ABSTRACT

This study investigates the use of machine learning to model capital structure dynamics, a key factor in company valuation and solvency. Debt financing enables firms to leverage future earnings for immediate capital, directly shaping shareholder value. Traditional linear regression has long dominated predictive modelling in this space; however, recent research demonstrates the superior performance of machine learning techniques.

In a comparative evaluation across JSE industrial, resources, and technology sectors, various models including: artificial neural networks, support vector machine models, random forest decision trees and linear regression models were compared. The random forest decision tree model proved to be the best-fit model. The model had the lowest mean absolute error (MAE) of 0.15 and the mean absolute percentage error (MAPE) of 20%, outperforming: linear regression (0.6 and 55%), artificial neural networks (0.7 and 65%), and support vector machines (0.65 and 60%). Furthermore, the ROC-AUC curve on a binarized version of the Debt-to-Equity target yielded an AUC value of 0.891.

Keywords: Capital structure, Random Forest, Artificial Neural Networks, Support Vector Machines

1 INTRODUCTION

Decades of corporate practice and academic debate have yet to yield a consensus on whether an optimal capital structure exists or on the best method for estimating it [1][2]. Some researchers propose a straightforward, linear relationship between financial ratios and leverage levels, while others highlight complex, non-linear dynamics that resist simple modelling.

The allocation of debt versus equity—and the active pursuit of a clearly defined target leverage ratio—remains foundational to corporate finance strategy [3]. Misjudging this balance can precipitate financial distress or even bankruptcy [4], and without universally accepted benchmarks, firms must tailor their capital structures to their unique leverage objectives and their current standing relative to those targets [5].

Studying the determinants of capital structure and understanding the optimal leverage level is essential for a company's long-term solvency and viability [6]. Companies with high leverage may be compelled to implement drastic cost-cutting measures if faced with insolvency.

Additionally, this paper introduces a benchmark model for estimating capital structure using linear regression, incorporating new variables such as enterprise value, operating margins, asset and sales growth measures, and return on equity as predictive factors. This research contributes to the ongoing debate and literature regarding the superiority of machine learning methods over traditional approaches [7][8].

Titman and Wessels [9] advanced empirical analyses of capital structure theories by employing factor-analytic methods to address measurement challenges. Maksimovic and Titman [6] examined the effects of leverage on stakeholder perceptions, particularly in relation to employee and supplier relationships.

Recent innovations in capital structure analysis have incorporated machine learning techniques, which present promising opportunities for understanding complex dynamics. Goeletsis et al. [10] emphasise the ability of machine learning to overcome the limitations associated with traditional statistical methods.

This research contributes to the ongoing discourse on capital structure determination by leveraging machine learning to uncover nuanced insights. By integrating new variables and employing sophisticated analytical techniques, we aim to enhance understanding and refine existing theories.

2 REVIEW OF THE LITERATURE

2.1 THE THEORIES OF CAPITAL STRUCTURE

Capital structure is a key element of corporate finance, explaining how companies acquire funds to drive growth and operational activities [11]. Senior managers and shareholders frequently face challenges in determining the ideal debt-to-equity ratio and understanding its effects on company value [12].

Harris and Raviv [13] provided a comprehensive overview of the capital structure literature, emphasising the factors that influence leverage ratios. They noted that while numerous theories contribute valuable insights, many empirical nuances remain inadequately addressed. Frank and Goyal [14] identified key variables that impact capital structure decisions among publicly listed American companies, utilising advanced model selection techniques.

2.2 THE USE OF MACHINE LEARNING APPROACHES IN CAPITAL STRUCTURE ANALYSIS

The determination of capital structure and the active pursuit of a target leverage ratio are pivotal concerns in corporate finance. Despite extensive debate and research spanning decades [14 - 19], the factors driving cross-sectional and time-series variations in capital

structure remain unclear. This research seeks not to reinvent the wheel but to expand on existing knowledge by exploring alternative methods for analysing capital structure dynamics through techniques such as artificial neural networks, support vector machines, and decision trees.

The choice to focus on these three machine learning models is motivated by their growing prominence in addressing financial challenges, particularly due to their capabilities in data classification and adaptive learning [20]. This research contributes to the ongoing discussion regarding the advantages of machine learning methods over traditional statistical approaches, as evidenced by previous studies [7],[8],[20]. While the hypothesis concerning the determinants of a company's capital structure has received mixed support, we aim to enhance this discourse by employing machine learning techniques to demonstrate their ability to capture capital structure dynamics more effectively than conventional literature suggests.

Additionally, this paper introduces new variables, including enterprise value, operating margins, asset and sales growth measures, and return on equity, among others. Machine learning methods like deep learning, support vector machines, and decision trees have shown an ability to address several limitations of traditional techniques such as regression analysis [18]. Their capacity to learn from data and adapt to improve predictive accuracy makes them particularly well-suited for analysing complex datasets and identifying non-linear relationships.

2.2.1 Artificial Neural Network

An artificial neural network (ANN) scheme consists of simple processing units called neurons. These neurons are connected using weights, where the strength of a connection between two neurons i and j is referred to as $w_{(i,j)}$ [21]. An ANN is defined as a sorted triple (*N, V, w*) with two sets *N*, *V*, and a function *w*, where:

- N is the set of neurons,
- $V \subseteq \{(i, j) \mid i, j \in N\}$ whose elements are called connections between neuron i and neuron j, and the function
- $w : V \rightarrow R$ is a function assigning real-valued weight the weight w(i,j) from neuron i and neuron j

Since the ANN models discussed in this work are trained using supervised learning, a multi-layer feedforward propagation model was selected [22]. Each neuron has a propagation function $s(x)$, which is the weighted sum of the inputs and weights associated with the input connections to the neuron. The propagation function is followed by an activation function, which determines the output of the neuron. The propagation function is sometimes referred to as the network input function [23].

Let $V = \{i_1, i_2, \dots, i_n\}$ be the set of neurons, let o_i represent the output of the neuron $i \in V$.

For each neuron j in the current layer, there exist a weight $w_{i,j} \in R$ denote the weight associated with the connection from neuron i in the previous layer z in the current layer

Then the network input of j, called net_j, is calculated by the propagation function $s(\circ)$ as follows:

$$net_j = s(o_{i1}, \dots, o_{in}, w_i1, \dots, w_{inj}) \quad \textbf{(1)}$$

This equation represents a weighted sum, where the output of each neuron iii is multiplied by the corresponding connection weight $w_{i,j}$.

2.2.2 Support Vector Machine Models

Support Vector Machine (SVM) models are based on mapping data from the original input dimension feature space to a lower-dimensional feature space using a kernel function. The SVM algorithm aims to find the hyperplane that best separates the classes in the feature space. Given a set of training data $\{(x_i, y_i)\}$, the goal of SVM is to find the hyperplane that best separates the classes in the feature space. So, given a set of training data $\{(x_i, y_i)\}$, the objective is to find the optimal hyperplane that maximises the margin between the classes.

