesses the viability of a new idea by presenting it to potential customers for feedback [5]. This process helps refine the concept and significantly increases the likelihood of a successful product launch while minimising the risk of failure.
- Conjoint Analysis: The technique is widely used in marketing and social sciences, and helps researchers understand consumer preferences by presenting them with product profiles consisting of different attribute combinations. By analysing respondents' rankings or ratings of these profiles, researchers can estimate the relative importance of each attribute [18], making it an essential tool for effective market research.
- Delphi Method: The technique collects and analyses expert opinions through anonymous questionnaires or surveys. This iterative process continues until a consensus is reached among participants [19].
- Focus Group: This technique involves gathering a small, targeted group of individuals to discuss and provide feedback on specific topics, offering valuable qualitative data [20].

Its key advantage lies in encouraging active engagement and participation among group members.

- In-home Use Test (IHUT): The technique assesses consumer products in their natural home environment, enhancing the validity of product evaluations by observing real-world usage [21]. This technique is particularly effective for products like household appliances and personal care items, as it offers insights into product performance and consumer satisfaction in a realistic setting.
- Limited Roll Out (LRO): The technique involves introducing a new product or service to a select group of customers or markets before a full-scale launch, helping to reduce risks and improve chances of success [7]. By gathering feedback from early adopters in a controlled environment, businesses can identify opportunities for refinement before expanding to a broader audience.
- Morphological Analysis: The technique involves breaking a problem into its parts and analysing different combinations to generate innovative solutions [4]. This technique enables the exploration of diverse solution options by combining problem dimensions in ways that might not have been previously considered [22].
- Product Life Cycle (PLC): The technique outlines a product's various stages from its market introduction to its decline and eventual discontinuation. This concept illustrates the S-shaped curve representing sales over time, offering valuable insights into product evolution and informing decisions regarding modifying existing products or developing new ones [7].
- Quality Function Deployment (QFD): The technique is a structured methodology for designing and developing new products by translating customer requirements into technical specifications [23]. This process involves creating a matrix that connects customer needs to engineering characteristics, facilitating a customer-centric approach throughout product development.
- Synectics: The technique leverages the combination of seemingly unrelated elements through analogy, metaphor, and fantasy to inspire innovative ideas [24]. By applying this approach in the NPD process, organisations can enhance problem-solving capabilities, improve decision-making, and foster greater creativity, ultimately developing innovative and feasible products and solutions.

The review of NPD techniques highlights key methods that enhance creativity, align products with customer needs, and support informed decision-making. These techniques are fundamental to achieving the desired outcomes from each stage of the NPD process and reducing the risk of product failure. This literature provides a solid foundation of the techniques included in the study, ensuring a comprehensive understanding of their application. Additionally, it offers valuable context for conceptualising the use of the most favoured NPD techniques.

3 CONCEPTUAL MODEL

The conceptual model proposed for this study is designed to realise the use of NPD techniques throughout the NPD process and identify the most favoured NPD techniques within the department.

NPD process encompasses activities aimed at identifying opportunities, generating ideas, assessing market feasibility, designing, testing, and launching new products or services. It is essential to acknowledge that different techniques are employed in each step of the NPD process, starting from idea generation to commercialisation.

[25] highlighted that the effective utilisation of NPD techniques contributes significantly towards the efficiency and effectiveness of the NPD process, resulting in improved innovation

performance and competitive advantage. The eleven selected NPD techniques serve a distinct purpose at the various stages of the NPD process.

This study identifies the NPD techniques employed at each stage of the NPD process. Additionally, it aims to determine which techniques participants most favour. A questionnaire, distributed as an Excel document, is sent to all participants to gather these insights. The overarching framework for this study is depicted in Figure 2 below.

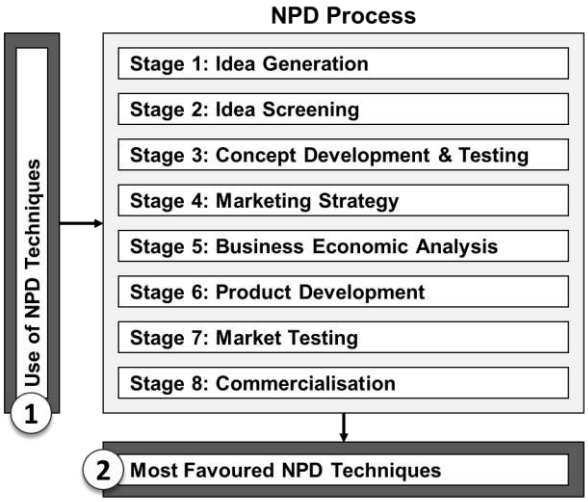

Figure 2: High-level framework (authors' compilation)

The high-level framework in Figure 3.1 illustrates the relationship between the NPD process, the use of various NPD techniques, and the most favoured techniques.

This study uses an efficient NPD model aligned with established literature and field domain investigation, but the process could be non-linear in practice. Modern NPD frameworks often include feedback loops between stages, allowing teams to revise earlier steps when it is necessary, for example market tests, cost analyses, or technical evaluations. Thus, Agile methods nowadays are commonly used in IT, addressing short iterative cycles, rapid prototyping, and continuous customer feedback. Many organizations now use hybrid frameworks, combining waterfall milestone control, and the Agile Manifesto. Incorporating these elements (loops, feedback, agile) into the traditional model improves adaptability and flexibility.

4 RESEARCH METHODOLOGY

This research is based on an empirical study that follows a qualitative approach. The process leverages the use of research instruments such as questionnaires, resulting in the collection of non-numerical data. The data is interpreted and reasoned to gain a clear understanding of the use of NPD techniques as well as the most favoured NPD techniques. Of all the methods available to gather data, questionnaires will assist the most in reaching more participants across the organisation.

4.1 Sample Setting

A sample is a subset of specific individuals or groups from a large population [26]. The sample size has been chosen based on the scope of the study and the depth required for meaningful analysis.

In today's rapidly evolving technological landscape, organisations must innovate using artificial intelligence, blockchain, and the Internet of Things to remain competitive [27]. Hence, an IT

department catalyses innovation and improvement, making it critical to improve the outcomes of the NPD process continuously.

Therefore, participants selected for this research are part of an IT department within a large insurance company based in South Africa, leading innovation, and new product (software) development. This includes lower management, middle management, senior management, and executives.

4.2 Data Collection & Analysis

A questionnaire was prepared to conduct the research. Questionnaires are structured to facilitate the collection of information about people's knowledge, beliefs, attitudes, and behaviour [28]. The questionnaire was sent to the participants via email, and they were followed up with calls as required. A total of 41 participants were contacted, of whom 27 responded, resulting in a response rate of 66%. The engagement after analysing responses from the twenty participants revealed new themes infrequently and progressively [29].

The questionnaire responses are compiled into an Excel document, providing a comprehensive view of all the collected data. Rigorous analysis is applied to both data sets, leading to the discovery of meaningful insights and conclusions that enhance the research. Where applicable, data is visualised through graphs presented in the paper.

5 RESULTS AND DISCUSSION

The analysis centres on two key areas: the use of NPD techniques and the most favoured NPD techniques. These focus areas are essential for comprehending the study's results and are visually depicted in Figure 3 below.

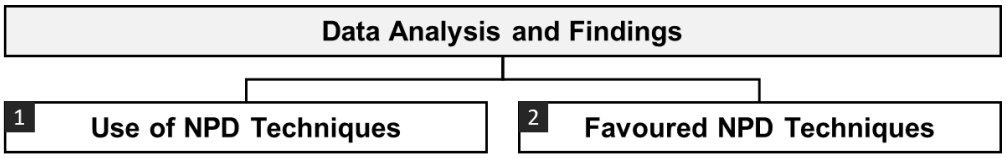

Figure 3: Focus areas (authors' compilation)

The following sections delves into these areas in detail, providing a comprehensive view of the insights gathered and the outcomes from the analysis.

5.1 Use of NPD Techniques

The research indicates a clear hierarchy in the utilisation of NPD techniques. The data reveals that the four most frequently employed NPD techniques account for 53% of the total usage. These predominant techniques include Focus Group, Concept Testing, LRO, and PLC. Figure 4 below depicts the use of NPD techniques.

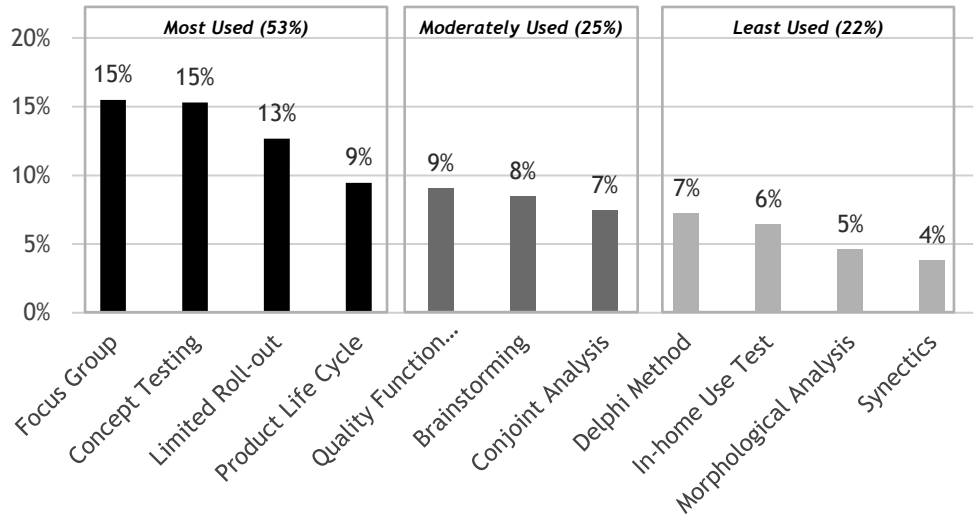

Figure 4: Total Use of NPD Techniques

In contrast, the next tier of techniques, categorised as moderately used, comprises 25% of the total usage. This category includes QFD, Brainstorming, and Conjoint Analysis. While not as widely used as the top four, these techniques still hold significant value in the NPD process, particularly in refining product features and aligning them with customer needs.

The least used techniques, making up 22% of the total, are the Delphi Method, IHUT, Morphological Analysis, and Synectics. This distribution of NPD technique usage highlights the varying levels of preference and perceived effectiveness among different techniques. Table 1 illustrates the use of various techniques across the different stages of the NPD process.

Table 1: NPD techniques used across the NPD process

NPD Technique	Idea Generation	Idea Screening	Concept Dev. and Testing	Marketing Strategy	Business Econ. Analysis	Product Development	Market Testing	Commerc-ialisation
Brainstorming	38%	4%	3%	11%	5%	2%	0%	2%
Concept Testing	12%	31%	25%	12%	9%	8%	14%	8%
Conjoint Analysis	3%	10%	4%	23%	13%	0%	3%	6%
Delphi Method	4%	15%	4%	11%	14%	2%	5%	4%
Focus Group	19%	25%	12%	19%	9%	14%	19%	4%
IHUT	0%	3%	12%	2%	4%	11%	14%	6%
LRO	1%	3%	18%	7%	14%	17%	29%	14%
Morphological Analysis	10%	4%	1%	0%	7%	5%	2%	8%
PLC	1%	3%	7%	5%	11%	17%	8%	28%
QFD	0%	1%	10%	2%	13%	26%	6%	16%
Synectics	12%	0%	3%	9%	2%	2%	0%	4%

The data presented in the table above has been utilised to create a graph (Figure 5), facilitating a straightforward analysis of the use of NPD techniques throughout the NPD process.

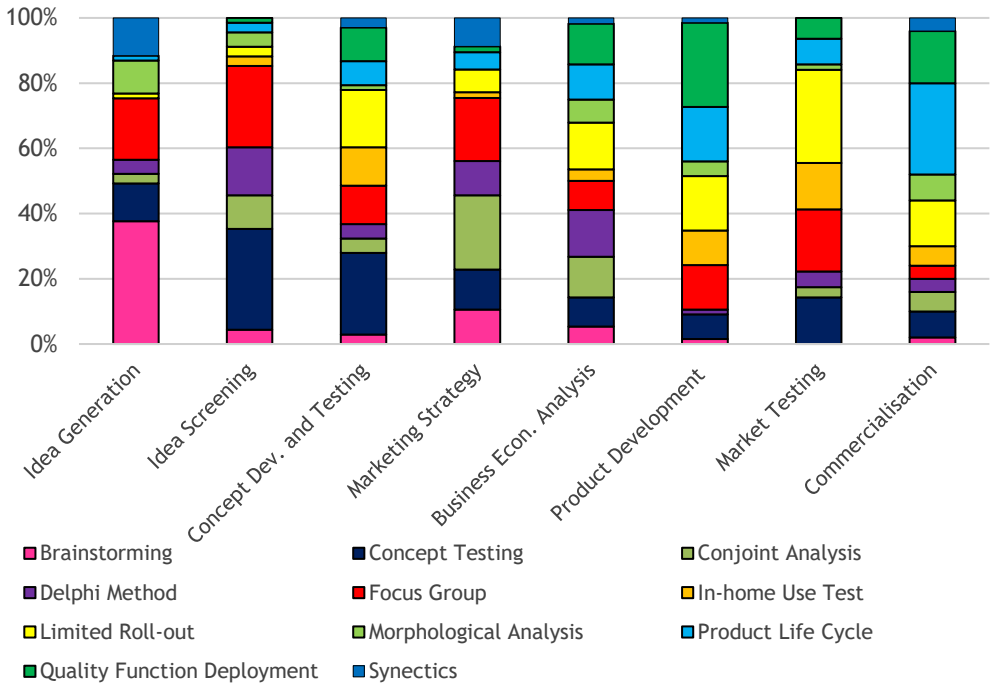

Figure 5: Visual representation of NPD techniques used in the NPD process

Each technique's usage is expressed as a percentage in Table 1 and Figure 5, indicating its relative importance or frequency at each stage. An in-depth analysis based on the data gathered is provided below.

- Brainstorming: The technique is mainly used in the Idea Generation stage, making up 38% of its application, which shows its importance for initial idea creation. However, its usage drops to only 8% later, indicating it is less relevant as the NPD process progresses.
- Concept Testing: The technique is mainly used in the Idea Screening (31%) and Concept Development and Testing (25%) stages, highlighting its role in idea evaluation. It also has moderate usage in the Marketing Strategy (12%) and Market Testing (14%), making it the second most used technique in the NPD process at 15%.
- Conjoint Analysis: The technique is mainly used in the Marketing Strategy stage (23%) to understand consumer preferences and optimise product features. It also has moderate application in Business Economic Analysis (13%) and a total usage of 7% across other stages, indicating its effectiveness in specific phases of the NPD process.
- Delphi Method: The technique is moderately used in Idea Screening (15%) and Business Economic Analysis (14%), demonstrating its value in gathering expert opinions and achieving consensus. However, its overall usage of 7% suggests it may not be as widely applicable or recognised as other techniques.
- Focus Group: The technique is heavily used in Idea Generation (19%), Idea Screening (25%), Marketing Strategy (19%), and Market Testing (19%), with key roles in Concept Development (12%) and Product Development (14%). Overall, at 15% total usage, this is the department's most widely used technique.

- IHUT: The technique is mainly used in Concept Development and Testing (12%) and Market Testing (14%) for real-world customer feedback. Its moderate use in Product Development (11%) underscores its value, though with a total usage of 6%, it is less common across other NPD stages.
- LRO: The technique is mainly used in Market Testing (29%) and Concept Development (18%) for small-scale performance checks. It also plays a role in Product Development (17%), Business Economic Analysis (14%), and Commercialisation (14%), ranking as the third most used technique with 13% total usage.
- Morphological Analysis: The technique is moderately used in the Idea Generation stage (10%) to explore complex problems. Its minimal use in later stages results in a total of 5%, indicating its primary role is in the early phase of the NPD process.
- PLC: The technique is primarily used in the commercialisation stage (28%) and is also applied in business economic analysis (11%) and product development (17%). With a total usage of 9%, it plays a key role in managing a product's journey to market.
- QFD: The technique is primarily used in Product Development (26%) and Commercialisation (16%) to convert customer needs into product specs. With 9% total usage, it ensures quality and customer satisfaction throughout the NPD process.
- Synectics: The technique has limited overall usage, with applications in Idea Generation (12%) and Marketing Strategy (9%) that support creative problem-solving. Its total usage of 4% indicates that, while it has niche applications, it is not widely adopted across all NPD stages.

The distribution of NPD technique usage highlights varying preferences and effectiveness among different methods. Techniques like Focus Group and Concept Testing are versatile and applicable across multiple stages of the NPD process. At the same time, methods like Brainstorming and IHUT are more specialised, with concentrated usage in specific stages.

5.2 Favoured NPD Techniques

The next component discussed is the favoured NPD techniques. Participants identified their most favoured techniques based on their proven effectiveness in navigating the complexities of the NPD process. These techniques are consistently relied upon for their success in addressing challenges and driving results. Figure 6 illustrates the most favoured NPD techniques by percentage.

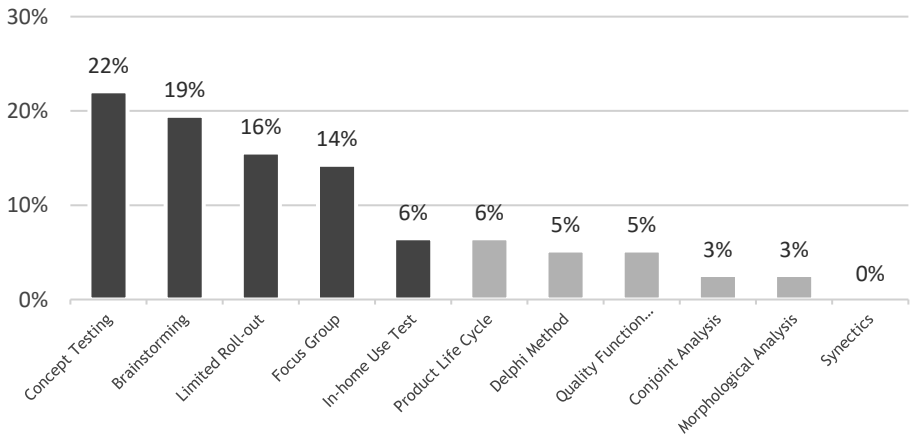

Figure 6: Favoured NPD techniques

The top five most favoured NPD techniques are Concept Testing (22%), Brainstorming (19%), LRO (16%), Focus Group (14%) and IHUT (6%) that collectively received 78% of the total votes. This significant support by the participants highlights the reliance and bias towards the use of these techniques.

The remaining six NPD techniques, which are PLC (6%), Delphi Method (5%), QFD (5%), Conjoint Analysis (3%), and Morphological Analysis (3%), collectively received 29% of the total votes. Synectics received no (0%) votes. Although these techniques are less favoured than the top five, they still play a significant role in the NPD process.

5.2.1 Most Favoured Technique: Concept Testing

Concept Testing is regarded as a crucial technique in the product development process, allowing valuable feedback from potential customers to assess the viability and success of new product ideas (Participant G, 2024). It ensures that customer requirements are translated into technical specifications, aligning development with market needs (Participant M, 2024). Participants emphasised their role in product augmentation and understanding consumer behaviour before costly development phases (Participant I, 2024; Participant A, 2024).

This technique helps inform decisions on whether to proceed, modify, or discard a concept, ultimately reducing the risk of product failure and ensuring alignment with consumer preferences (Participant A, 2024; Participant C, 2024). The iterative feedback process enhances the likelihood of successful product launches that meet customer demands (Participant W, 2024).

In conclusion, Concept Testing is ranked as the most favoured technique because it plays a pivotal role in bridging customer expectations with technical development, providing a structured approach to refining product ideas and mitigating risks before significant investments are made.

5.2.2 Second Most Favoured Technique: Brainstorming

Participant G (2024) highlights Brainstorming as an effective technique for generating new ideas and solutions, fostering creative thinking and collaboration that leads to diverse perspectives. Participant J (2024) notes its suitability for closed group research, aligning with company strategy while focusing on market trends without external input.

Brainstorming thrives in diverse groups, where different expertise enhances idea generation (Participant B, 2024). It promotes a free flow of ideas, allowing team members to build on each other's thoughts and encouraging inclusivity (Participant S, 2024; Participant I, 2024). Participants emphasise its value in constructive discussions and ensuring that all ideas are considered in the early stages of ideation (Participant A, 2024; Participant C, 2024).

In conclusion, Brainstorming is ranked as the second most favoured technique due to its ability to harness team collaboration and diverse viewpoints, making it a valuable tool for driving creativity and innovation.

5.2.3 Third Most Favoured Technique: Limited Roll-out

LRO has become a crucial technique in product development, enabling rapid market entry while adhering to design thinking principles through continuous iteration and feedback (Participant B, 2024). It is invaluable for testing products in real-world settings, allowing teams to gather tangible input from a small audience and refine products before broader launches (Participant Q, 2024; Participant P, 2024).

Participant D (2024) highlights the significance of direct user insights in assessing product functionality and usability, while Participants R (2024) and W (2024) note the scalability of ideas and the importance of diverse customer feedback in managing risks effectively.

In conclusion, LRO is ranked as the third most favoured technique because it mitigates risk and enhances product agility through iterative refinements based on user feedback, ultimately improving overall product quality (Participant M, 2024).

5.2.4 Fourth Most Favoured Technique: Focus Group

Focus Group method is effective for faster idea generation and shorter product testing cycles, enabling quicker market readiness through immediate feedback (Participant Z, 2024). Participants L (2024) and T (2024) highlight the value of feedback loops, noting that Focus Groups facilitate rapid ideation and iterative development, avoiding the overengineering that can occur in larger groups.

Participants' diverse perspectives enhance the development process, leading to more innovative products (Participant U, 2024). Focus Groups provide detailed insights into customer requirements, allowing for in-depth exploration of preferences and immediate feedback (Participant Q, 2024). Participant X (2024) underscores the importance of direct customer experience testing and competitor analysis in aligning product development with market demands (Participant F, 2024).

In conclusion, Focus Group is ranked as the fourth most favoured technique because it can leverage detailed feedback and diverse insights to refine products and ensure alignment with market needs.

5.2.5 Fifth Most Favoured Technique: In-home Use Test

IHUT is a vital product development strategy assessing market responses and refining products before full-scale launches. It allows product performance evaluation in real-world settings, helping to identify technical challenges early in the process (Participant K, 2024).

Participants appreciate its controlled deployment, enabling detailed feedback and adjustments based on user experiences (Participant T, 2024). Additionally, testing with internal staff before broader releases provides valuable insights and a preliminary filter for potential issues (Participant AA, 2024).

In conclusion, IHUT is ranked as the fifth most favoured technique for its effectiveness in minimising risks and enhancing market readiness.

5.3 Findings and contributions

After running an in-depth analysis of the results, the following findings and contributions are given:

Although NPD models and methodologies have been frequently discussed in the literature, such as NPD in production and operations management, NPD models applicable to IT-based firms have been rarely considered.

Considering loops and feedback within the conventional NPD framework, the Agile Manifesto or hybrid framework are suggested to be incorporated.

Based on field investigations and literature review, to analyse NPD in IT-based organizations, the focus area has been broken down into two categories: the use of NPD techniques and the most favoured NPD techniques, including both types of areas individually.

Focusing on “employed NPD techniques”, the data reveals that Focus Group, Concept Testing, LRO, and PLC employed NPD techniques account for 53% of the total usage.

According to data analysis, the top three “most favoured NPD techniques” are Concept Testing (22%), Brainstorming (19%), and LRO (16%), which account for 57% of total usage.

Among all techniques, concept testing and Brainstorming are the most efficient methodologies to develop new products.

6 CONCLUSION & RECOMMENDATIONS

The study offers valuable insights for organisations seeking to enhance the use of NPD techniques. This use of NPD techniques represents an important method to improve NPD outcomes, including management's decision-making quality, higher levels of collaboration, and a clear understanding of requirements at different stages of the NPD process to improve the overall success rate [3]. Other organisations can use the insights derived from the study to improve the effectiveness of their NPD process.

A structured approach was used to collect qualitative data from participants through questionnaires, focusing on their perspectives regarding eleven NPD techniques. Out of 41 participants contacted, 27 responded with a 66% response rate. As responses from 20 participants were analysed, new themes emerged less frequently [29]. The data was then organised to generate insights on the use of NPD techniques and the most favoured NPD techniques.

The findings reveal a distribution of NPD techniques used across the NPD process, highlighting varying levels of preference and perceived effectiveness. Techniques like Focus Group and Concept Testing are highly valued for their versatility, while more techniques, such as Brainstorming and IHUT, are concentrated in specific process stages.

The four most used NPD techniques account for 53% of the total usage. These techniques include Focus Group, Concept Testing, LRO, and PLC. The moderately used techniques account for 25% of the total usage, comprising QFD, Brainstorming, and Conjoint Analysis. The least used techniques account for 22% of the total usage, comprising the Delphi Method, IHUT, Morphological Analysis, and Synectics. Despite being less used, these techniques still play an essential role in refining product features and aligning them with customer needs within the NPD process.

The top five most favoured NPD techniques are Concept Testing, Brainstorming, LRO, Focus Group and IHUT, which collectively received 78% of the total votes. The remaining six techniques are PLC, Delphi Method, QFD, Conjoint Analysis, and Morphological Analysis, collectively receiving 29% of the total votes. Synectics received no (0%) votes. Although these techniques are less favoured than the top five, they still play a significant role in the NPD process.

There is a subtle correlation between the NPD techniques and those favoured. Concept Testing and Focus Group are among the most used and favoured techniques, while Morphological Analysis and Synectics are among the least used and favoured techniques. This implies that individual preferences of the technique derive the use of these NPD techniques. This could overlook the value or purpose of NPD techniques, resulting in the misapplication of the techniques. By extension, it negatively impacts the overall success of the NPD process and innovation.

The study's limitations include the small sample size, with only 27 participants involved. Additionally, the study was conducted within a single department of one organisation, limiting its scope. This restricted context makes it insufficient to generalise the findings or apply them universally to other industries, organisations, or teams.

A key recommendation to comprehensively understand these factors is to conduct similar research with a broader sample. This would validate the results, conclude the findings on the correlation between the use of NPD techniques and most favoured techniques, and provide a holistic view on the general use of NPD techniques within the NPD process. The results from

such research will provide organisations with the insights required to ultimately enhance the application and effectiveness of NPD practices in various organisational settings.

ABSTRACT

The food industry is the cornerstone of global economic activity, and it faces significant challenges. Unlike many other manufacturing sectors, food producers must contend with the inherent perishability of raw materials and finished goods, which compresses production timelines and elevates the financial risk of delays or errors. This is compounded by some of the most stringent quality and safety regulations of any industry, where non-compliance can lead to costly recalls, reputational damage, and significant public health risks. This paper explores the integration of Lean Six Sigma (LSS) methodologies and Industry 4.0 technologies within the food industry. The research focuses on understanding how these tools can collectively enhance operational efficiency and product quality in food manufacturing facilities. Examining the potential benefits and challenges associated with implementing these strategies, the study emphasizes the importance of training staff on Six Sigma and Industry 4.0 tools. It also highlights the need for standardized data formats and processes to facilitate data-driven decision-making. The research findings suggest that adopting these technologies can lead to improved product quality, reduced waste, cost savings, a reduction in defect rate by 25% and enhanced operational efficiency. The study utilizes a mixed-methods approach, combining qualitative interviews with managerial staff and quantitative surveys among production employees, to explore the practical application of LSS.

Keywords: Lean Six Sigma, Industry 4.0, Food Manufacturing, Operational Excellence

1 INTRODUCTION

The food industry is critical to global economic stability and human sustenance; however, it contends with unique challenges, such as stringent quality standards, perishable products, and high operational costs. Continuous improvement methodologies Lean Six Sigma (LSS) have been instrumental in enhancing efficiency and quality in various industries [1][2]. The advent of Industry 4.0 technologies offers a paradigm shift, enabling manufacturers to achieve unprecedented levels of automation, data-driven decision-making, and process optimization [3] These challenges are compounded by the growing consumer demand for transparency, traceability, and sustainability in food production [4] . The integration of LSS methodologies with Industry 4.0 tools provides an opportunity to address these issues. For instance, IoT sensors and big data analytics enable real-time monitoring and predictive maintenance, while blockchain enhances supply chain traceability [5][6].

This study investigates the integration of LSS with Industry 4.0 tools in the food manufacturing sector to enhance operational excellence. Specifically, it examines how this synergy can address persistent inefficiencies, improve product quality, and enhance overall operational performance. The paper focuses on a South African meat processing company, leveraging both qualitative and quantitative data to provide practical insights and recommendations [7][8]. The food industry is critical to global economic stability and human sustenance, however it grapples with unique challenges, such as stringent quality standards, perishable products, and high operational costs. Continuous improvement methodologies like Lean Six Sigma (LSS) have been instrumental in enhancing efficiency and quality in various industries [1]. However, the advent of Industry 4.0 technologies offers a paradigm shift, enabling manufacturers to achieve unprecedented levels of automation, data-driven decision-making, and process optimisation [3]

1.1 Aim of the study

This study aims to utilize Six Sigma methodologies to enhance quality and efficiency in a South African meat processing organization through Industry 4.0 tools.

1.2 Objectives of the study

- To analyse and comprehend the Six Sigma methodology utilization in the context of the food sector and improvement thereof on efficiency and quality.
- To explore the potential benefits and impact of executing Six Sigma within the food sector.
- To examine how Industry 4.0 technologies can enhance and complement the utilisation of Six Sigma in terms of eradicating waste in the food sector.

2 LITERATURE REVIEW

2.1 Lean Six Sigma

Lean Six Sigma (LSS) combines the waste-reduction principles of Lean Manufacturing with the defect-reduction strategies of Six Sigma. The DMAIC framework is central to LSS, guiding organizations through a structured process of problem identification, analysis, and resolution [1][2]. LSS enhances efficiency, reduces costs, and improves customer satisfaction [8]. The application of LSS in industries such as healthcare and automotive demonstrates its adaptability and effectiveness.

2.2 Industry 4.0

Industry 4.0, also known as the Fourth Industrial Revolution, encompasses technologies like IoT, AI, big data, robotics, and automation. These tools enable real-time data collection and analysis, predictive maintenance, and enhanced process control [3][6]. Industry 4.0 has revolutionized traditional manufacturing by fostering greater flexibility, scalability, and

precision [9]. Studies on Industry 4.0 adoption in sectors such as logistics and aerospace highlight its potential for operational excellence [4][13].

2.3 Synergy Between LSS and Industry 4.0

The integration of LSS and Industry 4.0 creates a synergistic approach to operational improvement. IoT sensors and big data analytics enhance the DMAIC process by providing real-time insights and predictive capabilities, while automation reduces human error and variability [1][6]. For example, the use of predictive analytics in quality control has significantly reduced defects in automotive manufacturing [5]. Lean Six Sigma (LSS) is a synergistic methodology that combines Lean's focus on waste elimination and value stream optimization with Six Sigma's data-driven approach to reducing process variation and defects. At its core is the Define-Measure-Analyze-Improve-Control (DMAIC) framework, a structured problem-solving cycle that guides organizations toward sustainable process improvements. Within the food industry, LSS has proven effective in addressing key operational challenges. For example, studies in dairy processing have demonstrated its utility in optimizing resource utilization, reducing milk consumption, increasing production capacity, and minimizing process variability, leading to significant cost savings and improved product yield. Despite these successes, traditional LSS implementation in the food sector faces barriers, including the high variability of biological raw materials and human factors such as resistance to change [10][11][12].

The emergence of Industry 4.0 (4IR) presents both a challenge and a profound opportunity for traditional continuous improvement paradigms. 4IR encompasses a set of digital technologies—such as the Internet of Things (IoT), Big Data analytics, Artificial Intelligence (AI), Machine Learning (ML), and robotics—that enable the creation of "smart factories" where physical and digital processes are deeply intertwined [5]. This technological revolution is not merely an addition to existing processes; it transforms the very foundation upon which LSS operates. The integration of 4IR technologies with LSS principles gives rise to what is increasingly termed LSS 4.0 or Quality 4.0, a new paradigm for achieving operational excellence.

2.4 An Integrated Conceptual Framework for LSS 4.0 Adoption

Based on the synthesis of existing literature, a conceptual framework is proposed to guide the investigation of LSS 4.0 adoption in Figure 1. This framework moves beyond a simple input-output model to represent a socio-technical system where technological enablers and methodological principles are mediated by organizational factors.

The framework posits that 4IR technologies (e.g., IoT, Big Data, AI) act as the primary enablers, providing the data and automation capabilities necessary for advanced process control. These technologies are applied through the structured methodology of LSS Principles (e.g., DMAIC, waste reduction). However, the successful translation of these inputs into desired outcomes is not direct. It is moderated by a set of Implementation Challenges, which the literature consistently identifies as critical barriers. These include high financial costs, a lack of requisite digital and analytical skills, employee resistance to change, and data security concerns. The effective management of these challenges determines the extent to which an organization can realize the goal of operational excellence, which is measured through key performance indicators such as improved quality, increased productivity, reduced costs, and enhanced customer satisfaction. This framework suggests that a failure to address the moderating challenges will severely limit the potential benefits of LSS 4.0, resulting in a disconnect between strategic investment and operational outcomes.

Figure 1: Conceptual research framework based on literature review

3 METHODOLOGY

3.1 Research approach

To address the research objectives, this study employed a mixed-methods, single case study design. This approach was deliberately chosen as the most suitable for capturing a holistic and multi-layered understanding of the LSS 4.0 integration phenomenon. A purely quantitative approach might have identified trends in perceptions but would have failed to uncover the underlying strategic reasoning and contextual nuances behind them. Conversely, a purely qualitative approach would have lacked the broader, operational-level data needed to validate the themes emerging from managerial interviews. The mixed-methods design allows for triangulation, where quantitative findings on operational realities (from surveys) can be explained and enriched by qualitative insights into strategic decision-making (from interviews), providing a more robust and credible analysis. The single case study design is appropriate for an exploratory investigation into a contemporary phenomenon within its real-life context, particularly when the boundaries between the phenomenon and context are not evident.

3.2 Data Collection

- **Interviews**: Conducted with five managerial staff to understand strategic perspectives. Semi-structured interviews were conducted with five senior managers, including the Operations Manager, Quality Manager, and Lead Engineer. An interview protocol was developed to guide the conversations, focusing on themes such as the strategic drivers for technology adoption, the perceived benefits and challenges of integrating LSS and 4IR, the decision-making process for investments, and the organizational culture surrounding change and innovation. This method was chosen to elicit rich, detailed narratives and expert opinions on the strategic dimensions of the research problem.
- **Surveys**: Distributed to 40 employees involved in production, achieving a response rate of 80%. A structured survey was administered to a target population of 50 production-level employees, including engineers, data analysts, and quality controllers. A final sample of 40 completed responses was obtained, achieving a strong response rate of 80%, surpassing the targeted rate of over 70%. The survey instrument was designed to gather data on: (1) demographic and professional roles; (2) familiarity with LSS and specific 4IR technologies (e.g., IoT, Big Data Analytics, Robotics); (3) perceived benefits of LSS implementation; and (4) perceived challenges in adopting new technologies. The survey used a combination of multiple-choice questions and Likert scales to quantify operational-level perspectives.

3.3 Case Study selection and context

The case study was conducted at "Company X," a large, established meat processing company located in South Africa. The company was selected for its representativeness of the sector, as it operates multiple production lines, deals with high-volume throughput, and faces the typical industry pressures of quality control, cost management, and regulatory compliance. The company has expressed strategic interest in continuous improvement and has made initial, albeit fragmented, investments in 4IR technologies, making it an ideal setting to study the nascent stages of LSS 4.0 integration.

3.4 Data Analysis

Qualitative Data: The audio-recorded interviews were transcribed verbatim. The transcripts were then subjected to a rigorous thematic analysis. This process involved an initial phase of open coding to identify salient concepts, followed by a process of axial coding to group these concepts into broader categories. Finally, these categories were refined into overarching themes that directly corresponded to the research objectives, such as "Perceived Strategic Benefits," "Operational Barriers," and "Cultural Resistance."

Quantitative Data: The survey data were analysed using the Statistical Package for the Social Sciences (SPSS) software. Descriptive statistics, including frequencies and percentages, were calculated to summarize the respondent profile and their perceptions. To ensure the reliability of the survey instrument, a reliability analysis was conducted. The survey contained 15-item Likert scale measuring perceptions of LSS and 4IR. Cronbach's alpha was calculated on these items to assess the internal consistency of the scale. The resulting alpha value was 0.78, which is above the commonly accepted threshold of 0.7, indicating acceptable reliability for the measurement scale.

4 RESULTS AND FINDINGS

4.1 Descriptive analysis of the study

Most of the responses from the survey were from the Quality Controllers who hold permanent positions in the company and in most cases that means that it is people that are experienced in the food manufacturing field. From the results, it is evident that 59% of the participants are somewhat familiar with the concept of Six Sigma with 32% of them very familiar with it. About 45% of the respondents are somewhat familiar with Industry 4.0 with 36% of them very familiar with it.

Table 1: Respondents based on job position

Position	No. of participants	Percentage
Engineer	1	5%
Quality Control	19	86%
Data Analyst	2	9%
Total	**22**	**100%**

The highest number of respondents is the Quality Controllers. These employees, who mostly work directly with the products are the ones that see firsthand how efficient the company's productivity is and how effective the utilization of Industry 4.0 tools is; therefore, the responses enhance the strength of the responses.

One of the main reasons for the company to utilise the 4IR tools was to enhance operational efficiency and after implementing the tools, the goal was achieved. The biggest benefit of Six Sigma that the company gained is improved quality products, which goes together with operational efficiency.

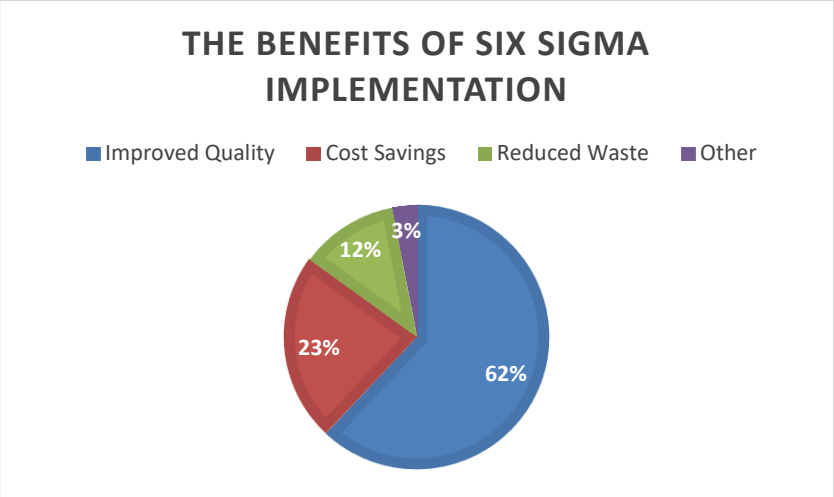

Figure 2: Benefits obtained from implementing Six Sigma in Company X.

The main need to implement 4IR tools is to improve the operational efficiency of the company. Company X has not implemented the 4IR tools to full potential due to various reasons.

These quantitative findings were strongly corroborated by the qualitative data from managerial interviews. One manager emphasized the direct link between technology-enabled LSS and quality, stating, "Applying Six Sigma's DMAIC procedure using Industry 4.0 tools can significantly reduce defects in production lines by leveraging data, automation, and real-time insights". The interviews also revealed that the primary motivation for investing in 4IR tools like IoT and Big Data Analytics was to "enhance operational efficiency," a goal the management believes was achieved post-implementation. For example, the use of IoT sensors for real-time temperature monitoring during storage and transportation was highlighted as a key technological intervention that improved product integrity and traceability.

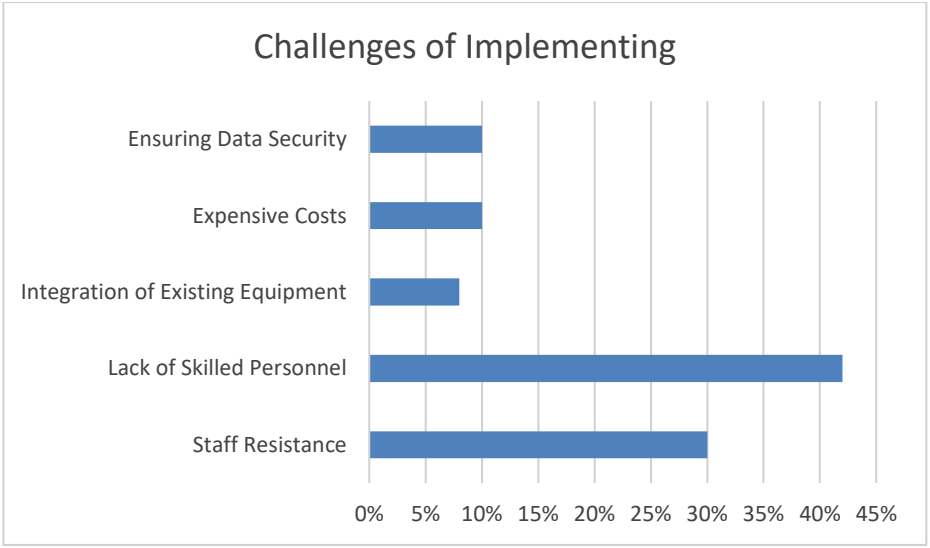

Figure 3: Challenges faced by the company in implementing 4IR

The quantitative findings were strongly corroborated by the qualitative data from managerial interviews. One manager emphasized the direct link between technology-enabled LSS and quality, stating, "Applying Six Sigma's DMAIC procedure using Industry 4.0 tools can significantly reduce defects in production lines by leveraging data, automation, and real-time insights". The interviews also revealed that the primary motivation for investing in 4IR tools

like IoT and Big Data Analytics was to "enhance operational efficiency," a goal the management believes was achieved post-implementation. For example, the use of IoT sensors for real-time temperature monitoring during storage and transportation was highlighted as a key technological intervention that improved product integrity and traceability.

The thematic analysis of managerial interviews provided a deeper context to these challenges. Managers acknowledged the significant upfront capital investment required for advanced technologies, a hurdle that could be prohibitive for many firms, especially small and medium enterprises (SMEs). The "skill gap" was also a recurring theme in interviews. Managers highlighted the difficulty in recruiting and retaining staff with the expertise to manage and maintain advanced analytical and automation systems, underscoring the need for specialized training programs. Furthermore, employee concerns about job security in the face of increasing automation were identified as a key driver of resistance to change. Survey data indicated that over 45% of employees expressed apprehension about the potential for automated systems to replace manual jobs, confirming the cultural challenges that must be navigated during implementation.

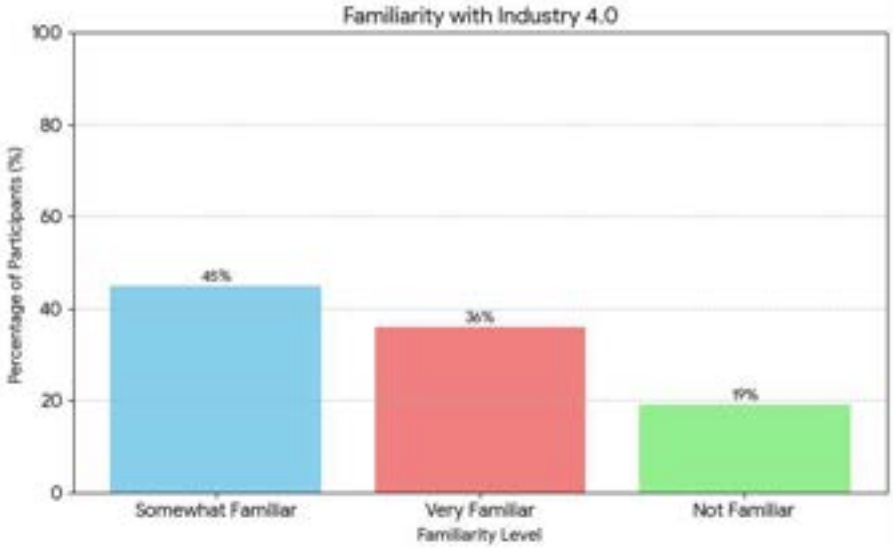

Figure 4: Familiarity with 4.0

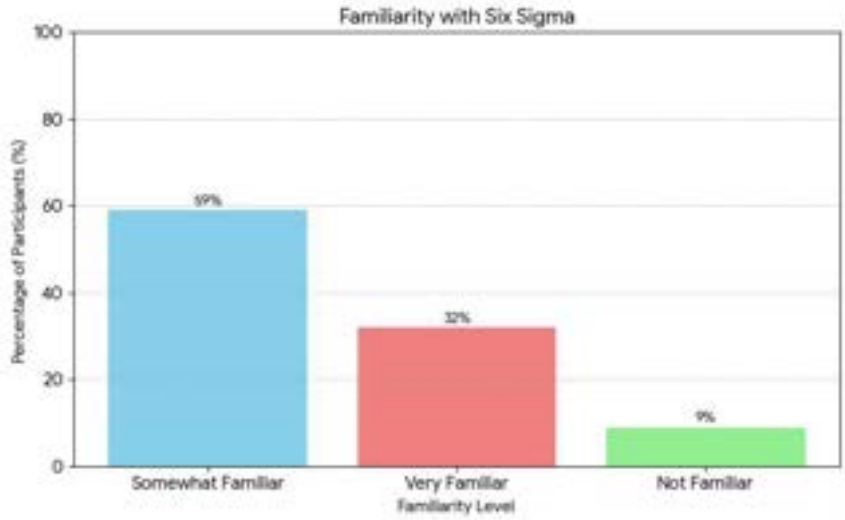

Figure 5: Familiarity with LSS

The study revealed a notable level of conceptual awareness among employees regarding both LSS and 4IR. Figure 5 illustrates the employees' self-reported familiarity with Six Sigma. A significant majority of participants reported being either "somewhat familiar" (59%) or "very familiar" (32%) with the methodology. Only a small fraction (9%) were "not familiar."

A significant number of participants, predominantly experienced Quality Control (QC) personnel holding permanent positions, demonstrated awareness of these methodologies.

A similar pattern was observed for 4IR, as shown in Figure 4. The data indicates that 45% of respondents were "somewhat familiar" and 36% were "very familiar" with 4IR concepts. This suggests that information about these modern paradigms is being disseminated within the organization, though the level of deep understanding varies.

4.2 Reliability Analysis

The Cronbach's alpha (α) is defined as a statistic that measures the correlation of the set of answers as a collective. The reliability values range from 0 to 1 where values above 0.7 indicate a good reliability. In this study, the Cronbach alpha value of this study is 0.78 which makes it acceptable and reliable.

4.3 Interviews

From the interview, the participant provided sufficient information to show that Six Sigma coordinates with 4IR tools such as IoT for the greater good of the company. Company X is a large company of over 500 employees. It has multiple production lines for different products, and this results in a lot of data to capture into the system, including the raw materials used and batch numbers. Such data can be analysed using Big Data Analytics to ensure that everything is on record and can be easily traced. This tool also helped in monitoring the temperature fluctuations during the storage and transportation of products.

4.3.1 Thematical analysis

Six Sigma is a data-driven methodology used to improve business processes by identifying and eliminating the causes of defects and minimizing variability in manufacturing and business processes. This approach enhances efficiency and quality by focusing on process improvement and waste reduction. For Company X, a food sector company already using Lean manufacturing, integrating Six Sigma principles, specifically the DMAIC procedure, can significantly improve product quality and reduce costs.

Six Sigma DMAIC in the Food Sector

The **DMAIC** (Define, Measure, Analyse, Improve, Control) procedure is the core of Six Sigma and provides a structured approach to process improvement.

- **Define**: Clearly define the project goals and customer deliverables. For Company X, this could involve defining a specific quality issue, like inconsistent product weight or texture, that negatively impacts customer satisfaction and operational costs.
- **Measure**: Collect data to establish the current performance of the process. This involves quantifying the defect rate, waste levels, or process cycle time. For example, Company X might measure the percentage of products that fall outside the specified weight range.
- **Analyse**: Analyse the collected data to identify the root causes of the defects. This step uses statistical tools to understand why the process isn't meeting the defined standards. The analysis might reveal that a specific piece of equipment or a variation in raw material quality is the primary cause of the issue.

- **Improve**: Develop and implement solutions to eliminate the root causes of the defects. This could involve adjusting machine settings, updating standard operating procedures, or improving supplier quality control.
- **Control**: Implement systems to monitor and sustain the improved process. This ensures that the gains made during the "Improve" phase are not lost over time. Tools like statistical process control (SPC) charts can be used to continuously monitor the process and alert operators to potential issues before they cause defects.

Benefits of Six Sigma for Company X

Implementing Six Sigma offers several key benefits for Company X, aligning with the company's goals of improving quality and efficiency.

- **Improved Product Quality**: This is the most significant benefit, as it directly impacts customer satisfaction and brand reputation. By reducing defects and variability, the company can ensure that every product meets high standards, fostering customer loyalty and trust.
- **Reduced Waste**: Six Sigma's focus on identifying and eliminating the root causes of defects naturally leads to a reduction in waste. This includes raw materials, energy, and time, which contribute to lower production costs and a more sustainable operation.
- **Cost Savings**: The reduction in waste, defects, and reworks directly translates into significant cost savings. Less waste means lower material costs, while fewer defects mean reduced labour costs associated with re-processing or discarding products.

Six Sigma and Industry 4.0

Industry 4.0 technologies can significantly enhance the effectiveness of Six Sigma, particularly the DMAIC procedure, by providing better data and more control.

- **Enhanced Data Collection**: Internet of Things (IoT) sensors on the production line can automatically collect real-time data on temperature, pressure, fill levels, and other critical parameters. This eliminates manual data collection, which can be prone to human error, and provides a continuous stream of accurate data for the **Measure** and **Analyse** phases.
- **Real-time Insights and Analysis**: Automated systems and AI-powered analytics tools can instantly analyse the data from IoT sensors, providing real-time insights into process performance. This allows for quicker identification of potential issues and root causes, accelerating the **Analyse** phase.
- **Automated Control and Improvement**: Industry 4.0 tools enable automated process adjustments based on real-time data and analysis. For example, a system can automatically adjust a machine's settings to maintain consistent product weight, effectively implementing the **Improve** and **Control** phases of DMAIC with minimal human intervention.
- **Predictive Maintenance**: By analysing data from sensors, Industry 4.0 systems can predict equipment failures before they occur. This reduces unplanned downtime and prevents defects caused by malfunctioning machinery, further supporting the **Control** phase of Six Sigma.

4.4 Adoption of LSS and Industry 4.0

The case study revealed that the company has partially implemented Lean Six Sigma (LSS) and Industry 4.0 tools. IoT sensors are predominantly used to monitor production line conditions

and identify potential bottlenecks, while big data analytics are employed to enhance quality control processes. Automation technologies are limited to the packaging segment, which has resulted in a measurable increase in operational efficiency.

4.4.1 Benefits

- **Improved Quality**: Since implementing LSS and Industry 4.0 tools, defect rates have decreased by 25%. The incorporation of IoT sensors allows real-time quality monitoring, reducing production errors.
- **Enhanced Efficiency**: Cycle times across production lines have reduced by an average of 18%, leading to an increase in throughput. Big data analytics have enabled predictive maintenance, significantly reducing equipment downtime.
- **Traceability**: The integration of blockchain technology within the supply chain has improved traceability, ensuring compliance with food safety regulations and boosting consumer trust.

4.4.2 Challenges

- **Resistance to Change**: Employee concerns about job security due to automation were significant. Over 45% of surveyed employees expressed apprehension about the potential replacement of manual jobs by automated systems.
- **Skill Gaps**: A lack of skilled personnel to manage and maintain advanced Industry 4.0 tools was identified as a barrier. The need for specialized training programs was highlighted by managerial staff during interviews.
- **High Costs**: Initial investment in IoT, automation, and analytics technologies was a significant hurdle. Small and medium enterprises (SMEs) may find these costs prohibitive without external funding or phased adoption strategies.

4.5 Proposed framework for the meat processing industry

To bridge the identified strategy-practice gap and provide an actionable path forward for Company X and similar organizations, this study proposes a phased LSS 4.0 integration framework tailored for the meat processing industry (Table 2). This framework is designed to be a practical, low-risk roadmap that builds organizational capability incrementally, directly addressing the primary challenges of high cost and skill gaps. It structures the integration journey into three manageable phases, each with a clear focus, specific technological and methodological tools, and defined outcomes.

Table 2: Proposed framework for the meat processing industry

Phase	Focus	LSS Tools	4IRTechnologies	Key Challenge Addressed	Expected Outcome
Phase 1: Foundational	Stabilize and Standardize (DMA)	Value Stream Mapping (VSM), 5S, Standard Work, Statistical Process Control (SPC)	Basic IoT Sensors (e.g., temperature, line speed), Digital Data Capture	Overcoming poor data quality and non-standardized processes.	A stable, predictable process baseline with reliable data streams.
Phase 2: Analytical	Analyze and Optimize (MAI)	Root Cause Analysis (Fishbone, 5 Whys), Regression Analysis	Big Data Analytics Platforms, Data Visualization Dashboards	Bridging the analytical skill gap through focused training and hiring.	Data-driven insights into root causes of waste and variability; initial ROI demonstrated.
Phase 3: Predictive and Automated	Predict and Control (IC)	Design of Experiments (DOE), Advanced Process Control (APC)	AI/ML for Predictive Maintenance, Robotics (e.g., in packaging), Digital Twins	Justifying high costs through proven ROI from earlier phases; managing change.	Autonomous process optimization, reduced downtime, and a culture of continuous, data-driven improvement.

Phase 1: Foundational. The journey begins not with expensive technology, but with LSS fundamentals. The focus is on stabilizing processes and establishing a reliable data foundation. Using tools like VSM and 5S, the organization first eliminates obvious waste and standardizes work. Basic, low-cost IoT sensors are introduced to automate the collection of critical data, moving away from manual logs. This phase directly tackles the problem of poor data quality and provides a solid baseline for all future analysis.

Phase 2: Analytical. With reliable data streams established, the focus shifts to building analytical capability. The organization invests in a data analytics platform and trains or hires personnel (like the data analysts in the survey sample) to use it. LSS tools like root cause analysis are now supercharged with large datasets, allowing for deeper insights. This phase directly addresses the "skill gap" in a targeted manner and is designed to generate a clear return on investment (e.g., through targeted waste reduction), which helps build the business case for further investment.

Phase 3: Predictive and Automated. Having proven the value of data analytics, the organization can now justify the higher costs of advanced 4IRtechnologies. AI and ML models can be developed for applications like predictive maintenance on critical machinery (e.g., grinders, mixers), and robotics can be implemented in high-repetition areas like packaging to improve consistency and reduce ergonomic strain. This final phase leverages the capabilities built in the preceding stages to move toward a truly "smart" and self-optimizing production system.

5 CONCLUSION

The integration of Six Sigma methodologies and Industry 4.0 technologies holds significant potential for enhancing operational efficiency and product quality within the food industry. The research findings indicate that adopting these strategies can lead to improved product quality, reduced waste, cost savings, and enhanced operational efficiency. However, successful implementation requires addressing challenges related to staff training, data security, and integration with existing systems. The integration of Lean Six Sigma with Industry 4.0 represents a transformative approach to addressing inefficiencies in the food manufacturing sector. This study highlights the tangible benefits and challenges associated

with this integration, offering a conceptual framework for its implementation. Future research should explore cross-sector applications and strategies for scaling these methodologies in small and medium enterprises (SMEs).

The findings confirm that integrating LSS with Industry 4.0 enhances operational performance in the food industry. However, successful implementation requires addressing cultural and technical challenges. Employee training, stakeholder engagement, and phased deployment are crucial for overcoming resistance and maximizing ROI.

This research investigated the integration of Lean Six Sigma and Industry 4.0 within the South African meat processing sector. The study found that while there is a strong strategic desire and high conceptual awareness for LSS 4.0 adoption, a significant "strategy-practice gap" exists. This gap is primarily driven by substantial operational barriers, most notably a lack of skilled personnel to manage advanced systems and the high financial costs associated with implementation. Despite these hurdles, the benefits of integration are recognized, with tangible improvements in product quality and waste reduction. The findings underscore that the journey toward LSS 4.0 is a complex socio-technical endeavour where organizational readiness is as critical as technological sophistication

This study contributes to the body of knowledge by highlighting the practical implications of integrating Six Sigma and Industry 4.0 in a food manufacturing context. The findings provide insights for food manufacturers looking to adopt these strategies to improve their operational performance and competitiveness. Further research exploring specific applications of these technologies within different segments of the food industry would be beneficial in expanding our understanding of their potential and limitations.

5.1 Theoretical and Managerial Implications

From a theoretical perspective, this study contributes a valuable empirical case to the nascent LSS 4.0 literature, specifically within the under-researched food processing industry. It validates existing conceptual models of Quality 4.0 and highlights the critical mediating role of organizational factors (skills, cost, culture) in the technology adoption process.

For managers and practitioners in the food industry, the implications are highly practical. The research cautions against a purely technology-centric approach to modernization. Instead, it advocates for a balanced strategy that aligns investments in technology with investments in people and processes. The proposed phased integration framework in Table 2 offers a concrete, actionable roadmap for industry leaders. This framework allows for a gradual, de-risked approach to digital transformation, enabling organizations to build internal capabilities, demonstrate value at each stage, and foster a sustainable culture of data-driven continuous improvement.

ABSTRACT

The financial industry has witnessed widespread adoption of digital banking services and platform enterprise architectures. The literature highlighted gaps in linking enterprise architecture and platforms and facilitated the synthesis of a conceptual framework. A mixed methods study validated enterprise architectural elements and characteristics critical to the success of banking platforms in South Africa from a customer perspective. Two data collection methodologies were applied to five anonymized South African banks: banking application content analysis and observation, and quantitative analysis of social media customer reviews of customer's perceptions towards the banking platforms. Vital enterprise architectural elements are strategies, products, services, technical design, privacy, security, governance, communication and trust. Social media review analysis found that the predominant complaints were inefficient services and long service times. While banks invest in their digital platforms, high operational costs and operational inefficiencies within current processes must be resolved to reduce customer complaints.

Keywords: Enterprise architecture, platforms, platform architecture, digital banking platform, South African banks

1 INTRODUCTION

With the rapid advancement of technology induced by the digital age, organizations find it imperative to re-evaluate their business strategy to remain competitive. Furthermore, organizations encounter escalating complexity of information systems [1]. The use of complex legacy systems creates inflexible organizations which are unable to adapt to the rapidly changing environment [1].

Financial services have encountered a great degree of disruption due to advancements in information technology realising significant improvements in data, computing, the Internet and social networks [2]. This has prompted many financial institutions to undergo digital transformation that has changed the financial services industry [3]. Digital transformation involves business and IT strategies and incorporates digital technology in products and services [4]. Traditional banking institutions in South Africa are thus investing in re-engineering their organizational structure, adopting new technologies, and directing greater focus on customer centricity [3]. Traditional banking methods of using cheques or physical money for transactions are being replaced progressively by digital banking services [5]. A prevailing business decision amongst the South African financial institutions is the adoption of the digital platform to provide banking services to their customers.

For many years, platforms have existed physically in various forms such as malls, which facilitate the interaction of merchants and customers [2]. However, in the digital age, the progression of information technology eliminates the necessity of physical platforms. The digital platform can be described as “technology architecture” that facilitates the integration of information, networking and computing, and allowing for the progression of computing performance [6]. The global banking industry has implemented digital platforms to reduce service times and operational costs, and to provide digital financial services [7]. These banking platforms are in the form of banking apps, online banking interfaces, cell phone banking and other software.

South Africa has encountered socio-economic issues such as poverty, crime and corruption, which may need to be accounted for when analysing the adoption of digital banking platforms [8]. Therefore, the availability and usage of international studies of banking platforms may not generalize to South Africa. Louw and Nieuwenhuizen’s comparative analysis of banking platforms highlights the gaps in the literature relating to digital banking from a South African perspective and the importance of further research on banking platforms [9]. In a recent study, it was found that 79% of banking executives believed that the adoption of platforms would assist in attaining organizational goals and enhance competitiveness [10]. However, the integration of platforms and sophisticated technological tools is associated with the revamping of business strategies, through enterprise engineering methodologies such as enterprise architecture.

Enterprise architecture (EA), and enterprise engineering were developed as methodologies for designing and redesigning businesses and incorporate an organization’s mission, vision, strategy, goals, actions and operations [11]. Enterprise architecture is regarded as a tool to map out interconnections between IT systems and business strategy [12]. The role of enterprise architecture for business-IT alignment is applicable in this research, since the focus of this research is centred on the relationship between enterprise architecture and platforms. The existence of gaps in the literature pertaining to the adoption of enterprise architecture in different sectors emphasizes the necessity of performing research on enterprise architectures in the financial sector [4]. Furthermore, there is a lack of literature highlighting the link between platforms and enterprise architecture [13].

This research is driven by the following question: *"From a customer perspective, what are the critical enterprise architectural elements and associated characteristics of banks implementing a digital banking platform in South Africa?"* Within this research, elements refer to the enterprise architectural components being investigated, while characteristics refer to the descriptions of how the banks have implemented these elements. A comparative analysis of selected South African banking platforms will be executed, pertaining to five traditional banks.

2 LITERATURE REVIEW AND RESEARCH FRAMEWORK

Conventional banking services encompass the acceptance of monetary deposits, provision of loans, and execution of transactions [14, 15]. Banking may be characterized according to the services offered, such as services targeting many customer groups (personal (retail) and commercial customers), multiple products (deposit accounts, insurance, credit accounts and so on), or multiple channels to provide financial services (branch, mobile app, online banking, ATMs and cell phone banking) [14, 15, 8]. Banking services may be traditional or digital (e-services). Traditional banking refers to the provision of in-person conventional banking services, such as offering financial services at physical branches [14]. Digital banking or e-banking allows customers to access financial services electronically [14].

The South African banking industry has an immense impact on the South African economy due to the ownership of a large percentage of the country's financial assets and a substantial customer base [15]. Ifeacho and Ngalawa report that South African banks are estimated to contribute approximately 20% to the country's gross domestic product (GDP) [15]. Available literature on the banking industry is extensive, spanning from bank efficiency and performance to digital banking [15]. However, Louw and Nieuwenhuizen (2020) mention that gaps in literature exist, relating to South African digital banking [9].

The field of enterprise engineering was formulated to address the gaps in coherency between enterprise aspects including enterprise ontology and enterprise architecture [16]. Enterprise architecture is defined as the principles that integrate the people, processes, data, technology, and organizational structure [11] and assists with mitigating complexity of organizations. To answer the research question, a digital banking platform framework was synthesized using literature and two other frameworks, namely the Integrated Enterprise Architecture Framework (IEAF) [17], and the "Conceptual framework for theorizing digital platforms" [18]. This framework contains the elements which were investigated in this study and displayed in Figure 1 below.

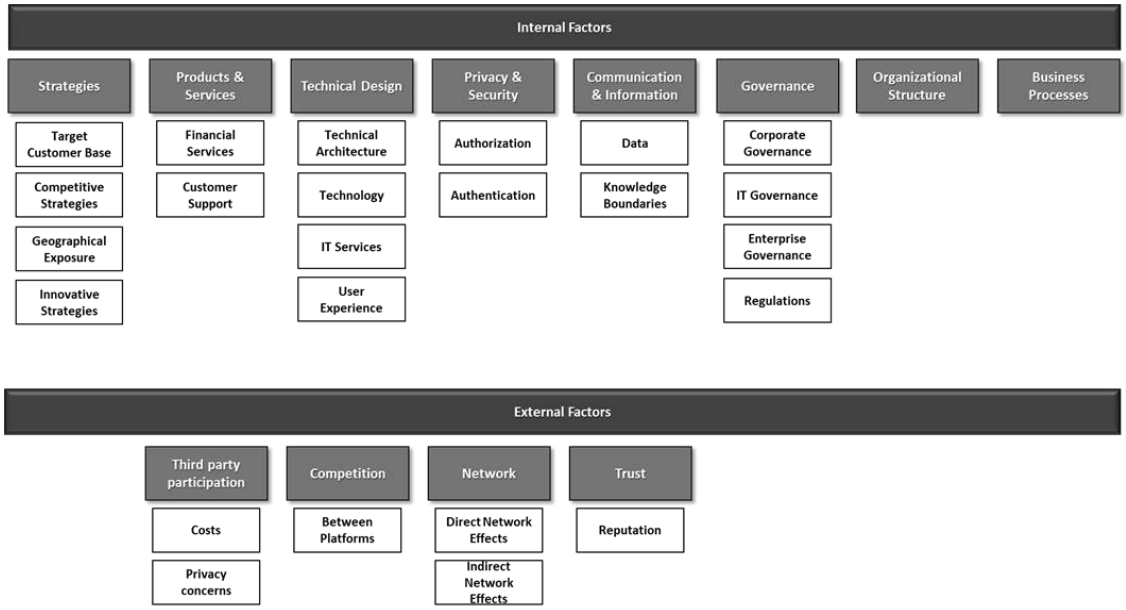

Figure 1: Enterprise Architectural Framework for Banking Platforms

The objective of this synthesized framework is to communicate factors that should be considered when developing or investigating banking platforms, while also addressing the deficiencies of the preceding frameworks, including the absence of governance and platform components in the IEAF. This Enterprise Architectural Framework for Banking Platforms was structured similarly to that of the "Conceptual framework for theorizing digital platforms", in that factors were distinguished in terms of two classes, namely Internal and External Factors. Table **1** indicates the operational definitions of the elements in the enterprise architectural framework for banking platforms depicted in Figure 1.

Table 1: Operational definitions of elements in the Enterprise Architectural Framework for Banking Platforms

EA Element	Operational Definitions
Strategies	Strategies refer to the plan or direction of an organization over a long-term period to meet organizational goals [19].
Products and Services	Banks offer a range of financial products and services to customers, inclusive of deposits, lending, investment and insurance products [14].
Technical Design	Technical Design comprises elements of technology, architecture, information technology (IT) services and user experience related to digital banking services [19].
Privacy and Security	Privacy relates to the protection and confidentiality of sensitive data. Security refers to the level of protection or confrontation against destruction, precious assets, individuals, nations, institutions, and so on [19].
Governance	Governance concerns the coordination and control of activities and interactions within a platform [20, 18].
Communication and Information	Communication and information concepts pertain to a comprehensive set of both financial and non-financial information [16].
Third-Party Participation	Third parties' involvement pertains to various external actors interacting on a platform [18].
Network	Network effects refer to the users that facilitate the introduction of both direct and indirect network effects [21].
Trust	Trust is the level of confidence users have in a platform's ability to sufficiently satisfy their needs effectively [19].

3 METHODOLOGY

A deductive approach was employed for the study based on the enterprise architectural framework for banking platforms established from the literature in the previous section. Due to the sensitivity and risk associated with obtaining the necessary internal information, certain enterprise architecture factors such as organizational structure, business processes and competition were excluded from data collection and analysis in this research. A mixed methods study investigated the frameworks' validity via two avenues of data collection, including content analysis of the banking platforms and the collection of social media reviews relating to each bank included in the study.

Since the researcher acted as a solo user (customer) and observer, participant sampling was not required. However, a sample of banks to be included in the study was selected. The sample was based on exhaustive sampling usually applicable for research in which a limited population or group is available to be studied and institutions that meet pre-determined criteria were to be included [22]. The criteria adopted to determine the banks' eligibility for analysis included the bank's customer base, reputation, ability to provide both traditional and digital services, and the significance of the bank's presence on the market. Thus, five banks were selected accordingly. The banks included were traditional banks with a mobile banking application as the digital platform. The banks were anonymized to prevent any reputational impact to the institution from the results obtained in this study and will be designated as Bank A to E. Content analysis of banking platforms was performed from September to December 2024.

Social media reviews were extracted for the sample of banks included in the study, with a data collection method adapted from Greene, et al. [23]. Reviews from social media were extracted manually from X (Twitter) and HelloPeter, omitting sensitive personal details of the customer. Due to time constraints, only the first 50 reviews (per bank) which appeared when searching for the banks on X (Twitter), and the first 20 reviews which were displayed on each bank's HelloPeter website were extracted. Consequently, 250 postings between January 2022 and December 2024 were analysed.

Table 2 illustrates the analysis methods that were executed in both parts of this investigation. Miles, Huberman and Saldana provide three stages of a concurrent process of data analysis, including data condensation, data display and conclusion drawing, which was used for the analysis [24]. This is aligned to the final step of the content analysis process outlined by Krippendorf [25].

Table 2: Method of data analyses

Data Source	Method of Analysis
Banking platforms	Qualitative analysis via coding of observation notes – The researcher recorded notes during the interaction with banking platforms, thereafter codes were applied to these notes. The elements observed using this methodology are indicated in Figure 1.
Social Media Reviews	Quantitative & qualitative analysis of social media reviews – The results were compiled into a graphical format.

As part of data condensation, notes were transcribed during the interaction with banking platforms; these notes, along with the social media reviews were thereafter coded in two consecutive cycles [24]. The deductive coding approach was selected since the enterprise architectural framework was synthesized from literature, which formed the list of codes for the initial cycle of coding. The coding method of data analysis involves distinct steps, which include separating data into "codable units" and thereafter assigning codes to these units [24], which was then applied to the qualitative data obtained. This research incorporated two cycles of deductive coding to investigate consistency between the two cycles of coding. The first cycle of coding involved assigning the codes to portions of data to investigate patterns.

The second cycle of coding condensed the coded portions of data from the first cycle into reduced categories [24]. These coding cycles were also applied to the social media reviews.

The stability component of reliability was measured for the qualitative content analysis of banking platforms, via the "test-retest" design for intra-coder reliability [25]. Cohen's Kappa (κ) was then calculated as an estimate of the agreement level between the first and second coding cycles, which was computed as $\kappa = 0.94$. This is strong or near perfect agreement [25]. The discrepancies identified between the two cycles of coding were due to overlap between the different elements investigated.

The study ensured external validity through the triangulation of multiple sources. This encompassed the qualitative content analysis of banking platforms and the quantitative analysis of social media reviews. The enterprise architecture features derived during the research were subsequently compared with the existing literature.

Additional information pertaining to this research may be obtained from Singh and Goncalves[†] [26].

4 RESULTS AND DISCUSSION

The study results are presented, starting with an analysis of social media reviews on X (Twitter) and HelloPeter pertaining to each bank, thereafter observation and content analysis of banking platforms. *Figure 2* illustrates the proportion of positive and negative customer posts per bank encountered on Twitter. Bank B exhibited the highest proportion of negative customer posts (46%), alongside the greatest discrepancy between negative and positive posts, with merely 6% of the search results reflecting positive customer experiences. Results for all banks indicated a disparity between positive and negative posts, with a greater percentage of complaints obtained compared to compliments.

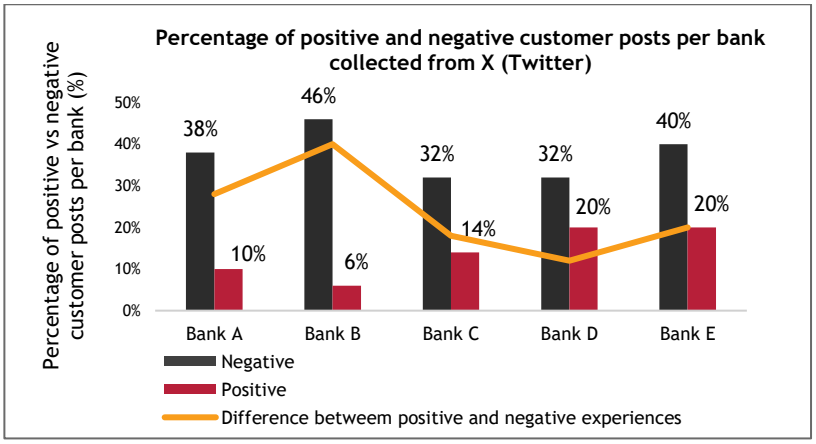

Figure 2: Positive and negative customer posts per bank collected from X (Twitter)

Figure 3 below depicts the categories of customer complaints extracted from X (Twitter) and HelloPeter. The "Other" category pertains to customer complaint causes that were not

[†] This article is based on a dissertation for the degree of Master of Science in Engineering submitted to the Faculty of Engineering and the Built Environment, University of the Witwatersrand.

evident from the post. The substantial proportion of unfavourable evaluations may highlight gaps within the South African banking sector, indicating a need for appropriate measures to be undertaken to enhance customer experience.

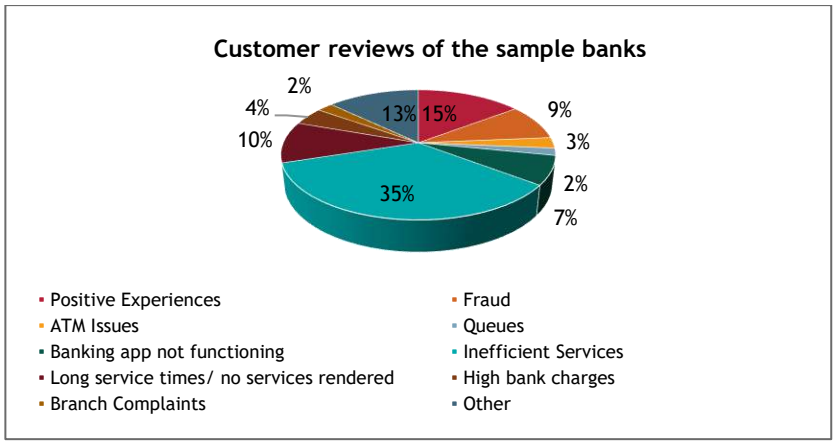

Figure 3:Complaint categories obtained from X (Twitter) and HelloPeter customer posts

The reviews collected from X (Twitter) and HelloPeter revealed similar customer sentiments across positive and negative experiences (fraud, queues and so on). The following sections discuss the results of the various architecture elements based on the observation and content analysis of banking platforms, and the analysis of social media reviews.

4.1. Strategies

4.1.1. Target customer base

It was noted that Bank B predominantly serviced retail (personal) customers and recently expanded their services to include business banking. The other 4 banks provided services to retail, commercial and private customers. It was therefore intriguing to observe that at the time of the study Bank B also acquired the highest share price. A higher share price is indicative of flourishing company performance, which may be attributed to the bank's strategy of prioritizing simplicity, as evidenced by its banking platform [27].

Unemployed and lower-income citizens in underprivileged neighbourhoods who may not have access to physical or digital financial services, must be considered during the development of South African banking strategies and architectures [28]. Additionally, Bank B's simplicity strategy and recent venture into business banking may appeal to small-to-medium enterprises. Therefore, Bank B has adopted a strategy which appeals to a large portion of the South African population, thus acquiring a substantial customer base and remarkable company performance (as indicated by the share price).

As depicted in Figure 2, approximately 46% of the negative posts obtained for Bank B indicated customer dissatisfaction due to fraud, long queue times, frequent banking app downtime, inefficient services and high bank charges (as displayed in Figure 3). It is possible that while this bank prioritizes a straightforward banking app, this may lead to greater demand for customers to be serviced at ATMs and branches, either due to an absence of sufficient technology literacy of the target customer, or for accessing certain activities which are not available via the banking app.

Based on the evaluation of banking platforms, it can be deduced that two main target customer strategies have been adopted by the banks. These two strategies involve directing focus on a targeted market and providing specialized financial services or facilitating a wider customer base and investing accordingly to satisfy each customer segment. However, servicing multiple customer segments may induce a higher degree of complexity in the design of banking

platforms. Additionally, a Kenyan commercial bank study found that by focusing on a specific target customer base, market segment or geographical location, banks may gain a competitive advantage [29].

4.1.2. Geographical Exposure

The five banks examined in the study are categorized as conventional banks with a significant branch presence throughout South Africa. Users may leverage the branch or ATM location feature to locate the nearest branch or ATM. Moreover, four of the five banks operate in many African nations, excluding Bank B which operates only in South Africa. As previously noted, Bank B exhibited a higher share price relative to the other banks, underscoring its exceptional market success despite its restricted geographical presence compared to its counterparts. This was consistent with previous literature where it was deduced beneficial strategies for banks include specialization of services according to a niche segment or location [29].

Although banks are evidently promoting heightened platform utilization, the presence of branches suggests that certain South African clients prefer in-person help over smartphone usage. This correlates with a study performed on the South African banking landscape which stipulated certain generations of users, such as elderly users, prefer to access physical banking services [9]. The authors recommended that South African banks adopt a blended digital and traditional banking model [9]. However, bank branches may also provide services which cannot be addressed with the banking app, because of business rules or governance.

4.1.3. Competitive Strategies

Digitalisation is evident in several strategies adopted by the banks, including investing in their digital banking platforms [2]. To further encourage customers to utilize digital banking services, the banks have adopted strategies such as a “digital bonus” or providing rewards for transacting using virtual cards. All banks have customized offers and rewards schemes to appeal to customers. Research conducted on customers of South African banks revealed that users depicted positive sentiments towards the allocation and utilization of rewards on the banking applications, which were often associated with South African retailers [30].

4.1.4. Innovative Strategies

Banks A, C, D and E have expanded into other sectors, with Banks C and D offering the sales of automobiles and electronics on their platforms. This is indicative of "Beyond Banking," a strategy by which banks attract consumers by offering a wide variety of products and services [31]. With increased focus on climate change, and the complex electricity landscape in South Africa [32], many banks are now offering sustainability products catered to customers who want to reduce dependency on South Africa’s electricity grid. Banks C and E offer sustainability finance, initiatives and education and assist customers to select a green solutions supplier. These products include loans to purchase solar power systems. These innovative strategies utilize existing technologies to provide innovative services to customers.

4.2. Products and Services

New customers are required to register on banking platforms. Personal information was required by all five banks including the following categories: personal information, contact details, address information, education and employment information. All banks required the customer to complete facial scanning, which is then verified using information from the Department of Home Affairs (DHA). Customers are prompted to provide consent for sharing of their biometric information with pertinent third parties, such as DHA, to enable the bank to conduct verification. The consumer is also required to accept banking agreements and establish their profile credentials. Upon completion of this process, the consumer can access their profile on the banking application. Confirmation of the successful verification of the account opening procedure was delivered within seven days via the app or email.

The five banks provide a diverse array of products, including current accounts, savings and investment options and insurance offerings which was found to be consistent with the literature [14].The five banking applications also provide a variety of basic functions such as the ability to access multiple banking profiles, view banking accounts, and perform general money management activities such as withdrawals, transfers or deposits. Customers may transact on these accounts using physical or virtual cards. Virtual cards enable users to utilize the tap-to-pay capability on mobile devices. Personal, home and vehicle loans or insurance are also accessible on all five applications. Additionally, Banks A, C and D facilitate the ability to purchase the property or vehicle itself on the actual application. The platforms offer various payment options, including general payment options on the banking app, PayShap, Quick Response (QR) code payments, contactless card payments, location-based payments, cellular number payments and digital tap-to-pay methods. This is consistent with the literature as basic services offered by banks [14, 33].

The banks offer tailored products to customers in lower income segments, middle-income segments and higher-income segments. For lower income segments, the banks offer reduced monthly fees and free ATM cash deposits or withdrawals. Bank C also offers the ability for customers to purchase white or brown bread from shops for 99 cents. Banks A, C, D and E provide higher-income customers with private banking services, including the allocation of a dedicated advisor to assist the customer with financial services. The middle-income segment monthly service rates range between the cost of private banking and low-income banking. Banking institutions refrain from charging fees for using their platforms; nonetheless, charges apply based on the customer's accounts or for executing certain operations, such as transferring funds to accounts at other banks.

The banking applications also offer customers connectivity products, including airtime, data bundles or SMS. Gertze and Petersen report that general banking applications often offer connectivity products, with users displaying positive sentiments towards this since a variety of services are accessible via one application [30]. All five banks have also implemented financial management education in their applications through courses or quizzes. This promotes greater financial literacy among customers. Khera, Ogawa and Sahay stipulate that improved financial literacy allows customers to improve their money management and boosts their trust in the financial system, thereby also benefitting the banks [34].

International banking services are accessible on platforms, enabling consumers to conduct transactions or invest in foreign currencies. The banks have also developed products for younger individuals, enabling minors to hold a banking account often linked with a parent or guardian's account. Thus, this study corroborates previous literature reporting that South African banks customise platforms and products to appeal to younger generations [30, 9]. Moreover, the banks have developed solutions tailored for the Islamic community in South Africa requiring certain regulations for financial management [35].

From Figure 3, 35% of overall customer complaint types were due to service inefficiency, which was significant compared to the other complaint types. From the posts analysed, customers portrayed frustration due to prolonged wait times, high product or service fees, fraud, banking app downtime, or inadequate servicing at branches. A user criticized the insurance services of Bank A, deeming the service "appalling" owing to insufficient support after two days of phone inquiries. These issues highlight inefficiencies in banking processes and must be resolved through investments in their banking platforms and enterprise architectures.

4.3. Technical Design

The banks have four methods to access financial services: mobile banking applications, online banking, cell phone banking, and ATMs. Cell phone banking, utilising Unstructured Supplementary Service Data (USSD), enables users to access financial services by dialling a

number that begins with an asterisk or hash. It was observed that updates made on one platform reflected when users logged into another platform.

From the results obtained, certain features were similar across the banking platforms. Lewis and Davis mention that banks globally may tend to follow similar patterns of functionality and services offered [36]. An example noted was the tab at the bottom of the screen on the banking applications, after the customer had successfully logged into their banking application. The tab usually displays “Home”, “Payments”, “Notifications” and “Menu”, which are standard banking functions that the user can access swiftly. When a user selects a particular account on the app, the transaction history and amount are displayed. All five banking apps send push notifications via the app, email, or SMS for transactions processed.

Certain mobile banking applications also facilitate the ability to search for functionality on the app. Only Bank C provided the ability for users to search for functionality across the entire app, while Bank E incorporated search functionality on screens which featured extensive product or application catalogues to customers.

4.3.1. Technology and User Experience

A relationship exists between the technology and user experience decisions made by banks [37]. The banks have implemented similar account dashboard layouts, with viewable account balances and transaction history. Banks leverage clients’ transactional history data to assess their financial status and provide customized products, as stated in the privacy notices of all five banks. The screen design of mobile banking platforms corresponds with the bank's branding. Users personalize the banking application by choosing backgrounds and selecting their most utilized or preferred features for immediate display on the “Home” or “Overview” panels.

4.3.2. IT Services

During the evaluation of two mobile banking applications where errors were encountered, a message was displayed to inform the user of the error. Furthermore, Bank C displayed a screen informing the user of the app’s restricted functionality during application downtime. It is essential to acknowledge that the researcher may not have encountered all the possibilities of errors that may occur on the banking platforms.

4.4. Privacy and Security

All five banking platforms displayed a privacy agreement and terms and conditions detailing their methodologies for processing personal information. This is in accordance with the South African Protection of Personal Information Act (POPIA) [38], which regulates the acquisition and transfer of personal information involving consumers and third parties. All five banks inform the customer of their right to provide or withdraw consent to the processing of their personal information at any time. The banking apps prompt the customer for consent when requiring the use of their personal information, as stipulated by POPIA [38].

The banks have implemented several security verification mechanisms for user login, including biometric authentication, passwords, and application PIN numbers. It was observed that when accessing online banking, the user was prompted to complete two-factor authentication. These security methods are consistent with the security features of banking applications mentioned in literature [39]. When a user engages in a phone call while logged into a banking platform on the same device, three banking platforms issued a notification regarding fraudulent phone calls, which cautioned against disclosing any sensitive information during the call. Users are able to report fraud on the app or by contacting an advisor. These fraud reporting features are consistent with those in literature [39]. Banks A and C incorporated activity tracking which enables users to examine prior activities conducted on the banking application.