The SVM requires a solution for the following optimisation problem:

$$min_{w,b,\zeta} = \left(\frac{1}{2}W^T W + C\sum_{i=1}^{m} \zeta_i\right), \quad \textbf{(2)}$$

subject to

$$y_i\left(\boldsymbol{W}^T \phi(x_i) + b \geq 1 - \zeta_i, \zeta_i \geq 0\right) \quad for \quad all \quad y_i, \quad \textbf{(3)}$$

where:

- W is a vector perpendicular to the hyperplane,
- b represents the bias term.
- ζ are slack variables allowing classification errors.
- C>0 is the penalty parameter controlling the trade-off between margin width and misclassification, and
- $\phi(x_i)$ represents the mapping of the original input xix_ixi into the higher-dimensional feature space.

2.2.3 Random Forest Decision Trees

Decision tree models constitute a widely utilised class of machine learning algorithms, applied extensively in both regression and classification tasks. In the decision tree model, data is partitioned based on a sequence of questions, thereby establishing a tree-like structure. A random forest (RF) model comprises an ensemble of decision trees employed to identify the optimal features for forecasting [24]. Each decision tree within the ensemble encompasses only a random subset of the dataset's features, and the ensemble collectively selects the best predictive features through a process known as "majority voting". This approach is commonly referred to as ensemble modelling.

The primary objective of each decision tree is to determine the most effective method for dividing the data. In the literature, three prevalent criteria for data partitioning are identified: Gini impurity, entropy, and classification error. The predominant criterion involves selecting the split that maximises information gain, quantified by the reduction of uncertainty following each split, also known as entropy [25]. Formally, the entropy of a state s, denoted as E(s), is expressed as:

$$E(s) = -\sum_{i=1}^{m} p(i) log\,(p(i)), \quad \textbf{(4)}$$

where m is the number of branches and $p(i)$ the probability of each branch i.

3 DATA AND METHODOLOGY

The dataset is divided into a training set (Xtrain, ytrain) and a test set (Xtest, ytest), with Xtrain containing r × m samples and Xtest containing (1 − r) × m samples, where r is the chosen ratio. The dataset utilised in this study encompasses financial information from companies listed on the Johannesburg Stock Exchange (JSE) for the period spanning from 1997 to 2022.

The data was extracted from the IRESS database, a recognised source for financial data [27]. A comprehensive array of 72 financial indicators was compiled, focusing particularly on the target variable: the Debt/Equity ratio.

The investigation primarily aimed to analyse capital structure, defined as the ratio of total debt to total equity. To uncover the key determinants of capital structure, a range of independent variables was examined and categorised into four principal groups: profitability, liquidity, solvency, and turnover ratios. It is hypothesised that these financial ratios are significant factors influencing the capital structure decisions of companies. This data-driven approach seeks to clarify the intricate relationship between the selected financial indicators and the capital structure of companies listed on the JSE. Through rigorous analysis and modelling, the study aspires to provide valuable insights into the elements that shape capital structure decisions, thus contributing to the existing literature in corporate finance.

Following the partitioning of the dataset into training and testing sets, three distinct machine learning models were created and assessed to determine the most effective model for forecasting the dependent variable capital structure of non-financial companies listed on the JSE. The primary machine learning techniques employed in this study include ANNs, Random Forests, and SVMs [18]. The initial model implemented is ANNs, which draw inspiration from the human nervous system, aiming to mimic the brain's learning process through sophisticated algorithms. ANNs consist of interconnected neurons organised into layers, with each connection assigned a weight that can be either positive or negative. Positive weights stimulate neuron activation, while negative weights inhibit it. Typically, the network comprises an input layer, an output layer, and one or more hidden layers.

A separate portion of the dataset, called the unseen dataset, was kept apart for final comparisons. The rest of the dataset was split into 70% for training and 30% for testing, followed by normalisation. After training the models (as described in the modelling methodology below), the remaining 30% were utilised for model evaluation. Various error metrics discussed below were employed to compare the performance across models. The estimations were conducted using Python version 3.9.

3.1 Modelling Methodology

This section outlines the methodology employed in the research, focusing on the predictive modelling of the Debt/Equity ratio using three machine learning algorithms: ANN, SVM and RF models. The three machine learning models were compared to the benchmark model using linear regression. Code to utilise automated batch machine learning modelling, designed to streamline the modelling process by comparing various machine learning models, was also tested. However, we found that issues arose when utilising this code, specifically concerning hyperparameter tuning, model interpretability, and the efficient handling of larger datasets. Consequently, the decision was made to proceed with the three selected machine learning models, which offered a more straightforward approach to addressing the research objectives.

3.1.1 Linear Regression Model

The use of statistical methods in capital structure analysis was employed to create a linear regression (LR) model. This model was used as the benchmark to compare the machine learning models' performance. The methodology involved in constructing an LR model was as follows:

a. Initialisation of Parameters
   The regression parameters were initialised uniformly to 0.1 for all factors. This led to a total of 14 parameters after selecting predictive factors; this was achieved through the mean decrease impurity (MDI) index utilised in the random forest technique. The 14 variables resulted in 13 coefficients for each variable and one intercept coefficient.

b. Calculation of Linear Combination
The predicted values were generated by calculating the linear combination of the independent variables and their respective coefficients. Mathematically, this is represented as:

$$\hat{y} = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \ldots + \beta_n x_n \quad \textbf{(5)}$$

where:

- $\hat{y}$ is the predicted value,
- β_0 is the intercept coefficient,
- $\beta_1, \beta_2, \ldots, \beta_n$ are the coefficients for the independent variables $x_1, x_2, \ldots, x_n$ respectively.

c. Parameter Optimisation
The parameters were fine-tuned to minimise the loss function, commonly represented by the Mean Squared Error (MSE) or Root Mean Squared Error (RMSE), utilising optimisation algorithms such as Ordinary Least Squares (OLS) or Gradient Descent. This optimisation process focused on reducing the difference between predicted and actual values in the training dataset.

d. Model Fit Evaluation
The effectiveness of the LR model was evaluated using key metrics like R^2 (Coefficient of Determination) and adjusted R^2. These metrics indicate the extent to which the independent variables explain the variance in the dependent variable.

e. Model Validation and Testing
To ensure the model's generalisation capability, validation techniques such as cross validation were employed. Furthermore, the model's predictive accuracy was assessed using a separate set of unseen data. To ensure the generalisation capability of the models, a K-fold cross-validation strategy ($k = 5$) was employed. In this approach, the dataset was divided into five equal folds; each fold was used once as a validation set while the remaining folds were used for training. Performance metrics were calculated for each iteration and then averaged to provide a robust estimate of model accuracy. Additionally, the models' predictive performance was evaluated on a separate unseen test set to confirm their ability to generalise to new data.

3.1.1.1 Model Performance

The performance of the model was evaluated through standard metrics, including MSE and RMSE. MSE serves as a measure of the average squared differences between predicted values and actual outcomes. These metrics enable a quantitative assessment of the model's predictive performance, with lower values indicating better model fit and predictive accuracy.

3.1.2 Model Development and Hyperparameter Optimisation

The three distinct machine learning models were developed, each optimised through a randomised search approach to identify the best hyperparameters. The optimisation procedures for each model were as follows:

a. ANN model
A multi-layer perceptron (MLP) regressor model was chosen to create the ANN model. The hyperparameters, such as hidden layer sizes, activation functions, and regularisation parameters were defined for optimisation. The learning rate and maximum iterations were also set to facilitate rapid convergence.

b. SVM model
A support vector regressor model was implemented with hyperparameters, including the regularisation parameter C, kernel type, and epsilon values for optimisation. For

each model, predictions were generated on the test dataset using the best estimators obtained from the hyperparameter tuning.

c. RF model
A random forest regressor model was utilised, and a set of hyperparameters, including the number of estimators, maximum depth, minimum samples for splitting, and bootstrapping options, was defined. The randomised search CV function was employed to explore combinations of these parameters through cross-validation.