Users on X (Twitter) and HelloPeter raised fraud concerns due to unknown transactions on their banking apps. Several posts also conveyed frustration regarding the inadequacy of fraud reporting and feedback processes at banks. This highlights a gap where the banks might improve banking app security and mitigate cybercrime. Analysis of X (Twitter) postings revealed that the banks' social media accounts raised awareness about fraud mitigation.

4.5. Governance

The five banks implemented processes to ensure their customers remain compliant according to the Financial Intelligence Centre Act (FICA). Thus, customers are requested to provide identification and proof of address when registering and opening an account. For customers who are acting or transacting on behalf of another party such as a family member, the customer is also required to provide proof of authority. In addition to this, the five banks' existing customers are required to confirm their personal information periodically. This forms part of the banks' "KYC" (Know Your Customer) or ongoing due diligence processes, which ensure that banks have verified their customers' identity [40]. If the customer fails to satisfy these requirements, their accounts may be frozen, preventing them from accessing their funds. These processes were found to align to the processes stipulated by the South African Reserve Bank [40]. From the analysis of social media reviews, complaints were obtained regarding banks' KYC processes, including incorrect freezing of accounts or prolonged service times for KYC queries.

4.6. Communication and information

The banks have an array of methods to facilitate communication between customers and banking advisors including app notifications, banners or offers on the app, calls, emails, chat messaging functionality on banking applications, and social media platforms such as X (Twitter), LinkedIn, and HelloPeter. Banks A, D and E have developed a virtual assistant to assist customers with frequently asked queries. Banks C, D and E have incorporated call and chat functions into their banking applications, which customers may use to contact support teams directly via the app. If customers do not favour digital communication methods, they may also visit a branch.

All banks maintained active social media profiles to communicate important information and respond to consumer inquiries. Gertze and Petersen concluded that to improve the adoption of e-banking, institutions must guarantee that consumers receive assistance within reasonable response times [28]. Thus, it is beneficial for banks to implement multiple methods of contact with adequate resources to handle customer requests.

4.7. Third-Party Participation

A variety of businesses have established partnerships with the five banks included in the study, which benefits users through the rewards schemes offered by the bank. Clients of a specific bank receive rewards when they conduct transactions with affiliated retailers, restaurant chains or fuel companies. For instance, shoppers may be eligible for rewards in the form of cash-back or the rewards currency of their financial institution when they purchase supplies from Checkers. These rewards become credit for subsequent purchases. The third-party services employed by the banks, such as Pay-as-a-Service (PaaS) providers, were excluded from this study as this information was not available on the platforms investigated.

4.8. Trust and Network Effects

It is evident that customers place their trust in the bank and its facilities to secure their funds and provide efficient financial assistance. However, customers' trust in their bank is impacted by fraud, adverse news concerning the bank and poor service, among other issues. One user on X (Twitter) conveyed dissatisfaction regarding the frequent downtime of Bank E's application. Another user commented that their bank is "corrupt" and involved in "rand

fixing". This post was seen by 2400 people, with 125 comments and 1700 reposts. Thus, social media posts and reviews regarding banks are far reaching and may influence the opinion of other customers, thereby impacting banking platforms. It is therefore imperative that banks focus on customer pain points to improve customer experience.

5 CONCLUSION

This study identified enterprise architectural elements and characteristics that are essential to the success of digital banking platforms. The enterprise architectural framework and elements synthesised from the literature review for a digital banking platform was subsequently validated using the study's methodology. The study determined that the elements essential for organizations to develop a successful, functional digital platform are strategies, technical design, privacy and security, products and services, governance, communication, third-party participation and trust and network effects. The enterprise architecture framework for banking platforms is aligned with literature results with two gaps or shortcomings identified: organizational flexibility and customer demand.

Customer preferences cause variations in the customer experience as evidenced with the social media reviews [37]. Therefore, banks should integrate principles of customer experience and demand into their enterprise architectures. This is further necessitated by the evolving demands of customers and the advancement of technology. Consequently, the digital banking design processes must be customer-centric to address customer needs, improve customer experience and company performance. Based on the findings of banking platforms, banks have implemented strategies that extend beyond the banking sector in recent years. This suggests that banks must integrate a certain degree of flexibility into their operations to facilitate the rapid and efficient advancement of technological trends. These two factors are regarded as fundamental considerations for modern banking enterprise architectures, to ensure responsiveness given technological trends. The comparison of the results obtained from the two methodologies revealed that while banks offer secure and accessible digital services, customers highlight issues pertaining to long queues, app downtime, and high fees. Figure 4 illustrates how the results acquired have altered the enterprise architectural framework for banking platforms.

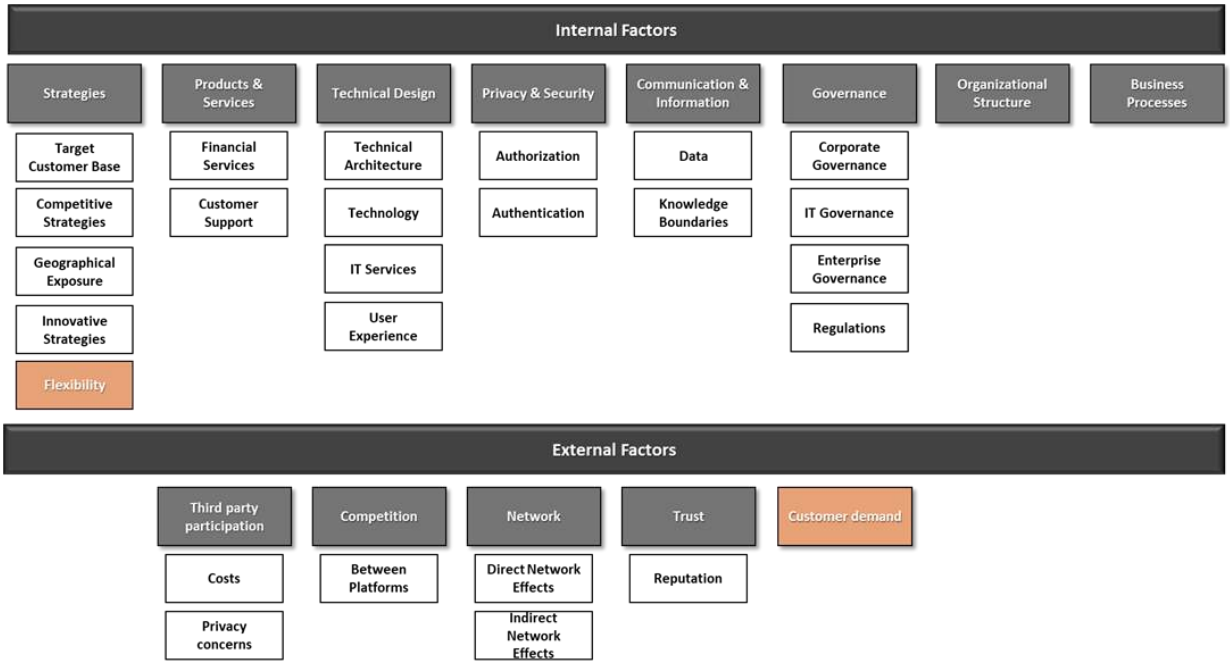

Figure 4: Modified Enterprise Architectural Framework for Banking Platforms

Post these modifications, the Enterprise Architecture for banking platforms is believed to provide an accurate depiction of considerations for designing and maintaining a robust banking platform. This research also highlighted the need for the banking industry to invest in research and resources to maintain the provision of efficient and effective services. Additionally, while banks expand into other sectors with "Beyond Banking" features, they must ensure that operational inefficiencies within current processes are resolved to reduce customer complaints.

While this research revealed significant insights, the study was limited to the five traditional South African banks. Future work could include the expanding this analysis to other banks and other countries. It would be interesting to compare the results in this research and that of digital-only banks (such as those with no branches or ATMs). Moreover, an in-depth organizational analysis may be required to gain an accurate depiction of how enterprise architecture influences performance metrics and other platform characteristics.

ABSTRACT

Electronic commerce has provided significant global competitive advantages to large enterprises. This research project aims to examine the impact the e-commerce applications of electronic marketing (EM), electronic advertising (EA), electronic customer support services (ECSS), electronic order and delivery (EOD), and electronic payment systems (EPS) have on the organisational performance (OP) of small, micro, and medium enterprises (SMMEs) in the clothing manufacturing sector within Gauteng. Additionally, the purpose of this study was to indicate the extent of knowledge that stakeholders have, regarding the influence of e-commerce on the OP of SMMEs. The mixed-method data for this study was obtained through questionnaires and semi-structured interviews. The quantitative data analysis involved descriptive statistics, reliability analysis, correlation analysis, regression analysis, and a comparative t-test. The qualitative data was analysed using thematic analysis. The study's results revealed a strong positive correlation between e-commerce applications and OP.

Keywords: e-commerce, organizational performance, service delivery

1 INTRODUCTION

Internet innovation has enhanced efficiency, effectiveness, and ergonomic well-being in production and service sectors, profoundly impacting organisational performance. The First Industrial Revolution (1IR) introduced steam-powered machines and mechanised manufacturing. The Second Industrial Revolution (2IR) brought electricity, mass production, and division of labour. The Third Industrial Revolution (3IR) introduced electronics, computers, and automated manufacturing. The current Fourth Industrial Revolution (4IR) embodies technologies like Artificial Intelligence (AI), Big Data, Robotics, e-commerce (e-com), and Cyber-Physical systems, driven by the demand for flexibility and speed to meet changing customer needs. 4IR technologies are believed to provide a competitive advantage [24][25].

Globalisation has interconnected national markets through trade and technology. Post-apartheid, South Africa rejoined the global economy, leading to economic growth, albeit unevenly distributed. The manufacturing sector struggled to compete globally, particularly against countries like China and India. SMMEs are seen to address economic inequality. Previously, businesses focused locally, leading to unnoticed inefficiencies and inhibiting export growth. Competition from South-East Asia and reduced demand for local products are attributed to poor OP. The clothing and textile (C&T) industry, being labour-intensive, has seen a decline in performance due to global competition and poor operating conditions, resulting in job losses and a decreased GDP contribution. Retrenchments led to the emergence of SMMEs. The definitions for SMMEs in the manufacturing sector are based on employee numbers and annual turnover.

1.1 The Fourth Industrial Revolution and the COVID-19 Catalyst for E-commerce

While the 4IR laid the technological groundwork for the digital transformation of business, the COVID-19 pandemic served as an unprecedented and powerful catalyst for e-commerce adoption among South African SMMEs [25] The imposition of national lockdowns and social distancing protocols made online operations a matter of survival, forcing a rapid shift from traditional face-to-face business models to digital platforms [23] This accelerated transition highlighted both the opportunities and the significant hurdles associated with e-commerce in a developing economy.

The pandemic-driven surge in e-commerce, which saw a 66% rise in South Africa in 2020, was predominantly capitalized upon by large enterprises with existing infrastructure, budgets, and skills. In contrast, many SMMEs, despite recognising the necessity of going online, struggled to adapt. They faced a confluence of challenges, including a lack of agility in altering their operating models and significant deficits in digital infrastructure. Key barriers included access to reliable and affordable broadband, the development of effective e-shop platforms, the integration of secure digital payment systems, and the management of complex logistics. Furthermore, this forced digitalisation occurred amidst a spike in cybercrime, making it difficult for resource-constrained SMMEs to guarantee the safety and security of online transactions. This context of a rapid, necessity-driven, and challenging transition is essential for understanding the specific ways in which e-commerce applications have impacted the performance of SMMEs in the post-pandemic landscape [23][24][25].

1.2 Problem Statement

Innovation holds immense potential for enhancing organisational performance. E-commerce offers advantages like eradicating poor OP, inadequate supply chain management, and subpar customer satisfaction, while fostering employee motivation, flexibility, and high-quality product/service delivery. However, SMMEs in Gauteng lack essential knowledge of e-commerce benefits and resources for effective implementation, impeding their ability to harness its advantages.

1.3 Aim of the Study

This study aims to investigate the impact of e-commerce applications on the OP of SMMEs in the clothing manufacturing sector in Gauteng.

1.3.1 Objectives of the study

- To explore the level of knowledge that relevant interested parties (owners & employees of SMMEs and potential investors) have on the role of e-commerce applications in SMMEs.
- To study the relationship between e-commerce applications and OP of SMMEs in the clothing manufacturing sector in the Gauteng province.

1.3.2 Research Questions

- What is the level of knowledge regarding the role of e-commerce applications among owners, employees of Small, Medium, and Micro Enterprises (SMMEs), and potential investors?
- What is the relationship between the use of e-commerce applications and the operational performance (OP) of SMMEs in the clothing manufacturing sector within the Gauteng province?

1.4 Hypotheses The following hypotheses guide the study:

- H_1: The e-commerce application of EM has a significant impact on OP in SMMEs.
- H_2: The e-commerce application of EA has a significant impact on OP in SMMEs.
- H_3: The e-commerce application of ECSS have a significant impact on OP in SMMEs.
- H_4: The e-commerce application of EOD has a significant impact on OP in SMMEs.
- H_5: The e-commerce application of EPS has a significant impact on OP in SMMEs.

2 LITERATURE REVIEW

2.1 Electronic Commerce (E-commerce) E-commerce, originating about 40 years ago, has improved OP for many businesses due to innovations like faster internet, product review gateways, secure online payments, and new technologies. E-commerce is a business model for selling and purchasing goods online via smart devices [1].

2.1.1 Background of E-commerce: Industrial revolutions shifted from manual labour to automated operations. Technological innovation introduced speed, flexibility, and simplicity, enhancing OP and stimulating economic development. The 4IR, driven by technologies like AI, Big Data, Robotics, and e-commerce, aims to enhance OP, efficiency, and productivity. This evolving landscape requires organisations to be agile, prioritize customer relationships, shorten lead times, and provide personalized, quality goods and services. E-commerce offers ultimate convenience for customers, defined as buying and selling products/services over the internet. The evolution includes [2][3][4][5][6]:

- **1960s: Electronic Data Interchange (EDI):** Exchanging information (orders, invoices) computer-to-computer to minimize human intervention.
- **1970s-1980s: Teleshopping:** Established by Michael Aldrich for B2B transactions, forming the basis for online shopping. Boston Computer Exchange emerged in 1982 as an online market for used computers.
- **1990s: World Wide Web (WWW):** Created by Tim Berners Lee and Robert Cailliau, making services available on the internet. Amazon and eBay launched in 1995.

- **1990s-2000s: Electronic Funds Transfer (EFT):** PayPal, established in 1998, facilitated online payments, leading to exponential growth in e-commerce sales.

2.1.2 E-commerce Transaction Models: Various models exist, including Business-to-Business (B2B), Business-to-Consumer (B2C), Consumer-to-Consumer (C2C), Consumer-to-Business (C2B), Business-to-Administration (B2A), and Consumer-to-Administration (C2A). E-commerce can be viewed from service, online, communication, and business process perspectives.

2.1.3 E-commerce Applications: These extend the perspectives and include:

- **Electronic Marketing (EM):** Marketing products/services via the internet using smart devices, offering a cost-effective global reach. Channels include email, social media, video, SMS, and website marketing (leveraging SEO). EM involves customers, competitors, and suppliers. Benefits include targeted reach, cost-effectiveness, measurable results, personalization, and global reach [3].
- **Electronic Advertising (EA):** Online advertising using internet devices to generate sales. Types include wallpaper, pop-up, and floating advertising. 'Cookies' help target relevant ads. Benefits include targeted reach, real-time tracking, global reach, and interactive content [7].
- **Electronic Customer Support Service (ECSS):** Online assistance contributing to brand loyalty. Channels include chat (including chatbots), email, social media, and AI/automation for FAQs. Benefits include improved service quality, faster response times, cost-effectiveness, and personalization. Best practices involve being organized, 'me-commerce' (personalized approach), customer reviews, and prompt responses [3].
- **Electronic Order and Delivery (EOD):** The entire online purchase transaction process. It reduces lead times through departmental integration. EDI systems automate online orders and invoicing. Efficient delivery includes electronic proof of delivery (e-POD). EOD also includes product tracking [1].
- **Electronic Payment Systems (EPS):** Eliminates cash/check payments, involving capital transactions via electronic devices. Includes electronic cash and credit systems (credit cards, e-wallets, direct debit, e-check). EPS can increase financial inclusion and economic growth but faces challenges like privacy concerns and cryptocurrency stability. It represents a shift towards a cashless economy [8].

2.2 Organisational Performance (OP) OP is the comparison of actual outputs to planned outputs, goals, or objectives. Initially focused on financial measures, recent studies include non-financial measures linked to long-term operational goals. OP can be seen as how people with a common goal efficiently perform a function, or as dependent on design quality and relationships within the organisation. Key sub-constructs for this study include:

- **Quality of Leadership:** A process where a leader motivates a team towards a goal. Future leadership skills involve embracing transformation, fostering collaboration, encouraging creativity, capacity building, and empowering team members [9].
- **Employee Satisfaction:** Employees being happy and fulfilled at work is a prerequisite for productivity and quality. It correlates positively with job performance. Compensation, rewards, education, and training influence satisfaction and SMME success [10].
- **Customer Satisfaction:** The outcome felt when an organisation's performance meets or exceeds expectations, linked to loyalty and retention (e.g., ACSI model). It applies to both internal and external customers. Strategies include complaint resolution (compensation, contrition, complaint-recovery process), feedback, guarantees

(unconditional, meaningful, understandable, communicable, painless to invoke), and corrective action [11].

- **Product/Service Quality:** Ability of a product to meet/exceed customer expectations. Garvin's eight dimensions of product quality are performance, features, reliability, conformance, durability, serviceability, aesthetics, and perceived quality. PZB's service quality dimensions are tangibles, service reliability, responsiveness, assurance, and empathy (measured by SERVQUAL). Employee training is crucial for service quality [12].
- **Supplier Performance:** Integrated supply chains allow real-time information sharing. Local suppliers can offer smaller batches and shorter lead times. Advantages of local suppliers include shorter lead times, face-to-face interaction, inventory efficiency, and no import tax. Disadvantages include potential quality issues, limited capacity, biased selection, and higher costs. Supplier development (identifying essential products/suppliers, forming teams, meeting management, identifying projects, defining agreements, and monitoring) improves performance [13].
- **Quality Improvement (QI):** A systematic approach to evaluate performance and establish improvements, focusing on process failures. Key variables identified by quality gurus include leadership, employee improvement, quality assurance, customer role, and philosophy. Juran emphasizes reducing customer-related problems [14].
- **Technology Orientation:** An organisation's capability to embrace and integrate new technologies. It promotes effective learning and innovation. ICT supports business activities and connects functional areas, increasing output, productivity, and profits. It can lead to increased market responsiveness and supply chain flexibility [15].

2.3 The Relationship Between E-commerce Applications and OP

The literature suggests distinct relationships between specific e-commerce applications and dimensions of organisational performance, as detailed below. E-commerce positively influences OP by enhancing information flow regarding customers, markets, suppliers, and competitors. Studies show e-commerce applications boost operational efficiency, financial results, and market competitiveness in SMMEs. E-commerce applications cover trading aspects from marketing to after-sales support, using ICT to facilitate operations and connect functional areas. Big Data Analytics (BDA) in e-commerce catalyses performance improvement. Organisational commitment mediates this relationship; a strong dedication to e-commerce enhances performance. Technological readiness and management characteristics are important. Employee engagement and well-being are pivotal. E-commerce adoption allows SMMEs access to wider markets and operational flexibility. However, challenges like low computerization, high technology costs, and internet security concerns persist, especially in developing countries [16][17] [18].

- *EM and OP:* Adoption of EM helps reach global markets and larger customer groups. It improves engagement and reduces costs compared to traditional marketing. Internet usage for daily operations increases EM performance. Social media influences online purchases [1].
- *EA and OP:* Effective marketing strategies, including EA, positively impact OP by improving business capabilities and customer engagement. EA can indirectly boost performance by elevating employee morale and dedication. Training in EA enhances productivity and efficiency. Effectiveness depends on technology orientation [19].
- *ECSS and OP:* Benefits include automated routine procedures and easily updated technical information. Customers prefer cost-effective, personalized, convenient, fun, prompt, and self-serviceable shopping. Personalization increases customer satisfaction and sales. Online complaint resolution saves time and costs [1].

- *EOD and OP:* EOD improves efficiency, service quality, and customer satisfaction. It can be used as an inventory cost and availability strategy, keeping customers informed. E-commerce reduces inventory levels (JIT approach). Advanced order processing improves delivery speed and accuracy. EOD streamlines delivery by automating order management and optimizing routes, enhancing service quality and customer satisfaction [20][21].
- *EPS and OP:* EPS quality directly impacts customer satisfaction and OP. EPS enhances customer experience, boosts operational efficiency, improves cash flow, and reduces transaction times. They simplify financial transactions, increasing productivity and reducing errors. Digital e-payment services positively impact business performance. Transitioning to EPS improves service delivery and financial sustainability for SMMEs. EPS empowers SMMEs to compete effectively. Challenges like system downtimes and trust issues can impact performance [21][22].

2.4 The Implementation of E-commerce in SMMEs: In the Clothing and Textile Manufacturing Sector

Post-apartheid, South Africa's manufacturing sector struggled globally. 4IR technologies offer a competitive advantage. Many SMMEs in eThekwini are internet-connected, but technology orientation is key. The COVID-19 pandemic accelerated e-commerce adoption, providing an entry point for SMMEs in the C&T sector [24].

Factors limiting adoption: Many customers and suppliers do not use e-commerce. Unreliable telecommunications and cybersecurity are major concerns. Lack of consumer trust due to parcel theft, high data costs, fraud, and last-mile delivery challenges hinders adoption in SA. SMMEs often lack knowledge of or access to government funding and possess insufficient innovation, skills, and expertise. Minimal education and training contribute to C&T SMME failure. Online stores can be unprofitable and expensive to maintain if resources are not allocated to user-friendly digital interactions [1][2].

3 METHODOLOGY

This study utilises a mixed-methods approach. Qualitative data was collected through semi-structured interviews, and quantitative data was collected through questionnaires. The interviews helped to understand employees' perspectives and comprehension of e-commerce applications. The questionnaires were used to define the relationship between e-commerce applications and OP, as well as to explore the level of implementation of e-com applications in SMMEs.

The questionnaires were pre-tested using a pilot study to determine their reliability and validity. The reliability of the questionnaires was assessed using Cronbach’s Alpha Coefficient.

The hypotheses were tested using multiple regression analysis. A t-test was used to determine the differences in the application of e-commerce solutions between online and traditional SMME clothing manufacturing organisations.

3.1 Population and Sampling

The target population was 2500 clothing manufacturing SMMEs in Gauteng. A sample size of 150 participants (75 from online stores, 75 from traditional stores) was deemed feasible and sufficient for robust comparative analysis. 15 managers/owners were interviewed.

- *Sampling Methods:* A non-random, voluntary response method was used for questionnaires (participants clicked a Google Form link on social media). Simple

random sampling was used to select 15 interviewees from questionnaire respondents who volunteered their contact details (owners/managers).

- *Quantitative Data Analysis:* Analysed using SPSS. Descriptive statistics (charts, tables, graphs) summarized characteristics from questionnaires and interviews. Correlation analysis tested hypotheses and determined relationships between variables. Regression analysis described relationships by fitting a line to experimental data.
- *Comparative Analysis using T-test:* Used to identify differences in e-commerce application between online and traditional SMMEs.

3.2 Justification of sample size

Quantitative Sample (N=150): A total of 150 participants successfully completed the questionnaire. This sample size is considered robust for the intended statistical analyses. According to guidelines for quantitative research, a sample size of N=82 is sufficient to detect a moderate effect size in a correlational design with 80% statistical power at a 5% significance level. Therefore, the achieved sample of 150 provides more than adequate power for the multiple regression analysis performed in this study, strengthening the reliability of the quantitative findings.

Qualitative Sample (N=15): The qualitative sample consisted of 15 owners or managers who participated in semi-structured interviews. This sample size was deemed appropriate based on the principle of **thematic saturation**. Thematic saturation is the point in data collection when new interviews no longer generate new insights or themes, indicating that the data set is sufficiently rich to address the research questions. Peer-reviewed studies suggest that for research involving a relatively homogenous population—in this case, owners/managers of C&T SMMEs within a specific geographic and industrial context—saturation is often achieved with a sample size of 9 to 17 participants. Therefore, a sample of 15 was determined to be sufficient to achieve the necessary depth and informational redundancy for a rigorous qualitative analysis without being so large as to impede a deep, case-oriented analysis.

3.3 Quantitative data analysis

The quantitative data collected via the questionnaires were analysed using the Statistical Package for the Social Sciences (SPSS). The analysis involved several stages:

- **Descriptive Statistics:** Frequencies, means, and standard deviations were calculated to summarise the sample characteristics and responses.
- **Reliability Analysis:** Cronbach's Alpha coefficient was calculated for each construct to assess the internal consistency and reliability of the measurement scales.
- **Correlation Analysis:** Pearson's correlation coefficient was used to examine the strength and direction of the relationships between the e-commerce applications and OP.
- **Multiple Regression Analysis:** A multiple regression model was developed to test the hypotheses and determine the extent to which the e-commerce applications could predict OP.
- **Independent Samples T-test:** A t-test was conducted to compare the mean usage of e-commerce applications and the mean OP scores between online-based and traditional clothing stores.

3.4 Qualitative data analysis

The qualitative data from the 15 semi-structured interview transcripts were analysed using **qualitative content analysis**. This method was selected for its systematic and rigorous approach to condensing large volumes of text into meaningful categories or themes based on

valid interpretation. The analysis followed an inductive process, allowing themes to emerge directly from the data. The specific steps were as follows:

1. **Data Familiarisation:** All 15 interview transcripts were read and re-read multiple times to gain a deep and holistic understanding of the content.
2. **Inductive Coding:** The transcripts were systematically coded. Key concepts, ideas, and experiences related to e-commerce adoption and its impact were identified and labelled with descriptive codes.
3. **Theme Development:** Related codes were grouped to form broader, overarching themes. This involved a process of constant comparison, where codes and developing themes were compared across all transcripts to ensure consistency and coherence.
4. **Interpretation:** The final themes were analysed to understand the relationships between them and to develop explanations for the phenomena observed in the study. This interpretive step focused on uncovering the underlying meanings and patterns in the participants' experiences.

4 RESULTS AND FINDINGS

4.1 Description of the Study Sample

- *Education Level:* 29.3% held postgraduate degrees, 24.7% undergraduate degrees, 22% certificates/diplomas, 14% matric, and 10% had not acquired matric. This indicates a highly educated sample (54% with higher education) but also a 10% gap in secondary education completion.
- *Size of Organisation:* 69.3% micro-sized (0-10 employees), 22.7% small-sized (11-50), and 8% medium-sized (51-250). Majority are micro-enterprises, suggesting new or non-growing businesses.
- *Age of Respondent:* Majority aged 28 (20%), followed by 40 (7.3%). This suggests clothing manufacturing SMMEs comprise young adults, potentially impacted by high unemployment.
- *Years Working in Enterprise:* Majority had not been in the industry for more than two years (18% for two years, 13.33% for one year). 12% for 3-4 years, 10% for five years. Few worked beyond five years, possibly indicating low survival rates for SMMEs past this mark.
- *Respondent's Position:* 60.7% owners, 16% production (seamstress), 15.3% managers, and 7.9% in other roles (sales, student, designer, intern, marketing, quality supervisor). Few positions directly support efficient e-commerce use.
- *How Organisation is Based:* 43% online, 38% traditional stores, 18.7% hybrid.

4.2 Descriptive Measures – Constructs

- *Electronic Marketing (EM):*
    - 49.4% disagreed they don't send marketing emails; 40.7% agreed.
    - 80% agreed to using social media for product awareness/brand loyalty.
    - 42.7% disagreed with using video marketing; 40.6% agreed.
    - 38.6% disagreed with online information sharing with competitors; 34% agreed.
    - 78% agreed customers/suppliers communicate via contact sales offices.

- *Electronic Advertising (EA):*
    - 64% agreed websites are used for advertising.
    - 63.3% disagreed with using pop-up advertising.
    - 57.3% disagreed with using floating advertising.
    - 76% agreed majority of advertising is via internet devices.
    - 82% agreed products on sale are posted on social media.
- *Electronic Customer Support Service (ECSS):*
    - 74% agreed online assistance is seamless/easy.
    - 45.3% disagreed that FAQ responses are kept uniform; 42% agreed.
    - 84% agreed a personalized approach to customer communication is offered.
    - 48.7% disagreed a reviews page is offered; 43.3% agreed.
    - 68% agreed the organisation is active online for prompt responses.
- *Electronic Order and Delivery (EOD):*
    - 72.7% agreed an online catalogue is available.
    - 80% agreed customers place orders via online platforms.
    - 77.4% agreed delivery services are available at checkout.
    - 50% agreed orders can be tracked online; 46.7% disagreed.
    - 44.6% agreed deliveries are recorded using ePOD; 41.3% disagreed.
- *Electronic Payment System (EPS):*
    - 49.3% disagreed with using mobile payment apps (PayPal, etc.); 42.6% agreed.
    - 62% agreed to using cash send or e-wallets.
    - 88% agreed to using direct bank deposits.
    - 75.3% agreed to using cash on delivery.
    - 83.3% agreed to using ATM deposits.
- *Organisational Performance (OP):*
    - 58.7% agreed the organisation has set clear long-term performance goals.
    - 52.6% agreed outputs are measured against planned outputs.
    - 68% agreed a CRM strategy is used.
    - 60.6% agreed quality improvement strategies are in place.
    - 86.7% agreed the organisation ensures on-time delivery.

4.3 Reliability Analysis Cronbach's Alpha coefficients for all e-commerce applications and OP were > 0.60, indicating favourably good reliability for the study in Table 1.

Table 1: Cronbach Alpha Coefficient

E-Commerce Application	Cronbach's Alpha
EM	0.768
EA	0,725
ECSS	0,744
EOD	0,753
EPS	0,642
Organisational Performance	**Cronbach's Alpha**
OP	0,827

4.4 Correlation Analysis Pearson's correlation (Table 2) indicated moderately positive impacts on OP for four e-commerce applications and a moderately negative effect for one. Significant correlations with OP:

- EM: r = 0.618, p = 0.00 (stronger moderate)
- EA: r = 0.401, p = 0.00 (moderate)
- ECSS: r = 0.463, p = 0.00 (moderate)
- EOD: r = 0.492, p = 0.00 (moderate)
- EPS: r = -0.434, p = 0.00 (moderately negative).
- Significant correlations also existed between e-commerce applications (e.g., EA and EM: r = 0.602; ECSS and EOD: r = 0.728).

Table 2: Correlation matrix

		Organisational Performance	E-Marketing	E-Advertising	E-Customer Support Service	E-Order and Delivery	E-Payment System
Organisational Performance	r	1.000	0.618	0.401	0.463	0.492	-0.434
	p	*0.00	*0.00	*0.00	*0.00	*0.00	*0.00
E-Marketing	r	0.618	1.000	0.602	0.610	0.660	-0.387
	p	*0.00	*0.00	*0.00	*0.00	*0.00	*0.00
E-Advertising	r	0.401	0.602	1.000	0.559	0.676	-0.298
	p	*0.00	*0.00	*0.00	*0.00	*0.00	*0.00
E-Customer Support Service	r	0.463	0.610	0.559	1.000	0.728	-0.281
	p	*0.00	*0.00	*0.00	*0.00	*0.00	*0.00
E-Order and Delivery	r	0.492	0.660	0.676	0.728	1.000	-0.309
	p	*0.00	*0.00	*0.00	*0.00	*0.00	*0.00
E-Payment System	r	-0.434	-0.387	-0.298	-0.281	-0.309	1.000
	p	*0.00	*0.00	*0.00	*0.00	*0.00	*0.00

4.5 Regression Analysis

This method estimated how changes in OP are associated with e-commerce applications.

4.5.1 Regression Model Summary

The correlation coefficient (R) was 0.633, indicating a relatively high positive correlation between variables. The R-squared (R^2) value was 0.440, meaning the model explains 44% of the variance in OP.

Table 3: Regression model

Model Summary[b]				
Model	R	R Square	Adjusted R Square	Std. Error of Estimate
1	0.633[a]	0.440	0.421	0.68948
a. Predictors: (Constant), EPS, ECSS, EA, EM, EOD				
b. Dependent Variable: OP				

4.5.2 ANOVA Test

The regression model significantly predicted OP (Sig. = 0.00, which is < 0.05). This indicates the model is a suitable fit for the dataset.

Table 4: ANOVA results

ANOVA[a]						
Model		**Sum of Squares**	**Df**	**Mean Square**	**F**	**Sig.**
1	**Regression**	53.812	5	10.762	22.640	0.00[b]
	Residual	68.455	144	0.475		
	Total	122.267	149			
a. Dependent Variable: OP						
b. Predictors: (Constant), EPS, ECSS, EA, EM, EOD						

4.5.3 Coefficients

Table 5: Regression coefficients and equation

Model		**Unstandardized Coefficients**		**Standardized Coefficients**	**t**	**Sig.**
		B (β)	**Std. Error**	**Beta**		
1	**(Constant)**	2.709	0.469		5.774	0.00
	E-Marketing	0.423	0.087	0.443	4.859	0.00
	E-Advertising	-0.047	0.085	-0.048	-0.548	0.585
	E-Customer Support Service	0.081	0.094	0.081	0.857	0.393
	E-Order and Delivery	0.103	0.105	0.106	0.988	0.325
	E-Payment System	-0.254	0.078	-0.222	-3.267	0.001

EA (t = -0.548) and EPS (t = -3.267) did not significantly contribute to OP variation and were excluded from the final model equation. The estimated regression model:

$$y\ (OP) = 2.709 + 0.423(x_1) + 0.081(x_3) + 0.103(x_4)$$

Where:

OP = Organisational Performance

x_i = Relates to each element

i = 1, 2,3,4,5

x_1 = E-Marketing

x_2 = E-Advertising

x_3 = E-Customer Support Service

x_4 = E-Order and Delivery

x_5 = E-Payment System

Therefore,

a) For each unit increase in the EM variable, an increase of (0.423) units in OP are anticipated, assuming all other independent variables remain constant.
b) For each unit increase in the ECSS variable, an increase of (0.081) units in OP are anticipated, assuming all other independent variables remain constant.
c) For each unit increase in the EOD variable, an increase of (0.103) units in Organisational Performance are anticipated, assuming all other independent variables remain constant.

The beta (ß) coefficient presented in Table 23 outlines the values utilized in the regression equation that predicts the dependent variable from the independent variable. EM (independent variable) exhibits the highest beta (ß) coefficient of 0.423, indicating that a one standard deviation increase in EM is associated with a 0.423 standard deviation increase in Organisational Performance. Likewise, the other positive beta (ß) coefficients concerning ECSS (0.081) and EOD (0.103) suggest that a one standard deviation increase in any of these beta (ß) coefficients would result in a standard deviation increase in OP. It is evident that EM (4.859) significantly affects OP, as focusing on online marketing of products and services, is crucial in reaching global markets by attracting and engaging with customers or clients.

4.5.4 Hypothesis Testing

All five hypotheses were accepted based on p-values < 0.05, though the interpretation should consider the coefficient signs from the regression output.

Table 6: Hypothesis

Hypothesis	R	R-Squared	p-value	Decision
H_1	0.618	0.382	0.000	Accepted H_1
H_2	0.401	0.161	0.000	Accepted H_2
H_3	0.463	0.214	0.000	Accepted H_3
H_4	0.492	0.243	0.000	Accepted H_4
H_5	0.434	0.189	0.000	Accepted H_5

4.6 Comparative Analysis of Online and Traditional Stores

Table 7: T-TEST analysis

	Online store		Traditional Store		
	N = 65		N = 57		
Electronic commerce Applications	Mean	Standard deviation	Mean	Standard deviation	Mean differences
E-Marketing	3.5385	0.71320	2.6351	0.88085	0.9034
E-Advertising	3.7415	0.73716	2.6386	0.86968	1.1029
E-Customer Support Services	3.9015	0.52455	2.8526	0.99249	1.0489
E-Order and Delivery	3.8585	0.58280	2.7684	0.98908	1.0901
E-Payment System	3.8962	0.74594	4.0132	0.75211	-0.117
	Mean	Standard deviation	Mean	Standard deviation	Mean differences
Organisational Performance	3.6246	0.93575	3.4737	0.90288	0.1509

Both online and traditional stores use e-commerce applications. Largest mean differences (online > traditional) were in EA (1.1029), EOD (1.0901), and ECSS (1.0489), suggesting greater commitment in online-based organisations. EPS was used more in traditional stores (mean difference -0.117), aligning with findings of limited trust in online payment systems. OP in online organisations differed from traditional stores (mean difference 0.1509), suggesting e-commerce use impacts OP.

4.7 Analysis of Semi-Structured Interviews

Interviews with 15 owners/managers explored e-commerce knowledge and use. Data was analysed using content analysis.

- 35% of organisations did not know what e-commerce applications were or their purpose.
- 65% were aware of individual functions rather than umbrella terms (EM, EA, etc.).
- Traditional stores often viewed competitors as colleagues and didn't see information sharing as a threat, unlike online organisations.
- Most were familiar with EM, EOD, ECSS, and some EPS (cash payments preferred for safety). This shows fair awareness but a lack of confidence in full e-commerce benefits and security.
- A key reason traditional stores lacked interest in order/delivery was past issues with online material colour discrepancies leading to returns; they prefer in-store material viewing.
- Online organisations preferred immediate payment methods (e.g., deposits before manufacturing) over cash on delivery due to risks of refusal or payment issues upon delivery.
- Both store types found online marketing brought new business.
- However, the labour-intensive nature of clothing manufacturing meant daily EA, ECSS, and EOD tasks became overwhelming for small staff numbers, discouraging reaching large audiences they couldn't manage efficiently.

4.7.1 Thematical analysis

Theme 1: Social Media as the Primary Gateway to E-commerce

A dominant theme was the overwhelming reliance on social media platforms (primarily Instagram, Facebook, and WhatsApp) as the main tool for electronic marketing. For most SMMEs, particularly the micro-enterprises, social media was not just a marketing channel but their entire e-commerce ecosystem. It was perceived as a low-cost, accessible entry point to reach new customers. One participant stated, *"Everything happens on Instagram. That's where we post new designs, talk to customers, and even take orders. We don't have a proper website... it's too expensive to maintain"*. This explains the strong positive impact of EM on OP, as it represents the most widely adopted and central e-commerce activity for these businesses.

Theme 2: Deep-Seated Distrust in Electronic Payment Systems

This theme directly addresses the counter-intuitive negative correlation between EPS and OP. Participants expressed significant apprehension regarding online payment systems, citing issues of security, fraud, and high transaction fees. Many customers were also described as being wary of paying online. As a result, many SMMEs, including those operating primarily online, still rely heavily on traditional payment methods. A common practice was to take orders online but arrange payment via direct bank deposit (EFT) or even cash on delivery. An owner of an online store explained, *"We tried a payment gateway, but the fees were killing our margins. Additionally, customers fear putting their card details online. They prefer to do an EFT. It's safer for everyone"*. This preference for methods outside of integrated EPS creates administrative burdens and cash flow challenges, turning what should be an efficiency driver into a point of friction, thus explaining its negative impact on performance.

Theme 3: Operational Overload as a Barrier to Scale

While SMMEs embraced social media for marketing, they often felt overwhelmed by the operational demands that came with increased online visibility. The tasks of managing daily electronic advertising, providing constant electronic customer support, and processing electronic orders and deliveries were described as immensely time-consuming for small teams or sole proprietors. One manager noted, *"You post something nice, and suddenly you have 50 DMs [direct messages] asking for prices, sizes, colours... You spend the whole day just replying to messages instead of making the clothes. We can't handle a huge audience"*. This operational strain explains why applications like EA, ECSS, and EOD, while positively correlated with OP, did not emerge as significant predictors in the regression model. Their benefits are often offset by the capacity constraints of the micro-enterprises, preventing them from being leveraged strategically for growth.

4.8 Summary of Findings

- *Descriptive Analysis:* The SMME landscape in this sector is characterized by highly educated individuals, often owners in their late twenties/early forties, managing micro-sized enterprises with limited industry experience (often <2 years). This reflects South Africa's unemployment challenges and the rise of youth entrepreneurship. Business survival appears challenging beyond five years. Mean scores for e-commerce application usage and OP dimensions were above the midpoint of the Likert scale, suggesting accurate representation by the constructs.
- *Impact of E-commerce on OP:* Correlation and regression analyses revealed that EM, ECSS, and EOD have a significant positive impact on OP. EA showed a positive correlation but not a significant independent impact in the regression. EPS demonstrated a significant negative correlation with OP, likely due to customer trust issues with online payments in South Africa.
- *Knowledge and Adoption:* Interviews showed varied knowledge levels; many understand specific functions but not broader strategic applications. Awareness existed, but confidence in the benefits and security of full e-commerce suites was lacking. Operational burdens and specific industry concerns (e.g., product returns) also limit adoption.

5 CONCLUSION

This study investigated the impact of five e-commerce applications on the organisational performance of clothing manufacturing SMMEs in Gauteng. The findings confirm that e-commerce has a significant, albeit complex, influence. The quantitative analysis established that Electronic Marketing (EM) is a strong positive predictor of OP, while Electronic Payment Systems (EPS) are a significant negative predictor. The other applications—EA, ECSS, and EOD—were positively correlated with OP but did not emerge as significant independent predictors in the regression model, suggesting their impact is constrained.