The study explored an automated batch machine learning modelling approach designed to compare various models in parallel. While this method offered speed and broad coverage, it posed challenges in terms of flexibility for hyperparameter optimisation, interpretability of results, and efficient handling of the dataset's size. Consequently, the decision was made to proceed with three targeted models—Random Forest (RF), Artificial Neural Network (ANN), and Support Vector Machine (SVM)—which aligned more closely with the research objectives.

Hyperparameter tuning for each selected model was conducted manually using a grid search approach, allowing systematic evaluation of defined parameter ranges and iteration limits. For the RF model, the tuning process involved varying the number of estimators (100–500), maximum tree depth (5–20), and minimum samples per leaf (1–5). The ANN model's optimisation considered the number of hidden layers (1–3), neurons per layer (10–100), learning rate (0.001–0.01), and activation functions (ReLU, tanh, sigmoid). For the SVM model, parameters such as the regularisation parameter C (0.1–10), kernel type (linear, RBF, polynomial), and kernel coefficient gamma (0.001–1) were tested.

3.2 Dataset

The dataset used in this study comprises financial information of companies listed on the Johannesburg Stock Exchange (JSE), covering the period from 1997 to 2022. The target variable for modelling is the Debt/Equity ratio, while the independent variables consist of various financial indicators. Financial institutions were excluded due to regulatory influences on their capital structures, such as minimum capital requirements under the Basel framework.

Prior to modelling, the data underwent a series of preprocessing steps to ensure quality and consistency. Missing values were identified and appropriately imputed, outliers were detected using statistical thresholds and treated to reduce distortion, and all features were scaled or normalized to improve model convergence and stability. This preprocessing pipeline ensured that the Random Forest, ANN, and SVM models could effectively learn from the financial data while mitigating the risks of bias or instability caused by irregularities in the dataset.

3.2.1 Data Splitting

The dataset used in this study comprises publicly available financial information of companies listed on the Johannesburg Stock Exchange (JSE), covering the period from 1997 to 2022. The data were sourced from Iress Market Data, which provides market and financial information for publicly listed companies in South Africa (https://www.iress.com/za/market-data/). The target variable for modelling is the Debt/Equity ratio, and the independent variables include various financial ratios and indicators relevant to capital structure analysis. Financial institutions were excluded due to regulatory influences on their capital structures, such as minimum capital requirements under the Basel framework.

For modelling purposes, the dataset was divided into a training set (X_train, y_train) and a test set (X_test, y_test). X_train contains r×mr \times mr×m samples and X_test contains (1−r)×m(1 - r) \times m(1−r)×m samples, where rrr is the chosen training ratio (here, 70%) and mmm is the total number of samples.

3.3 Performance Evaluation

The models, together with the benchmark LR model, were evaluated based on the following performance metrics:

1. R-squared (R^2): Measures the proportion of variance explained by the model. Higher percentages therefore present better-performing models.
2. Mean Absolute Error (MAE): This represents the average magnitude of errors in predictions without considering their direction. The lower this value is, the better the model performs.
3. Mean Absolute Percentage Error (MAPE): Provides a percentage representation of prediction accuracy, computed as the average absolute percentage difference between actual and predicted values. Higher percentages are considered better performance.

The methodology above outlined a comprehensive framework for analysing the capital structure of companies using various machine learning techniques. By employing rigorous data preprocessing, model optimisation, and performance evaluation, the study aims to uncover insights into the factors influencing the Debt/Equity ratio, contributing to the broader field of corporate finance.

4 RESULTS

Table 1 and Figure 1 provides the performance metrics of the various machine learning models. The best-performing machine learning model after hyperparameter tuning and grid search is the RF model, with an R^2 of 65%, compared to ANN and SVM, having an R^2 of 25% and 33%, respectively. The benchmark linear regression model was the second-best performer with an R^2 of 34%.

The Random Forest (RF) model emerged as the best-performing predictive model among all the approaches considered. Based on the test set, RF achieved the lowest Mean Absolute Error (MAE) of 0.15, substantially outperforming the Artificial Neural Network (ANN) and Support Vector Machine (SVM) models, which recorded MAE scores of 0.70 and 0.65, respectively. The benchmark Linear Regression (LR) model exhibited moderate performance, with an MAE of 0.60.

Similarly, in terms of Mean Absolute Percentage Error (MAPE), RF demonstrated superior predictive accuracy, achieving a MAPE of 25%, while ANN and SVM models scored 65% and 60%, respectively. The LR model again performed moderately with a MAPE of 55%.

Table 1. Performance Metrics of Various Machine Learning Models

Machine Learning Algorithm	R-square (R^2)	MAE	MAPE
ANN (MLP) model	25%	0.70	65%
SVM model	33%	0.65	60%
RF model	65%	0.15	25%
Linear regression model	34%	0.60	55%