The study's primary contribution lies in its use of a mixed-methods approach to explain these results. The qualitative findings revealed that the positive impact of EM is driven by the widespread, low-cost use of social media, whereas the negative impact of EPS is a direct result of a lack of trust, security concerns, and high costs, which force SMMEs into inefficient manual workarounds. The limited impact of other applications is attributed to the operational overload experienced by resource-constrained micro-enterprises. Ultimately, the research demonstrates that e-commerce adoption in this context is largely tactical and fragmented, preventing the full realisation of its strategic benefits.

ABSTRACT

Efficient transport logistics are crucial in the pharmaceutical industry to ensure the timely and secure delivery of vital products. This paper presents an exploratory case study on the application of Power BI, a business intelligence (BI) tool, as a technological enabler for Business Process Re-engineering (BPR) within the transport logistics of a leading South African pharmaceutical company. The study identifies key logistical challenges, including route inefficiencies, delivery delays, and the absence of supply chain transparency. Using a qualitative methodology, this research draws on semi-structured interviews with key stakeholders who use the company's Power BI dashboard. The findings indicate that the BI dashboard provides significant perceived benefits in performance monitoring, operational visibility, and compliance tracking. However, its full potential is constrained by challenges related to data scalability, user adoption, and the need for more advanced predictive capabilities. The study concludes that while Power BI is a powerful tool, its successful implementation as a cornerstone of BPR requires a strategic approach that integrates technology with process redesign, addresses human factors through change management, and establishes robust data governance.

Keywords: Power BI, transport logistics, Business Intelligence, Business Process Re-engineering

1 INTRODUCTION

The pharmaceutical industry is facing mounting pressure to optimize operations and decision-making processes in transportation logistics [1]. The cold chain presents unique challenges, including the need for precise temperature control and the ability to identify potential disruptive events. These challenges were magnified by the COVID-19 pandemic, leading to issues such as loss of vaccinations and damaged inventory [2]. The integration of advanced technologies like Power BI shows promise in addressing these challenges [3]. A pharmaceutical Company has implemented a Power BI dashboard to enhance logistics operations.

1.1. Aim of study

This study aims to explore how Power BI can transform and improve transport logistics within the pharmaceutical industry by integrating all the systems that are used in logistics.

1.2 Research Objectives

- To analyse the current challenges and inefficiencies in transport logistics within the industry.
- Investigate the technical and architectural aspects of integrating systems with Power BI.
- To streamline operations, reduce costs, and ensure the safe and timely delivery of pharmaceutical products.

2 LITERATURE REVIEW

2.1 Business Process Re-engineering in Supply Chain Logistics

Business Process Re-engineering (BPR) offers a framework for achieving radical, rather than incremental, improvements. BPR advocates for redesigning processes from a cross-functional perspective to increase efficiency and effectiveness. In logistics, this can involve re-engineering processes like order fulfilment, route planning, and inventory management. The successful application of BPR in logistics has been shown to lead to significant reductions in cycle times, improved delivery accuracy, and lower operational costs. Information Technology (IT) is widely recognized as a critical enabler of BPR, as it allows companies to break old rules and create new ways of organizing work [13][20].

2.2 4IR and Power BI

4IR refers to the current era of digital transformation in manufacturing and business [4].The 4th Industrial Revolution (4IR) is driving digital transformation in manufacturing and business, fuelled by trends like data growth and robotics advancement [5]. Power BI dashboard aligns with 4IR's focus on data-driven automation, AI, Internet of Things, and innovation, with the potential to completely transform the logistics and transportation industry [6]. It provides access to logistical data, optimizing transport operations effectively. Power BI enhances transportation planning through improved visibility, high-quality data, and analytics [6][13].

2.3 Supply Chain

A supply chain encompasses all stages involved in delivering a finished product to a customer [7]. It begins with raw material producers and ends with the delivery of finished products. An optimized supply chain leads to a more efficient production cycle and reduced costs, making supply chain management essential [8]. Businesses must streamline their supply chain to save expenses and maintain competitiveness [8]. While logistics is often used interchangeably with supply chain management, it is just one link in the chain. Logistics involves the planning, management, and transportation of products and services from their origin to their destination, ensuring timely and undamaged delivery at every stage, thus reducing costs for the business [9].

2.4 The Role of Business Intelligence as a BPR Enabler

Business Intelligence (BI) refers to the technologies, applications, and practices for the collection, integration, analysis, and presentation of business information. The purpose of BI is to support better business decision-making. Power BI is a prominent analytics tool that enables organizations to visualize data and share insights [13][21][22].

In a BPR context, BI systems serve as a powerful enabler by:

- **Providing Process Visibility:** BI dashboards can consolidate data from disparate systems (e.g., ERP, CRM, fleet management) to provide a holistic, real-time view of logistics operations. This visibility is the first step toward identifying bottlenecks and areas for redesign.
- **Facilitating Performance Measurement:** BPR is a results-driven methodology. BI dashboards are instrumental in tracking Key Performance Indicators (KPIs) before, during, and after a re-engineering project, allowing for data-driven evaluation of the impact of changes. Common logistics KPIs include on-time delivery rates, fuel costs, fleet utilization, and order accuracy.
- **Supporting Data-Driven Decision-Making:** By transforming raw data into actionable insights through visualizations and analytics, BI empowers managers to move from intuition-based to evidence-based decision-making, a cornerstone of successful BPR. The AI and machine learning capabilities within modern BI tools can further enhance this by enabling predictive analytics for demand forecasting and route optimization.

The integration of data is achieved through an Extract, Transform, Load (ETL) process [16][17], as shown in Figure 1. Data is extracted from various sources, transformed (cleansed and standardized), and loaded into a data warehouse, which serves as a central repository for analysis and reporting through BI systems.

2.5 Power BI

The transportation aspect of distribution and logistics is essential in maintaining cost-effectiveness and performance standards [10]. Fluctuations in fuel prices have a significant impact on the transportation industry. To stay competitive, organisations must track and understand their data and performance indicators [10]. Business Intelligence technology aids in data analysis and decision-making. Power BI reports offer insights into profit and loss, fleet performance and help address common challenges in transport logistics such as fuel costs, fleet maintenance and driver shortages [11].The system has features like slicers, graphs and filters, enabling specific data access based on time and geographic [12]. Power BI reports also help identify common challenges like fuel costs, cost of fleet maintenance and labour shortages [11].

In the pharmaceutical sector, big data and digitization drive industry evolution, with successful businesses adopting advanced and AI-driven solutions [13]. Power BI's AI capabilities facilitate machine learning models for improved traffic and weather predictions, offering practical KPIs and supply chain optimization [11]. The system's versatility allows for mobile integration, data sharing, and visibility improvements across teams [14].Power BI dashboard plays a crucial role in ensuring temperature-controlled transport of pharmaceutical products and contributes to environmental sustainability through the adoption of green technologies and IoT in supply chain management [14]. The IoT is being utilised in supply chain management, enhancing decision-making transparency and operational effectiveness [15]. It allows real-time tracking and monitoring, ensuring all products are traceable and allowing for on-the-go adaptation to keep customers satisfied ([15].

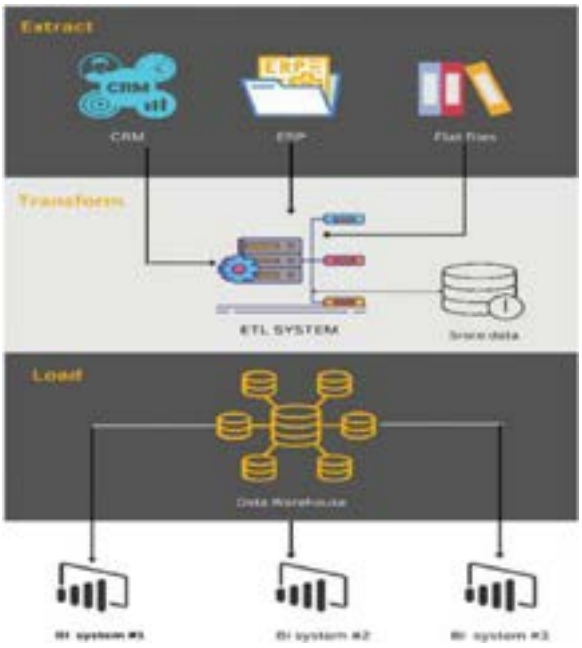

Figure 1: ETL process [13]

The ETL (Extract, Transform, Load) process, as shown in Figure 1, encompasses the data source, data warehouse and end user. Internal data source involves information obtained from operational systems like ERP and CRM, covering customers, products and sales data [13].Data extraction involves retrieving data from multiple sources, which may be incomplete or duplicated, requiring cleansing and transformation before staging [16]. The data warehouse serves as a repository for collecting and storing information that is utilized for strategic planning, querying and analysis [17]. It stores both aggregated and historical data for long-term analysis [17].

The dashboard uses ETL to integrate data from multiple sources, allowing for easy data visualization and analysis. However, Pharmaceutical Company X faces risks such as reliance on external consultants, cultural and procedural changes, and data security and privacy concerns. Recommendations for Pharmaceutical Company X BI stakeholders include real-time automated alarms and notifications, predictive analysis and machine learning for demand forecasting and risk management, mobile access for real-time data monitoring, a clear data visualization layout, and automatic notifications for non-users.

3 METHODOLOGY

The researcher employs research union methodology which is a multi-layered approach designed that help researchers understand the complexity of various research methods and their interrelationships [18]. It consists of different layers, each representing a different aspect of the research process. The layers include philosophy, approach, strategy, choice, time horizon and techniques [19]. The research employs a qualitative methodology. The study population consisted of sixty-one stakeholders within Pharmaceutical Company X who were identified as having access to and being users of the Power BI logistics dashboard.

3.1 Collection of data

Data was collected through in-depth, semi-structured interviews. This method allows for flexibility while ensuring that key topics are covered, enabling the researcher to probe for deeper insights into the participants' experiences, perceptions, and challenges related to the BI dashboard. Due to limitations including staff availability and recent resignations, fourteen

of the targeted sixty-one stakeholders participated in the study, resulting in a response rate of 23%. The responses were digitally recorded and transcribed for analysis.

3.2 Sampling method

The study population consisted of sixty-one stakeholders within Pharmaceutical Company X who were identified as having access to and being users of the Power BI logistics dashboard. A purposive sampling strategy was used to select participants who were best positioned to provide rich information on the research topic based on their roles and experience with the system.

3.3 Analysis of data

The transcribed interview data was analysed using thematic analysis, a method for identifying, analysing, and reporting patterns (themes) within data. The analysis followed a systematic process of data familiarization, generation of initial codes, searching for themes among codes, reviewing themes, defining and naming themes, and producing the final report. This approach allowed for a rich, detailed, and complex account of the data.

4 RESULTS AND FINDINGS

The research design had limitations, such as unavailable coworkers, resigned coworkers and as a result, only fourteen managed to respond to the study and their responses were recorded on form@app. The demographic profile of respondents is shown in Table 1 below.

Table 1: Demographic profile of respondents

Gender	Frequency	Total
Male	7	14
Female	7	
Race		14
Black Africans	12	
Coloureds	1	
Khoisan	1	
Age		14
18-35	9	
36-52	5	
Work experience		14
1-5	9	
6-10	3	
11-15	2	

4.1 Summary of the results derived from the interviews

Figure 3 below shows the main themes identified in the study. The second branches on the diagram represents the main themes. The reviews for these themes are discussed as follows.

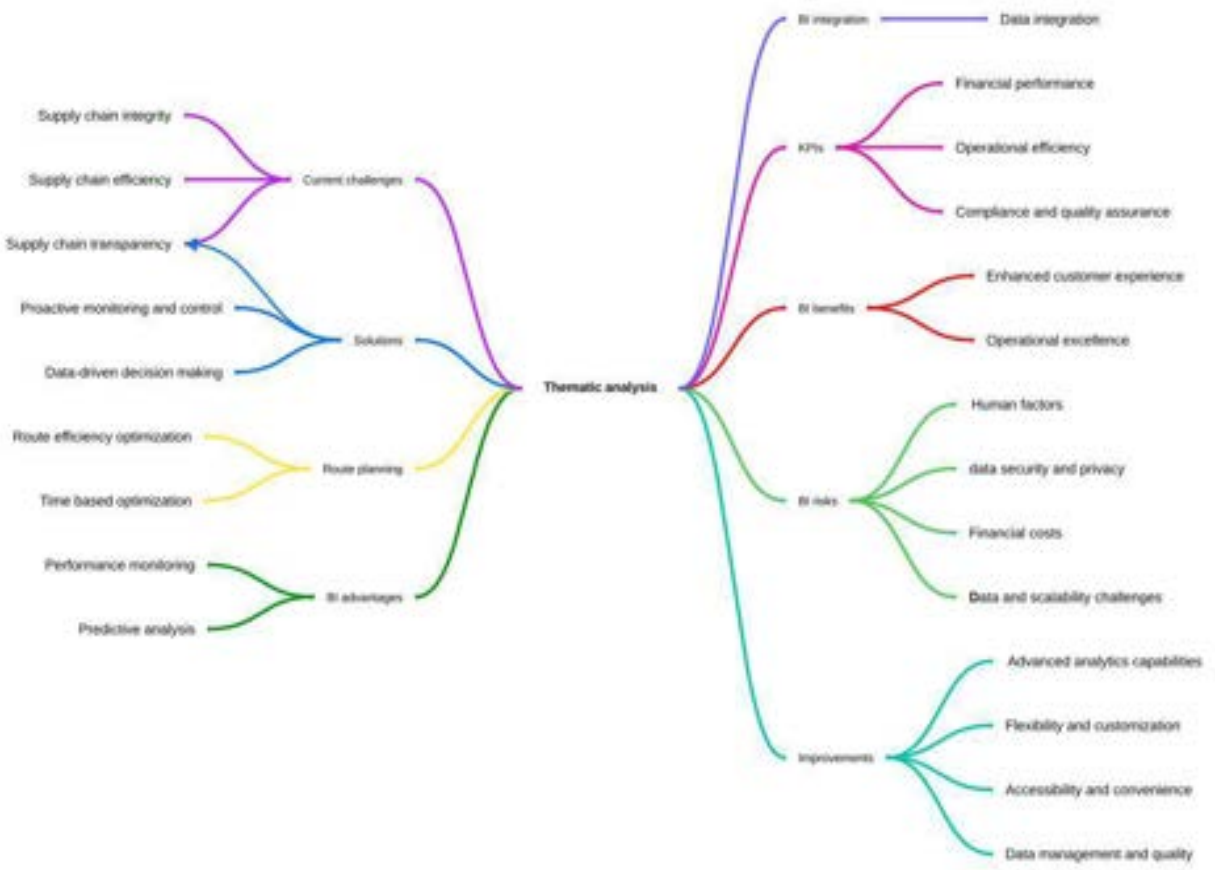

Figure 2: Main themes derived from the study

4.1.1 Current challenges

Three main themes are highlighted in Figure 3, supply chain integrity, supply chain efficiency and supply chain transparency. These challenges harm patient safety, real-time visibility and profitability. Based on Figure 3, the key themes revolve around the multifaceted challenges and solutions in modern logistics and supply chain management. The list highlights a number of critical issues, including a lack of **real-time visibility** into shipments, inefficient processes, and specific industry-related problems like **temperature control** for pharmaceuticals. These challenges can lead to tangible negative outcomes such as **damaged stock**, delivery delays, and security risks like theft. To mitigate these issues, Figure 3 implicitly suggests solutions centered on improving **supply chain visibility**, implementing robust inventory and route management, and ensuring strict **regulatory compliance**. Overall, the summary illustrates a comprehensive view of the operational difficulties faced in logistics and the key areas where process improvement and technology are necessary to increase efficiency and effectiveness.

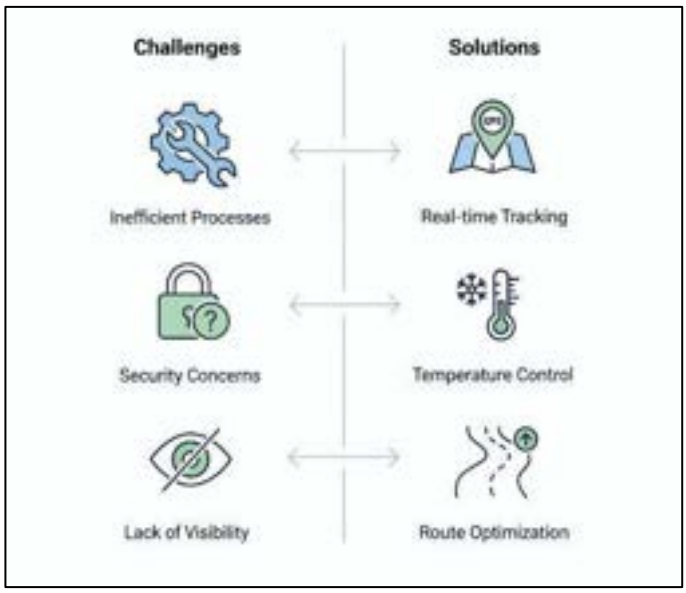

Figure 3: Current challenges and inefficiencies in transport logistics

4.1.2 Solutions

Pharmaceutical logistics can be improved by employing supply chain transparency, proactive and control and data-driven decisions. These themes allow for better monitoring, risk prediction and control which empowers responses to potential disruptions. The key finding in Figure 3 is the critical importance of implementing end-to-end visibility of the supply chain. This overarching concept addresses numerous challenges prevalent in logistics, such as delays, disruptions, and a lack of information regarding the location and condition of goods. Achieving this visibility necessitates the integration of various technologies and processes to provide a comprehensive view from the initial stages of production to the final delivery. By knowing where goods are and under what conditions, organizations can proactively manage risks, optimize routes, improve communication with stakeholders, and ultimately enhance overall efficiency and customer satisfaction. This proactive approach, enabled by complete supply chain visibility, is fundamental for building resilient and responsive logistics operations.

4.1.3 Route planning

Optimal route planning covers two main themes which is route efficiency optimisation and time-based optimisation. Route efficiency optimisation reduces logistics costs and improves supply chain efficiency by minimizing distance, less fuel consumption and increasing load capacity. Time-based optimisation uses time window management and predictive analysis to adjust routes based on delivery time window, traffic patterns and road conditions.

Route planning in Figure 4 is a critical component of logistics, and the provided information highlights several key strategies to optimize this process. The core focus is on leveraging **technology** and data-driven approaches to move from static to **dynamic routing**. Key strategies include using **route optimization software** and algorithms like the Vehicle Routing Problem (VRP) to create efficient, multi-stop routes. This software integrates **real-time data**, such as traffic updates and weather conditions, to allow for on-the-fly adjustments and avoid delays. The ultimate goal is to improve efficiency by maximizing cargo load, reducing the number of delivery attempts, and ensuring on-time delivery, all while managing costs and ensuring vehicle safety. This dynamic approach ensures that logistics operations are not only efficient but also adaptable to unforeseen challenges.

Figure 4: Optimal route planning strategies

4.1.4 BI advantages

BI dashboard offers essential advantages in logistics operations namely, performance monitoring and predictive analysis. BI is used to check and track KPIs in logistics; it stores historical data which is analysed and used to predict future demand or issues.

4.1.5 BI integration

The integration of systems into BI dashboard includes two processes which are data extraction and data transformation. This theme focuses on the ETL process, where data is extracted from different sources such as oracle and excel. The data is cleaned and converted into a usable format for analysis such as bar chart, donut charts and control charts.

4.1.6 Key Performance Indicators

BI measures key performance indicators of logistics operations which are centred around the following themes, operational efficiency, financial performance, compliance and quality assurance. KPIs under operational efficiency includes defect rate, delivery rate and cost per shipments. Financial performance is assessed through profit margin, fuel cost, providing insights into financial health and profitability of supply chain. adherence to regulations and quality control KPIs, such as temperature control compliance, make sure that quality standards and legal requirements are followed, which is especially important in products that are sensitive to temperature changes.

Maintaining **temperature control compliance** is a crucial key performance indicator (KPI) in logistics, directly impacting both **product integrity** and operational **efficiency**. Failure to adhere to required temperature ranges, especially for sensitive goods like pharmaceuticals or certain food products, can lead to spoilage, loss of efficacy, and regulatory penalties. Conversely, consistent and accurate temperature management throughout the supply chain ensures that products reach the end consumer in optimal condition, safeguarding their quality and value. Efficient temperature control also contributes to streamlined operations by minimizing waste and reducing the likelihood of returns or recalls, ultimately enhancing customer trust and business profitability. This KPI serves as a direct measure of a company's ability to maintain quality standards and operational excellence within its supply chain.

4.1.7 BI benefits

The BI benefits are summarised into two main themes, operational excellence and enhanced customer experience. Operational excellence involves streamlining operations, increasing efficiency and reducing costs. Enhanced customer satisfaction is achieved through customer satisfaction, faster delivery and on time delivery.

4.1.8 BI risks

The implementation of BI dashboard has potential risks, four main risks are covered as categorised, human factors, data security, financial cost and data scalability. Risks associated with technical proficiency and change management are considered human factors. Risks associated with protecting sensitive logistics data and ensuring the security and privacy of the logistics data. Certain cost is required to implement the system and for user license fee. The BI dashboard has a lot of different data which needs more storage, the Company must pay for data storage.

4.1.9 BI improvements

Four themes are covered: advanced analytics capabilities, flexibility and customisation, accessibility and convenience, and data management and quality. Enhanced analytics capabilities use real-time data and machine learning which can be used to make forecasts, obtain deeper insights and make well-informed decisions. Users may create customised reports and remove unnecessary data by adjusting the dashboard to meet their unique needs. Users can monitor the operations through mobile applications.

4.2 Thematical Analysis

4.2.1 Theme 1: Current Logistical Challenges

Respondents identified three interrelated challenges that instigated the need for a better solution:

Supply chain integrity – concerns included the risk of product diversion and the critical need to maintain product quality and authenticity, particularly adhering to temperature control regulations.

Supply chain efficiency – issues such as inefficient route planning, delivery delays and suboptimal inventory management were highlighted as key drivers of increased costs and reduced performance.

Supply chain transparency – a significant challenge was the lack of real-time, end-to-end visibility of shipments which hindered proactive problem solving.

Figure 5: Cause and effect diagram of the transportation challenges

Figure 5, a cause-and-effect diagram developed based on participant input, illustrates how various factors across materials, methods, machines, measurement, environment, and people contribute to these transportation issues.

4.2.2 Theme 2: The BI dashboard as a solution

The Power BI dashboard was implemented to address the challenges above by integrating data from various logistics systems. Figure 6 shows the home page of the dashboard used by Pharmaceutical Company X, which provides a high-level overview of key operational areas.

Figure 6: Pharmaceutical Company X's BI Dashboard Home Page

Participants reported that the dashboard provides solutions centered around **performance monitoring** and **data-driven decision-making**. The system enables the monitoring of a wide range of KPIs across different facets of the logistics operation.

Compliance and Equipment: The dashboard tracks employee training and the compliance status of equipment. As shown in Figure 7, users can monitor which equipment is in use, non-compliant, or in need of repair, ensuring adherence to safety and operational standards.

Figure 7: BI dashboard equipment summary

Fleet and Fuel Management: This provides real-time visibility of vehicle status (on-site vs. in-trip) and type. The dashboard also tracks fuel consumption and costs, enabling managers to identify opportunities for cost reduction. It further monitors on-time versus late departures, offering insights into route efficiency and driver performance.

Figure 8: BI dashboard fleet summary

Staff Management: The dashboard provides a comprehensive overview of personnel, including total employees, attendance, overtime, and late arrivals. This allows for better workforce management and productivity tracking.

Figure 9: BI staff management summary

Delivery and Inventory Status: The dashboard tracks key delivery metrics, including the number of delivered vs. undelivered parcels, returns, and total value. This information is crucial for optimizing delivery times, managing inventory levels, and improving customer satisfaction.

Figure 10: BI dashboard delivery details

4.2.3 Theme 3: Perceived benefits of the BI implementation

Respondents highlighted two primary benefits stemming from the dashboard's use:

Operational Excellence: This was achieved by streamlining operations, increasing visibility, and reducing costs. The ability to monitor KPIs in real-time allows for quicker responses to disruptions like temperature deviations or vehicle breakdowns.

Enhanced Customer Experience: This was a result of improved on-time delivery performance and greater transparency, which builds customer trust and satisfaction.

4.2.4 Theme 4: Risks and challenges of BI implementation

Despite the benefits, participants also identified significant risks, categorized into four areas:

Human Factors: A key challenge is ensuring users have the technical proficiency to utilize the dashboard effectively. Change management was also cited as a hurdle, with some resistance to adopting the new system.

Data Security and Privacy: Protecting sensitive logistics and commercial data on the dashboard is a major concern that requires robust security measures. **Financial Costs:** The implementation involves significant costs for software licenses, development, and data storage, requiring a clear return on investment.

Data and Scalability: As the volume of data grows, ensuring the dashboard remains fast and reliable is a critical technical challenge. Maintaining high data quality and integrity is also essential, as poor data leads to inaccurate insights.

5 CONCLUSION

The study explores the potential of Power BI in transforming logistics in the pharmaceutical industry. It focuses on Pharmaceutical Company X, a pharmaceutical organization facing challenges in managing complex supply chains, such as delays and temperature control issues. To address these, Pharmaceutical Company X implemented a BI dashboard that provides visibility, analytics, and insights into supply chain operations. The dashboard tracks employee training compliance, equipment status, temperature system alerts, and risk factors. It also offers insights into fleet operations, facilitating efficient monitoring and cost reduction.

Installing a BI dashboard in a pharmaceutical organisation can result in a variety of benefits, including improved supply chain operations, demand forecasting, and decision making. However, it does provide certain hazards and problems that must be rigorously evaluated. Technical skills, change management, data security and privacy, financial costs, data, and scalability as well as maintaining data quality and integrity, are all significant considerations for enterprises when establishing a BI dashboard. Understanding and minimizing these risks can help to achieve a successful implementation that increases business value and overall performance. A well-designed and implemented BI dashboard can be a valuable tool for pharmaceutical companies, allowing them to produce business value and maintain a competitive edge.

This exploratory case study examined the implementation of a Power BI dashboard to revolutionize transport logistics at a leading South African pharmaceutical company. Framed within the context of Business Process Re-engineering, the research found that the BI tool serves as a significant technological enabler by providing unprecedented visibility into operations, facilitating data-driven decision-making, and allowing for the real-time monitoring of critical KPIs. It has the potential to help re-engineer core logistics processes, shifting them from a reactive to a proactive paradigm.

However, the study also revealed that realizing the full benefits of this technology is contingent upon overcoming substantial risks related to human factors, data governance, financial investment, and scalability. The success of such an initiative is not guaranteed by the technology alone but depends on a holistic strategy that integrates the tool into a broader program of process and organizational change.

[2]School of Engineering, University of the West of England, Bristol, United Kingdom
ifije93@gmail.com

ABSTRACT

ISO 9001:2015 establishes comprehensive standards for a Quality Management System (QMS), widely adopted across various sectors, including the metal and automotive industries. This study aims to evaluate how ISO 9001:2015 influences organizational performance, identify key success factors for its implementation, and analyse the benefits of adopting a QMS. A purposive sampling method was used to select participants, comprising professionals from the metal industry and consulting firms. A quantitative approach was employed, utilizing structured questionnaires to gather primary data, complemented by secondary data sources. Seventy-five questionnaires were distributed. The findings suggest that implementing ISO 9001:2015 in the metal industry results in cost savings, increased customer loyalty, improved employee performance, higher productivity, enhanced production processes, and market expansion. Key performance indicators (KPIs) for successful implementation include customer satisfaction, feedback and complaint management systems, leadership involvement, continuous improvement, and on-time delivery.

Keywords: ISO 9001:2015, QMS, Metal industry, Organisational performance

1 INTRODUCTION

The metal industry is a cornerstone of many economies, providing essential materials for various sectors, including construction, automotive, and manufacturing. In this context, the implementation of ISO 9001 has become increasingly vital to ensure competitiveness and sustainable operations. The adoption of this quality management system (QMS) framework enables organisations to establish robust practices, such as systematic audits, performance reviews, and continual improvement processes, which are critical for achieving and maintaining operational excellence. According to [1] Stanojeska, Minovski, and Jovanoski, ISO 9001 nurtures a culture of continuous improvement, ensuring compliance and certification sustainability. In a globalised market, adherence to ISO 9001 equips metal industry organisations with a competitive edge, allowing them to meet growing customer expectations, enhance operational efficiency, and attain strategic objectives [2].

Despite its benefits, the practical implementation of ISO 9001 in the South African metal industry faces numerous challenges. Research by Chiarini et al. [3] identifies significant knowledge gaps related to technical and managerial competencies within the sector, as well as an underdeveloped understanding of technological advancements, such as those introduced by Industry 4.0. Addressing these gaps is crucial to ensure the successful integration of ISO 9001 and to harness its full potential in improving productivity, reducing errors, and elevating customer satisfaction [4]. This study is motivated by the need to explore these obstacles and identify critical success factors for the effective implementation of ISO 9001. It aims to provide valuable insights into overcoming the unique challenges faced by the South African metal industry, fostering a culture of quality excellence and supporting long-term competitiveness in a rapidly evolving market.

Recognising these challenges, senior management and board members are committed to identifying the root causes of non-compliance and developing effective solutions to address these issues. Key factors contributing to non-compliance include defective materials, insufficient employee training, equipment failures, product changeovers, delayed shipments, and outdated quality control procedures [5].

1.1 Objectives of the study

- To identify factors/challenges that affect the implementation of ISO 9001:2015 in the metal industry.
- To determine critical success factors of ISO 9001:2015 in the metal industries.
- To investigate the benefits of ISO 9001:2015 in the metal industry.
- To identify key performance indicators for the successful implementation of ISO 9001:2015 in the metal industry.

2 LITERATURE REVIEW

2.1 Implementation of ISO 9001:2015 in the Metal Industry: Factors and Challenges

Implementing ISO 9001:2015 in the metal industry involves navigating unique challenges and sector-specific complexities. Key issues include managing intricate supply chains with multiple suppliers and subcontractors, maintaining consistent QMS compliance, and standardising processes across diverse operations [6][7]. Establishing effective QMS practices aids in streamlining supply chain operations and enhancing communication among stakeholders, ensuring long-term efficiency and customer satisfaction [4].

Other challenges include high initial investments in training and equipment, which are essential for consistent quality across varied projects [8]. Compliance with safety, environmental, and product standards poses additional difficulties, especially in addressing workplace hazards, material quality, and equipment reliability [9]. Resistance to change from

employees or management further complicates adoption, requiring effective change management strategies [10].

The focus on documentation and ongoing improvement can overwhelm organisations new to ISO practices. Resource-heavy tasks like monitoring performance indicators and aligning culture with ISO principles can slow progress [11]. Internal barriers, such as limited resources, inadequate technical infrastructure, and a misaligned organisational culture, are worsened by bureaucratic procedures and a lack of management commitment [12].

Despite these hurdles, strong leadership, structured implementation plans, and fostering a quality-focused culture are critical to overcoming obstacles. This approach ensures ISO 9001:2015 transitions from being a compliance measure to a transformative framework, driving improved processes, product quality, and customer satisfaction [13].

2.2 Critical Success Factors for ISO 9001:2015 in the Metal Industry

This study examines the critical success factors (CSFs) essential for effectively implementing ISO 9001:2015 in the metal industry, emphasising their role in achieving organisational goals. Key factors include strong leadership commitment, employee engagement, and alignment with strategic objectives, all of which contribute to fostering a culture of quality and continuous improvement. Schmeleva [14] notes that QMS evaluations help standardise processes, leverage the Deming cycle for ongoing enhancement, and address challenges linked to global competition. By implementing a QMS, organisations can boost operational performance, adopt process-oriented practices, and comply with regulatory and customer requirements, ensuring the production of consistently high-quality products [15].

ISO 9001, particularly its 2015 iteration, is a globally recognised standard that adapts to diverse organisational contexts and supports maintaining customer relationships [16]. The metal industry benefits significantly from ensuring product conformity, which provides a competitive advantage [17]. Tannady [18] highlights the critical role of employee involvement, with engaged teams driving better performance and motivation. Additionally, customer satisfaction is prioritised through the delivery of high-quality products [19].

Brand image, encompassing functional and emotional attributes, adds symbolic value, helping organisations strengthen customer loyalty and exceed expectations [20]. Leadership aligned with organisational vision promotes a cohesive environment that supports compliance with ISO standards and unified strategic direction. Streamlined production processes enable early error detection, ensuring consistent quality and customer satisfaction [21]. Collaboration with suppliers is also pivotal in achieving successful ISO implementation [22].

Performance evaluations align individual and organisational goals, boosting employee engagement, reducing turnover, and improving outcomes [10]. Employee participation in decision-making fosters accountability, adherence to processes, and a commitment to continuous improvement. Prioritizing employee well-being enhances satisfaction and productivity, improving the likelihood of successful implementation [23].

Customer feedback is central to ISO 9001, allowing organisations to refine operations and proactively address needs. Islami, Mulolli, and Mustafa [24] emphasize that meeting customer expectations strengthens reputation and relationships. Leadership commitment to embedding ISO 9001 within strategic frameworks further ensures structured improvements and customer satisfaction [18].

2.3 Benefits of ISO 9001:2015 in the Metal Industry

The successful implementation of ISO 9001 allows organisations to maximize its benefits, especially when the decision to adopt the standard is driven primarily by internal motivations rather than external pressures [25]. ISO 9001 adoption has become a widespread management

practice, increasingly embraced in competitive markets. This standard establishes a foundation for cultivating a quality-oriented organisational culture, often developing into a comprehensive Quality Management System (QMS).

QMS facilitates consistent quality outcomes, process optimization, and sustainable development [26], fostering a culture of continuous improvement essential for long-term success [2]. It enhances productivity [27], improves employee performance, and protects an organisation's reputation by bolstering its brand image [26]. The implementation of quality management practices leads to better operational performance across industries, including the metals sector, and ensures high-quality products and services [28].

In today's competitive market, maintaining quality is critical for organisational survival [29]. As a result, many organisations adopt QMS to consistently meet customer expectations, access new markets, and expand their market presence. QMS also helps organisations address industry-specific challenges and continuously enhance production processes

External drivers, such as the need to meet high customer expectations and deliver superior quality products and services, as well as the desire to enter new markets, further motivate organisations to pursue ISO certification. Moreover, implementing a QMS fosters sustainable development and social responsibility within the metal industry, improving both product quality and operational standards [26].

2.4 Key Performance Indicators for Successful Implementation of ISO 9001:2015 in the Metal Industry

Implementing ISO 9001:2015 in the metal industry requires a strategic focus on key performance indicators (KPIs) to evaluate the Quality Management System's (QMS) effectiveness and overall organisational performance. These KPIs ensure alignment with customer expectations and compliance with industry standards.

Customer satisfaction is a primary KPI, emphasizing the need for metal industry organisations to meet or exceed customer expectations. According to Ali et al. [30], this can be measured using customer surveys, feedback mechanisms, and complaint tracking systems. Monitoring these metrics provides valuable insights into client perceptions, enabling companies to refine their offerings and enhance satisfaction levels. The systematic tracking of complaints and their resolution times also helps identify recurring issues and supports continuous service quality improvement.

Process efficiency is another critical KPI, involves regularly reviewing and optimizing processes to reduce waste and enhance productivity. Metrics such as cycle time and scrap rate serve as benchmarks for assessing process performance and driving improvements.

Employee training and competency are essential for successful ISO 9001:2015 implementation. Vlok [31] emphasizes the importance of ensuring employees are adequately trained and possess the necessary skills for their roles. This can be tracked through training records, skill assessments, and job performance evaluations, ensuring a competent and informed workforce.

Leadership commitment is vital for sustaining quality initiatives. Smith [32] emphasises that leaders in the metal industry must actively engage in the implementation and ongoing maintenance of the QMS. Leadership involvement can be assessed through feedback mechanisms, observation, and performance reviews, fostering a culture of quality and continuous improvement.

Supplier management is also a crucial aspect [33]. KPIs in this area include evaluating suppliers' on-time delivery performance, material quality, and adherence to contractual

terms. Additionally, tracking non-conformances identified during audits and the effectiveness of corrective actions reflects the QMS's robustness.

Finally, **audit results and non-conformance trends** serve as key indicators of QMS effectiveness. A declining rate of non-conformities, whether identified in internal or external audits, demonstrates the system's ability to proactively address issues and maintain high-quality standards, as noted by Njunguna and Bett [34].

In conclusion, these KPIs collectively provide a comprehensive framework for assessing and enhancing the implementation of ISO 9001:2015 in the metal industry, ensuring both operational excellence and customer satisfaction.

3 METHODOLOGY

The study employs a quantitative research approach, deemed most effective for gathering new information in this context. Quantitative research includes hypothesis testing, validation, and data analysis [35]. It focuses on statistical analysis and hypothesis testing, allowing researchers to examine relationships between variables. Setyoko et al. [36] highlight its usefulness in identifying correlations and variations at specific points in time. The research aims to identify obstacles to ISO 9001:2015 adoption in South Africa's metal industry, critical success factors, and benefits post-implementation, including improvements in quality, efficiency, and customer satisfaction. Quantitative methods allow the analysis of large data sets, offering insights into the factors influencing successful implementation and the establishment of measurable criteria for assessing QMS performance. This approach is effective in evaluating ISO 9001:2015's impact across various sectors, including the metal industry [27].

Purposive sampling was used to select participants with relevant knowledge and experience in ISO 9001:2015. This non-probability method was ideal for gathering in-depth insights from key employees in ISO-accredited businesses, such as directors of quality, quality systems managers, and QA/QC officers. The sample included 75 participants, with 53 completed questionnaires returned, yielding a 71% response rate. The study focused on primary data collected via questionnaires on ISO 9001:2015 advantages and accreditation significance.

4 DATA ANALYSIS AND FINDINGS

4.1 Perceived barriers of the implementation of ISO 9001:2015 in the South African Metal Industry

Table 1 shows that "lack of training" and "failure to understand the quality process" are the top barriers, indicating that the human element and intellectual capital in organizations are more significant obstacles than purely structural or financial issues. This suggests that effective ISO 9001 implementation requires substantial investment in human resource development and knowledge transfer. The lower ranking of "resistance to change" (Rank 9) is noteworthy; it implies that the ability to implement changes, due to a lack of training or understanding, might be a bigger problem than outright opposition to change among employees. These results agree with existing research emphasising the importance of top management support in guiding staff efforts and creating reward programs to boost employee motivation and morale. Additionally, the alignment with literature points out that team commitment is a vital factor in successful implementation, noting that external consultants making changes with limited internal involvement can cause disengagement.

Table 1: Perceived barriers of the implementation of ISO 9001:2015 in the South African Metal Industry

BARRIERS (CHALLENGES) THAT IMPEDE THE IMPLEMENTATION OF ISO 9001:2015	*(x̄)*	*(σX)*	*R*
Lack of training	3.95	0.306	1
Failure to comprehend the quality process	3.93	0.339	2
Lack of satisfactory planning	3.93	0.339	2
Lack of staff motivation by top management	3.92	0.299	3
Lack of Communication	3.91	0.420	4
Lack of cooperation between customers and suppliers	3.87	0.496	5
Lack of Resources	3.85	0.552	6
Insufficient materials	3.83	0.469	7
Financial and economic challenges	3.83	0.475	7
Failure to participate as a member of the Organisation	3.80	0.506	8
Resistance to change	3.79	0.584	9
Where: ***(x̄):*** *Sample Mean* ***(σX):*** *Standard Deviation* ***R:*** *Rank*			

4.2 Perceptions of critical success factors for ISO 9001:2015 in the Metal Industry

The shared top ranking of "Continuous Improvement" and "Meeting or exceeding customer expectations" highlights a crucial dual focus necessary for sustainable success: internal operational excellence combined with external market responsiveness. This indicates that ISO 9001 is most effective when it is not merely a compliance checklist but a strategic tool for market differentiation and customer value creation. The high ranking of "employee involvement" further reinforces the human element, which was also identified as a significant challenge. These findings are consistent with existing literature that emphasises enhanced customer satisfaction as a key focus of quality management and the critical role of employee involvement in decision-making for implementation efficiency.

Table 2: Perceptions of critical success factors of ISO 9001:2015 in the metal industry

CRITICAL SUCCESS FACTORS OF ISO 9001:2015 IN THE METAL INDUSTRIES	*(x̄)*	*(σX)*	*R*
Continuous Improvement	3.90	0.453	1
Meet or exceed customer expectations by providing high-quality goods	3.90	0.470	1
Understand production process	3.85	0.491	2
Comprehends an Organisation's vision	3.83	0.50	3
Employee Involvement in decision making	3.83	0.56	3
Cooperative attitude of suppliers	3.82	0.543	4
Online reviews, suggestion boxes, and surveys	3.82	0.496	4
Maintaining customer relationship	3.81	0.547	5

Measuring employee performance through training	3.77	0.563	6
Assigning employees, the responsibility of operating the system	3.76	0.599	7
Productivity facilities are a crucial factor	3.75	0.619	8
Understand production process	3.63	0.676	9
Where: ***(x̄):*** *Sample Mean* ***(σX):*** *Standard Deviation* ***R:*** *Rank*			

4.3 Perception of the benefits of ISO 9001:2015 in the Metal Industry

The strong correlation between ISO 9001 implementation and improved *employee performance* (tied for Rank 1 benefit) represents a crucial feedback loop. This suggests that directly addressing the "lack of training" barrier (which was identified as the Rank 1 challenge) contributes significantly to a major organizational benefit. This highlights a virtuous cycle where strategic investment in human capital, through training and ensuring comprehension, directly yields improved operational and individual performance. The "remove obstacles" aspect further implies a streamlining of internal processes that directly benefits the workforce. These findings align well with existing literature, which notes that metal firms adopting ISO 9001 often implement staff training to enhance competency and understanding of quality requirements, and that learning and development processes are essential for QMS efficacy.