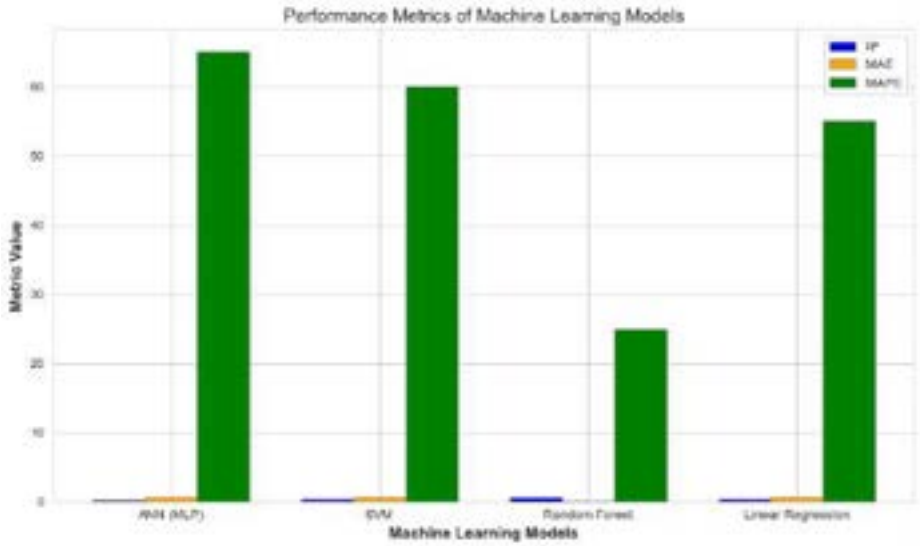

Figure 1. Graphical Performance Metrics of Various Machine Learning Models

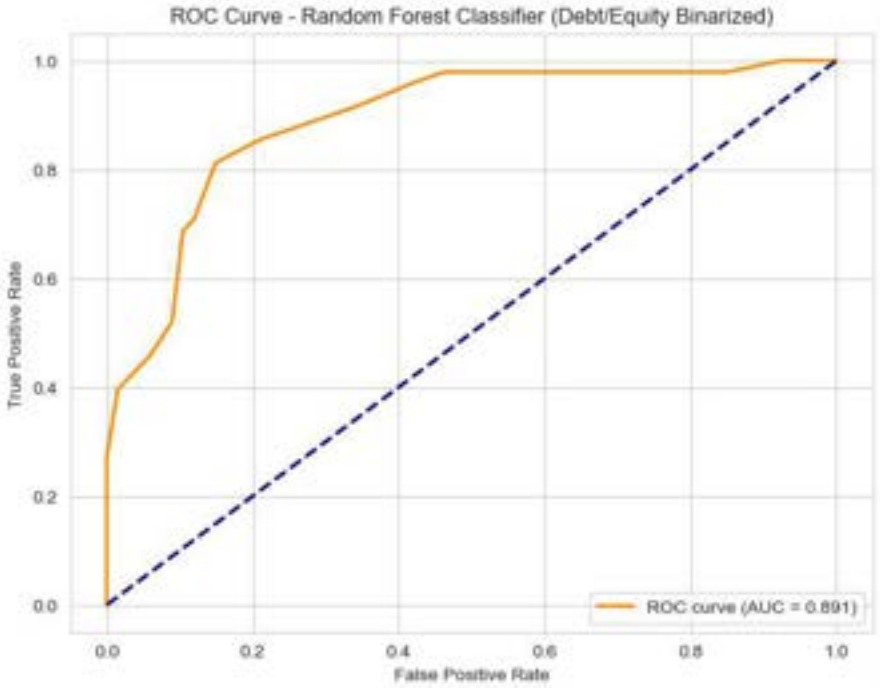

Figure 2: ROC Curve for the Random Forest Model

The RF model's strong performance is further corroborated by the ROC-AUC analysis performed on a binarized version of the Debt-to-Equity target, which yielded an AUC of 0.891. This is illustrated in Figure 2. The ROC curve indicates that RF is highly capable of discriminating between companies with higher versus lower leverage levels.

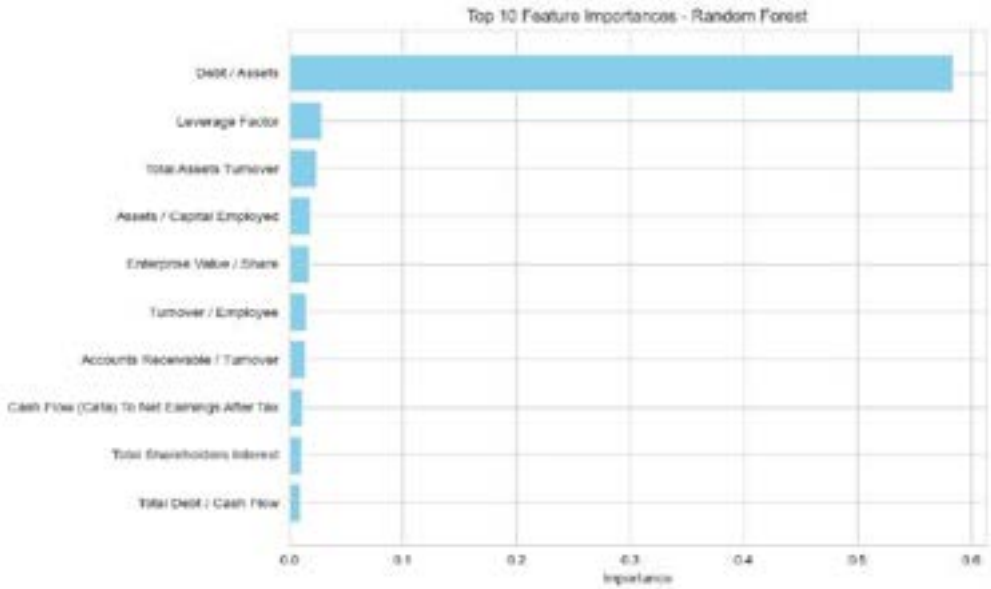

Figure 3: Top ten features of the Random Forest Model

The feature importance analysis from the RF model is shown in Figure 3. It revealed that the most predictive variables include Debt-to-Assets, Leverage Factor, and Total Assets, highlighting the critical role of leverage and firm size in explaining capital structure dynamics. Overall, RF's superior performance relative to ANN, SVM, and benchmark LR models reinforces the importance of capturing nonlinear interactions and complex relationships when modelling corporate capital structure.

5 CONCLUSION

The study confirmed that the Random Forest (RF) model outperforms traditional statistical methods like Linear Regression (LR) in predicting capital structure, particularly for listed South African companies on the Johannesburg Stock Exchange (JSE). RF achieved higher R^2, lower Mean Absolute Error (MAE), and lower Mean Absolute Percentage Error (MAPE), indicating a stronger predictive capacity and an ability to capture the intricate, nonlinear relationships inherent in capital structure dynamics. This superior performance can be attributed to RF's ensemble architecture, which reduces variance through averaging multiple decision trees, handles multicollinearity effectively, and is inherently robust to noise and overfitting — qualities particularly advantageous in financial datasets characterised by high dimensionality and complex variable interactions.

These findings are consistent with previous studies emphasising the utility of machine learning, particularly ensemble methods, in financial predictions. Notably, Adya and Collopy (1998) explored the effectiveness of neural networks in forecasting, aligning with our observation that machine learning approaches can outperform traditional models in contexts involving complex, nonlinear relationships [29]. Similarly, Atiya (2001) highlighted the advantages of neural networks in bankruptcy prediction, a related domain where AI models excel in recognising patterns within multifaceted financial datasets [30].

When comparing RF to LR, the limitations of traditional statistical models become clear. While LR provides interpretable coefficients and basic trend insights, it assumes linearity and struggles to model the nonlinear dependencies and interaction effects prevalent in corporate finance data. This conclusion is supported by Biau (2012), who demonstrated RF's robustness in capturing complex data patterns, and by Biau et al. (2008), who noted the consistency of RF and other averaging classifiers in high-dimensional settings [31][32].

Although Artificial Neural Networks (ANN) and Support Vector Machines (SVM) demonstrated some predictive merit, they underperformed relative to RF in this study. This is likely due to the relatively limited dataset size and the high variability in feature scales, which made ANN more prone to overfitting without extensive hyperparameter tuning and regularisation. SVM, on the other hand, faced challenges in kernel selection and parameter optimisation, as noted by Cortes and Vapnik (1995), particularly when dealing with heterogeneous financial data containing both continuous and categorical predictors [35].

From a managerial and industry perspective, these results have important implications. The ability of RF to accurately forecast capital structure provides corporate finance teams and strategic decision-makers with a reliable tool for assessing optimal leverage, planning debt issuance, and evaluating financing strategies in dynamic market conditions. Industry stakeholders, including investors and regulators, can leverage such predictive insights to better understand firm-level risk exposures, identify sector-specific financing trends, and design policies or interventions that improve capital allocation efficiency. Furthermore, the model's interpretability through feature importance rankings enables managers to pinpoint the key financial drivers influencing capital structure decisions, supporting evidence-based financial planning and risk management.

In conclusion, RF's ability to combine predictive accuracy with resilience to overfitting makes it particularly well-suited to capital structure prediction in emerging market contexts. Future research should explore hybrid modelling strategies that integrate the strengths of various algorithms — including deep learning approaches — and incorporate multifactor and temporal analyses to gain deeper insights into the drivers of corporate financing decisions [36].