Table 3: Perception of the benefits for successful implementation of ISO 9001:2015

THE BENEFITS OF ISO 9001:2015 IN THE METAL INDUSTRY	(x̄)	(σX)	R
Positive Impact on company performance	3.90	0.397	1
Improve employee performance and remove obstacles	3.90	0.416	1
Meet customer expectations	3.88	0.412	2
Increase Productivity	3.87	0.473	3
Safeguard brand image	3.86	0.433	4
Improve product quality	3.83	0.538	5
Positive Impact on company performance	3.82	0.496	6
Increase Customer Loyalty	3.81	0.485	7
Improve production Processes	3.76	0.650	8
Enhance employee competency	3.71	0.591	9
Where: ***(x̄):*** *Sample Mean* ***(σX):*** *Standard Deviation* ***R:*** *Rank*			

4.4 Perception on KPIs for successful implementation of ISO 9001:2015 in the Metal Industry

The participants were required to state their perceptions on KPI for successful implementation of ISO 9001:2015 in the metal firms. Table 4 shows participant's ranking of the KPI they believe results in a successful implementation of ISO 9001:2015 in the metal firms. Findings reveal that measuring customer satisfaction through tracking customer feedback was ranked first with a mean of 3.93 and a standard deviation of 0.314, continuous Improvement and leadership

Involvement were both ranked second with a mean of 3.90 and a standard deviation of 0.408 and 0.367, customer satisfaction was ranked third with a mean of 3.89 and a standard deviation 0.442, process efficiency and on time delivery were both ranked fourth with a mean of 3.87 and a standard deviation of 0.445 and 0.407, Surveys, Feedback, and compliant management systems was ranked fifth with a mean of 3.85 and a standard deviation of 0.474, supplier management process was ranked sixth with a mean 3.83 and standard deviation of 0.518.

Table 4: KPIs for successful implementation of ISO 9001:2015 in the metal industry

KPIs FOR SUCCESSFUL IMPLEMENTATION OF ISO 9001:2015 IN THE METAL INDUSTRY	**($\bar{x}$)**	**(σX)**	**R**
Measure customer satisfaction through tracking customer feedback.	3.93	0.314	1

Where: ***(x)****: Sample Mean* ***(σX)****: Standard Deviation* ***R****: Rank*			

5 CONCLUSIONS

The findings collectively underscore the transformative potential of ISO 9001:2015 as a strategic tool for fostering sustainable growth and competitive advantage in the metal industry. The study emphasises that successful implementation extends beyond mere certification; it necessitates continuous commitment, strategic investment in human capital, and a deeply ingrained customer-centric approach. The continuous nature of improvement, feedback loops, and leadership involvement implies that organizations must adopt a long-term, adaptive mindset to fully leverage the standard's benefits. This means that ISO 9001 is not a static achievement but a dynamic process. Therefore, organizations are advised against a "one-and-done" approach to certification. Instead, they should cultivate a pervasive culture of continuous quality management, recognizing that ongoing effort and adaptation are essential for maximizing the standard's impact on operational excellence and market competitiveness. The study successfully addressed each of the objectives by offering an in-depth exploration of how ISO 9001:2015 is currently adopted in the metal sector and by proposing actionable recommendations to enhance quality management systems. The findings highlighted significant benefits such as improved operational efficiency, enhanced customer satisfaction, and better compliance with international standards. Additionally, it identified measurable KPIs, key challenges, and success factors, providing a robust framework for organisations seeking to improve or sustain their ISO 9001:2015 certification.

This research makes a unique contribution to the body of knowledge by presenting a localized perspective on ISO 9001:2015 implementation within South Africa's metal industry. By addressing both the theoretical and practical aspects of quality management systems, the study provides valuable insights for industry practitioners, policymakers, and scholars. It bridges the gap between global standards and local industry practices, equipping stakeholders with tailored strategies to overcome implementation challenges and achieve sustainable quality excellence.

ABSTRACT

The packaging sector for the beverage industry is characterised by productivity and efficiency challenges due to high change-over times on product lines which are necessary to meet market demands. Minimising change-over time is critical to reducing downtime, enhancing equipment utilisation, and maintaining lean operations. This paper investigates the root causes of high change-over times through time studies, Pareto analysis, use of Ishikawa diagrams and 5 Why analysis. Proposed implementable solutions and action plans were actioned after preparation work and availing resources required to perform the change-over. Key challenges, such as data integration, workforce adaptation, and technology scalability, are also discussed. Through empirical analysis, the study furthermore evaluates the potential of artificial intelligence (AI) to reduce change-over times, improve operational flexibility, and support just-in-time manufacturing. The findings highlight how AI-driven solutions can revolutionize change-over management, providing a roadmap for the beverage industry to achieve greater efficiency and competitiveness in dynamic markets.

Keywords: change-over time, artificial intelligence, packaging

1 INTRODUCTION

Beer production involves malting, milling, mashing, extract separation, hop addition and boiling, removal of hops and precipitates, cooling and aeration, fermentation, separation of yeast from young beer, aging, maturing, and packaging [1]. The entire process is aimed to convert grain starches to sugar, extract the sugar with water, and then ferment it with yeast to produce the alcoholic, lightly carbonated beverage. Subsequent to beer production is the packaging process that has six essential functions: containment, protection, apportionment, unitization, convenience, and communication [2]. The brewer packagers several product varieties, and changing over from one brand to another becomes more important, as doing so quickly will increase actual production time.

Beer is packaged in bottles, aluminium cans and kegs and Figure 1 shows a flow diagram for beer packaging operations. The packaging process for beer in crates commences with de-palletising the palletised crates from warehouse, removal of any crowns by the de-crowner and separation of the bottles from the crates. Empty crates would undergo washing before being sent for packing of filled, crowned and labelled bottles. Empty bottles are washed, inspected for dirty and thereafter undergo filling, pasteurisation and labelling before packing [3]. During filling, the staff should pay attention to the pressure of the feeding pump and carry out relevant adjustment settings to ensure reasonable and correct operation and meet the filling specification.

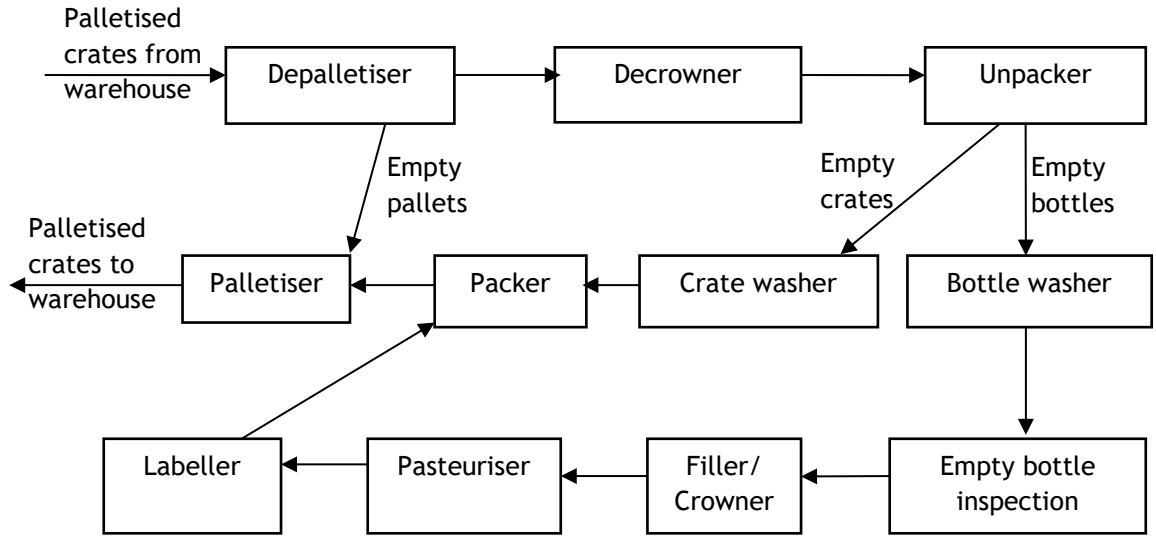

Figure 1: Flow diagram for beer packaging operations [4]

The change-overs for the brewer include pack change, bottle change and brand change and it was noted that the change-over time for beer packaging product lines was excessively high, leading to reduced production efficiency, increased downtime, and higher operational costs. The extended change-overs had a significant impact on the brewery, affecting production time and overall operational efficiency due to the average of 8 hours lost per week. This study is aimed to investigate the root causes of high change-over times and institute corrective measures to reduce the change-over times.

2 LITERATURE REVIEW

2.1 Introduction to Change-over Time in Packaging Processes

The concept of changeover time was coined by Shigeo Shingo, a Japanese industrial engineer who developed the SMED (Single-Minute Exchange of Die) methodology for identifying, calculating and reducing process or machine change time to reduce configuration time while

increasing flexibility and efficiency [5]. The terms change-over time and setup time can be used interchangeably, referring to the time from the last acceptable product produced to when the next good product or part comes off the same production line. When switching from producing one product to another, adjustments have to be made to the process or machine to accommodate diverse products that need to be packaged. Lengthy change-over times in packaging processes result in production inefficiencies, production delays, and higher operational costs [6, 7]. Hence, it is imperative that the changeover process is accomplished timeously in order to reduce downtime of the packaging line, and depending on the type of equipment, this process might be completed automatically by more sophisticated case-packing equipment or manually by the operators. Change-over in beer packaging is characterised by cleaning tasks, equipment reconfiguration, adjustment of machine or process settings, and implementing quality checks [8].

Historically, companies have focused on methodologies such as SMED to optimise change-over time in order to cope with high variability in customer requirements while concurrently maintaining better utilisation of the production resources, particularly in batch production systems. Eldardiry [9] proposed a framework that deployed DMAIC (Define-Measure-Analyse-Improve-Control) and DMADV (Define-Measure-Analyse-Design-Verify) six sigma methodologies as an integrated approach to provide the essential roadmap for changeover time reduction. The essence of the SMED system is to convert as many changeover steps as possible to “external” (performed while the equipment is running), and to simplify and streamline the remaining steps. The name Single-Minute Exchange of Die comes from the goal of reducing changeover times to the “single” digits of less than 10 minutes. A successful SMED program yields lower manufacturing cost, improved responsiveness to customer demand, lower Inventory Levels and standardized changeover processes improve consistency and quality [10].

2.2 Role of Artificial Intelligence in Packaging Process Optimisation

Studies have demonstrated that the implementation of automated solutions has the potential to reduce change-over times in packaging processes for beverages [6, 11]. Automated change-over systems utilise programmable logic controllers, robotics, and vision-based sensors to accelerate transitions, minimise human error and significantly improve efficiency by reducing labour-intensive interventions. Real-time analytics can aid organisations to adapt to fluctuating consumer demands and supply chain disruptions. The packaging processes for beverages has been revolutionised by recent advancements in Artificial Intelligence (AI) through predictive analytics, real-time decision-making, and adaptive learning [12].

Concerning process optimisation, AI algorithms such as process simulation models and reinforcement learning can be deployed to optimise beer packaging operations by enhancing line balancing solutions and managing bottlenecks to increase throughput [13]. The deployment of robotic arms for palletizing and automated guided vehicles for material handling within AI-integrated robotic systems can improve efficiency and reduced labour costs in packaging facilities [14]. By ensuring that packaged beer is stored and dispatched efficiently, warehouse management systems can be enhanced by artificial intelligence through improvement in inventory tracking and slotting strategies. Demand forecasting and inventory management are critical in beer packaging operations, AI-powered demand forecasting models can be used to leverage market trends, historical sales data, and external organisational factors such as promotions and de-seasonalising demand components to optimise beer production and scheduling packaging timelines to abate stockouts and reduce excess inventory [15].

Research has also demonstrated a reduction in packaging errors using AI-enhanced quality control systems where AI-driven sensors in packaging processes were used to monitor factors such as fill levels, cap sealing, and label accuracy, thereby ensuring compliance with the

prevailing industry standards [16]. AI-powered machine vision systems ensure quality control which is critical in beer packaging by enabling product safety and brand reputation. Process analytics through AI can aid to reduce beer losses during packaging through optimisation of filling precision and detection of any leaks in real time, which is also aligned with regulatory compliance and sustainable manufacturing practices. Additionally, when integrated with deep learning algorithms, AI solutions can detect defects in cans, bottles, and labels, with image recognition systems that can also outperform traditional manual inspections in detecting small defects [17].

Case studies indicate that AI-driven predictive maintenance strategies that utilise Internet of Things (IoT) sensors and machine learning models to anticipate equipment failures before they occur can yield substantial reduction maintenance costs [18-20]. AI models can be used for predictive analytics in beer packaging to detect anomalies in filling machines, conveyor belts and capping stations, by analysing real-time sensor data, and thereby reduce unplanned downtime, optimise maintenance schedules, and extend machine lifespan [21].

3 RESEARCH METHODS

An in-depth examination was conducted regarding various processes on packaging line 1 over a span of 13 weeks, with a consistent one-shift-per-day schedule. This study employs a mixed-methods approach, combining qualitative and quantitative research to analyse change-over time reduction and the role of AI in beer packaging processes. Academic papers were reviewed as secondary data to identify successful case studies on AI-driven packaging solutions.

Primary data were collected through direct observations and time-motion studies for operators and tracking the time taken for each change-over process over multiple runs in beer packaging process. Process flow analysis was conducted and flow diagrams were used to depict the beer packaging operations. All instances of downtime, which includes machine downtime, external downtime, and planned downtime were documented and categorised these into four areas: Machine, Man, Materials, and Methods. Pareto analysis was used for identification and prioritisation of the largest contributors to change-over time in beer packaging, thereby enabling focused improvement efforts that would positively and effectively impact productivity.

Within the root cause analysis technique, a 5 Why technique was used to drill down to the root causes through repeatedly asking the question "why?", generally 5 times, although the number was not fixed. An action plan was developed with a definitive checklist of tasks and resources that were required to implement improvement initiatives for the reduction of high change-over times on beer packaging operations. A comparative analysis was further conducted on the actual number of hours lost due to change-over time per week versus target loss to track the performance after implementation of action plans. Typical applications of IoT on beer packaging processes were identified and an AI-driven framework was developed for improvement of change-over time in packaging. It was also crucial to identify recommended IoT devices and software solutions for implementation by the brewery.

4 RESULTS AND DISCUSSION

4.1 Cause and Effect analysis

Changeover activities characterise the packaging process which entails rinsing of bottles to remove any residue or other elements that could affect beer taste and quality. Bottles can be sealed with crown or pressure caps depending on the bottle and cap type. An Ishikawa (Fishbone) diagram was used to investigate and portray the potential causes for high change-over time in beer packaging operations as illustrated in Figure 2. It was noted that with regards to people, inconsistent SOPs, lack of skilled operators, resistance to process improvement and standard procedures and insufficient training were potential causes for high change-over time

in beer packaging operations. Possible machinery causes for high change-over time include frequent breakdowns during changeover, maintenance delays, inefficient tooling and lack of automated change-over mechanisms.

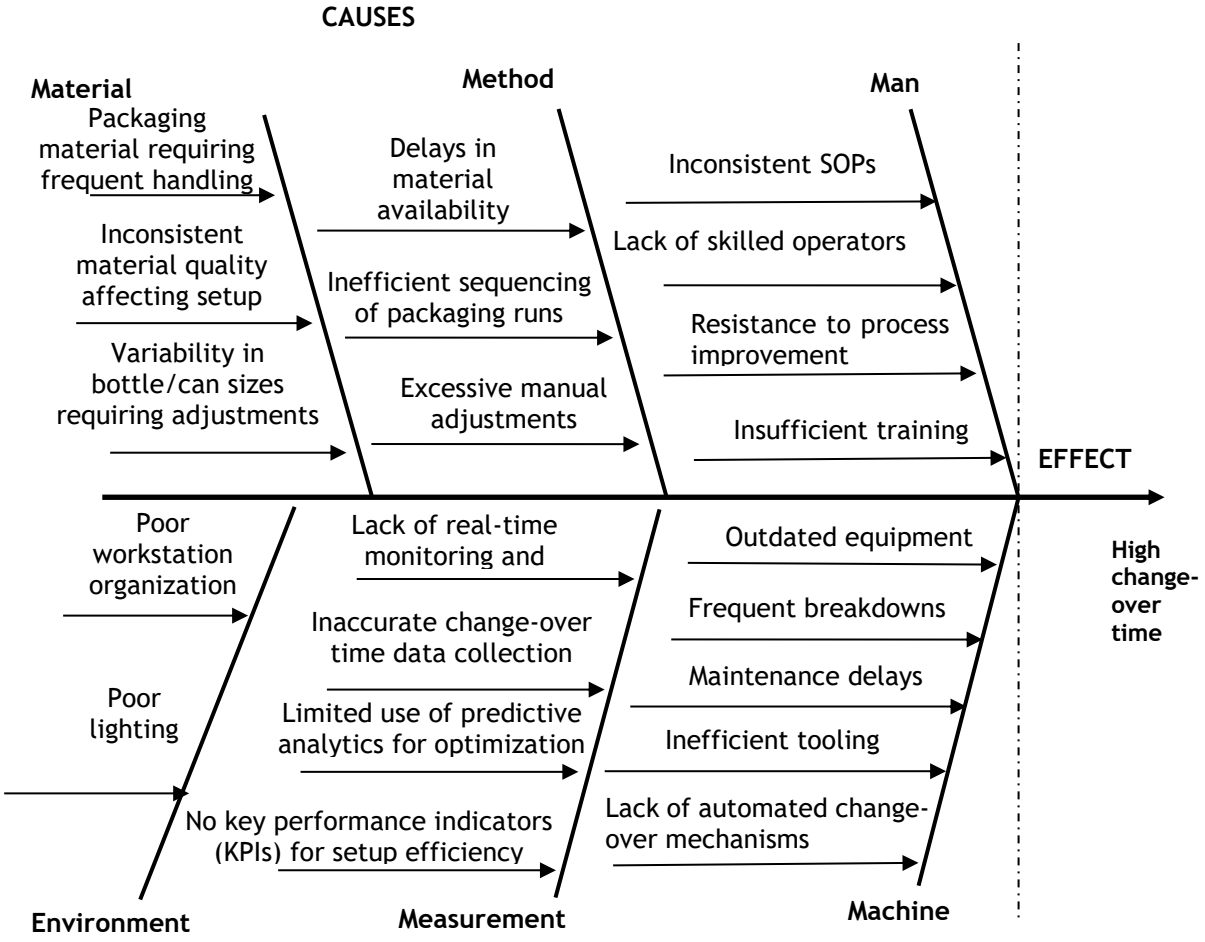

Figure 2: Ishikawa diagram for potential causes for high change-over time

Possible causes for high change-over time due to the method used include delays in material availability, excessive manual adjustments, inefficient sequencing of packaging runs, lack of SMED principles and no standardized change-over process. Concerning materials, it was noted that inconsistent material quality affecting setup, variability in bottle/can sizes requiring adjustments and packaging material requiring frequent handling adjustments were potential causes for high change-over time.

Concerning measurement or performance tracking of the system, it was noted that lack of real-time monitoring and feedback systems, lack of key performance indicators (KPIs) for setup efficiency, inaccurate change-over time data collection and lack of predictive analytics for Optimisation, were potential causes for high change-over time. Regarding environment or workplace factors, it was noted that poor 5S or workstation organization, inefficient workspace layout and inconsistent lighting, were potential causes for high change-over time.

4.2 Pareto Analysis

Pareto Analysis was used as a tool for identifying and prioritising the biggest contributors to change-over time in beer packaging, enabling focused efforts for the brewer to derive significant improvements. Figure 3 shows the Pareto chart for change-over time for the

packaging process. The results show that pack change contributed the highest change-over time.

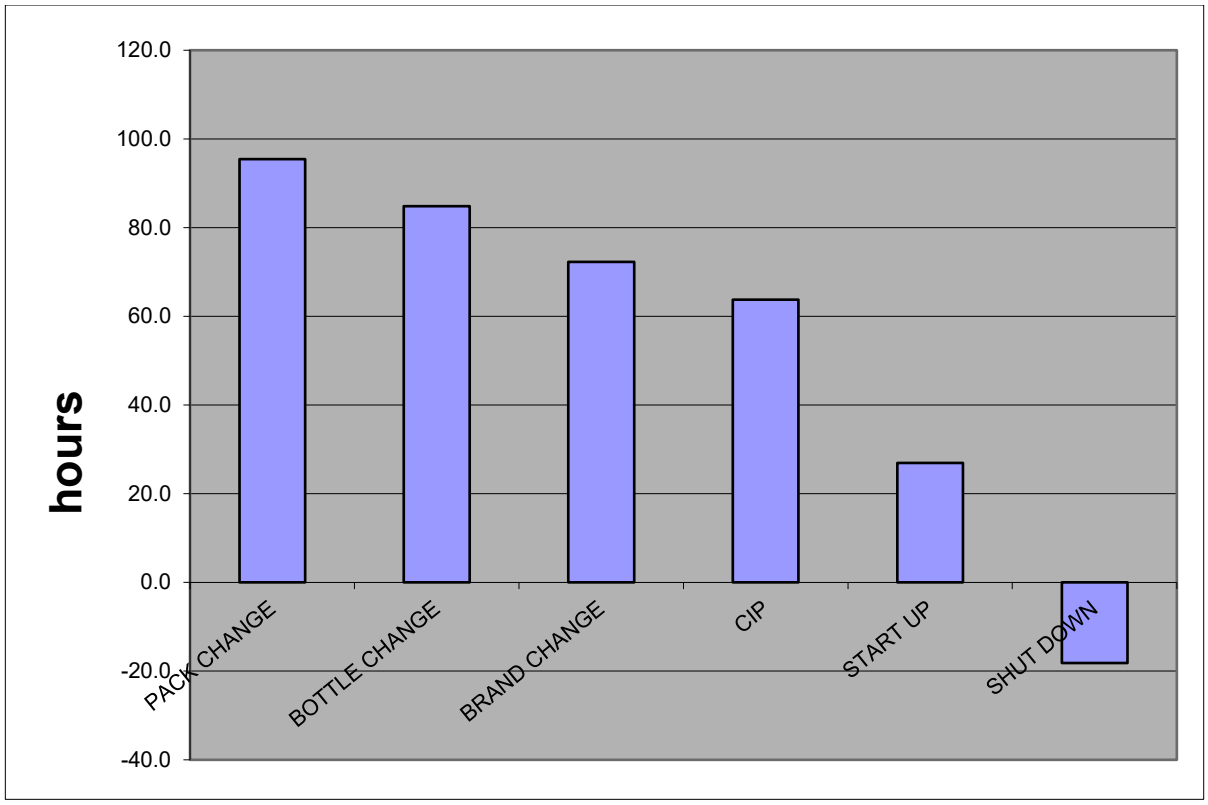

Figure 3: Pareto chart for change-over time in packaging operations

Clean-In-Place (CIP) is a standardized method of cleaning and disinfecting the interior surfaces of tanks, pipes, and process equipment, all without disassembly. The CIP system will run water, product or cleaning liquid through the product pathway of a machine, using spray balls or other methods to clean tanks without disassembling. It is worth noting that CIP systems have become a cornerstone of modern beverage production, helping to minimise downtime for change-over. A core principle of SMED is to make it easier to visually communicate where external setup tasks can be moved outside of downtime. By plotting shutdown tasks as negative, it visually distinguishes the preparatory or pre-stop tasks from post-stop activities.

Figure 4 shows the interactions between the change-over types, pack change is characterised by change in outer packaging, tray or case, and that would affect the packers, shrink wrappers and conveyors. The plant currently packages the smaller beer bottle and all beer-can sizes in 6 packs that are combined into a case of 12 or 24 units. On the other hand, bottle change is characterised by change in size or shape of bottle, and that would affect the filler, capper, labeller and conveyors. The plant currently packages 750ml, 660ml, and 340ml of bottles and for cans, uses 500ml, 440ml and 330ml of beer cans. Conversely, brand change is characterised by change in the brand of beer and that would affect the cleaning systems, labellers and printers. The plant currently packages 10 different brands of beer.

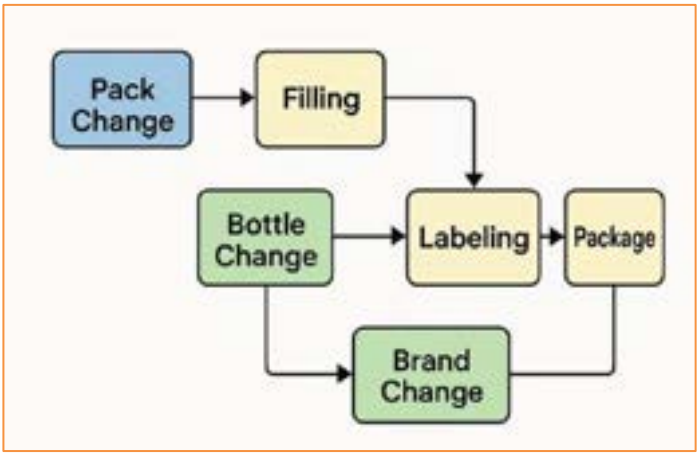

Figure 4: Interactions between the change-over types

4.3 5 Why Analysis

Through 5 Why analysis shown in Figure 5, it was discovered that lack of standard tools, ineffective data collection system, and lack of spare parts were key barriers to effective change-over time. It was found that bottles remained in the washer during bottle change, change parts were not colour coded, and change parts were found to be far from machine. In addition, gripper cylinder had not been serviced, magazines were not maintained to acceptable standard, the filler was characterised by poor timing of infeed and intermediate starwheels, and label prongs would require frequent adjustment.

	why	why	why	Why	Why	ROOT CAUSE
1 Change over parts far from machine	1.1 Lack of space					Man
2 Change parts not colour coded	2.1 Paints not available					Man
3 Labeler Gripper cylinder	3.1 No SOP					Man/Method
4 Magazine userviced	No SOP					Man/Method
5 Timing of infeed worm	5.1 Machine out of timing	5.1.1 Setting not right after aggregate service				Machine
		5.1.2 Oil pumps on Aggregates not functioning				Machine
6 Lack of Tools	6.1 Improper storage					Method
7 Lack of People	7.1 Insufficient resources	Poor allocation				Man/Method

Figure 5: 5 Why analysis

4.4 Action plan and implementation

An action plan was developed with a definitive checklist of tasks and resources that were required to implement improvement initiatives for the reduction of high change-over times on

beer packaging operations. Table 1 shows a listing of actions that were implemented to improve the process.

Table 1: Listing of actions for process improvement

Action	Description
1	Create space for change parts close to machine
2	Colour code all change parts
3	Create an SOP
4	Retime infeed worm
5	Order new oil pump for the labeller aggregates
6	Order tools for operators
7	Retime infeed and intermediate starwheels
8	Service gripper cylinder
9	Service label magazine
10	Provide trolley to carry change parts to machines
11	Order two extra tools for changing vent tubes
12	Provide three manual tools for changing vent tubes
13	Automate the CIP system
14	Connect permanent pipe connections to replace hoses

4.5 Tracking Performance after Implementation of Action Plans

Figure 5 shows comparison of actual number of hours lost due to change-over time per week versus target loss over a 32-week period, benchmarked against a 7-hour historical average loss.

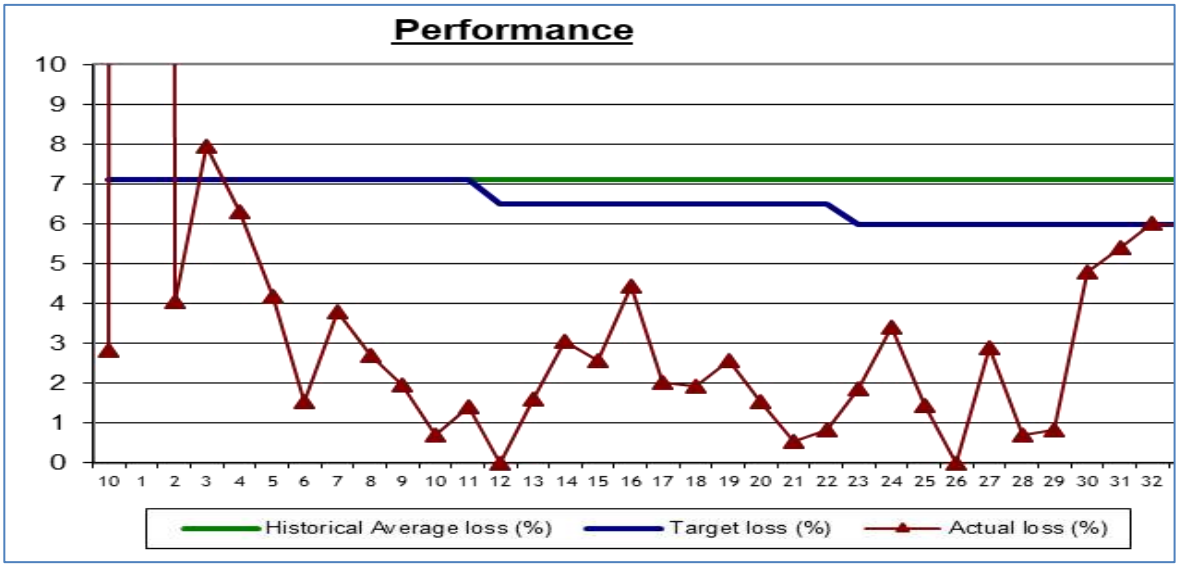

Figure 6: Comparison of actual loss vs target loss

These results demonstrate improvement in performance, showing a marked reduction in the number of hours lost due to change-over time per week. Table 2 also shows that regarding tracking performance improvement, the average change-over time and change-over errors per month were reduced while Overall Equipment Effectiveness (OEE) was improved for the plant.

Table 2: Tracking Performance Improvement

Metric	Before	After	Change
Average change-over time on bottle change	82 min	55 min	33% reduction
Change-over errors per month	8	2	75% reduction
OEE	52%	65%	+12 pts

5 IMPLICATIONS OF AI AND FRAMEWORK TO IMPROVE CHANGE-OVER TIME ON PACKAGING PROCESSES

5.1 Applications of IoT on Beer Packaging Processes

It was noted from the root cause analysis that lack of automated change-over mechanisms was a cause for high change-over time in beer packaging operations. The application of artificial intelligence has led to enhanced operational efficiency by optimizing resource allocation and reducing waste the FMCG supply chains (fast-moving consumer goods) [22]. There is much room for AI to revolutionise packaging processes in breweries, AI-driven scheduling algorithms can optimise sequencing production runs to minimise unnecessary changes while digital twin technology enables brewers to minimise trial-and-error adjustments by simulating change-over processes before execution. On the other hand, IoT can meaningfully enhance the performance of a beer packaging processes by providing real-time data, process optimisation and predictive maintenance [23]. IoT can be applied on beer packaging processes, with focus on the following:

- Equipment Monitoring & Predictive Maintenance - Predictive analytics can be deployed to detect wear and tear, reduce unanticipated breakdowns and downtime. Additionally, IoT sensors can be installed on fillers, decrowners, cappers, and conveyors to track performance in real time, while parameters such as temperature, vibration, and pressure can be monitored to detect anomalies before they cause machine failure.
- Automated Quality Control & Inspection – parameters such as cap tightness, bottle weight, and pressure can be tracked using smart sensor technology to ensure consistency in quality. Additionally, vision systems with IoT cameras can be used to detect defects such as fill levels, incorrect labels, or cap misalignment in real-time while automated rejection systems can be deployed to remove defective beer cans and bottles before they reach packaging.
- Energy Efficiency & Utility Management - Smart meters can be deployed to monitor water, energy, and compressed air usage across different areas of the packaging process. Additionally, leaks in compressed air systems used for bottle filling can be identified, while idle or underperforming machines can be detected to optimise power consumption.
- Workforce Efficiency & Safety - Real-time alerts can be deployed on hazardous situations such as machine failure or extreme noise levels. Additionally, remote monitoring and control for supervisors can be implemented to track production progress while wearable IoT devices for workers are used to monitor safety compliance and employee fatigue.
- Production Line Optimisation - Real-time production tracking can be deployed to identify production line bottlenecks and ensure optimal production scheduling. Furthermore, automatic adjustments can be made to machine speeds based on production demand and line conditions. AI-driven analytics can be implemented to reducing downtime, improve line balancing and maximising throughput.

- Smart Packaging & Traceability - Smart labels with QR codes can be deployed to track packaged beer products throughout the supply chain. Additionally, real-time tracking of beer batches can be done to ensure compliance with quality standards or expiration dates. There is also room for integrating blockchain with IoT for tamper-proof tracking of beer production from brewery to outlets as well as ensuring transparency.
- Real-Time Data & Decision Making - IoT dashboards can be deployed to visualize key performance indicators such as machine efficiency, quality and production rates, and downtime.

5.2 Recommended IoT Devices & Software Solutions

Table 3shows a summary of areas where recommended IoT devices and software solutions for reduction of high change-over time in beer packaging operations.

Table 3: Recommended IoT Devices and Software Solutions

Area	Recommended IoT Devices	Software Solutions
Equipment Monitoring & Predictive Maintenance	Vibration sensors (Fluke 3561), Smart pressure sensors (Honeywell DPS)	Predictive maintenance platforms (Siemens MindSphere, IBM Maximo, AWS IoT SiteWise)
Energy Efficiency & Utility Management	Smart meters (Schneider Electric PowerLogic), IoT-enabled flow meters (Endress+Hauser Proline)	Energy management systems (Siemens Desigo CC, Schneider EcoStruxure)
Automated Quality Control & Inspection	AI-powered vision systems (Keyence IV series, Cognex In-Sight), Fill-level sensors (SICK LL3).	AI-based quality control software (Cognex VisionPro, MATLAB Image Processing Toolbox).
Production Line Optimisation	IoT-enabled PLCs (Siemens SIMATIC S7, Rockwell Automation Logix), Smart conveyors (Dorner SmartMove)	Manufacturing Execution Systems (SAP MES, Siemens Opcenter, AVEVA MES)
Workforce Efficiency & Safety	Wearable IoT sensors (Kinetic Reflex, Modjoul SmartBelt), Noise level monitoring sensors (3M Edge 4)	Safety monitoring platforms (EHS Insight, EcoOnline)
Smart Packaging & Traceability	NFC/QR-code tags (Zebra ZD621R RFID printer), Smart label printers (SATO CL4NX)	Blockchain & traceability platforms (IBM Food Trust, VeChainThor Blockchain)
Real-Time Data & Decision Making	IoT gateways (Advantech WISE-6610, Dell Edge Gateway 3000), Industrial sensors (Bosch Connected Devices)	IoT cloud dashboards (Microsoft Azure IoT Hub, Siemens Mindsphere)

5.3 AI-Driven Framework to Improve Change-Over Time in Beer Packaging

An AI-Driven Framework was then developed to improve change-over time in beer packaging. Figure 6 shows the framework, characterised by four layers which include Data Acquisition, AI & Machine Learning, Digital Twin & Simulation, and Feedback & Continuous Improvement, with include Enterprise Resource Planning/Manufacturing Execution Systems (ERP/MES), Maintenance Systems and Workforce Management as integration points.

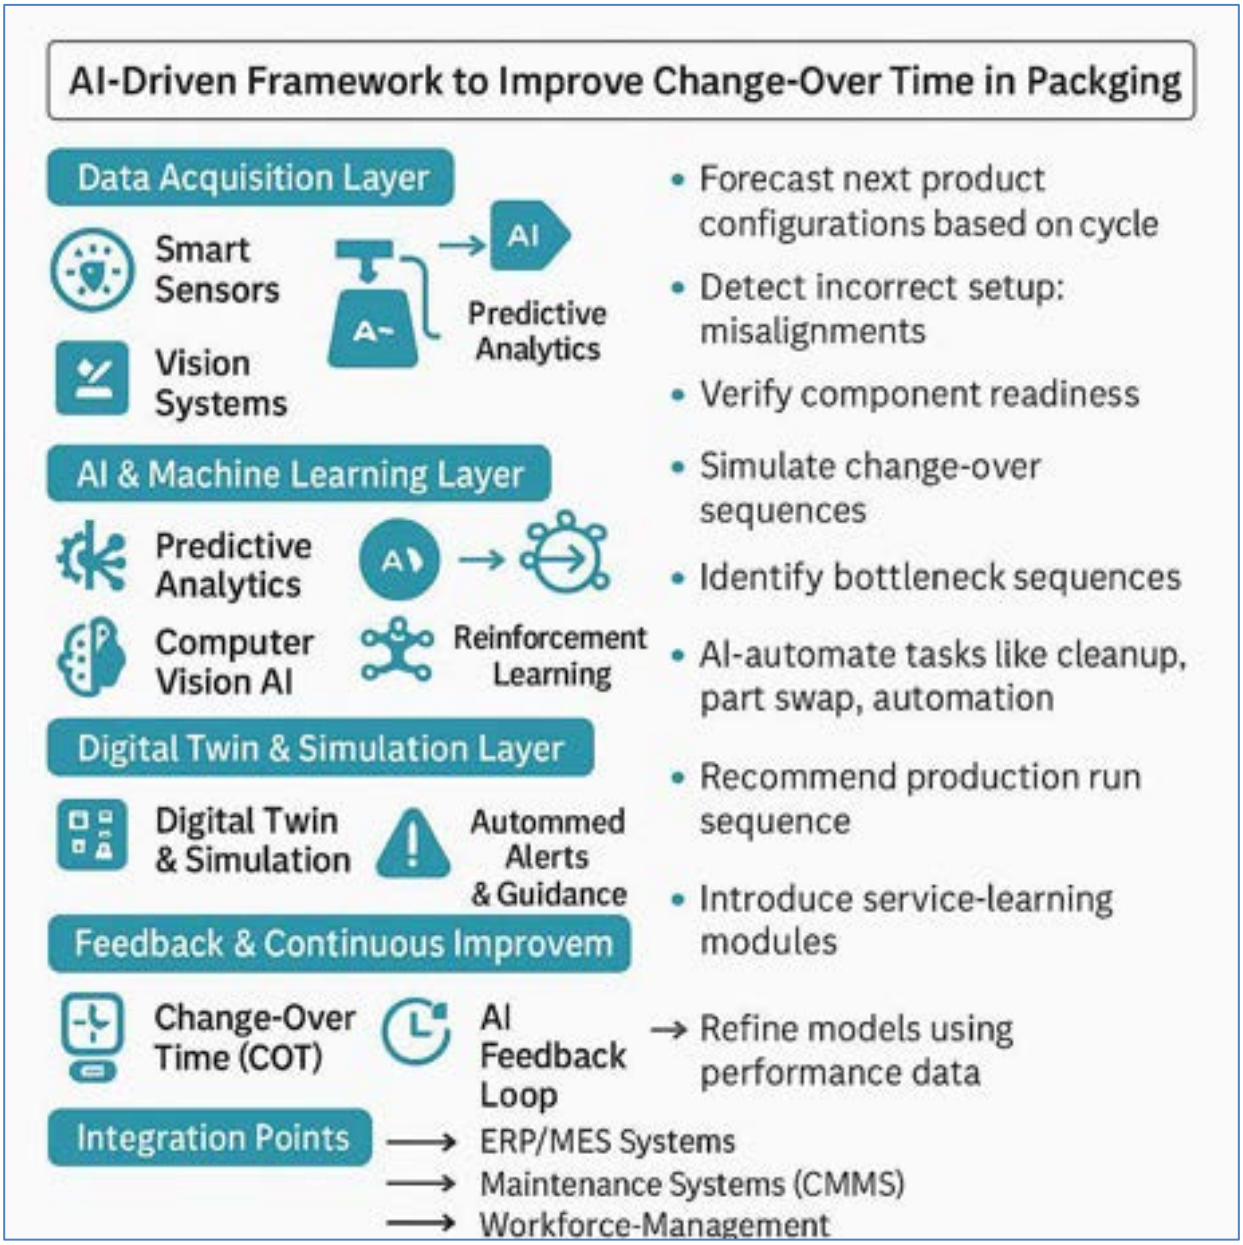

Figure 7: AI-Driven Framework to Improve Change-Over Time in Beer Packaging

- Data Acquisition Layer - Particularly during change-over events, this layer is responsible for collection, pre-processing, and transmission of accurate, real-time data from various sources of the packaging line. The key components of the data acquisition layer include smart sensor integration, programmable logic controller interfaces, machine vision systems and data synchronisation and time stamping. Data on machine states, operator activities, beer brands and specifications, downtime and delays, environmental factors and sensor readings from the line are captured and processed in real time. The data acquisition layer is crucial for the AI Framework, providing data for training machine learning models to predict optimal change-over sequences, benchmark operator performance, identify bottlenecks, support digital twin creation of the packaging line, and enable real-time decision support.
- AI & Machine Learning Layer - This layer is responsible for cleaning and configuring raw data from the data acquisition layer and synchronising time-stamped events across the

systems. The data collected during change-over processes is analysed in this layer to identify process inefficiencies, extract insights, predict delays, and provide recommended solutions for optimisations, striving to reduce change-over time and improving operational efficiency.

- Digital Twin & Simulation Layer - Encompasses digital twin and simulation, automated alerts & guidance. Digital twin technology has huge potential to streamline design, optimise manufacturing processes, and enhance supply chain management for the beer packaging industry. With digital twin technology, breweries are able to simulate packaging designs, virtually test them, and optimise packaging lines, eventually improving efficiency and reducing costs. When certain thresholds, conditions, or anomalies such as machine failure or likelihood of equipment failure, are detected within the digital twin, automated alerts or notifications are generated automatically. Automated guidance is characterised by prescribed actions or recommendations that are based on simulation and data analysis to aid in making optimised decisions regarding production lot quantities, rescheduling of jobs, actioning preventive maintenance suggestions and energy-saving recommendations to improve energy performance.
- Feedback & Continuous Improvement Layer - This layer is responsible for closing the loop by guaranteeing that the practical insights that are derived from AI models yield realistic improvements and that new data continuously boosts system performance to improve change-over time in beer packaging. Figure 7 shows the continuous improvement learning cycle, commencing from capturing the results of implemented changes, use of operator feedback interface to support human-in-the-loop AI approach, validating AI-driven recommendations and using new data to update models and SOPs.