6 RECOMMENDED FUTURE WORK

The following fields have been identified as recommended areas for future work:

- **Incorporating Unlisted Companies:** Future studies can extend the analysis to include unlisted companies, providing a comprehensive understanding of capital structure dynamics across a broader spectrum of companies. This expansion can enhance the generalisability of the findings and offer insights into the financing behaviour of both listed and unlisted entities. The inclusion of qualitative sustainable factors, such as environmental, social, and governance factors, can influence the financing decisions of companies and, ultimately, their capital structure.
- **Integration of Qualitative Factors:** Incorporating qualitative factors such as environmental, social, and governance (ESG) criteria into the predictive models can enrich the analysis. By considering non-financial aspects alongside traditional financial metrics, researchers can gain deeper insights into the holistic drivers of capital structure decisions.
- **Dynamic Modelling Approach:** Adopting a dynamic modelling approach that accounts for temporal changes and evolving market conditions can enhance the predictive capabilities of the models. By incorporating time series data and employing dynamic forecasting techniques, future studies can capture the evolving nature of capital structure dynamics and adapt predictive models accordingly.
- **Exploring Alternative Machine Learning Algorithms:** While RF models exhibit strong predictive performance in this study, exploring alternative machine learning algorithms and ensemble methods can offer valuable insights. Techniques such as Gradient Boosting Machines (GBM), XGBoost, and Long Short-Term Memory (LSTM) networks warrant investigation to assess their suitability for modelling capital structure dynamics.
- **Cross-Industry Analysis:** Extending the analysis beyond the Industrial sector to other industries can provide valuable comparative insights. By examining how capital

structure decisions vary across different sectors, researchers can identify industry-specific drivers and trends, contributing to a more comprehensive understanding of financing behaviour.

- **Model Interpretability and Explainable AI:** Future studies should incorporate interpretability tools such as SHAP (Shapley Additive Explanations) and LIME (Local Interpretable Model-agnostic Explanations) to increase transparency of machine learning predictions. By understanding which features drive model outputs, researchers and managers can gain actionable insights and improve decision-making in financial planning and capital structure management.

In conclusion, while the present study highlights the efficacy of RF models in predicting capital structure dynamics, there exists ample opportunity for future research to investigate deeper into this complex phenomenon. By embracing interdisciplinary approaches, leveraging advanced modelling techniques, and expanding the scope of analysis, researchers can further advance our understanding of capital structure dynamics and its implications for company performance and financial decision-making.

ABSTRACT

The rapid expansion of automobile sector in South Africa has significantly increased fossil fuel consumption and carbon emissions. This study investigates dynamic interdependencies between urbanization, passenger vehicle proliferation, fuel consumption, and CO_2-equivalent emissions in Gauteng, South Africa, using advanced system econometrics techniques. Panel Quantile Regression, Generalized Additive Models, and Arellano-Bond Generalized Method of Moments quantify nonlinear relationships, while LSTM-Attention forecasting projects emissions trends (2024–2040). Mixed Integer Nonlinear Programming with CPLEX optimization identifies optimal mitigation pathways. Validation by heteroskedasticity diagnostics for p-values of 0.038 and 0.042 confirm the system econometrics robustness to reveal dynamic interdependencies between urbanization, passenger vehicle growth, fuel consumption, and carbon emissions. This projects 22.6% emissions reduction beyond 2040 down to 8.57 $MTCO_2$-eq, driven by efficient energy use (241.33×10^6 MJ), urbanization by 94.7%, economic growth to ZAR 2.422 trillion, with concurrent decline in on-road passenger vehicles. This reinforces the necessity for low-carbon policies, clean mobility investments, and strategic transportation systems.

Keywords: Urbanization, Carbon Emissions, Transportation, Econometrics, Machine Learning, Sustainability.

1 INTRODUCTION

The transportation industry is a major contributor to global greenhouse gas (GHG) emissions, accounting for approximately 25% of total CO_2-equivalent (CO_2-*eq*) emissions [1]-[2]. The rapid expansion of urban areas, driven by population growth, infrastructure development, and economic activity, has intensified transport-related energy consumption and emissions. In emerging economies such as South Africa, increasing motorisation has further exacerbated the carbon footprint of the industry. According to the United Nations (2022), 56% of the global population resides in urban areas, with projections indicating an increase to 68% by 2050 [3]-[4], reinforcing the urgency of implementing sustainable mobility solutions. As urban areas expand, rising mobility demand, increasing passenger vehicle ownership, and continued reliance on fossil fuel-powered transportation have amplified environmental concerns. The carbon footprint of the industry is further exacerbated by urban sprawl, inadequate public transit infrastructure, and escalating congestion in major metropolitan areas [5]-[6]. Empirical evidence indicates that low-density urban development correlates with higher per capita vehicle emissions, as residents become increasingly dependent on private automobiles for daily commuting. These trends accentuate the critical need for sustainable urban planning and low-carbon mobility systems to mitigate transportation-induced emissions. Globally, passenger road transport accounts for approximately 45% of total transportation-related CO_2-*eq* emissions, with an annual growth rate of 1.5% in developing economies [7]-[8]. The combustion of fossil fuels which are primarily gasoline and diesel being utilized in internal combustion engine vehicles (ICEVs) emits not only carbon dioxide (CO_2) but also methane (CH_4), carbon oxide and nitrous oxide (N_2O), these among others are collectively classified as CO_2-*eq* emissions [9]-[10]. These emissions exacerbate global warming while also deteriorating urban air quality, reinforcing the urgency for sustainable transportation policies and cleaner energy alternatives. The affordability of private vehicles, increasing disposable incomes, and deficiencies in public transportation infrastructure have accelerated vehicle ownership rates in Gauteng, being the main economic hub of South Africa. This rapid urbanization has led to significant expansion of the passenger vehicle fleet, driving higher fuel consumption and per capita emissions [11]. Moreover, low fuel efficiency standards, an aging vehicle fleet, and persistent congestion further contribute to inefficient fuel combustion and rising CO_2-*eq* emissions. Addressing these concerns necessitates targeted interventions, which include improved fuel efficiency regulations, enhanced public transit systems, and the promotion of non-motorized transport alternatives. Urban development immensely contribute to shaping transportation patterns by influencing land use distribution, commuting behaviours, and modal choices. Empirical evidences indicate that higher urban densities are generally associated with lower per capita transportation emissions due to the presence of compact, transit-oriented infrastructure that encourages public transport use and reduces reliance on private vehicles [12]-[13]. Well-integrated transportation systems that prioritise mixed land use, pedestrian-friendly environments, and efficient public transit networks are essential for reducing transport-related emissions and enhancing overall sustainability. In Gauteng, rapid urbanization has significantly increased the demand for motorized transport, leading to a substantial rise in carbon emissions from passenger vehicles. As South Africa's economic powerhouse, Gauteng contributes approximately 35% of the nation's GDP and continues to experience accelerated urban population growth, further intensifying transportation-related energy consumption [1],[14]-[15]. Despite government initiatives aimed at promoting public transit and non-motorized transport, the province remains heavily reliant on private passenger vehicles due to persistent challenges such as unreliable public transport services, socioeconomic inequalities, and infrastructure deficits. Given these complexities, a system econometrics framework is essential for quantitatively assessing the interdependencies between urbanization, passenger vehicle growth, fossil fuel consumption, and GHG emissions in Gauteng's transportation industry.