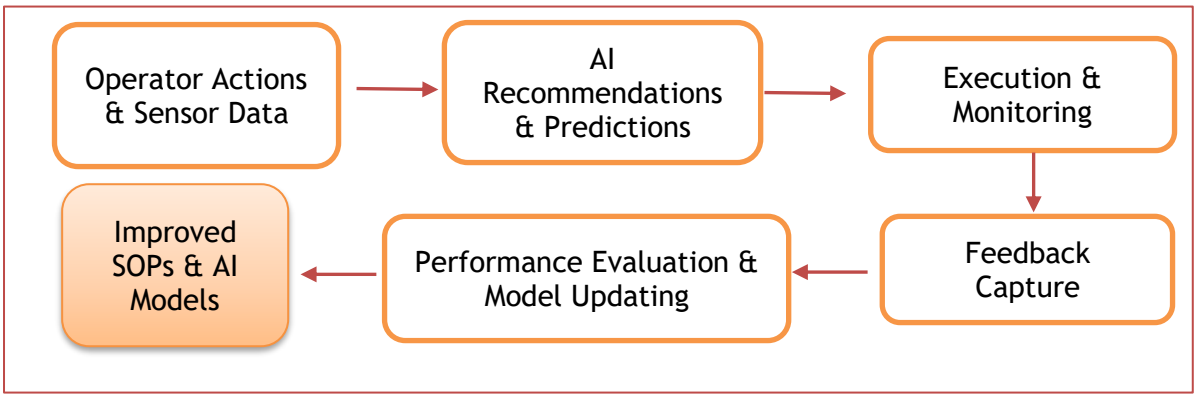

Figure 8: Continuous Improvement Learning Cycle

Integration Points are criucial for connecting physical systems, software platforms, human inputs, and AI models and the effectiveness of the AI framework depends on ERP, maintenance systems and workforce Management to functioning smoothly in real-time.

6 CONCLUSION

Reducing change-over time in beer packaging product lines remains a critical goal for improving productivity and cost efficiency. Traditional methods such as SMED, automation, and lean practices have proven effective, but AI introduces a new frontier in optimisation. By leveraging predictive analytics, real-time monitoring, and intelligent automation, breweries can significantly enhance their packaging processes. However, despite the benefits of AI in beer packaging, challenges remain, including high implementation costs, data integration complexities, and the need for skilled personnel. Future research should explore AI's long-term impact on packaging sustainability, cybersecurity in smart factories, and the ethical implications of automation in the workforce. As AI technologies continue to advance,

breweries that adopt AI-driven solutions can achieve higher efficiency, lower costs, and improved product quality. Future research should focus on overcoming implementation barriers and maximizing the potential of AI in beer packaging.

ABSTRACT

Organisations add new technology to improve system performance. Still, implementing technology suffers from integration challenges of an operational, technical, social, structural, or policy nature, which would interrupt successful implementation. This paper aims to enhance integration by conceptualising a method employing Systems Thinking, Systems Engineering, and Cognitive Work Analysis to analyse complex sociotechnical systems. Through Design Science Research, an artefact was designed to identify and resolve integration issues. The artefact was applied to a Smart Metering System, which was demonstrated to designers, engineers, and managers. An abstraction hierarchy was created to capture the functional purpose of the systems and the interactions. These components interact to produce system behaviour, whereas an unconvincing specification of interaction requirements may lead to negative consequences. Proper specification of requirements, along with appropriate policies and regulations, is essential to resolving the issues around technology integration to yield outcomes relevant to performance.

Keywords: Systems Thinking, Systems Engineering, Cognitive Work Analysis, Complex Sociotechnical Systems, Design Science Research.

1 INTRODUCTION

Systems may require, from time to time, the integration of new technologies to enhance performance levels. However, these systems face system integration challenges, operational capability challenges, social challenges, structural and policy challenges, and decision-making and strategy challenges that may result in stakeholders rejecting the new technology [1], [2]. Introducing new technology into the currently functioning system requires realising that the systems might become complex. Complex systems require whole-system analysis when introducing new technology. It requires Systems Thinking, Systems Engineering (SE), Cognitive Work Analysis (CWA) and associated processes to assist in managing system interactions as they become more complex when integrated with the new technology [3], [4], [5].

The challenges in complex systems include social and technical aspects requiring a sociotechnical systems development approach [6], [7]. The sociotechnical system approach and analysis is concerned with improving work performance and the well-being, experience and values of the people performing the work in the system with the technology [1]. Therefore, a sociotechnical systems approach is consistent with the whole system thinking approach as part of SE [8].

Applying Systems Thinking, SE, CWA, and Systems Thinking theories to manage complex sociotechnical system performance contributes to resolving organisational challenges during system designs and system implementation, ensuring successful integration of new technologies. The research study contributes to helping designers, engineers, and managers understand why systems fail, how to improve system designs in organisations, and how to implement new technologies successfully.

The first objective of this research is to investigate how Systems Thinking, SE, CWA, and System Dynamics theories resolve complex sociotechnical system problems to successfully integrate new technologies with existing systems. The second objective is to develop and test a framework model for resolving complex sociotechnical system transition problems to ensure that organisations can successfully integrate new technologies to increase performance.

2 LITERATURE REVIEW

2.1 Technology Implementation Problems

Innovation and new technology implementations can improve existing organisations' systems, contributing to sustainable development. The fourth industrial revolution innovations and technologies can transform societies, satisfy emerging social needs, revolutionise infrastructure, and significantly impact the economy and businesses [9], [10], [11]. The new technologies can improve the weaknesses of current systems by producing reliable materials and being more intelligent [10]. The integrated technologies will enhance the system's capabilities and ensure that the system can perform more efficiently [10], [12]. Integrating new technologies with the current system may also cause system failure due to emerging system complexities. The system complexities include technical and social system challenges experienced when using systems to complete work tasks [7], [13].

Failed system implementation results because the designers and engineers designed the complex system with incomplete requirements, including missing cognitive and other technical and social requirements, wrong perceptions of the stakeholders' expectations and lack of user influence during system development, resulting in ineffective and inefficient user interfaces [2], [14].

2.2 Sociotechnical Systems

The sociotechnical system theory introduces a systems view that includes both the social and technical systems to ensure that both the social and technical system requirements are

captured with their interaction requirements during the system design process. The environmental complexities and limitations that the system operates within are also analysed and made part of the system design to ensure complete system requirements, leading to better decisions when choosing alternative new technologies and system designs [2], [7], [13].

The social system consists of the structure of the organisation subsystem, organisational policies, people's social needs, attitudes, values, required knowledge and skills to operate the designed system, etc. The technical system consists of the physically designed system, including software, hardware, and work areas, as well as the work tasks that the physical system and people must perform to achieve system objectives [2], [14]. The interactions of the subsystems with themselves and the new technology may cause the system to be complex. A sociotechnical system approach ensures that all the complex system objectives and requirements are captured fully during system analysis and design [1], [7], [13]. The organisational structure influences work tasks, technical systems, and how the sociotechnical system is constrained by the environments, as shown in Figure 1.

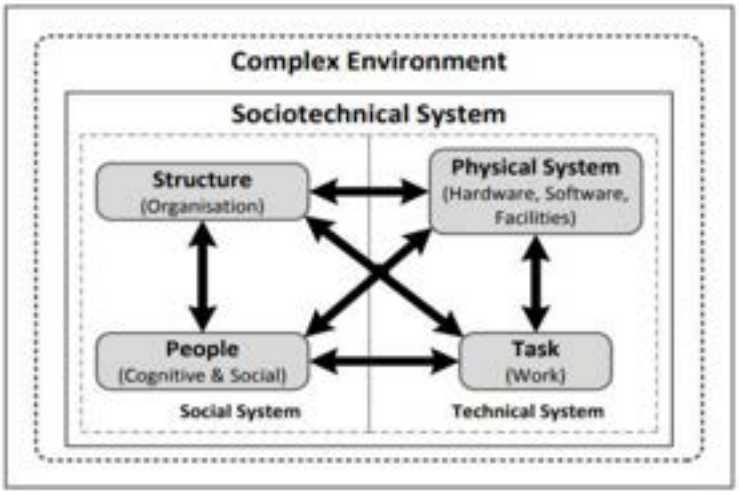

Figure 1: Sociotechnical System in a Complex Environment [13]

Implementing a sociotechnical systems approach aims to ensure that the introduced new technologies fit the organisation and workers by assisting the designers and engineers in designing new technologies acceptable to all the stakeholders. Workers need to find the technology satisfying to work with, thereby increasing work performance [2], [7].

2.3 Complex Systems

Complex system behaviour is non-linear; when one of the subsystems' behaviour changes and integrates with other subsystems, the changed behaviour may cause other subsystems to behave differently than intended, changing the whole system's behaviour. The complex problems that arise during system transitions when the system technology changes can result in undesirable system behaviours that can cause the system to fail to meet its objectives. These emerging dynamic behaviours of the system are difficult to perceive and to know during the planning phase [3], [12], [15].

When the system behaviour cannot be reduced to the sum of the behaviours of its subsystems, then that system has emergent behaviour. It requires a Systems Thinking approach to analyse all the non-linear subsystem interactions. Systems Thinking analyses complex system issues by studying how the subsystems change during the system integration, how the changes affect the other subsystems, and how the interactions of subsystems, elements or functions affect the whole system behaviour [3], [5], [16].

The challenge is to foresee and understand the undesired emerging behaviours that can destroy the system while the system is in the development phase, so that the system can be designed to defeat such challenges when they occur once the system is functional [13], [17]. The CWA framework can analyse the system's possible emergent behaviours and model such behaviour. The modelling can assist the designers and engineers in designing the system, even for behaviours the subsystems may not possess. However, that could emerge when the subsystems are integrated to perform the system objectives [17], [18], [19].

System models clarify requirements, help predict system complexities that might cause problems. Modelling of complex sociotechnical systems foresees the emergent behaviours of complex systems by describing them further or framing the system problems so that the system designers, engineers, managers and other stakeholders can understand them. A model is an abstraction of reality and helps make decisions about the designed system. Understanding the patterns and structure of the emerging behaviours of the system will reduce the system's complexities. CWA and modelling can help to evaluate the effectiveness of the designed system elements and their interactions [13], [20], [21], [22], [23], [24].

2.4 Systems Thinking

Systems Thinking studies the interactions and relationships of system elements with each other and analyses the system's behaviour that emerges because of the elements' interactions [13], [18], [25]. The system structure and data collected during the system modelling will ensure that the designers design the system with complete requirements during the development phase, enabling a close-to-perfect view of the system and integrated perceptions and expectations of all the stakeholders involved. CWA is based on Systems Thinking to ensure the system is resilient and adaptive when emergent behaviours occur [3], [4].

Systems Thinking assumes that the whole complex system is more than just its separate components or elements added together due to components interacting [26]. By adopting a holistic perspective, organisations can understand where and how to change complex systems to improve performance without emerging unwanted system behaviours. Organisations can, therefore, avoid policy conflicts, learn more quickly and efficiently, and make decisions that are best for the organisation in the long run due to the holistic view [27].

Implemented decisions and environmental conditions affect one another when they are changed, and the side effects from the changed decisions affect the environmental situations [27]. Organisational and stakeholder goals can change as the environment changes. This changes the stakeholders' actions, further changing the environmental conditions and problems looping until they meet the desired organisational objectives and goals. Hence, it is essential to model system behaviours of these complex systems because they are interconnected and have feedback [26].

The Causal Loop Diagram (CLD) is a Systems Thinking tool that assists in understanding and demonstrating the connections between several elements that affect a system's behaviour for a specific period. It is a schematic illustration that utilises feedback loops with arrows to explain the cause-and-effect interactions between various system elements [26]. It helps analysing and elaborating on complex sociotechnical systems and communicating the dynamic behaviour of systems to stakeholders [27], [28].

2.5 Systems Engineering

SE is a systematic and iterative application that assists in managing and resolving problems in a sociotechnical system with Systems Thinking theory [3], [15]. SE is the practical realisation, utilisation, and decommissioning of developed systems and increases the chances of developing successful systems through systems concepts, theories, and managerial techniques [15]. It ensures that customers' and stakeholders' needs are identified, defined, analysed, and

captured. The required system's functional requirements and specifications are defined, understood and captured to assist in designing the system's architectural design alternatives. Capturing complete requirements early during the conceptual stage of the new technology will ensure that there are fewer modified requirements at the subsequent stages of the system's life cycle [3]. System modelling ensures that the designers and engineers design the system with improved requirements during the development phase, enabling a close-to-perfect view of the system and integrated perceptions and expectations of all the stakeholders involved [25], [29], [30].

Systems architecting can be helpful during complex sociotechnical system transitions. When the social subsystem elements interact with the technical subsystem elements, the systems architecting tool can help demonstrate how the subsystems integrate to generate the required system behaviour through SE processes. The system's architecture model ensures a better view and understanding of the system. System requirements must be fully captured to ensure the correct system is designed. The system requirements define the system objectives, and the system architecture design interprets the system requirements [25], [29], [31].

Model-based systems engineering (MBSE) includes modelling methods, tools, and procedures used to model the SE framework structurally and practically to communicate and understand complex problems. The MBSE supports SE processes, including requirement analysis, functional analysis and the system's architectural design. It improves the design and quality of SE efforts, including requirements-capturing processes, system design processes, and system verification and validation processes. These improvements contribute to better analysis and management of complex systems [3], [15], [32].

2.6 Cognitive Work Analysis

CWA is a framework based on Systems Thinking that models a system's social and technical components to understand how systems work, intending to improve the system design and performance [1], [33]. It analyses cognitive work and models and structures the work demands and problems to improve understanding of technological and social systems interactions. The outputs assist in better understanding the system's cognitive work demands, enabling them to improve the system requirements and designs [8], [34]. CWA also considers the environmental constraints that constrain workers ' and workers' ability to perform [12], [35].

The CWA framework has five phases: Work domain analysis (WDA), control task analysis, strategies analysis, social organisation and cooperation analysis and worker competency analysis. Most system analyses use the first CWA phase, the work domain analysis [3], [34], [36]. It analyses the work environment and its constraints to determine the sociotechnical system's purpose and the capabilities of the interactions of the subsystems. The WDA analysis is independent of the workers performing the work and tasks. WDA uses the Abstraction Hierarchy (AH) to capture the system's functional purpose by capturing the system's interactions with physical objects. Analysing the interactions also contributes to understanding what the system can and cannot achieve, clearly understanding the purpose of the sociotechnical system [12], [34].

The AH has five stages or levels that capture the system environment, as shown in Figure 2. The lowest level of the AH shows the system's physical objects and all the equipment used to achieve the system's purpose. The next stage shows the purposes and uses of the physical objects. These are all functions that the objects can perform, even those not related to the current system's purpose. The third level represents the system functions performed by the objects driven by the system's purpose. The next level below the top level represents the system's values and priorities delivered by the objects. The top level of the WDA AH represents the system's purpose. The AH model shows which system purpose each physical object enables, why the object performs the system purpose, and how it performs it. The levels connect

through the relationships between the objects, their functions, the system's purpose they perform, and the value they bring to achieve the overall system purpose [12], [33], [37].

When new technology integrates with an existing sociotechnical system, it creates a complex sociotechnical system if the interactions of the system elements are non-linear [38]. The links between the different levels of the AH of the newly introduced physical objects integrate into the old system's AH structure and are analysed to understand the system problems that can emerge or have emerged because of the new technology links on the updated AH structure [12]. With this, CWA can assist in improving the system requirements; integrated system analysis through the AH diagram shows the missing functions the system needs to integrate new technology successfully. Capturing the missing requirements analysed using the AH diagram helps constrain the unwanted emerging system behaviour [3].

The purpose-related functions and the object-related functions of the WDA Abstraction Hierarchy are mapped onto the MBSE tool and help generate user requirements and functionality requirements; purpose-related functions are mapped onto use-case diagrams, and the object-related functions are mapped onto the functional activity diagrams. MBSE and CWA modelling assist in capturing complete, verifiable system requirements [3].

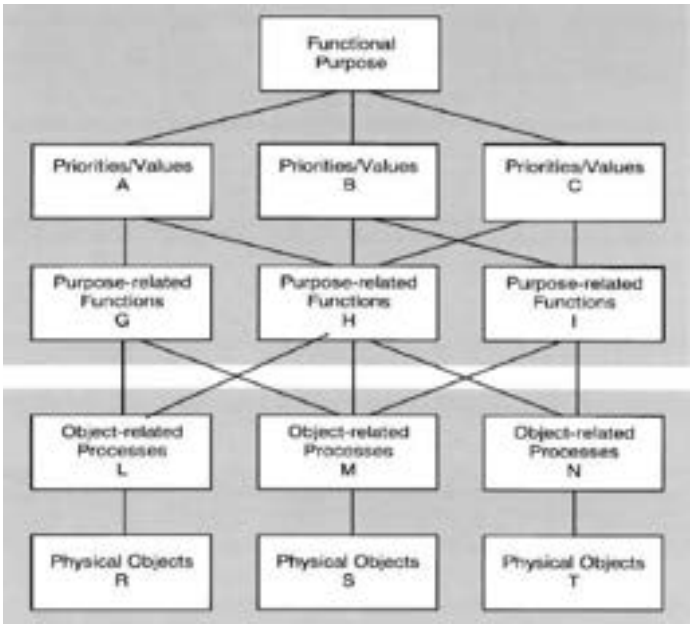

Figure 2: WDA Abstraction Hierarchy [37]

3 CONCEPTUAL METHOD

The conceptual framework model elements in Figure 3 explain how the theories and models will be applied to resolve the complex sociotechnical system problems experienced when new technology integrates with the existing system. The framework includes the following steps:

- **Problem Definition (STEP 1)**. Understanding stakeholders' requirements for improving the old system's performance is a critical SE process. SE processes analyse the existing sociotechnical system's gaps and shortfalls, which is part of the identifying and defining the problem stage. The system stakeholders and users are defined, and their needs are captured using a Use Case Diagram.
- **Requirement Analysis (STEP 2)**. The requirements and constraints of the system and the new stakeholder needs are elicited and analysed. The objectives are set to evaluate if the designed integrated system resolves the defined problems and meets the stakeholder needs.

- **Conceptual Modelling (STEP 3)**. MBSE assists the designers and engineers in capturing complete, traceable requirements and communicating with stakeholders using diagrams and models. Functional and system performance requirements analysis will be performed and demonstrated through Functional and Activity diagrams. The system components are iteratively analysed, and the system structure is determined.
- **Cognitive Work Analysis (STEP 4)**. The CWA determines the system requirements, constraints, and behaviour when the new technology integrates with the existing system. It also analyses environmental constraints to understand the system's capabilities and limits. CWA assists in uncovering the system's complexities, understanding the interactions between the elements, and predicting the emerging system behaviour from the interactions of the system elements.
- **Integrated Project Team and Design (STEP 5)**. Demonstrating the conceptually modelled framework to the Integrated Project Team and Design shows that the designed artefact integrates successfully and that the system behaves as expected. The team analyses and improves the defined problem, stakeholder needs, conceptual design and CWA AH structure.
- **Plan and Perform System Evaluation (STEP 6)**. Planning of the artefact's processes and designing artefact evaluation to determine how well it meets the stakeholders' needs.
- **Communicate Results (STEP 7)**. All the relevant information and models are communicated to the stakeholders.

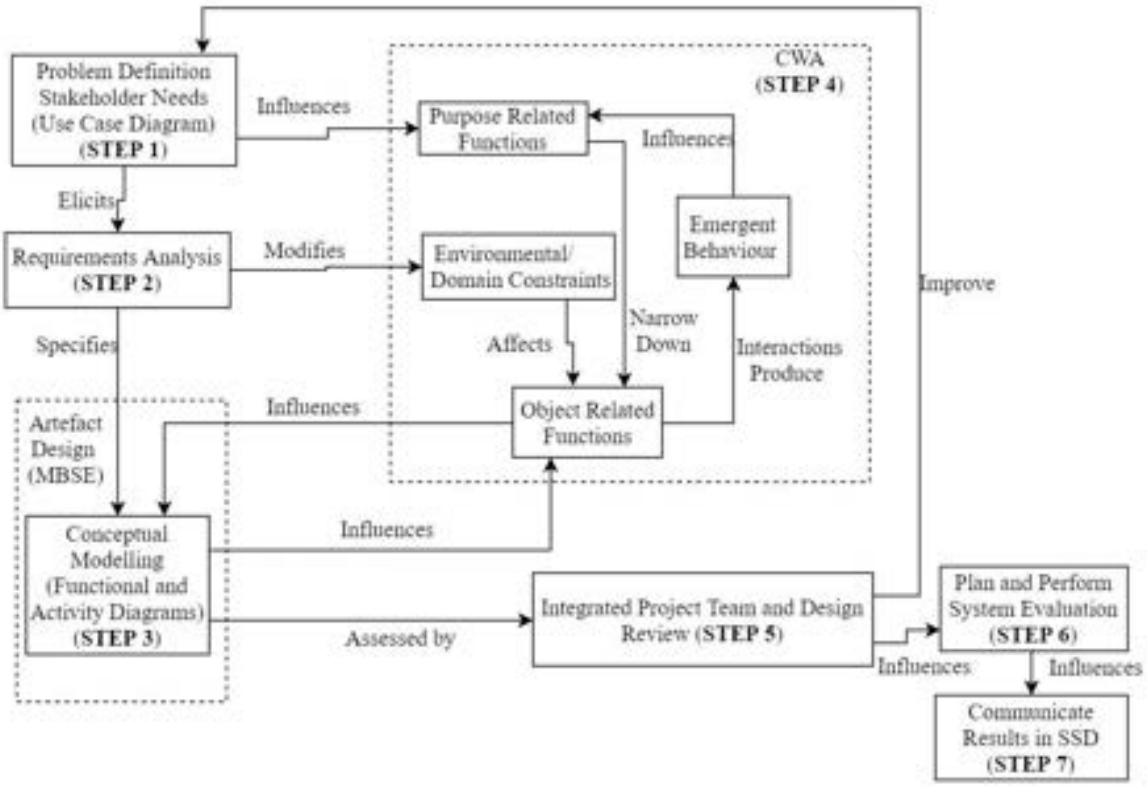

Figure 3: The Proposed Framework Model

4 RESEARCH APPROACH

4.1 Research Method

Applied research aims to produce further knowledge that policymakers and practitioners can use to improve organisations. The inductive methodology focuses on creating new theories, while the deductive methodology tests generally established theories on an identified problem or situation. This research applies the proposed framework model in Figure 3 to a complex sociotechnical system development project and uses deductive methodology. The qualitative methods captured constructive inputs and evaluations from the subjects involved in the studied environments. The positivist deductive qualitative research study employs a Design Science Research framework and processes [39].

This research implements a Design Science Research paradigm for solving problems to advance human understanding by producing creative artefacts. An artefact is an object created to solve issues and problems experienced by humans. Artefacts can be tangible or intangible objects. They are models, structures, constructs, methods, and instantiations. It seeks to improve the knowledge of science and technology theories by developing artefacts and design knowledge that solve complex sociotechnical system problems and enhance systems and working environments [40]. The approach intends to address the business needs by creating artefacts designed using the base knowledge. Researchers investigate how current systems should improve, design artefacts, and develop knowledge of why the artefacts work [41]. The artefacts were evaluated in a focus group of the Integrated Project Team members. A thematic analysis was performed on the meeting transcripts.

The methodology is applied to the case of integrating a smart metering system (SMS) with existing systems in municipalities to demonstrate the proposed framework model in Figure 3 (the designed artefact).

4.2 Advanced Metering Infrastructure or Smart Metering Infrastructure

Municipalities and other organisations are slowly implementing smart meters because of the following benefits and advantages of smart meters [42]:

- Upgraded outage services and expanded supply network monitoring, load management and forecasting.
- Smart meters integrate all the energy sources connected to the grid and assist organisations in effectively managing all linked energy sources.
- The remote meter readings, software updates, disconnection, and connection services contribute to operational budget savings.
- Reduced theft of electricity brings the organisation financial savings.
- Correct billing and Time of Use tariff implementation.
- Enhanced customer service is achieved by customers being able to monitor their energy consumption data and manage bills.

The effective deployment of smart meters depends heavily on the type of communications system employed. Many technologies can be used for communications systems for smart metering. In some cases, multiple communication technologies are utilised together in one operation to ensure efficient two-way communication and exchange of data or signals between the meter and data collector, as shown in Figure 4. Advanced Metering Infrastructure (AMI) aims to gather data from meters and transmit it to the municipality's control centre. Municipalities must address each customer's needs and issues, such as power outages, billing, load management, supply quality, and other customer needs at any time [42].

Managing data from several smart meters necessitates a data management subsystem. It is considered a crucial component in enhancing the grid and facilitating the integration of energy

generation sources. It aims to detect and accurately measure power usage and other parameters remotely [42].

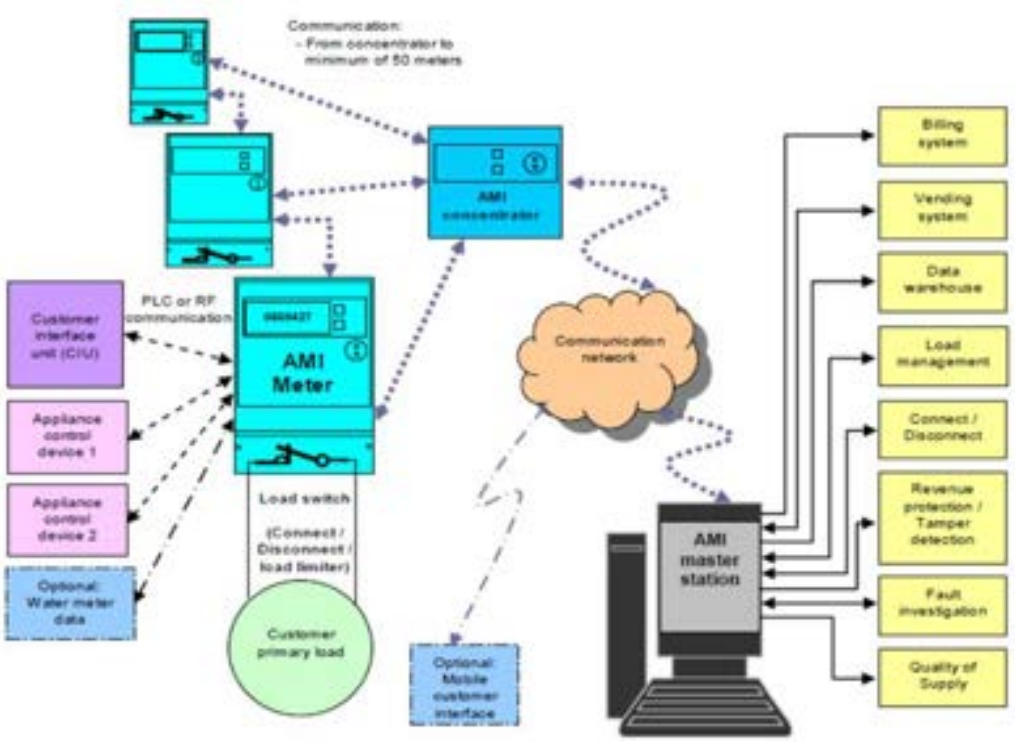

Figure 4: Advanced Metering Infrastructure (AMI) System [42]

4.3 Smart Meters as Complex Sociotechnical Systems

Smart metering systems (SMS) are complex because they exhibit emergent properties when their technical and social system elements interact, and their behaviour can only be comprehended by studying the whole system, the components and their interactions. Therefore, the transition requirements of the SMS must focus on both the technical and the social system and their interactions with each other in a constrained environment [3], [7], [43].

5 RESULTS

5.1 Problems Definition and Environment Needs (STEP 1)

Due to the early stage of smart meter installations in South Africa, many municipalities struggle to adopt and operate smart meters. There are many documented instances of inaccurate invoicing, faulty meters, and inadequate skills and services given to customers due to technical, policy, political, social, and organisational challenges [44], [45]. This indicates that there is still a need to improve knowledge, skills, services and policies when implementing smart meters in municipalities and other organisations.

Customer challenges with the new technology include unfulfilled perceptions and expectations, including user-friendly purchasing and loading of electricity credits, easy electricity usage monitoring, etc. Summary points of the problems still experienced when implementing smart meter projects in municipalities include [44], [45]:

- Skill deficiency across all aspects of their organisational systems.
- Difficulties in establishing the precise scope of work required for tenders.

- Deficiency in national regulations on smart meters.
- Projects require the development of policies and legislation to support them.
- A lack of a customer-centred approach is needed when implementing these projects.
- Infrastructure cannot manage the large volume of data that smart meters generate.

The SMS stakeholders include the Municipality and government, Employees, Regulators (NERSA, Treasury, IEC, etc.), Communities or Customers, Policy makers, Smart Meter Infrastructure Manufacturers and Software Suppliers, Contractors and Service providers.

The MBSE methods support SE processes, including requirement analysis, functional analysis, and the system's architectural design, which help analyse the SMS. Use Case Diagrams are used to uncover and analyse user needs; they elicit the stakeholders' requirements. Figure 5 shows the Use Case Diagram for an intelligent metering system. It shows the stakeholders' needs that the SMS must satisfy to realise the value of all stakeholders [15], [30].

5.2 Requirements Analysis (STEP 2)

From the problem definition and the Use Case Diagram, designers, engineers, and project managers can compile detailed stakeholder requirements that are measurable and verifiable to understand what is required. For the SMS, the Use Case diagram functions will be broken down further into measurable requirements that can assist in designing the required system.

5.3 Functional and Activity Diagram (STEP 3)

Functional requirements activity diagrams elaborate on the use cases and stakeholder requirements diagram to design the required SMS. The functional elements often do not consider the social system constraints and their interactions with the technical system. They need further analysis to capture the system requirements while compiling the scope of work and specifications for the SMS. Cognitive Work Analysis is utilised to analyse the whole system. The SMS components and functional elements are mapped on the CWA AH structure to further examine the system requirements, as shown in Figure 6 [3].

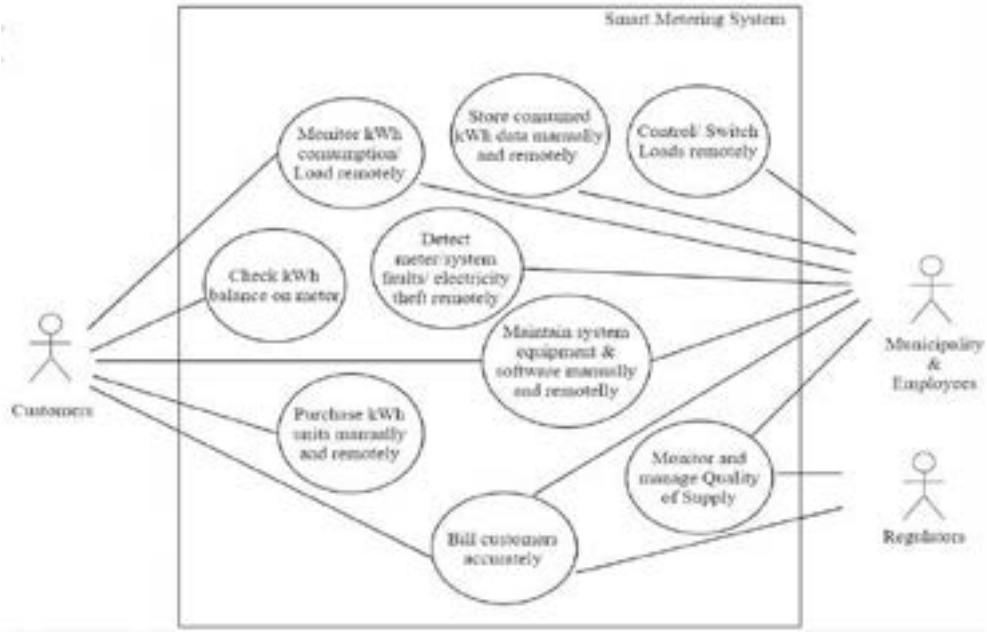

Figure 5: MBSE Use Case Diagram of a Smart Meter System

5.4 Cognitive Work Analysis AH Diagram (STEP 4)

The environmental complexities and limitations that the system operates within are also analysed using the CWA AH diagram shown in Figure 6 and made part of the system design to ensure complete system requirements, leading to better decisions when choosing alternative new technologies and system designs. The top row shows that municipalities' existence is structured according to governmental legislation and regulatory bodies, with requirements that municipalities must comply with to avoid penalties and continue supplying electricity to their customers. The policies drive municipalities to prioritise and value all the elements demonstrated in row two of the CWA AH diagram. The policies are the environmental constraints existing within municipalities that the SMS needs to function within, and they constrain the system's performance. Suitable policies will ensure the system performs well and emerge with the required purpose-related functions that stakeholders need [3].

The object-related functions and the priorities/values elements interact through the links, resulting in the purpose-related functions on the CWA AH diagram. The technical functions of the SMS need to interact well with the priorities and values of the municipalities to ensure a high-performing system. All the emergent behaviours of the system are complex, and the challenge is to foresee and understand the undesired emerging behaviours that can cause the system to fail. The subsystems' interactions must be analysed, and each behaviour must be modelled to assist the designers in making better design decisions. System Engineers are required in organisations to apply the SE practices that ensure that all stakeholders and SMS requirements are captured for all the system lifecycle stages and the risks are managed through system life cycle stages [4], [18], [46].

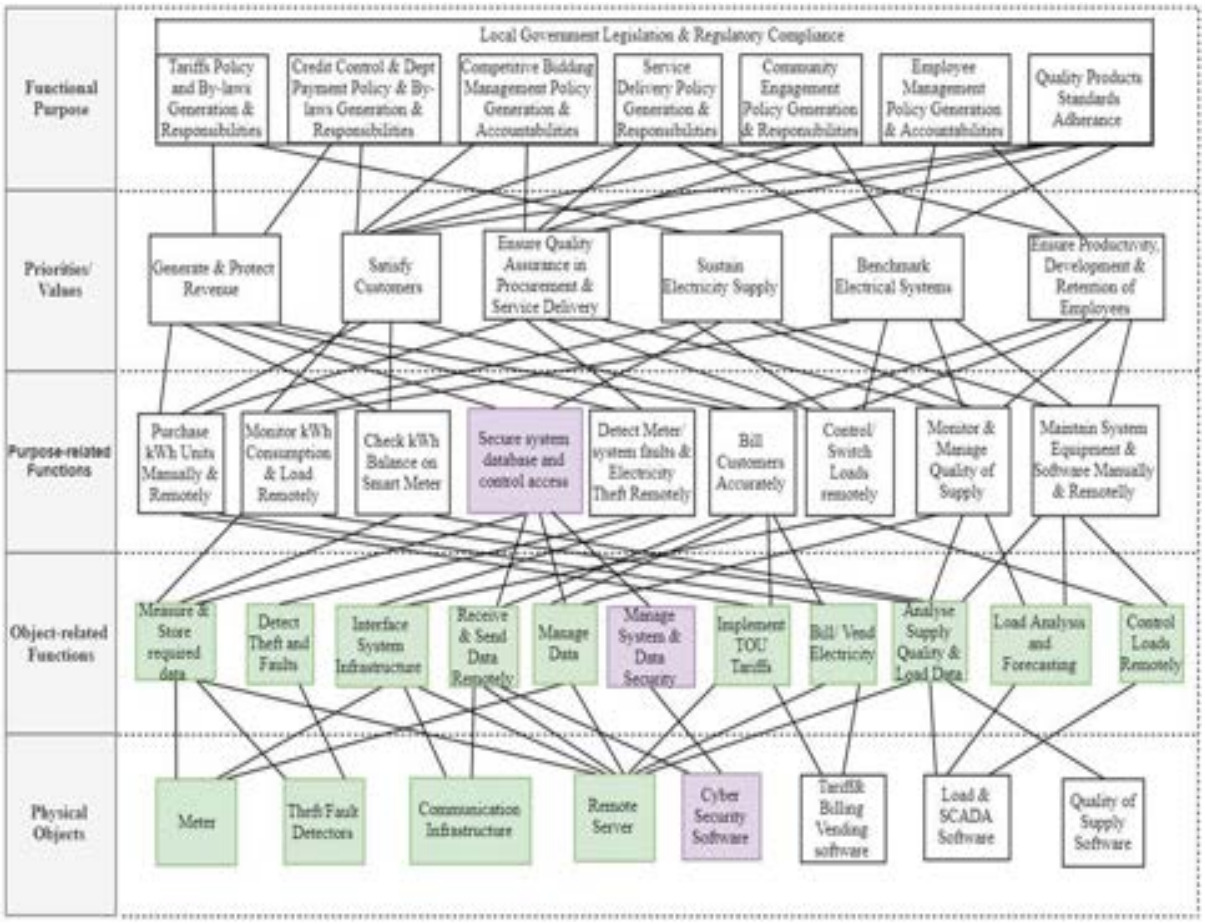

Figure 6: Updated CWA AH Structure with Participants' Inputs

Figure 7 shows how SMS integration problems can be resolved to improve system performance by shifting the burden of the generic system archetype structure. As the intelligent metering integration problems increase, most municipalities contract work to service providers due to skill deficiency. The part of the work is then handled by service providers, a symptomatic solution that causes side effects. The side effect is the reliance on service providers, which decreases opportunities for municipalities to gain system experience and learn how to manage and improve their systems. The fundamental solution is the municipalities' efforts to support and enable their employees. They should implement policies to ensure organisational leadership, enhance employee incentives and rewards systems, and encourage self-development. Also, it can focus on improving stakeholder value, standardising products and services, and ensuring procurement processes meet the needs of the SMS. This will improve system performance and ensure the integration of new technology with the current system [47].

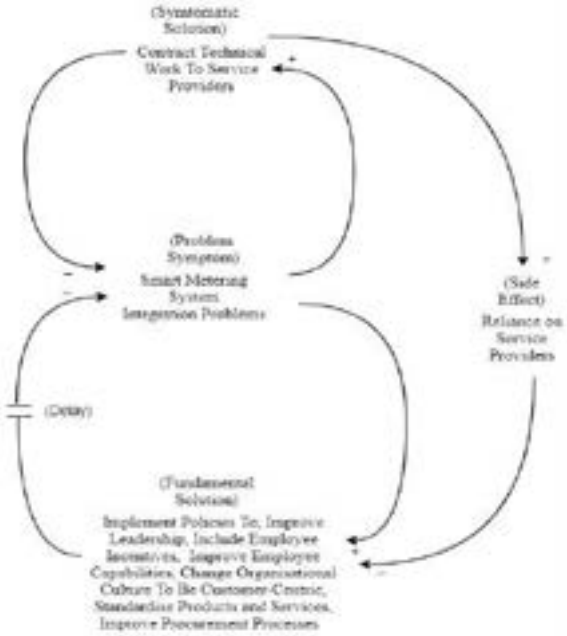

Figure 7: Smart Metering System Shifting the Burden CLD diagram

5.5 Integrated Project Team and Design Review (STEP 5)

A focus group was held with the Integrated Project Team to analyse and improve the designed artefact and framework model. The team included one power protection chief engineer, metering inspector, substation design engineer, supervisory control and data acquisition engineer, power system project manager, deputy director, and director. Every participant commented to help analyse and improve the CWA AH structure for the SMS. All the discussions and inputs from the Integrated Project Team were recorded and captured in Microsoft Teams transcripts. The sentiment analysis outputs are shown in Table 1.

Participants agreed that the framework model and CWA AH structure are helpful, and they are a perfect start when drafting specifications to ensure the new technology integrates well with the existing system. Participants commented that the CWA AH diagram assists in highlighting all the system questions that need to be answered when compiling system specifications, and that the CWA AH structure can be improved as specifications improve to better analyse the interactions. Participants agreed that the CWA AH structure, elements and links analysis assisted in analysing the system needs and uncovered further requirements that must be included in the system design to ensure that the new technology integrates well with the current system.

The participants commented that the designed artefact and framework model should be utilised for every new technology that each section or department tries to implement to improve system performance. Participants realised that some environmental constraints also limit the performance of the system elements and their interactions, and must be adjusted by introducing or changing the organisational policies. They also realised that the CWA AH structure can be presented to management, departments and other stakeholders to help them understand how the functions are interconnected and affect each other's performance and how systems can be improved by analysing the elements and their interactions.

Table 1: Summary of the Participant Comments and Sentiments

Participant	Opinion	Sentiment
1	Believes the approach is beneficial, especially for municipalities. Refers to it as an "incremental innovation" that requires continuous improvement	**Positive**: Sees it as a good technology that can be widely applied
2	Supports the approach but emphasises the need for better operational feedback loops to improve system acceptance and long-term success	**Constructively critical**: Appreciates the value but highlights concern about feedback
3	Suggests the approach could help integrate different factors in load forecasting, but notes a lack of current integration across the relevant section	**Cautiously optimistic**: Believes in the potential but questions how well the approach integrates
4	Acknowledges the value but highlights resistance to new technology from older personnel and issues like vandalism that hinder implementation	**Mixed**: Sees potential but expresses frustration with practical obstacles
5	Advocates for a holistic approach, considering all social and technical elements for successful implementation	**Positive**: Views it as flexible and applicable across various contexts
6	Strongly supports the approach, acknowledging its integration with existing systems and its potential for ongoing improvement	**Very positive**: Confident that the system is well-researched and promising

5.6 Evaluate Designed Artefact, Framework Model and Research Objectives (STEP 6)

The first objective of the research study was to investigate how systems thinking, SE, and CWA can resolve complex sociotechnical system problems and successfully integrate new technologies with existing systems. This objective has been met by the artefact and framework model, designed by applying the base theories mentioned to resolve complex sociotechnical system integration problems.

The second objective was to develop a framework model for resolving complex sociotechnical system transition problems to ensure that organisations can successfully integrate new technologies to increase performance in organisations. The designed artefact and framework model has been applied to integrate the SMS's new technology with the existing system in municipalities. The demonstrated artefact and framework model showed that the new technology integration problems arose because the systems are designed and implemented with incomplete requirements, are constrained by their environment, and cannot perform optimally.

When applied, the framework model could show where the incomplete requirements were missing by using the CWA AH structure most of the time. The missing requirements were at points where elements interacted with each other through the links. To capture complete requirements, designers, engineers and managers must apply Systems Thinking when implementing systems to ensure that the scope of the specification is designed for the system elements and their interactions. The CWA AH structure demonstrated that the constrained environment required top management to re-evaluate or introduce better policies, enabling

systems to perform optimally. Completely designed system requirements and better or new policies and regulations will resolve the latest technology integration problems.

5.7 Validity and Reliability Considerations

To strengthen the study's internal validity, the research design incorporated several measures. Firstly, the framework was applied according to a clear sequence of steps (Figure 3) to ensure consistent execution amongst the analyses of case studies. Secondly, stakeholder requirements, identified gaps, and emergent behaviours were derived from artefact outputs (Use Case Diagrams, Functional and Activity Diagrams, and the CWA Abstraction Hierarchy) and triangulated against Integrated Project Team feedback. Thirdly, the structured focus group questions were developed so that they directly tested whether or not the framework could handle the particular integration issues identified in Step 1. In other words, the research goals, methods used, and criteria for evaluating the results were all aligned; therefore, extraneous factors are unlikely to have caused the observed improvements.

The framework concerning the SMS was elucidated, providing for a complex sociotechnical integration challenge, a hallmark of many infrastructure projects. Contextual factors such as regulatory environments, organisational structures, and straightforward skill availability all influence outcomes, and one should consider other settings. The framework essentially lends itself to scenarios where: (a) some new technology needs to be integrated within an extant sociotechnical system, (b) both technical and social subsystems are to operate under some environmental constraints; and (c) stakeholder interaction is possible in the early design phases. The study in other industries (for example, transport, health care, and defence) is encouraged as future work investigates the framework's generalisability further.

Constant processes and documented data collection and analysis protocols were ensured to address reliability. All focus group sessions were recorded with exact verbal transcription. Artefacts (models, diagrams, and analysis notes) generated during the study have all been archived along with the question protocols and coding scheme to allow replication by other researchers. The findings can be repeated because of the consistent application of the steps in the framework, coupled with the documented procedure.

6 CONCLUSION

To achieve the research objectives, the Systems Thinking, SE, CWA and Complex Socio-technical Systems base theory were surveyed and analysed, and their core elements were structured into a framework. The designed artefact and framework model ensures that the new technology system design requirements are complete by exposing the social and technical interactions impacting the system's purpose. The element's interactions, once exposed by the framework, can be analysed and scoped better to ensure complete system requirements are met. The framework also assists in analysing system capabilities and exposes environmental constraints that limit new technologies' performance in organisations.

The research study provides an approach that may improve how municipalities and other organisations can better integrate new technologies with existing systems and how to analyse and resolve new technology integration problems to enhance system performance. The designed artefact and framework model has demonstrated that significant effort should be made when designing the system specifications and capturing system requirements. The complete requirements ensure minimum scope changes and project risks.

The demonstrated CWA AH structure analysis exposed that the system elements can be in different departments. Some elements are social, and some are technical, interacting to form the whole system's behaviour. Therefore, all stakeholders and departments involved should analyse the CWA AH structure to ensure that all the requirements for the links and interactions are analysed and specified completely to provide complete system requirements. The CWA AH

structure also demonstrated that environmental constraints must be investigated, and policies must be improved or changed to maximise system performance. Further research can assist in better understanding how policy can be modelled to maximise system performance.

STATISTICAL RELIABILITY MODELING FOR HEAVY-DUTY ROTARY TIPPLERS IN BULK MATERIAL HANDLING OPERATIONS

N. Malinga[1]

[1]Department of Industrial and Systems Engineering
University of Pretoria, South Africa
malinga_nkosinathi@yahoo.com

ABSTRACT

Rotary wagon tipplers are crucial to South Africa's pit-to-port rail logistics, enabling efficient offloading of bulk commodities at export terminals. However, reliability issues and equipment downtime disrupt operations, hampering volume throughput across the iron ore export value chain. Reliability, defined as a system's ability to consistently perform its intended function, is influenced by complex factors across the equipment life cycle, making root causes difficult to isolate. This study analyses operational data from a bulk material offloading terminal, applying two-parameter Weibull and Lognormal statistical models to predict offloading equipment reliability and assess the performance of electrical and mechanical components over time. Results reveal that the Lognormal Maximum Likelihood Estimator (MLE) model best fits electrical failures, while the Weibull MLE model is optimal for mechanical failures. These insights underscore the value of shifting from reactive to proactive maintenance, enabling data-driven planning and improved tippler reliability.

Keywords: reliability prediction, statistical modeling, rotary wagon tipplers

1 INTRODUCTION

1.1 Background

South Africa was ranked as the fourth-largest exporter of iron ore in 2023, accounting for approximately 4.1% of global market share [30]. Central to this performance is the Sishen–Saldanha Iron Ore Export Line, an 861-kilometre heavy-haul railway that connects the mineral-rich Northern Cape to the Port of Saldanha. This strategic corridor is essential to South Africa's mineral-driven economy, facilitating the efficient movement of bulk commodities to international markets. Within this logistics value chain, the reliability of rotary wagon tipplers at the downstream port plays a critical role. These machines are responsible for the rapid and continuous offloading of iron ore from rail wagons to stockpiles and conveyors for ship loading. Any downtime or performance degradation in these systems can disrupt value chains, affecting volume throughput.

The concept of seamless "pit-to-port" logistics is vital in mining economies, where consistent and efficient flows of mineral cargo underpin economic performance [9], [18] as illustrated in Figure 1. Recent studies and technological advancements highlight the importance of enhancing bulk handling equipment reliability through predictive maintenance, digital monitoring systems, and robust mechanical designs [27]. Despite the critical role of rotary tipplers on downstream offloading performance, rotary tipplers face persistent reliability challenges, with frequent operational downtime causing significant disruptions and cascading delays throughout the export value chain upstream processes. Statistical data analysis such as the Pareto principle shows that failures related to mechanical and electrical components are among the leading contributors to overall reliability issues.

Predicting tippler reliability and optimising offloading performance requires robust statistical modeling that integrates failure analysis and predictive maintenance strategies. This includes the application of reliability modeling statistical methods such as the Weibull and Lognormal statistical distributions capable of capturing component-level failure patterns to make rotary tippler reliability and Mean Time Between Failure (MTBF) more predictable [16]; [32]. Weibull and Lognormal analysis serve as critical modes in reliability engineering for assessing product lifetime performance by modeling failure-time data. These statistical methods enable engineers to address key reliability concerns, such as identifying failure patterns, forecasting future failures, and optimizing maintenance strategies [32].

1.2 Problem Statement

Industrial systems are generally subject to degradation due to continuous use and exposure to environmental factors. This degradation ultimately leads to system failure, which in turn can result in safety issues, equipment damage, quality problems, and unexpected machine unavailability. In the past, maintenance was largely viewed as a reactive task performed only after failures had occurred, and it was often considered difficult to manage. Today, however, maintenance is widely recognized as an essential business function and a critical aspect of asset management [2]. Organisations now increasingly understand that they can enhance their efficiency and reliability by planning maintenance interventions more effectively. As a result, there is greater emphasis on preventive maintenance actions, which are better coordinated with other business functions, such as operations and spare parts management.

Rotary tipplers at a port terminal, which are essential for the rapid offloading of iron ore from rail wagons, experience frequent operational downtime caused mainly by mechanical and electrical component failures. These reliability issues lead to significant disruptions and cascading delays throughout the iron ore export value chain, negatively impacting throughput performance. The rotary tippler is designed to offload an entire 116-wagon iron ore loaded train (rake) in approximately two hours as shown in Figure 1. Any unplanned equipment

downtime increases production losses and can have substantial revenue implications. Current maintenance strategies are insufficiently predictive, lacking robust statistical modeling to effectively forecast failures and optimize maintenance interventions. There is a need to develop and apply advanced statistical models that can accurately predict equipment reliability and Mean Time Between Failures to reduce downtime and enhance operational performance.

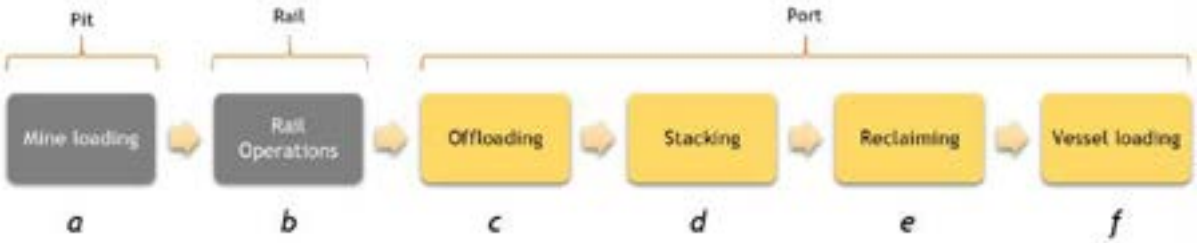

Figure 1. Illustration of the Pit-to-Port Value Chain, with the study focusing specifically on element **(c).**

By linking empirical data to predictive insights, advanced statistical analysis bridges theoretical reliability models with practical operational outcomes. Predicting equipment reliability and MTBF for electrical and mechanical components in rotary tipplers, which is the focus of this paper, is essential. Building on recent studies, this paper proposes the application of two-parameter Weibull and Lognormal statistical models to effectively assess and predict equipment reliability and MTBF for these critical components. The framework presented in this study represents a preliminary step forward in implementing and emphasizing the use of statistical modeling in reliability analysis.

2 RELATED WORK

In this section, the foundational literature on equipment reliability and predictive maintenance is reviewed, with a focus on bulk material handling equipment. It highlights the evolution from reactive to data-driven maintenance strategies and underscores the role of both Weibull and Lognormal statistical modeling in predicting equipment failure behaviour. Key insights are drawn from studies demonstrating the impact of reliability improvements on operational performance. Challenges related to data quality and model limitations are also discussed to contextualize the study's focus.

2.1 Equipment Reliability and Maintenance Strategies

Reliability engineering is concerned with quantifying a system's ability to perform its intended function without failure over a defined period, under stated operational conditions [34]. In high-throughput environments such as iron ore offloading in export terminals, equipment reliability directly affects operational continuity and throughput performance. Traditional maintenance strategies such as reactive maintenance (run-to-failure) and calendar-based preventive maintenance are increasingly being replaced by data-driven predictive maintenance approaches [11], [23]. These predictive strategies leverage historical failure data, statistical modeling and machine learning algorithms to anticipate failures and schedule timely interventions [15].

Recent research further highlights that predictive maintenance now incorporates advanced technologies such as artificial intelligence and digital twins, enabling real-time monitoring and proactive decision-making to optimize maintenance schedules, enable effective condition-based maintenance and reduce unplanned downtime [24]. The shift from reactive to proactive maintenance has been widely validated in the literature. Dhillon [5] argues that the integration of quantitative reliability models enables improved asset utilization and optimized maintenance schedules. Moreover, predictive maintenance strategies have been shown to

reduce unplanned downtime by up to 30% and extend component life in various industrial case studies [3], [23].

2.2 Statistical Methods in Reliability Prediction

Among the statistical methods widely used in reliability analysis, the Weibull and lognormal distributions stand out as two of the most robust and versatile techniques. Both excel in modeling right-skewed time-to-failure data, which is common in industrial systems, and provide the flexibility to capture diverse failure patterns across different equipment life stages [1].

The Weibull distribution is defined by two key parameters: shape and scale. Its major strength lies in its ability to model various hazard rate behaviours, constant, increasing, or decreasing, making it suitable for a broad range of reliability scenarios, from early-life failures to wear-out phases. This adaptability has been validated across multiple industries such as manufacturing, mining, and transportation. For example, Meeker & Escobar [20] demonstrated Weibull's superiority over normal and exponential distributions, especially in handling censored and skewed failure data. In addition, Elsayed [7] emphasized the Weibull shape parameter's role in identifying dominant failure modes, which supports condition-based maintenance and design optimisation.

Complementing the Weibull model, the lognormal distribution is particularly effective in reliability contexts dominated by degradation, fatigue, or cumulative wear [7], [16]. It assumes that the logarithm of time-to-failure follows a normal distribution, aligning well with degradation mechanisms observed in rotating machinery, electrical motors, and structural components [16]. The lognormal hazard function typically starts low, increases gradually, and then accelerates, reflecting common mechanical system failure patterns after initial operation. Like Weibull, lognormal parameters are often estimated using MLE, an estimation method well-suited for censored or incomplete data [17], [20]. MLE maximizes the likelihood of observing the data under specified parameters, reliably estimating the log-mean (μ) and log-standard deviation (σ), making it preferred in complex industrial applications [10].

Alternatively, the Least Squares Estimation (LSE) method, a simple yet efficient approach, is often used to estimate model parameters. LSE works by minimizing the sum of squared residuals between observed data and corresponding predicted values from a model [10]. Combining these distributions with robust estimation methods has significantly advanced predictive maintenance and system reliability in asset-intensive industries.

In mining and bulk material handling, the application of Weibull and lognormal models has led to notable reliability improvements. Rao et al. [28] reported a 23% increase in MTBF for haul truck components using Weibull analysis. Similarly, Murthy et al. [25] achieved a 28% reduction in failures in mechanical conveyor systems through Weibull modeling. Lognormal models, especially when paired with MLE, have proven effective in analyzing gearboxes and motors, where wear and fatigue are predominant failure mechanisms [13]. Despite their widespread use, the application of Weibull and lognormal distributions to the reliability analysis of iron ore offloading equipment remains relatively underexplored, presenting an opportunity for further research.

2.3 Reliability in Bulk Material Handling Equipment

In bulk material handling systems, equipment such as conveyors, stackers, reclaimers, and rotary wagon tipplers represent critical links in iron ore logistics value chains. The operational reliability of these assets is frequently undermined by high-load cycles, abrasive environments, and a complex interaction between mechanical and electrical subsystems. Studies have consistently found that mechanical failures dominate unplanned downtime in high-duty bulk handling systems [8], [14]

In the context of iron ore terminals, Marais and Saleh [19] conducted a South African case study that identified mechanical degradation in rotary tipplers and wagon movers as the primary contributors to operational delays and reduced throughput. Their findings support the use of component-level reliability modeling using Weibull and lognormal distributions to diagnose root causes and inform maintenance strategies. Such modeling enables targeted interventions, such as identifying whether failure behaviour is governed by wear-out mechanisms (lognormal) or random failures (Weibull).

Studies in mining demonstrated that 3-parameter Weibull models significantly improve the reliability of Load-Haul-Dump (LHD) subsystems. In a detailed study of underground coal mines in India, Bala et al. [3] applied a 3-parameter Weibull distribution to analyze failure and repair data from multiple LHD machines. By classifying LHD subsystems and fitting Weibull models to time-between-failure data, the study enabled the estimation of optimal preventive maintenance intervals for each subsystem. The results showed that this approach allowed for more accurate prediction of subsystem reliability and failure rates, supporting the scheduling of preventive maintenance to improve equipment uptime and operational efficiency.

2.4 Reliability Data Characteristics and Challenges

Despite their benefits, reliability modeling efforts face persistent data challenges. Industrial datasets often contain censored observations, where failures are not observed within the monitoring period, and class imbalance, where rare failure types are underrepresented. Moreover, failure data typically exhibit skewed, non-normal distributions, making traditional normal-based methods such as the normal distribution less suitable. To address these challenges, parametric models such as Weibull and lognormal distributions paired with MLE estimation methods are favoured for their robustness in modeling censored and skewed data [16]. Non-parametric techniques such as Kaplan-Meier are also employed when the failure distribution is unknown, although they lack the predictive capacity of parametric methods [17]. Another challenge is the integration of human judgment and operator interventions into maintenance decisions. Such subjective factors introduce uncertainties not easily captured by traditional models. Methods such as Bayesian inference and Human Reliability Assessment (HRA) have been proposed to account for these complexities [4], but their application in terminals remain constrained by data availability and implementation complexities. The following section presents a detailed methodological framework.

3 METHODOLOGY FOR RELIABILITY MODELING

This section outlines the study's analytical framework, which is structured around three core components. The first step involves data collection and preprocessing, including the extraction of operational records, detailed logs of tippler failure events, and subsequent data cleaning. The second step focuses on model fitting, employing the two-parameter Weibull and lognormal distributions to statistically model failure behaviour and derive predictive insights. The final step centers around the assessment of tippler reliability, failure rate and MTBF, providing a data-driven basis for proactive maintenance planning.

3.1 Data Source

The data used for this study was sourced from a South African export iron ore offloading operator. The operator operates two rotary tipplers offloading iron ore which each tippler comprising the barrel or drum, the wagon clamping system and a controls system unit which is operated by designated operators. The rotary type wagon tippler is used to offload iron ore from loaded wagons into tippler hoppers or bins. Loaded wagons are positioned inside the tippler barrel by a rail shunting locomotive and a tippler arm positioner, then securely held in place by wagon clamps also referred to as car clamps. Once secured, the barrel rotates 140 - 160 degrees, causing the wagons to tip and offload the cargo [12]. The dataset used in this

study comprised logs of tippler failure events for a wagon tippler, along with the recorded duration between each failure. A total of 344 event logs were studied, spanning a 12-month period from March 2024 to March 2025. This period provided an adequate dataset, sufficient to support the objective of the study.

3.2 Problem Definition

Predicting MTBF and equipment reliability is inherently complex due to several key factors:

3.2.1 Right-skewed time between failure distributions

Failure times data typically exhibits a right-skewed distribution, often characterized by a long tail of high values, as illustrated in Figure 2 (a). This skewness signals a significant departure from normality, complicating the use of parametric models that assume normal distribution. Traditional statistical models like normal distributions and linear regression become inadequate, potentially leading to biased estimations. In such cases, generalized distributions such as Weibull, Gamma, and Lognormal are better suited due to their flexibility in modeling skewed data [7], [34]. For instance, the Weibull distribution accommodates varying hazard rates which is increasing, decreasing, or constant rates, making it particularly effective in modeling failure behaviour in complex systems.

3.2.2 Failure modes data class imbalance

The time between failures dataset exhibits a notable imbalance between mechanical and electrical failure records, with 63% attributed to mechanical failures and only 37% to electrical failures [21], as depicted in Figure 2(b). This imbalance risks model overfitting to the mechanical failures dominant class, thereby reducing the predictive performance and sensitivity to electrical failures minority class events. To mitigate this, research recommends applying resampling techniques such as stratified sampling, or using flexible distributions such as Weibull, Lognormal, Gamma or non-parametric models that can better accommodate skewed and imbalanced data distributions. These methods improve the generalization ability of predictive models and reduce potential class-based bias [32].

3.2.3 Censored failure data and analytical challenges

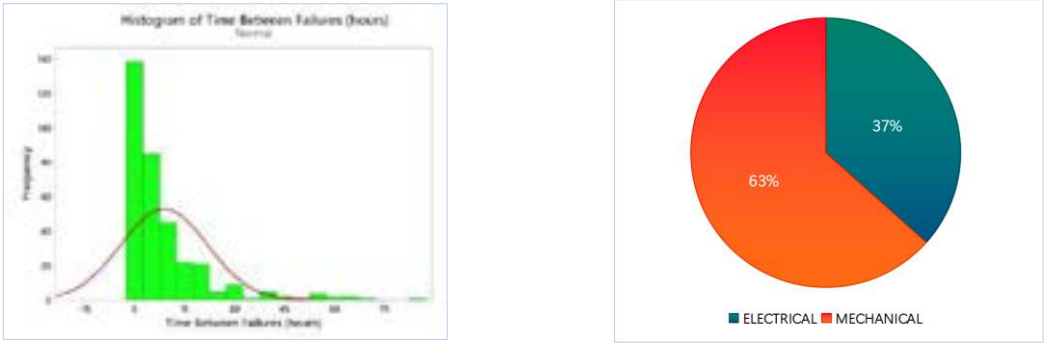
Reliability datasets often contain censored observations, particularly right-censored data, where certain equipment remains functional beyond the study period. This censorship leads to incomplete failure time data, which introduces bias and underestimation of failure probabilities when using traditional reliability analysis. As a result, non-parametric methods like the Kaplan-Meier estimator and parametric approaches using Weibull or Lognormal distributions using MLE are preferred for accurate MTBF estimation under censoring [13]. These techniques account for both complete and censored data, enabling more robust modeling of failure time distributions [17], [20].

3.2.4 Human decision-making and behavioural factors

Maintenance strategies and planning are significantly shaped by human judgment and contextual decision-making. These human factors, including technical staff experience, prioritization of tasks, cognitive biases, and levels of compliance with standard procedures introduce variability that is difficult to capture using conventional statistical model [4]. Traditional reliability models often assume objective, consistent behaviour, overlooking this critical layer of influence. As a result, there is a notable gap in integrating qualitative human factors into quantitative reliability prediction models [21]. This limitation is recognised in the literature and methodology but is not addressed within the scope of this study.

At a systemic level, time between failures and reliability improvements often follow the Pareto principle, which implies that approximately 20% of failure modes (i.e., mechanical and electrical failures) drive over 80% of equipment failures. Identifying these high-impact

factors through structured root cause analysis and failure mode prioritization is critical to improving reliability.



(a) *(b)*

Figure 2. The right-skewed histogram in subfigure **(a)** illustrates the distribution of time intervals between successive failure events for the rotary wagon tippler system while the pie chart in subfigure **(b)** presents the relative distribution of failure times for mechanical and electrical failure modes.

3.3 Statistical reliability modeling approach

The Weibull distribution was applied alongside the lognormal distribution to model tippler reliability and predict MTBF. While the Weibull distribution is ideal for capturing increasing, decreasing, or constant hazard functions due to its flexibility in representing diverse failure patterns, the lognormal distribution excels in modeling skewed datasets with all-positive values, particularly when the natural logarithm of the failure times follows a normal distribution [10], [13]. This dual approach ensures robustness across varying data characteristics, as the lognormal distribution often provides a superior fit for scenarios involving wear-out mechanisms or multiplicative degradation processes. Both distributions efficiently handle small sample sizes and accommodate diverse failure modes. Together, these methods support data-driven decisions in maintenance planning and life-cycle management by balancing Weibull's adaptability and lognormal's specificity [16]. Figure 3 illustrates this integrated methodological analytical framework, illustrating the comparative analysis approach employed in this study.

Figure 3. Methodological Analytical Framework

3.3.1 Data extraction and pre-processing

The tippler failure records were sourced from a system that captures real-time equipment failure events. The raw data underwent comprehensive preprocessing including data cleaning, validation, and formatting to ensure accuracy and suitability for subsequent reliability analysis. This preparation was vital for preserving data integrity and supporting robust statistical modeling. Key preprocessing steps involved transforming failure time log events into time-between-failure metrics and incorporating electrical and mechanical failure modes,

which account for more than 80% of rotary tippler downtime. In addition, converting failure time formats into integer values was essential to enable efficient and precise data analysis.

3.3.2 Weibull and Lognormal Statistical Model Fitting

The Weibull and lognormal distributions were applied to predict tippler reliability and MTBF using Minitab Statistical Software Reliability/Survival Analysis toolkit [23]. Mean Time Between Failures is a fundamental metric in reliability engineering, representing the average operational time between consecutive failures of a system. It is calculated by dividing the total operating time by the number of failures observed. As a reciprocal of the failure rate, MTBF offers a practical measure of system longevity. Higher MTBF values indicate more reliable systems, while lower values reflect frequent breakdowns and reduced operational uptime. Notably, MTBF tends to decline as cumulative failure rates increase, signifying that systems experiencing frequent failures will demonstrate lower average times between breakdowns [15].

Table 1. Weibull and lognormal Distribution Equations and Interpretation [7], [10], [16]

Parameter	Weibull Distribution	Interpretation	Lognormal Distribution	Interpretation
(1) Probability Density Function	$f(t) = \frac{\beta}{\lambda}\left(\frac{t}{\lambda}\right)e^{\left(-\frac{t}{\lambda}\right)}, \quad t \geq 0$	Shape parameter (ß) controls failure trends: ß < 1: Decreasing failure rate (infant mortality) ß = 1: Exponential distribution ß > 1: Increasing failure rate (wear-out)	$f(t) = \frac{1}{t\sigma\sqrt{2\pi}}\, e^{\left(-\frac{(lnt-\mu)^2}{2\sigma^2}\right)}, \quad t > 0$	Models multiplicative degradation processes Positively skewed, with long right tail
(2) Mean Time Between Failures	$MTBF = \lambda \times \Gamma\left(1 + \frac{1}{\beta}\right)$	Γ: Gamma function MTBF ≠ λ unless ß = 1	$MTBF = e^{\left(\mu + \frac{\sigma^2}{2}\right)}$	Sensitive to σ (variance of log-transformed data) Higher σ increases MTBF
(3) Reliability Function	$R(t) = e^{-\left(\frac{t}{\lambda}\right)\beta}$	Probability of survival beyond time "t" Directly linked to the hazard rate/failure rate	$R(t) = 1 - F(t) = \varphi\left(\frac{lnt-\mu}{\sigma}\right)$	φ: Standard normal CDF Reliability decreases as σ increases
(4) Cumulative Distribution Function	$F(t) = 1 - e^{-\left(\frac{t}{\lambda}\right)\beta}, \quad t \geq 0$	Inverse of the Reliability Function, R(t)	$F(t) = \varphi\left(\frac{lnt-\mu}{\sigma}\right), \quad t > 0$	φ: Standard normal CDF, t > 0
(5) Hazard Function (Failure Rate)	$h(t) = \frac{f(t)}{R(t)} = \left(\frac{\beta}{\lambda}\right)\left(\frac{t}{\lambda}\right)^{\beta-1}$	Monotonic: Increasing (ß > 1) Constant (ß = 1) Decreasing (ß < 1)	$h(t) = \frac{f(t)}{R(t)} = \frac{\frac{1}{t\sigma\sqrt{2\pi}}\, e^{\left(-\frac{(lnt-\mu)^2}{2\sigma^2}\right)}}{\varphi\left(\frac{lnt-\mu}{\sigma}\right)}$	Non-monotonic: peaks then declines Suitable for wear-in followed by aging

As shown in Table 1, the Weibull and Lognormal distributions were used to fit the failure data into the statistical models, offering distinct yet complementary perspectives on system failure behaviour. The Weibull distribution is highly versatile, shaped by its scale and shape parameters, enabling it to model decreasing, constant, or increasing failure rates which correspond to the classic three phases of a system's life-cycle, namely, infant mortality, useful life, and wear-out. This adaptability makes Weibull ideal for engineering applications across various asset lifespans. In contrast, the lognormal distribution is more appropriate for systems

that degrade through multiplicative processes, featuring a positively skewed profile and a non-monotonic hazard function where failure risk rises, peaks, and then declines [10],[16], [26].

Both distributions utilize a reliability function to represent the probability of survival up to a given time, with Weibull's reliability closely tied to the shape of its hazard function, while the hazard function for the lognormal distribution tends to display a long tail of surviving components, highlighting durability in a portion of the population. Similarly, the cumulative distribution functions (CDFs) reflect these behaviours. Weibull's CDF aligns with its failure rate phase, while lognormal's gradual slope and long right tail signify extended failure timelines. The hazard function offers the most striking contrast. Weibull's monotonic behaviour produces the well-known "bathtub curve," as shown in Figure 4, capturing distinct failure stages, whereas lognormal's peak-and-decline pattern reflects more nuanced degradation dynamics. Furthermore, while MTBF in Weibull models depends on the shape parameter and only equals the reciprocal of the failure rate when the shape parameter is one, the Lognormal MTBF is more sensitive to the variance of log-transformed data, with higher variance leading to greater MTBF values [32].

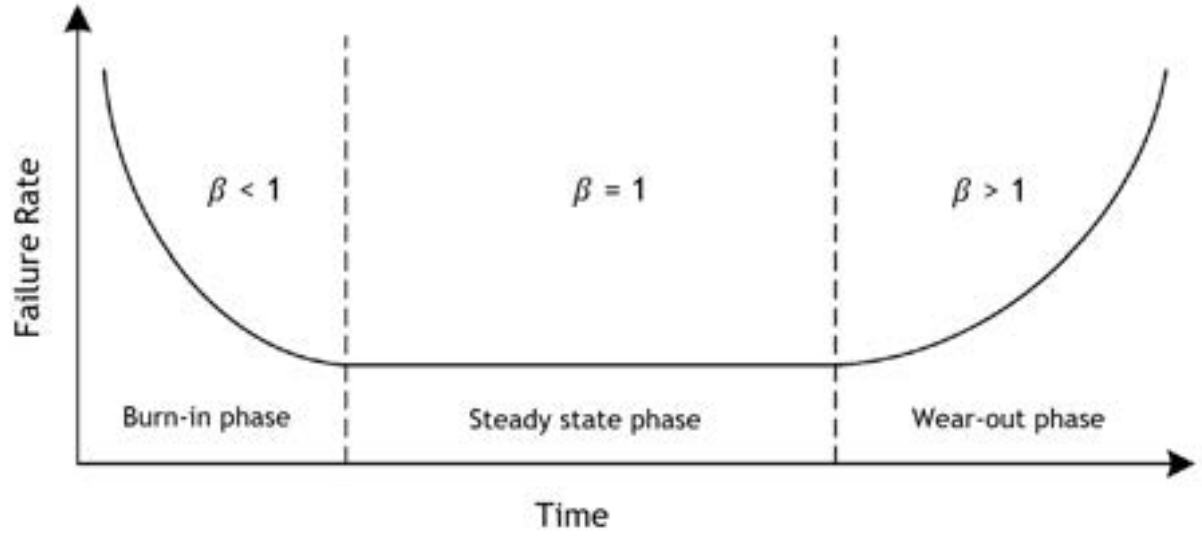


Figure 4. A typical "bathtub" curve showing failure stages, modified from [3], [32]

3.3.3 Statistical Model Validation

The Weibull and Lognormal models were validated using three statistical validation methods combining Pearson correlation coefficient, probability plots and the Anderson-Darling test. Probability plots provided visual verification of alignment between failure data and the Weibull and Lognormal distributions, while the Anderson-Darling (AD) test quantified goodness-of-fit, prioritizing accuracy in distribution tails. Correlation coefficients further assessed linearity between transformed observed and predicted failure times. Table 2 presents the AD test results and correlation coefficients for both models. The low AD values, combined with correlation coefficients close to 1, indicate a strong goodness-of-fit and demonstrate that both models accurately represent the observed failure data.

Table 2. Goodness-of-fit test Validation

Distribution	Failure Mode	Anderson-Darling	Correlation Coefficient
Weibull	Electrical	5.516	0.936
	Mechanical	6.214	0.949
Lognormal	Electrical	1.186	0.985
	Mechanical	0.614	0.993

3.3.4 Model Evaluation and Parameter Estimation

The performance of the two statistical models, the Weibull and Lognormal, was evaluated using the Maximum Likelihood Estimation (MLE) and Least Squares Estimation (LSE) methods. For the Weibull distribution, these methods iteratively optimized the scale parameter (λ) and shape parameter (ß) to maximize the likelihood function or minimize residual errors between observed and predicted failure times [10]. For the Lognormal distribution, analogous parameters were estimated, which are the location parameter (μ), representing the mean of the natural logarithm of failure times, and the scale parameter (σ), corresponding to the standard deviation of the log-transformed data. Table 3 below presents the specific computational frameworks used for parameter estimation in both distributions, highlighting the mathematical distinctions between their optimization criteria [10],[32].

Table 3. Model Validation Parameter Estimation Methods [10]

Model	Estimation Method	Equation
Weibull	Maximum Likelihood	$\ln(\bar{\beta}) = \frac{\sum \ln(t_i).t_i^{\bar{\beta}}}{\sum t_i^{\bar{\beta}}} - \frac{1}{n}\sum \ln(t_i)$
Weibull	Least Squares	Linearised form: $\ln(-\ln(1-F(t))) = \bar{\beta}\ln(t) - \bar{\beta}\ln(\lambda)$
Lognormal	Maximum Likelihood	$\mu = \frac{1}{n}\sum \ln(t_i),\ \ \sigma^2 = \frac{1}{n-1}\sum(\ln(t_i) - \mu)^2$
Lognormal	Least Squares	Linearised form: $\ln(t) = \mu + \sigma.z$

3.3.5 Reliability and MTBF Values Derived to Inform Maintenance Planning

Reliability and MTBF were estimated using Weibull and lognormal models, yielding critical insights that informed the development of targeted and effective maintenance strategies and planning. The detailed analysis and discussion of results are presented in the following section.

4 RESULTS AND DISCUSSION

This study assessed the reliability of tippler components, with a focus on electrical and mechanical failure modes. Model evaluation using MLE and LSE methods helped identify the most suitable estimation method, which informed optimal parameter estimation. The analysis revealed key failure characteristics, including MTBF and reliability trends. Comparative reliability and failure rate analysis highlighted distinct failure behaviour between electrical and mechanical failure modes. Notably, MLE outperformed LSE method across both failure modes for Weibull and lognormal models as shown in Table 4 and Table 5.

Table 4. Weibull and Lognormal models comparison parameter estimation

Estimator	Weibull				Lognormal			
	Electrical		Mechanical		Electrical		Mechanical	
	Scale	*Shape*	*Scale*	*Shape*	*Location*	*Scale*	*Location*	*Scale*
LSE	21.81	1.25	15.16	1.25	2.93	1.40	2.34	1.19
MLE	32.99	0.94	18.20	1.00	2.99	1.44	2.35	1.18
Variation(%)	34%	33%	17%	25%	2%	3%	0%	1%

4.1 Parameter Accuracy

Table 4 shows the LSE and MLE parameter estimations for both the Weibull and lognormal distributions. The Weibull Distribution shows substantial variation between LSE and MLE estimates for both electrical (up to 34%) and mechanical (up to 25%) data for the scale and shape parameters. The lognormal distribution on the other hand shows minimal variation between LSE and MLE ranging from 0 to 3% for both electrical and mechanical data. This indicates that, for lognormal data, both methods yield similar parameter estimates, likely because the data better fit the assumptions underlying both estimation techniques. This suggests that the two estimation methods can yield notably different results for Weibull models, possibly due to the distribution's sensitivity to estimation technique and the nature of the data. MLE method generally outperforms the LSE method in parameter accuracy and prediction quality for both models [10].

Table 5. Model Evaluation: Weibull and Lognormal models performance comparative summary

Model	Parameter Estimation Method	Failure Mode	Parameter Accuracy	Prediction Accuracy	Time Scale Coverage	Reliability at 80%	Failure Rate
Weibull	**MLE**	Electrical	High	Good	0-160 hours	~8 hours	Decreasing
		Mechanical	High	Very good (for random failures)	0-80 hours	~4 hours	Nearly constant
Weibull	**LSE**	Electrical	Medium	Moderate	0-80 hours	~5.5 hours	Increasing
		Mechanical	Medium	Good	0-48 hours	~3.5 hours	Increasing
Lognormal	**MLE**	Electrical	High	Excellent	0-600 hours	~6.5 hours	Non-monotonic
		Mechanical	High	Very good	0-160 hours	~4 hours	Non-monotonic
Lognormal	**LSE**	Electrical	Medium-High	Good	0-480 hours	~6 hours	Non-monotonic
		Mechanical	Medium-High	Good	0-160 hours	~4 hours	Non-monotonic

Figure 5. Comparable reliability and hazard plots for Lognormal (MLE) and Weibull (MLE) models: (**a**) Lognormal reliability (survival) plot, (**b**) Weibull reliability (survival) plot, (**c**) Lognormal hazard (failure rate) plot, and (**d**) Weibull hazard (failure rate) plot. The comparison illustrates distinct behaviours between the two models in characterising failure and survival patterns. Further analytical details are provided in Table 5.

4.2 Prediction Accuracy, Reliability and Failure Rate

Based on Table 5, the Weibull model with MLE shows high parameter accuracy but behaves differently across failure modes. For electrical failures, the Weibull exhibits a decreasing failure rate as shown in Figure 5(d), while for mechanical failures, it maintains a nearly constant failure rate, consistent with a shape parameter near 1.00. The Weibull MLE model reliably predicts mechanical component failures with high accuracy and time coverage up to 80 hours, though the model tends to give more conservative reliability estimates. In contrast, the Lognormal model excels in modeling electrical failures, offering excellent prediction accuracy with MLE and a broader time scale coverage from 0 to 600 hours, making it effective for long-tailed failure distributions. The Lognormal model maintains consistently high prediction performance between MLE and LSE, while the Weibull model's accuracy varies from moderate to very good, reinforcing the Lognormal model's higher precision.

The reliability analysis in Table 5, and in Figure 5(b) further reveals that the Weibull MLE model maintains about 80% reliability for electrical failures over roughly 8 hours within a 0-to-160-hour range coverage, benefiting systems affected by wear-out or aging due to its decreasing failure rate. For mechanical failures, the Weibull model's 80% reliability horizon shortens to about 4 hours, reflecting a constant failure rate suited for random failures. Using LSE reduces the Weibull model's parameter accuracy and prediction quality, especially for

electrical failures. The Lognormal model with MLE depicted in Figure 5(a) provides exceptional prediction accuracy and extensive time coverage for electrical failures, though its 80% reliability threshold is slightly lower at 6.5 hours. Its adaptability to non-monotonic failure rates across both failure modes offers greater flexibility for complex behaviour modeling. Even with LSE, the Lognormal model maintains strong accuracy and coverage, making it a more versatile choice for nuanced reliability prediction in rotary tipplers.

4.3 Model Selection and Practical Implications

For electrical failures, the Lognormal MLE model emerges as the superior choice, providing a conservative MTBF estimate of 37.3 hours while effectively capturing the extended tail of the failure distribution. This model's exceptional time scale coverage surpasses all alternatives and offers excellent prediction accuracy for electrical failures. The higher location and scale parameters inherent in this model appropriately reflect the longer potential lifetimes typically observed in electrical components, making it ideally suited for comprehensive reliability planning of electrical components. Mechanical failures, conversely, are best represented by the Weibull MLE model, whose shape parameter of 1.00 perfectly characterizes the pure random failure behaviour predominant in mechanical systems. This model yields a realistic MTBF estimate of 18.2 hours and demonstrates remarkable fidelity to observed failure data. Its relatively simpler mathematical structure aligns naturally with the physical mechanisms of mechanical wear, providing enhanced prediction accuracy that directly benefits preventive maintenance scheduling and resource allocation decisions.

Implementing this dual-model approach, Lognormal MLE for electrical components and Weibull MLE for mechanical components creates a comprehensive reliability framework that maximizes prediction accuracy for rotary wagon tipplers. This differentiated modeling approach acknowledges the differences in failure mechanisms between electrical and mechanical components, ensuring more precise reliability predictions and optimised maintenance intervals.

5 CONCLUSIONS

This study applied Weibull and Lognormal statistical models to predict reliability for rotary wagon tipplers, focusing on distinct electrical and mechanical failure modes. The results demonstrate that statistical modeling is a viable technique for forecasting reliability in offloading terminal equipment, with each failure mode requiring a tailored model approach. The findings suggest that the selection of the appropriate model for each failure mode should be guided by the accuracy of the parameter estimation method as well as the precision of the estimated parameters for each model.

The reliability analysis of electrical and mechanical failures reveals distinct optimal modeling approaches for each failure mode. The study establishes that Weibull MLE and Lognormal MLE models are optimal for distinct failure modes in rotary wagon tipplers. Weibull excels for mechanical failures with shape parameter equals 1.00 and MTBF of 18.2 hours, capturing random failure behaviour, while Lognormal dominates for electrical failures at a MTBF of 37.3 hours, accommodating non-monotonic failure rates and extended time coverage ranging from 0 to 600 hours. This integrated dual approach ensures precise reliability predictions tailored to component specific degradation patterns. Mechanical components exhibit significantly lower reliability at 80% reliability at approximately 4 hours and shorter MTBF compared to electrical systems with 80% reliability at approximately 6.5 to 8 hours time intervals. This divergence stems from mechanical wear-out dynamics and random failure modes, necessitating prioritized maintenance for mechanical subsystems to mitigate cascading operational delays.

Future research should focus on integrating complementary statistical methods, such as the Kaplan-Meier non-parametric survival analysis alongside parametric models such as 3-parameter Weibull and 3-parameter lognormal models to develop a robust hybrid framework for equipment reliability assessment and to further substantiate the findings of this study. Moreover, expanding investigations to other critical offloading equipment such as stacker-reclaimers and conveyor belts, with a focus on both electrical and mechanical failure modes may reveal universal reliability patterns or unique operational risks that warrant critical attention. Future research directions should also emphasize the integration of statistical modeling frameworks with real-time monitoring systems, machine learning approaches, and automated maintenance scheduling systems to enhance predictive capabilities and operational efficiency.

in summary, enhancing wagon tippler performance and reducing downtime is crucial for optimizing overall system efficiency. Utilizing advanced statistical analysis can significantly improve tippler reliability and increase MTBF. Adopting a hybrid maintenance approach that integrates the Weibull MLE distribution for mechanical systems and the Lognormal MLE distribution for electrical systems is recommended. The methodology and insights presented in this paper not only advance the understanding of tippler reliability but also provide a foundation for further research and practical implementation of predictive maintenance in bulk material handling systems.