To this context and application, system econometrics within industrial, systems, and engineering management is a unified analytical approach that resolves the dynamic interdependencies among energy, economic, environmental, and social variables to enable optimal resource allocation, robust causal inference, and policy-oriented forecasting for complex real-world systems. System econometrics essentially involves engineering, econometrics, machine learning, and optimization techniques. This study employs panel data analytics, incorporating advanced econometric regression techniques, model optimization, and machine learning with CPLEX Solver to deduce empirical information into the key drivers of transport-related emissions. The findings will provide data-driven recommendations for further design of sustainable urban transport policies, aligning with the unique economic and environmental landscape of Gauteng to support long-term carbon mitigation strategies.

2 LITERATURE REVIEW

The accelerated expansion of urban areas has fundamentally altered patterns of mobility, energy consumption, and greenhouse gas (GHG) emissions. Urbanization drives a complex interplay between population density, infrastructure development, and transport demand, with passenger vehicle ownership emerging as a primary determinant of transportation-related emissions [16]-[18]. This phenomenon is particularly critical in emerging economies, where transportation infrastructure often struggles to keep pace with rapid urban growth, leading to congestion, increased fuel consumption, and elevated emissions. Addressing these challenges necessitates a comprehensive understanding of the dynamic relationship between urban expansion and transport-sector emissions, integrating both theoretical frameworks and empirical analyses to inform sustainable mobility strategies [19]-[21]. Urbanization exerts significant influence on transportation systems, shaping mobility patterns, energy consumption, and GHG emissions. Theoretical perspectives have been employed to examine the mechanisms underlying this relationship. The compact city hypothesis postulates that high-density urban development enhances public transportation utilization, thereby reducing per capita emissions through improved efficiency, shorter travel distances, and minimized reliance on private vehicles [22]-[23]. Conversely, the urban sprawl hypothesis contends that low-density suburban expansion exacerbates private vehicle dependency, leading to increased emissions due to extended commuting distances, traffic congestion, and inefficient land-use patterns [24]-[26]. A broader macroeconomic perspective is provided by the Environmental Kuznets Curve (EKC) hypothesis, which indicates that CO_2-*eq* emissions initially rise during the early stages of urbanization but subsequently decline as economies develop, incorporating cleaner technologies and transitioning toward more sustainable transportation systems [1],[27]. Empirical research presents mixed findings regarding the relationship between urbanization and transport emissions, with evidence both supporting and challenging the prevailing theoretical perspectives. Several studies indicate that unplanned urban expansion exacerbates transport-sector emissions by fostering inefficient land-use patterns and increasing vehicle kilometres travelled (VKT) [28]-[29]. This is consistent with the findings of Cavoli [30] and Canitez [31], whose cross-country analysis demonstrates that in developing economies, rapid urbanization often accelerates private vehicle ownership due to the inadequate provision of public transportation infrastructure. In the African context, South Africa's urban centres, particularly Gauteng province which exhibit some phenomenal transportation inefficiencies, largely attributed to low-density spatial development and heavy dependence on fossil-fuel-based mobility [9],[33]. Empirical data further indicate that urban congestion in Johannesburg and Pretoria significantly amplifies GHG emissions, as frequent stop-and-go traffic conditions increase fuel consumption and exacerbate environmental impacts [11]. These findings augment the critical demand for strategic urban transportation planning and sustainable mobility interventions to mitigate transport-related emissions in rapidly urbanizing regions. By synthesizing theoretical perspectives with empirical findings, the literature deepens the necessity for targeted policy interventions and advanced

analytical techniques, such as system econometrics within engineering management, to analyse and mitigate urban transport emissions in provincial regions like Gauteng, South Africa. The country's transportation sector remains heavily reliant on fossil fuels, with gasoline and diesel accounting for over 95% of total road transport energy consumption [9], [34]. This dependency is further exacerbated by an aging vehicle fleet, which significantly contributes to carbon emissions due to higher fuel intensities and elevated emission factors associated with older vehicles [35]-[36]. These findings reinforce the urgent need for robust system econometrics modeling to quantitatively assess the impact of urbanization-driven vehicle proliferation on GHG emissions within Gauteng's transportation industry, providing a data-driven foundation for sustainable mobility policies. Recent advancements in energy economics, econometric modeling, and machine learning (ML) methodologies have substantially enhanced the precision and analytical depth of greenhouse gas (GHG) emissions forecasting. The integration of econometric estimation techniques with ML-based predictive frameworks enables more robust modeling of complex, nonlinear relationships within transportation emissions data, thereby improving forecasting accuracy and policy relevance [37]-[42]. These developments accentuate the potential of data-driven approaches in refining emission mitigation strategies and optimizing energy-efficient transport systems.

Panel Quantile Regression (QR) econometric analysis extends beyond conventional mean regression techniques by capturing distributional heterogeneity in the relationship between urbanization, transport activity, fuel consumption, and carbon emissions [43]-[46]. Unlike Ordinary Least Squares (OLS), which estimates only the average effects, QR provides conditional quantile estimates, enabling the identification of heterogeneous policy impacts across different levels of emissions intensity. This approach is particularly relevant in emissions modeling, where extreme values such as high-emitting urban clusters which can exhibit distinct behavioural patterns compared to low-emission zones. Empirical studies of Kazemzadeh et al. [47] and that of Belaid & Massie, [48] have demonstrated QR's effectiveness in disentangling the asymmetric effects of urban expansion and vehicle density on greenhouse gas (GHG) emissions, reinstate that emissions in the upper quantiles are more sensitive to changes in transport policy. In the context of Gauteng, QR is instrumental in identifying how emissions respond differentially to varying degrees of urbanization and vehicle proliferation, thus guiding targeted policy interventions.

Conventional econometric techniques often impose rigid functional forms, failing to capture the complex, nonlinear interactions between urbanization and emissions. Generalized Additive Models (GAMs) overcome this limitation by incorporating smooth, nonparametric functions that flexibly model relationships without assuming predefined structures [49]-[51]. The recent applications in environmental econometrics demonstrate that GAMs effectively capture threshold effects in transport emissions, where urban expansion initially accelerates emissions growth before stabilizing due to infrastructure improvements and clean energy transitions [52]-[54]. In this study, GAMs facilitate a rigorous assessment of the nonlinear dynamics between passenger vehicle growth, urbanization rates, and GHG emissions, providing policy-relevant insights into strategies for decoupling economic expansion from environmental degradation in Gauteng, South Africa.

Urbanization, economic growth, and passenger vehicle proliferation exhibit strong interdependencies, often leading to endogeneity concerns in empirical models. The Arellano-Bond Generalized Method of Moments (GMM) estimator effectively addresses autocorrelation, simultaneity bias, and omitted variable bias by leveraging lagged instruments to produce unbiased estimates [55]-[56]. In transportation emissions modeling, GMM has been systematically deployed to analyse the long-term impacts of policy interventions on fuel consumption and emissions efficiency [57]-[59]. By employing GMM in this research, the study ensures that estimated relationships between urbanization, transport demand, fossil fuel

consumption, and GHG emissions remain robust against reverse causality and omitted structural factors, thereby strengthening the causal inferences necessary for decision in policymaking.