ABSTRACT

This study develops a conceptual framework for understanding technology and innovation adoption in the South African construction industry. Using the Unified Theory of Acceptance and Use of Technology (UTAUT) as a foundation, the study synthesises empirical literature to identify core drivers and context-specific barriers. While Performance Expectancy, Effort Expectancy, Social Influence, and Facilitating Conditions remain central, three emergent constructs – Perceived Risk, Cost, and Resistance to Change – are introduced to capture the sector's distinct challenges. The conceptual framework was informed by framework and thematic analysis, as well as construct clustering reported in the original studies. The resulting model provides a context-sensitive explanation of adoption behaviour and highlights areas for practical intervention. The study contributes to theory by extending UTAUT and to practice by offering grounded recommendations for improving adoption outcomes. It also identifies directions for future research.

Keywords: technology adoption, innovation barriers, construction industry, UTAUT, South Africa

1 INTRODUCTION

The South African construction industry (SACI) is facing a long-term decline in output. According to Statistics South Africa, the body charged with planning, producing, documenting and storing official statistics for South Africa [1], when accounting for inflation, the construction industry has steadily declined, shrinking by 30% from R147.1 billion in 2017 to R103.5 billion in 2024. On an annual basis, the industry declined by 5.1% between 2023 and 2024, continuing a downward trajectory [2]. The industry currently represents approximately 2% of the gross domestic product (GDP), a decrease from its previous contribution of 4%, making it one of the smallest industries by GDP [3]. The reduction in construction projects – especially building projects – has been blamed for this decline [2], driven by key issues, including uncertainty in the sector and high logistics costs, as well as context-specific challenges such as the "construction mafia" and load-shedding in South Africa [3].

Other industries are effectively harnessing technological innovations to address inefficiencies, reduce costs, and bolster resilience. For instance, technology and innovation capabilities have been linked with increased growth and employment in the manufacturing industry [4], [5], and the logistics sector [6]. The construction industry, on the other hand, is widely regarded as hostile to innovation and technology adoption [7], [8], [9]. For industrial engineers and engineering managers, the construction industry presents a high-potential, yet underutilised domain for applying industrial engineering (IE) principles. Although traditionally treated as separate, distinct fields, evidence is growing on how IE can influence construction [10], [11], [12]. Forbes [13] outlined several core IE principles that can be applied to enhance outcomes in the construction industry. In the SACI, several studies have already explored the application of IE methodologies. The use of lean methods [14], [15], radio frequency and identification (RFID) [16], robotics and automation [17], [18] and total quality management [19] are just a selection of IE methodologies whose adoption and application have been investigated.

While several studies have explored adoption factors in the SACI, these investigations have largely been fragmented, focusing on isolated innovations. As a result, there is limited understanding of how these factors compare across different technologies and whether common underlying threads exist. This study addresses this gap by synthesising existing research under a common framework, allowing for a comparative analysis of factors impacting technology and innovation adoption in the SACI. This study makes three key contributions to innovation and technology adoption studies. First, it provides a synthesis of current empirical evidence on the adoption of technologies from the South African context. Secondly, it extends the Unified Theory of Acceptance and Use of Technology (UTAUT) by identifying and integrating emerging constructs not covered by the original framework. Finally, it develops a conceptual framework to explain adoption in the SACI.

2 THEORETICAL FRAMEWORK

2.1 The concepts of technology and innovation

The varied ways in which technology and innovation are described pose a challenge for researchers working in technology and innovation management. These terms are often used broadly and inconsistently across different disciplines, making it difficult to draw clear boundaries around what qualifies as a technology or an innovation [20]. However, for this study, it is important to settle on a working definition that is clear enough to guide the identification and classification of technologies or innovations relevant to the construction industry context. In this study, technology is described as the practical use of knowledge and skills to solve problems or generate change. It includes physical tools, machines, and systems, as well as the less visible processes and techniques we use to make things work [21]. Similarly, innovation is defined as any idea, method, or product that individuals or groups consider to be new, regardless of whether it is objectively new or not [22]. These definitions allow for the

inclusion of both digital systems, as is the contemporary view of technology, and physical materials, which are commonplace in the construction industry. Furthermore, the subjective perception of innovation from the adopter's perspective allows this study to consider the adoption of technologies that might be commonplace in other contexts but still new to the South African context.

2.2 Theories of technology adoption

The adoption of technology and innovation has been studied extensively, and several frameworks have been proposed to explain the science of adoption. One of these frameworks is the diffusion of innovations theory (DOI). DOI explains that for a new technology to be widely adopted, certain qualities of the technology – its relative advantage compared to the incumbent option, compatibility with existing norms, minimal complexity, the extent to which the new technology can be tested and the extent to which it can be observed in action – are essential decision-making factors that potential adopters take into account [22], [23]. The Theory of Reasoned Action (TRA) is another framework that states that an individual's intention to perform a behaviour is based on their beliefs about that behaviour and the perceived societal norms about the behaviour. Specifically, TRA suggests that behavioural intentions are formed through two main factors: attitude and subjective norms [24]. TRA was further expanded by conceptualising perceived behavioural control – a person's perception of their ability to perform a behaviour – as a critical factor in shaping the intention and, ultimately, behaviour. This extension of TRA is the Theory of Planned Behaviour (TPB) [25].

The Technology Acceptance Model (TAM) hypothesised that the perceived ease of use and usefulness of a technology are the primary determinants influencing users' acceptance of that technology [26]. The underlying idea behind TAM is that in the adoption of information technology, the intention to adopt the technology revolves around beliefs about the benefit of the technology and the effort required to learn how to use the technology [27]. While initially developed for the information systems space, TAM has been used to explain the adoption of technology and innovations across various industries. TAM has also been extended with different constructs by several authors [28]. Beyond the above-listed theories, the Theory of Task-Technology Fit, the Decomposed Theory of Planned Behaviour, the Combined TAM and TPB (C-TAM-TPB), TAM2 and TAM3 are just some examples of frameworks that have been proposed to explain adoption behaviour among individuals [28], [29], [30], [31]. Several of these theories were driven by the potential of information technology to provide benefits and the need for organisations to investigate users' responses and intentions to adopt these systems [26], [27], [29], [32]. However, several challenges and limitations to using these frameworks arose. Since these models came from various fields, their relevance in other fields was debated [33]. For instance, TAM was developed in part to adapt TRA and TPB for better applicability in the information systems space [26]. Additionally, the models differed in their perspectives, incorporating various constructs [33]. Moreover, in recent times, researchers have faced the challenge of choosing appropriate constructs from an array of models [32].

2.3 Unified theory of acceptance and use of technology

Viswanath Venkatesh and colleagues developed the Unified Theory of Acceptance and Use of Technology (UTAUT) by incorporating constructs from different frameworks to form a streamlined approach that could be applied in several contexts [33], [34]. UTAUT was created by comparing eight existing models of technology adoption: TRA, TAM, the Motivational Model (MM), TPB, C-TAM-TPB, the Model of Personal Computers Utilisation (MPCU), Innovation Diffusion Theory (IDT), and the Social Cognitive Theory (SCT) [33]. Venkatesh [32] identified common patterns across these frameworks and unified these constructs into a singular theory. UTAUT specifies four key constructs that directly influence behavioural intention and, by extension, technology use: performance expectancy (PE) – how useful people think the

technology is; effort expectancy (EE) – how easy it is to use; social influence (SI) – whether others encourage them to use it; and facilitating conditions (FC) – whether they have the right support to use it. UTAUT also predicts that age, gender, voluntariness of use and experience can affect how strongly PE, EE, SI, and FC influence technology adoption [32].

Given the various frameworks available for studying technology adoption, this study adopts UTAUT as its guiding lens for several reasons. First, UTAUT integrates key elements from earlier models, making it a comprehensive model for understanding adoption behaviour [33]. Moreover, the framework's testing explains technology adoption better than previous models [32], [35]. In addition, UTAUT is particularly useful as it helps managers understand the factors influencing the adoption of complex technologies [32]. Beyond the established benefits of UTAUT, however, a gap exists that this study attempts to bridge. Established bibliometric and systematic analyses of existing literature by [36], [37], [38] spanning published studies from 2003 to 2014 have revealed that UTAUT has been widely applied in various industries, including education, medical services and healthcare. Only one paper across these studies mentioned UTAUT in the context of the construction industry. A systematic literature review of technology adoption theories used in the construction industry revealed that since 2015, there has been a slight uptick in the construction industry's technology adoption literature [39]. Of the 35 relevant studies identified in [39], however, only seven studies used UTAUT, in whole or in part, as a framework. Available evidence suggests that the use of UTAUT in the construction industry appears to be limited; this study will, therefore, contribute to the literature by applying UTAUT as a framework to provide insights into the factors influencing technology adoption in this sector.

3 METHODOLOGY

A systematic literature review (SLR) of existing studies investigating the adoption of innovations and technologies in the SACI was conducted to achieve the study's aim. Linnenluecke's framework for conducting SLRs [40] was adopted for this study. It involves identifying literature, data cleaning, analysing and synthesising the data and finally, presenting the results. The Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) framework [41] was also used to model the process. A comprehensive search strategy to locate relevant studies on the Scopus and Web of Science (WoS) databases was first developed. Both databases are established repositories for journal indexing [42]. The search terms included several combinations of words and phrases describing the adoption of innovation and technology in the SACI. The search was conducted in April 2025, and terms, results and links have been documented to ensure potential repeatability by other authors.

3.1 Data screening

A total of 1,012 articles, from Scopus and WoS, were sourced and recorded. Relevant data, from the sourced studies, including titles, author names, and abstracts, were uploaded into the EndNote reference management software for further screening. The first step of this process was to identify duplicate records. EndNote's "Find duplicates" function was used to identify 200 duplicate records automatically. An additional 58 duplicate articles were manually identified for removal. After the initial screening process, 754 articles remained. A secondary screening was performed on the remaining articles, focused on reviewing each article's title, abstract, and in some instances, content, against the inclusion and exclusion criteria. Records were selected for analysis if they: dealt with the adoption of a specific technology or innovation within the SACI and in line with the definitions in *2.1*, followed a defined methodology and used empirical or case study data, and explicitly identified barriers, enablers or factors that impact adoption. Studies that merely described the benefits or applications of technologies in the industry were excluded; so too were literature reviews and studies with methodological limitations. For instance, multiple studies with no defined sample

sizes were identified and were, thus, excluded. No restrictions were placed on the dates of publication.

Following the two screening processes, 84 articles met the inclusion criteria. However, only 76 were retrieved. The retrieved articles were then uploaded to ATLAS.ti software programme for further screening. Following the first round of analysis, 15 studies were rejected – 11 for not identifying or exploring specific factors impacting the adoption of technology, and the remaining four for not specifying study sample sizes. After the first ATLAS.ti screening, 61 articles remained. To align with PRISMA recommendations, the reference lists of the remaining 61 articles were also reviewed for possible identification of articles that could be included in the study. Through this process, an additional 79 articles were identified. From the 79 sourced articles, 46 duplicate articles were manually removed, and a further seven were removed due to their unavailability. The full-text articles of the remaining 26 records were retrieved using Google Scholar. Of these, 14 studies met the inclusion criteria. They were added to the initial 61 selected articles for data analysis, while the remaining were rejected for not identifying factors impacting technology adoption in South Africa. A final number of 75 articles was considered for analysis. The PRISMA flow diagram in Figure 1, based on the PRISMA 2020 flow diagram guideline by [41], outlines the study screening process applied.

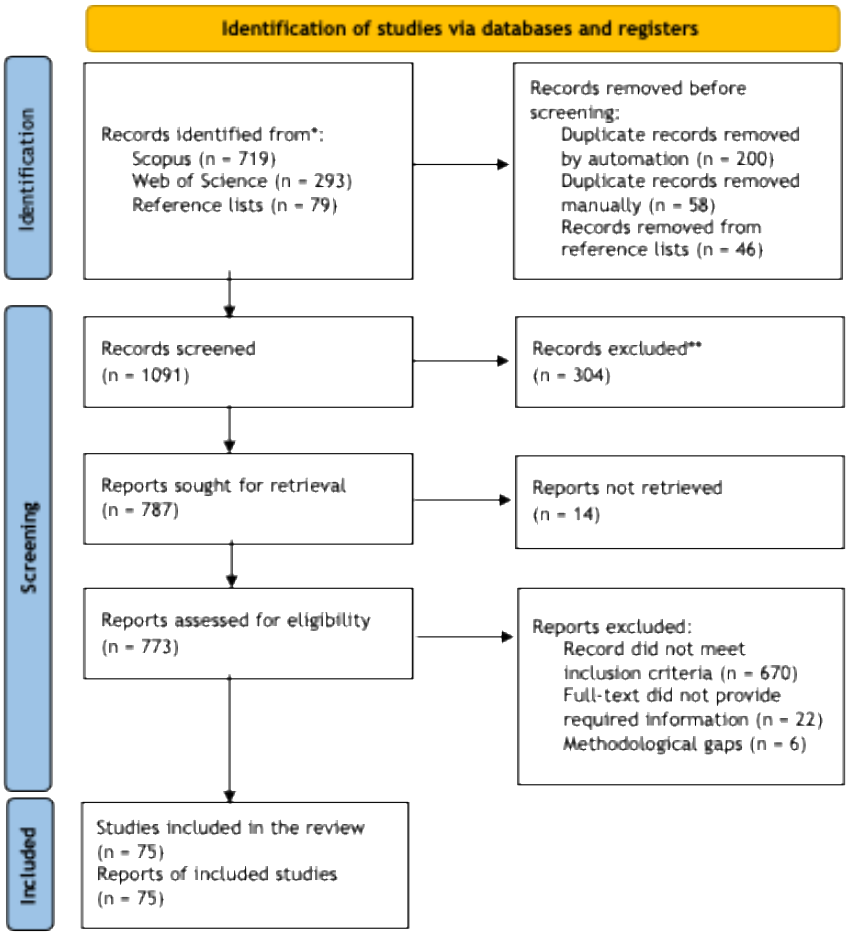

Figure 1: PRISMA flow diagram illustrating the screening process.

3.2 Data analysis

Data analysis was performed on the 75 articles from *3.1*, using the framework analysis approach. An initial round of coding, thematic categorisation, and cross-study comparisons was conducted using the ATLAS.ti programme, and followed an iterative process. First, the framework codes were established, following the UTAUT framework's core constructs – PE, EE, SI and FC. Secondly, relevant barriers, enablers or factors from the selected studies were coded against the UTAUT constructs with the best fit. Factors that did not align with the predefined UTAUT framework were assigned a provisional construct labelled: Emergent themes (EM). To determine the significant factors from quantitative studies, only factors with a mean score above 3.0 (on a 5-point Likert scale) were considered. This scoring method was based on previous studies, which adopted a 3.0 mean score as a benchmark for a factor to be considered significant [43], [44], [45], [46]. For qualitative studies, all factors deemed relevant by their authors were included and coded. A second coding round was conducted to promote consistency, address potential misclassifications and incorporate insights gained from the first coding round. The identified factors were reviewed and evaluated to ensure they were mapped into the appropriate construct. A final coding round was conducted to extract themes from the data. For the UTAUT constructs, themes were organised according to the respective core constructs based on observed patterns and similarities. For the emergent themes, thematic synthesis was performed to inductively develop new constructs based on how related factors clustered or conceptually aligned. These new constructs captured recurring factor types that were not adequately addressed by the original UTAUT framework.

4 RESULTS AND DISCUSSION

4.1 Study overview

In total, 75 articles were reviewed and analysed for this study. Each article investigated the adoption of a type of technology or innovation. Table 1 shows the number of articles per technology or innovation adoption study type in the SACI. The most common topics were the adoption of Building Information Modelling (BIM), digital technology/Information and Communication Technology (ICT)/Information Technology Systems (ITS), and Green Building (GB), with seven studies each. The adoption of sustainable construction was investigated by six studies, Sandbag building technology by four studies and Blockchain technologies by three studies. Technologies that were investigated by two studies are the Fourth Industrial Revolution/Construction 4.0 technologies (4IR), Alternative Building Materials (ABM), Circular Economy (CE), Lean Construction (LC), prefabrication, robotics and automation, and timber technologies.

Table 1: Number of articles per technology or innovation adoption study in the SACI.

Number of articles per technology	Technology or innovation type	Study references per technology/innovation type
7	BIM Digital technologies / ICT / IT Green building	[47], [48], [49], [50], [51], [52], [46]; [53], [54], [55], [56], [57], [58], [59]; [60], [61], [62], [63], [64], [65], [66].
6	Sustainable construction	[67], [68], [69], [70], [71], [72].
4	Sandbag building technology	[73], [74], [75], [76].
3	Blockchain technology	[77], [78], [79].
2	4IR ABM CE Lean construction Prefabrication Robotics and automation Timber.	[80], [81]; [82], [83]; [84], [85]; [14], [15]; [86], [87]; [17], [18]; [88], [89].
1	3D printing, artificial intelligence (AI), big data analytics, safety measures for the coronavirus, data management systems, data sharing, e-procurement, e-tendering, eco-friendly building, green retrofitting, immersive technology, intelligent wearable devices, laser scanners, lifecycle analysis, machine learning, metaverse, modular construction, prevention through design, private finance initiatives, RFID, safety leading indicators, sensing technology, sustainability assessment tools, sustainable project management, unmanned aerial vehicles, value management, virtual teams.	[90], [91], [92], [93], [94], [95], [96], [97], [98], [99], [100], [101], [102], [103], [104], [105], [106], [44], [107], [16], [43], [45], [108], [109], [110], [111], [112].

The majority of the studies under review (56) utilised a quantitative approach for their empirical investigations, while another 17 used qualitative methods. Only two studies used mixed methods approaches. Similarly, the most common research instrument was through a questionnaire, which was used by all quantitative and mixed-method studies and two qualitative studies. Interviews were the preferred choice for the remaining 15 qualitative studies. Respondent sizes for each study were also reviewed, and it was discovered that most studies used a respondent size that was less than 100. Most qualitative studies used respondent sizes in the 1-to-50 range, while sample sizes for most quantitative studies were in the 51-to-100 range.

Most studies did not use a theoretical or conceptual framework, with only six framing their investigations using established frameworks. The frameworks identified in these studies were the UTAUT [63], an extended UTAUT [92], TOE [101], the Theoretical Domains Framework [70], TPB [64], and Institutional Theory [71]. Architects were the most frequently surveyed group of professionals across 48 studies. Engineers – including civil, electrical, mechanical, and structural engineers – were next with 47 studies. They were closely followed by quantity surveyors in 44 studies. Construction managers (34), project officers (23), construction project managers (16) and technical professionals for specific technologies (12) were also involved. Contractors (11), health and safety professionals (8), academics (7), site supervisors (6), developers (6), clients (4), regulators (3), and urban planners (3) were the least surveyed construction industry stakeholders.

4.2 Factors that influence the adoption of innovation and technology in the SACI – core UTAUT constructs

4.2.1 Performance expectancy (PE) factors

Performance expectancy refers to the degree to which individuals believe that using a particular technology will help them achieve gains in job performance [32]. The first theme grouped under PE was named productivity, efficiency and operational gains, referring to factors related to improved performance outcomes such as time savings, faster delivery and efficiency improvement. It also includes instances where performance is perceived through external outcomes. Some of the factors that were grouped under this theme include the ability of big data analytics (BDA) to improve the speed of task delivery, productivity and overall performance [92], the perceived benefits of wearable technologies in improving safety outcomes for construction workers [101], positive outcomes from using BIM [48], speedy completion of transactions when using e-procurement technology [96], faster project completion and improved service delivery when using private finance initiatives [107], and the improved performance derived from the use of AI in the industry [91].

The next two themes encompass expected benefits to the organisation. Strategic and organisational alignment consists of factors that describe how technology or systems align with an organisation's broader objectives, strategy, or competitive positioning. They include the use of digital technologies because they align with an organisation's objectives and strategy [56], improved competitive advantage when an organisation adopts sustainable building construction practices [72], and enhanced brand recognition for companies that adopt eco-friendly building construction [98]. This was a common factor for studies examining sustainable construction, green building and similar environmentally friendly practices, as the adoption of these practices was deemed as aligning with organisations' intent to be perceived as environmentally conscious or to influence environmental consciousness [63], [65], [72]. The other theme describing organisational benefits was named economic value and cost competitiveness and describes factors reflecting financial benefits, including cost savings, profitability and return on investment. They include the lower operating costs, increased property values and higher return on investment in green buildings [61], the opportunity to expand into secondary markets by adopting circular economy principles [84], and the lower cost of transactions using e-procurement tools [96]. Concerns about the potential for prefabricated buildings to command a lower value due to having the same appearance [86], low profit margins when using alternative building materials [82], and uncertainty about the gains to be made when using drones in construction project delivery are some other factors included in this theme.

4.2.2 Effort expectancy (EE) factors

Effort expectancy describes the degree of ease associated with the use of a system or technology [32]. Within the reviewed studies, this construct captured a range of factors related to ease of use and learnability, technical complexity and the lack of required skill levels. The first main theme identified was named ease of use and learnability, and it describes factors that relate to how easy or difficult a system or technology is to use, learn and operate. Positive effort expectancies were expressed for several technologies, including the use of big data analytics [92], wearable technologies [101], and e-procurement tools [96]. Negative effort expectancies were identified for immersive technology adoption [100], proactive prevention strategies [44], COVID-19 safety measures [93], 3D printing as a construction methodology [90], and the use of RFID technologies in construction [16], among others. The next theme describes the resources and time required to learn or adapt to a new system. It includes factors such as the time required to develop a suitable machine learning model for construction [104], the learning curve needed to navigate in adapting to the use of ICT in

construction site management [55], the difficulty in developing procedures for using several different construction 4.0 technologies [81], and the learning curve that must be navigated when inexperienced builders try to adopt sustainable construction practices [62]. Another theme that emerged is the inherent complexity of the systems or technology to be adopted. These include the diverse and complex nature of digital systems as a barrier to digital collaboration within the construction industry [59], the complex outputs derived from machine learning systems [104], and the complexity of building codes and regulations on green building and sustainable construction [109].

4.2.3 Facilitating conditions (FC) factors

Facilitating Conditions refer to the degree to which an individual believes that an organisational and technical infrastructure exists to support the use of the system [32]. In the context of this review, this construct was the most categorised and encompasses a broad group of factors. FC had the most data points coded across the reviewed studies. The theme with the highest number of factors was technological infrastructure and resources, describing the availability and compatibility of the innovation or technology necessary for implementation. Several factors for this theme operate at the organisational level, including the availability of BIM detection software [47], safety tools [43], sustainable and green building construction materials [60], [67], [69], data analytics software [92], wearable devices [101], and modular construction materials [106], among others. Challenges with the integration of newer technologies with existing technologies and practices [58], [59], [79], [95], [110] were also classified under this theme. Other factors relate to the responsibility of the national government including, the availability of required infrastructure for some technologies, such as power supply [16], [45], [58], transport infrastructure [86], internet infrastructure [96], [97], and material manufacturing facilities and supply chains [82], [85], [98], [106].

Another national-level theme identified was the existence of legal and regulatory frameworks. This theme describes the availability and clarity of regulations, policies, codes, standards and enforcement mechanisms supporting adoption. Factors under this theme include a lack of building codes and regulations for sandbag building material [73], [75], [76], modular construction practices [106], green building construction [60], and sustainable construction practices [108]. Other factors include government policy [63], [84], [97], legal support [49], [51], [77] and industry guidelines [65], [102], [103]. Similarly, the presence of financial resources and incentives was revealed as another common national and industry-level theme. Factors under this theme include tax breaks, reliefs and fines [47], [69], [109], and access to loans, investments and other financial resources [46], [49], [53], [59], [61], [75], [101], [109]. At the organisational level, one key facilitating condition identified was organisational readiness. This theme described the commitment of the organisation's leadership to provide the structure and systems to support innovation adoption. Factors under this theme include organisational size and capabilities and business model [43], [80], [101], company culture [14], [72], [91], [101], leadership commitment [14], [110], [112], and provision of resources [43], [44], [68], [81], [91].

Across many of the technologies and innovations identified in this review, the lack of awareness, knowledge and information was constantly identified as a barrier to adoption [17], [64], [78], [88], [93], [111]. This lack of awareness and knowledge was attributed to major stakeholders in building projects, including the public [51], [73], [87], clients [109], government [98], and construction professionals [18], [54], [61], [111]. A related theme to the lack of knowledge, awareness and information is the availability, or lack thereof, of qualified individuals to implement and manage new technologies. Specific factors include the lack of trained or skilled personnel [49], [85], [105], the scarcity of experts in some fields [75], [83], [106], and the highly unskilled labour that typically works on construction projects in South Africa [49], [74], [80], [82]. Conceptually, access and provision of training and skill

development to individuals should assist in combating the lack of knowledge and skilled personnel. Many factors under this theme addressed the need for structured training programs [46], [56], [59], [109], continuing professional development (CPD) training [63], [71], for construction workers, and curriculum development and ongoing research [51], [63], [73] at higher educational levels. Initiatives to provide real-world data and validation of construction innovations were also included in this theme. The use of pilot projects is a common recommendation to improve the adoption of innovations in the construction industry [51], [63], [73].

4.2.4 Social influence (SI) factors

Social influence refers to the degree to which individuals perceive that people who are important to them believe they should use a particular technology [32]. In the context of this review, SI was shaped by various groups. The first theme was client expectations and demands, referring to the presence or absence of pressure from clients to adopt specific technologies [60], [67], [88], [101]. The presence of market demand is particularly influential as an enabler for the adoption of sustainable and green construction practices [64], [71], [109], while the lack of client interest has been observed as a barrier to the adoption of technologies such as data sharing [95], sandbag as a building material [74], metaverse technologies in construction [105], and BIM utilisation by quantity surveyors [52]. Market orientation was also classified under this theme as competitive pressure plays a role in the decision-making at the organisational level on whether to adopt a new technology [56], [71], [72], [92]. Another organisation-level theme identified was the influence of top management. When top management approves the use of a technology such as BIM [47] or is supportive of innovation [59], [73], employees are encouraged to adopt the technology. On the other hand, the lack of top management support disincentivises workers from considering new technology [43], [78], [102]. Public opinion and social acceptance also influence adoption in the SACI [70], [77], [82]. The adoption of innovative building processes such as prefabrication [86] and sustainable construction practices such as green building and timber construction [88], [89] is especially limited by public perception of their inferiority, driven in part by a long tradition of brick construction in South Africa [75].

At the individual level, the influence of professional peers [64], [70], expert opinions [67], [109], professional bodies and groups [49], [64], [71], and even research institutions [71], also influence the considerations of new technologies by industry professionals. The project-based nature of the industry, often regarded as a negative influence for adoption, has the potential to act as a positive influence. When some members of a project team adopt a technology, others may also be influenced to adopt it, although resistance could also have the opposite effect [109]. A related theme identified was the frequent reference to the influence of "stakeholder" participation and collaboration for the adoption of technologies [46], [60], [69], [72], [82]. One critical stakeholder that was frequently named was the government. The construction industry in South Africa seems to view the government as critical for the adoption of new technologies. Several studies highlighted the lack of government support, interest and promotion as major barriers to the adoption of different technologies [45], [50], [74], [88], [103]. Others believed that mandatory edicts or pressure from the government would accelerate adoption [46], [47], [86], [91]. While the government has served as a positive change agent in the adoption of some innovative construction processes, especially sustainable construction efforts [113], proponents for government influence must be aware that government influence to promote the adoption of certain technologies may be regarded by some as overreach and may further entrench resistance [114].

4.3 Factors that influence the adoption of innovation and technology in the SACI – Emergent constructs

4.3.1 Perceived risk

Perceived risk in this study refers to the uncertainties and consequences that individuals anticipate from adopting a new technology. Perceived risk emerged as a recurring factor expressed as concerns in relation to the safety of workers or clients [17], [100], fear of data breaches and misuse, specifically for internet-based technologies [16], [59], [95], legal liability and accountability [45], [49], [111], and job security in some instances [18], [80], [81]. Perceived risks also included a lack of trust, whether in suppliers [93], [101], other team members [93], or the technology [86], [88]. Concerns about the technology were mostly related to the need for more evidence or guarantees, rather than scepticism in its efficacy. In this sense, hesitation about adoption was not about ease of use, but about broader implications of adopting something unfamiliar and uncertainty about possible unintended consequences [45], [85], [88], [91], [104]. While some aspects of perceived risk may seem similar to cost or effort-related concerns, such as in the example about technology concerns, the key difference lies in how risk is experienced. In this context, risk is more about anticipation and hesitation. It reflects a fear of potential downsides or unknowns that could hold people back from adopting, rather than a straightforward comparison of options or an assessment of how much effort is involved.

4.3.2 Perceived cost

Another of the most frequently referenced barriers to the adoption of technologies in this review was perceived cost. The high upfront cost of implementing new technologies was frequently flagged as a barrier [61], [106], [111]; so too, operational costs [18], [83], [95], and maintenance costs [45], [102]. Other cost elements include the financial demands of training staff, not just in terms of effort, but as a tangible budget line item that requires funding for workshops, training, seminars and continuous development programs [81]. In some cases, doubts about the return on investment or uncertainty around long-term profitability added another layer of hesitation [78], [102], [105]. And at times, costs were not clearly defined at all. Instead, they reflected general assumptions, such as the idea that modular construction is expensive [106], or perceptions that certain technologies are expensive, even when those perceptions were not backed by data [44], [55], [67]. There were also mentions of costs that may not always be explicitly factored in during planning stages, including deconstruction costs or salvaging reusable materials [85]. It is expedient at this point to delineate between cost as an emerging construct and similar themes, such as financial incentives, as discussed under the Facilitating conditions sub-section. Although both cost and financial incentives relate to economic considerations, they play distinct roles in the adoption process. Cost is understood as a perceived or actual burden, and anxiety experienced internally about the financial burden and investment needed to adopt a technology, thereby shaping or influencing the perceived feasibility of a technology. On the other hand, the financial incentives theme under FC often consisted of external enablers or systemic supports, often from the government, that were expected to cajole or further incentivise companies already adopting certain technologies to scale. While financial incentives may mitigate high cost, they do not necessarily change perceptions of cost uncertainty and value through which cost is experienced.

4.3.3 Resistance to change

Resistance to change describes the tendency to oppose, delay or avoid the adoption of new technologies, often in favour of retaining familiar and long-established ways of working. Within the SACI, this resistance was widespread, with evidence spanning over 30 studies, and across multiple technologies, including information systems technologies like data analysis

[92], e-procurement tools [96], [97], and digital technology [111], safety measures such as proactive design [44] and the deployment of robotics [17], processes such as modular construction [106] and lean construction [15], and sustainable construction efforts such as green building [60] and timber construction [88]. Resistance to change also showed evidence of being a multi-level construct with factors at the individual [15], [44], [95], organisational [62], [92], and sectoral [88], [95], [106] levels. Conceptually, this construct is related to the effect of habit in UTAUT2, which refers to the extent to which behaviours are performed automatically due to years of repetition. However, while habit serves as a positive reinforcement of continued use of technology, resistance to change acts as a barrier. Furthermore, while the construct was identified as a barrier to the adoption of several technologies, it was not technology-specific. Instead, it presented as a general quality of the construction industry, like an inertia that must be overcome, even when enabling conditions are present and performance advantages have been demonstrated.

4.3.4 Others – Attitude and Industry Fragmentation

In this review, several factors provided the foundation for two themes that were classified as attitude and industry fragmentation. Attitude covered preference for and pleasure from green construction [64], while industry fragmentation was often described in those words and the project-based nature of work in the industry [15], [17], [106]. However, these elements were mentioned in passing without extensive elaboration or detailed empirical exploration. Acknowledgement of these factors is a recognition of their potential contextual relevance, but further evidence is required to describe them as full emergent constructs.

4.4 Synthesis of Constructs

The review of the factors that impact the adoption of technology in the SACI against the UTAUT framework has revealed clear distinctions in how the factors align with the framework to influence adoption. However, some cross-cutting patterns were also observed. The strongest pattern was the relationship between factors assigned to the FC construct and the emerging constructs. Similarly, a strong relationship was observed between FC and SI factors. These relationships were primarily identified through a combination of construct clustering reported in the original articles, typically based on factor analysis or similar statistical techniques, and thematic analysis of narrative descriptions in qualitative studies. For instance, [111] identified a factor component that grouped the high cost of digital technologies with a lack of awareness. In another study, lack of education and fear of job losses were grouped under the same component, highlighting how weak facilitating conditions may reinforce perceived risk attached to the adoption of a technology [80].

One instance of the FC-SI association is how leadership influence, classified as SI, is evidenced in the provision of resources, training, budget, and equipment [43], which is classified as FC. Additionally, expert opinions, competitive pressures and the influence of industry organisations could influence top management to commit to organisational adoption of a technology [77], [91]. Similarly, it is important for top management to establish a company culture of innovation to influence workers to seek and adopt technologies that will improve work output [91]. Another instance of the FC-SI relationship is how the active support of the government could not just influence the development of legislation and regulations but also encourage the provision of investment by financial institutions that many organisations need to be able to afford new technologies [101]. Moreover, a lack of knowledge and insight about new technologies has been blamed for the poor acceptance levels among the public [87].

The analysis also showed that some constructs carried more weight than others. FC was the most coded construct among the factors and covered a lot of depth, including factors like the presence (or absence) of infrastructure, funding, training, policies and technical support. On the other hand, EE was cited the least often and was often associated with the lack of

facilitating conditions as a reason. Penfield [115] has noted the tendency of construction professionals to blame other stakeholders for slow technology adoption rather than confess to a lack of expertise. Another insight relates to the bidirectionality of the constructs. Rather than functioning solely as drivers or barriers, many factors could act in both ways. A good example is how members of a project team could be influenced to adopt a technology by other members [109]. However, resistance can have a similar ripple effect, as others are discouraged from using the technology. Finally, across the constructs, adoption was shaped by a mix of individual, organisational, industry and wider social factors. This multi-level nature of adoption factors creates dependencies in the adoption process; an individual may find a technology to be useful to complete their work, but might still be influenced against using the technology by the lack of institutional support or enabling legislation.

4.5 A conceptual framework for the adoption of innovation and technology in the SACI

Following the detailed synthesis of core and emergent constructs in the preceding sections, this review proposes a conceptual framework to explain the adoption of innovation and technology in the SACI. The framework treats technology and innovation adoption as the dependent variable, influenced by a set of independent variables including core UTAUT constructs, and the emergent constructs identified in this study. For the purposes of this framework, adoption is treated as a composite dependent variable, representing the intention to use and actual use. This is because, although behavioural intention plays a central role in UTAUT as a predictor of actual adoption, the studies in this review do not distinguish between intention to adopt and actual adoption.

The core UTAUT constructs – EE, FC, PE and SI – remain as key predictors of this combined adoption variable. PE and EE exert positive effects on adoption; the easier and more useful a technology is perceived to be, the greater the likelihood of its adoption. SI plays a dual role; individuals, organisational culture, industry pressures, and governmental support may positively and negatively affect the uptake of a technology. FC also has a direct effect on adoption, with the presence of facilitating conditions easing the implementation and uptake of new technologies. Perceived risk, perceived cost and resistance to change are conceptualised as barrier constructs that exert negative effects on adoption. These emergent constructs may suppress adoption even when a technology is perceived as useful. Further insights may be gained from the interaction of constructs with each other. Specifically, FC and SI may interact as the influence of authority figures may ensure the availability of resources needed to enable smoother adoption. Similarly, FC may influence the emergent constructs, and perceived cost and perceived risk may likely be correlated. The framework is modelled in Figure 2.

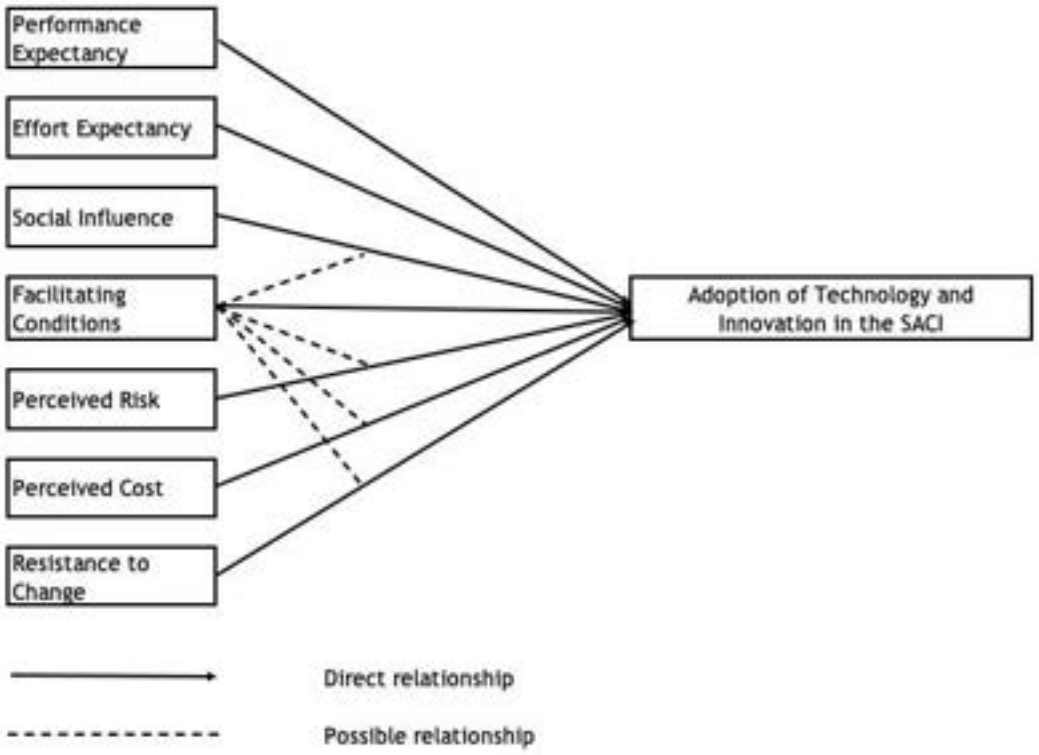

Figure 2: A conceptual framework for technology and innovation adoption in the South African construction industry

This framework positions adoption as a complex outcome shaped by the interplay of established and emerging constructions at individual, organisational and systemic levels. While some factors can encourage adoption, others, such as cost, risk and resistance to change, can inhibit adoption, even when the technology seems beneficial. The framework offers comprehensive and contextually grounded explanations for understanding why some innovations are embraced while others are not, and may serve as a practical tool for engineering managers and industrial engineers seeking to design interventions to promote the adoption of technologies in the SACI.

4.6 Recommendations for promoting technology and innovation adoption in the SACI

Drawing on the findings and the proposed conceptual framework, this study provides several recommendations to support the adoption of technology and innovation in the SACI. Central to these is the need to strengthen facilitating conditions through improved access to training, alongside targeted investments in infrastructural development and financial support mechanisms such as grants and tax incentives. Regulatory frameworks must also be updated to accommodate innovation more effectively, with flexible but robust standards and codes.

Reducing perceived risk is another priority, as uncertainty about performance, safety, and liability often limits uptake. Pilot projects and demonstration sites can serve as proof of concept, while expert validations should promote user confidence. Addressing cost barriers requires interventions at multiple levels, including subsidising initial investments, encouraging low-cost or open-source tools, and promoting lifecycle costing to shift focus from upfront expense to long-term value. Resistance to change remains a deeply rooted challenge that must be addressed. Highlighting the success of early adopters and framing innovation as a pathway to familiar goals such as efficiency, safety, and client satisfaction may help ease this resistance.

5 CONCLUSION

This study explored and synthesised the factors influencing the adoption of technology and innovation in the South African construction industry, using the Unified Theory of Acceptance and Use of Technology (UTAUT) as its foundational lens. Through a review of empirical literature, it not only confirmed the relevance of UTAUT's core constructs – Performance Expectancy (PE), Effort Expectancy (EE), Social Influence (SI), and Facilitating Conditions (FC) – but also identified a series of emergent barriers that could not be sufficiently explained within the original or extended UTAUT models. Three emergent constructs – Perceived Risk, Perceived Cost, and Resistance to Change – were identified through thematic analysis and supported by co-occurrence patterns and factor groupings across multiple reviewed studies. These constructs reflect the complex realities of innovation adoption in the construction sector. The proposed conceptual framework integrates both sets of constructs to present a more comprehensive, context-sensitive understanding of innovation adoption in the SACI.

A key insight from the analysis is the interconnectedness between constructs. Notably, the relationship between FC and SI was shown to be particularly strong, as leadership, clients, and institutional actors often create or withhold the enabling conditions necessary for adoption. Furthermore, FC was shown to be strongly linked with the emergent constructs. Where enabling structures were lacking, perceptions of risk, cost burden, and resistance to change became significantly more pronounced. However, the study is not without limitations. It is based entirely on secondary data and literature drawn from previously published studies, meaning that no new primary data were collected to empirically test the framework. Additionally, while the review was thorough and grounded in a clearly articulated methodology, some constructs, particularly those classified as emergent, may still evolve as more empirical data become available. Relatedly, constructs like industry fragmentation were observed but not elevated due to insufficient depth or frequency in the data; future research may be able to revisit and validate their influence more explicitly.

Despite these limitations, the study's strength lies in its breadth and contextual relevance. The framework developed is not an abstract theoretical contribution; it is grounded in real-world evidence from the SACI. Future research on technology and innovation adoption in the SACI would benefit from a varied mix of research methods and drawing more clearly on established theoretical frameworks. There is considerable value in conducting methodological and bibliometric reviews to map trends, identify research gaps, and assess the evolution of studies in this field. In addition, researchers should consider exploring alternative theoretical frameworks beyond UTAUT to capture themes that may be underemphasised in this study. More importantly, there is a need for greater use of established theoretical foundations in empirical studies, as many investigations to date have relied on descriptive or exploratory approaches without clearly linking their findings to any theoretical models. Researchers should also be more deliberate and precise in data collection, particularly by encouraging respondents to specify key actors or stakeholder groups, rather than relying on vague references to "stakeholders." Doing so will enable more targeted analyses and practical recommendations that reflect the realities of the adoption of innovation and technology in the South African construction industry.