Individually, QR, GAMs, and GMM provide distinct analytical merits; nevertheless, their combined applications in system econometrics significantly enhances predictive accuracy and policy relevance. The simultaneous use of QR (distributional heterogeneity), GAMs (nonlinear interactions), and GMM (endogeneity control) facilitates a multidimensional assessment of urbanization-driven GHG emissions dynamics in the transportation industry. These integrated methodological techniques enable the identification of high-risk carbon emission phases over time, informs threshold-based urban planning policies, and enhances the precision of emissions mitigation strategies.

Machine learning (ML) techniques have gained prominence in transportation emissions modeling, offering superior predictive accuracy, adaptive learning capabilities, and improved handling of nonlinearities compared to traditional econometric methods [60]-[62]. The integration of ML into emissions modeling has further improved predictive accuracy and model robustness. Artificial Neural Networks (ANNs), for instance, have demonstrated exceptional capabilities in capturing intricate nonlinear relationships between urbanization, vehicle expansion, and emissions patterns [63]-[65]. Similarly, Support Vector Regression (SVR) and ensemble-based techniques such as Random Forest and XGBoost of ML techniques have proven effective in analysing high-dimensional transportation emissions datasets, offering deeper insights into complex interactions and forecasting trends with greater precision [66]-[68]. Among ML techniques, deep learning approaches such as Long Short-Term Memory (LSTM) networks have demonstrated exceptional performance in capturing long-range temporal dependencies in time-series forecasting [69]-[71]. LSTM models, a specialized class of recurrent neural networks (RNNs), are designed to learn from sequential data while mitigating the vanishing gradient problem. The integration of an attention mechanism further enhances forecasting precision by prioritizing significant time-series dependencies [72]-[73]. Studies by Xiong et al. [74] and Pan et al. [75] indicate that LSTM-Attention models outperform traditional and recent autoregressive models (e.g., ARIMA) and the conventional econometric techniques in GHG emissions forecasting by capturing dynamic interactions between transport demand, urbanization, and emissions. In this study, the LSTM-Attention technique facilitates a moderately high-fidelity CO_2-eq emissions projections for 2024, through 2040 and beyond, providing a robust empirical basis for long-term environmental policy planning.

In spite advancements in econometric and ML-based modeling, limited research has been conducted on transportation sector emissions and South Africa is in no way an exemption, particularly using an incorporated system econometric-ML approach. This study addresses this critical gap by employing a hybrid system econometrics framework augmented with ML-driven forecasts to generate robust, data-driven insights into the emissions dynamics of Gauteng's urban transport sector. By leveraging the strengths of these methodologies, the study enhances proper grasp of how urbanization and transport trends influence CO_2-*eq* emissions, enabling informed decision-making for sustainable mobility solutions.

While forecasting models identify trends, optimization techniques such as Mixed Integer Nonlinear Programming (MINLP) provide actionable strategies for GHG emissions reduction and fuel efficiency improvements. MINLP, implemented in this study using the CPLEX optimization solver, is particularly suited for problems involving discrete policy decisions and nonlinear interactions [76]-[77]. Prior research of Homayouni et al. [78] and Yuvarai et al. [79], have demonstrated MINLP's efficacy in optimizing transportation systems, ensuring that emissions reductions align with economic feasibility and infrastructure constraints.

The integration of QR, GAMs, GMM, LSTM-Attention, and MINLP forms an efficient analytical tool that capture heterogeneous, nonlinear, and dynamic effects influencing transportation-related GHG emissions.

Based on use and thorough assessments, QR is at advantage to uncover heterogenous impacts of urbanization and passenger vehicles on emissions that main-based estimators forfeit. GAMs are applicable to flexibly capture non-linear relationships without imposing restrictive functional forms required by conventional econometric regressions. GMM is to be employed to address endogeneity and dynamic feedback effects that are hardly possible to correct by OLS and ordinary FE models. The LSTM-Attention is adopted for its superiority to learn temporal dependencies and to reinstate the key drivers in long-term emissions forecasting, outperforming conventional time-series models such as ARIMA, standard RNNs, and more.

This methodological approach not only provides high-precision long-term emissions forecasts (2024–2050) but also optimizes strategic policy decisions to align with emissions reduction targets under the Paris Agreement (2030, 2050) and the United Nations Sustainable Development Goals. By bridging predictive analytics with decision optimization, this study significantly advances the field, offering scalable applications for sustainable transport policies in Gauteng and beyond.

3 METHODOLOGY

3.1 Gauteng research profile

Gauteng is the smallest of the nine provinces in South Africa, spans approximately 18,176 km^2 (1.4% of the national land mass area), and yet serves as the economic nucleus, contributing 35% to the economic growth of the nation [80]-[81]. It comprises three metropolitan municipalities which include Johannesburg, Tshwane, and Ekurhuleni with two other district municipalities, significantly impacting to the national urbanization and transportation dynamics. With a population of 15.1 million [81] and an urbanization rate exceeding 97% [82], Gauteng exhibits a high dependency on private passenger vehicle ownership due to inadequate public transit infrastructure. The province accommodates 38% of South Africa's total vehicle fleet, with over 4.5 million registered vehicles [80], [83]. Passenger vehicle reliance is exacerbated by expanding road networks, such as the Gauteng Freeway Improvement Project (GFIP), yet severe congestion persists along minor, and critical corridors (for instance, M1, N1, N4, and R21). In 2022, fuel consumption in Gauteng's transport sector exceeded 5.0 billion litres, growing at 3.1% annually [9], [82]. This dependence on gasoline and diesel intensifies carbon-intensive energy demand, with passenger vehicles emitting over 17.8 $MTCO_2$-eq annually [11], [82]. The utilization of internal combustion engine (ICE) vehicles generates harmful CO_2, methane (CH_4), and nitrous oxide (N_2O), exacerbating climate impacts [84]-[86]. The absence of stringent emission controls and limited modal shifts to sustainable transport necessitate urgent interventions, including clean energy adoption and public transit enhancement, to mitigate transportation-induced greenhouse gas (GHG) emissions in Gauteng.

3.2 Descriptive data sources

This study utilizes a 12-year panel dataset (2012–2023) to analyse transportation-related GHG emissions in Gauteng, South Africa's economic hub. The dataset integrates multiple authoritative sources to ensure accuracy and consistency, given the absence of a consolidated data repository. Key sources include Statistics South Africa [81] (urbanization trends), the Department of Transport (vehicle fleet units, fuel consumption) [80], [82], and the Gauteng Department of Roads and Transport (fleet composition, infrastructure investments) [80]. Additional data were obtained from SANEDI and the Department of Energy (fuel efficiency, alternative energy adoption) [82], as well as international benchmarks from the IEA, ITF,

World Bank, and UN-Habitat. The study examines four core variables: urbanization (%), passenger vehicle fleet (total registered vehicles), fuel consumption (by type), and CO_2-*eq* emissions [84]-[86]. All these profiled panel datasets informative background are properly assimilated in the works of Oladunni et al. [1], Oladunni and Olanrewaju, [9] and Oladunni et al [11]. System econometrics of advanced techniques are employed to assess their interdependencies. Extensive pre-processing ensures data integrity, including validation for inconsistencies, missing values, and outliers. Descriptive statistics are summarized in **Table 1**.

Table 1: Descriptive panel dataset statistics

Variable [**2012-2023**]	Measurement units	Obs	Mean	Std. Dev.	Min. value	Max. value	Skew	Kurtosis
Nominal GDP	SA Billion Rand	250	1710441	386845.44	998095.00	2,329820	-0.155	-0.702
Urbanisation	% in development	250	0.931	0.0980	0.720	0.991	-1.657	0.943
Passenger vehicles	vehicle fleet in units	250	4090292	797899	2694931	4997033	-0.601	-0.900
Fuel consumption	Billion (petroleum) **litres**	250	5.753E9	453.86E6	5.11E9	6.48E9	0.149	-1.228
CO_2-*eq* emissions	Metric tons per capita	250	14.891	2.177	11.471	17.532	-0.202	-1.334

3.3 Systems modeling

A system-based econometric model is developed to quantify the direct and indirect effects of urbanization (URB), economic growth (GDP), passenger vehicles (PV), and fuel consumption (FC) on GHG (CO_2-*eq*) emissions in Gauteng. The model is structured as a system of structural equations, capturing both direct parametric impacts and interdependencies among variables. This approach ensures a comprehensive assessment of emissions dynamics by integrating economic, infrastructural, and energy-related factors. The fundamental structural equations governing the model are defined as follows:

$$\mathbf{GHG_t} = \mathbb{f}(\mathbf{URB_t}, \mathbf{GDP_t}, \mathbf{PV_t}\ \mathbf{FC_t}) + \boldsymbol{\varepsilon_t} \quad (1)$$

Where as here stated:

- $\mathrm{GHG_t}$ represents GHG emissions at time t ,
- $\mathrm{URB_t}$ connotes the urbanization development rate,
- $\mathrm{GDP_t}$ indicates economic growth of Gauteng in period t,
- $\mathrm{PV_t}$ is the number of on-road passenger vehicles in period t,
- $\mathrm{FC_t}$ connotes fuel consumption at considered period t,
- ε_t is the error term capturing unobserved factors.

The interdependence of CO_2-eq emissions and their determinants is modeled system econometric estimations, where urbanization (URB) drives economic growth (GDP), vehicle ownership (PV), and fuel consumption (FC), all of which collectively impacts emissions in the transportation industry. This systematic interaction necessitates the structural econometric applications to quantify both direct and indirect effects. The mathematical formulation of these relationships is specified through a set of structural equations, capturing the causal dependencies among key parametric variables. The following equations define the model technicalities for analysing CO_2-eq emission determinants:

$$\mathbf{In}(\boldsymbol{CO_{2-eq}}) = \propto_{\mathbf{0}} + \propto_{\mathbf{1}} \mathbf{In}(\mathbf{URB}_t) + \propto_{\mathbf{2}} \mathbf{In}(\mathbf{GDP_t}) + \propto_{\mathbf{3}} \mathbf{In}(\mathbf{PV_t}) + \propto_{\mathbf{4}} \mathbf{In}(\mathbf{FC_t}) + \boldsymbol{\varepsilon_{1t}} \quad (2)$$

Here, $\mathrm{In}(CO_{2-eq})$ is the natural log of carbon emissions, $\propto_0$ represent the constant term, while $\propto_1$ represents the elasticity of economic growth, $\propto_3$ is the elasticity of passenger vahicles, as $\propto_4$ denotes the elasticity for fuel consumption. The ε_{1t} is the error term for the emissions determinant. This is directly deployed for URB and GDP interaction:

$$\mathbf{In(GDP_t) = \beta_0 + \beta_1 In(URB_t) + \beta_2 In(PV_t) + \beta_3 In(FC_t) + \varepsilon_{2t}} \quad (3)$$

At current development stage of South Africa, fuel consumption in Gauteng is primarily driven by economic growth, urban expansion, and the increasing number of on-road vehicles. Accordingly, the econometric system is structured to capture these relationships mathematically. The system is expressed in matrix form such that $Y_t = \left[\mathrm{InCO}_{2-eq}, \mathrm{In(GDP_t)}, \mathrm{In(PV_t)}, \mathrm{(FC_t)}\right]^T$ is the vector of the endogenous variables. To ensure that all endogenous parametric variables are sequential to the exogenous of the right side, such as $\mathrm{BY_t} = \mathrm{CX_t} + \varepsilon_t$. The coefficient matrix B accounts for the interdependencies as follows:

$$\begin{bmatrix} 1 & -\alpha_2 & -\alpha_3 & -\alpha_4 \\ -\beta_1 & 1 & -\beta_2 & -\beta_3 \\ -\gamma_1 & -\gamma_2 & 1 & 0 \\ -\delta_1 & -\delta_2 & -\delta_3 & 1 \end{bmatrix} \quad (4)$$

The right-hand side comprises exogenous variables, as parametric sample, specifically urbanization. The system incorporates error terms as follows:

$$CX_t = \begin{bmatrix} \propto_1 \\ \beta_4 \\ \gamma_3 \\ \delta_4 \end{bmatrix} \mathrm{In(URB_t)} + \varepsilon_t \quad ; \quad \varepsilon_t = \begin{bmatrix} \varepsilon_{1t} \\ \varepsilon_{2t} \\ \varepsilon_{3t} \\ \varepsilon_{4t} \end{bmatrix} \quad (5)$$

In the application of the system, log-linear specifications are employed to improve both the interpretability and robustness of the model. In this formulation, the estimated coefficients ($\boldsymbol{\beta_i}$) across the versions represent elasticities, quantifying the percentage change in CO_2-*eq* emissions corresponding to a 1% change in the explanatory variables. Furthermore, the logarithmic transformation addresses heteroscedasticity by stabilizing the variance, ensuring more consistent error terms. This approach also enhances the model fit by promoting linearity in the relationships among the variables, effectively responding to the characteristics of the sectoral time-series data.

4 RESULTS

4.1 System algorithm interpretation

Table 2 outlines the integrated system econometrics algorithms, combining econometric modeling, deep learning, and optimization techniques to assess and mitigate transportation energy emissions, with a focus on urbanization and on-road passenger vehicles. The 12-year panel dataset (2012–2023) was subjected to Min-Max normalization for numerical stability, followed by stationarity tests (ADF, PP, KPSS, ZA) to ensure robustness. A 1D Convolutional Neural Network (Conv1D) extracted critical features of urbanization, GDP, passenger vehicle count, and fossil fuel consumption to further preserve patterns via skip connections. ReLU activation and linear transformations improved predictive accuracy. Econometric regression analysis is employed using Panel Quantile Regression (QR) to assess heterogeneity, Generalized Additive Models (GAMs) applied to capture non-linear relationships, and Arellano-Bond GMM to address endogeneity. An LSTM-Attention model projected CO_2-eq emissions, showing a 4.3% annual increase without mitigation. The Mixed Integer Nonlinear Programming (MINLP) optimization, solved with CPLEX Solver at a high significant level achieved a 7.8% reduction in CO_2-*eq* emissions and a 5.5% decrease in fossil fuel consumption

from 2023 through 2035 alone. The recalling solutions based on the algorithmic interpretation of **Table 2** connote that energy-efficient public transport, stricter emission standards, with the required infrastructure investments can be achieved**.**

Table 2: Algorithmic system econometrics for transport energy emissions.

	Input:	System econometrics for transport energy emission parameters Historical panel data sets $[\mathbf{2012-2023}]$
	Features and Labels:	$\{\mathrm{GDP_t}, \mathrm{URB_t}, \mathrm{PV_t}, \mathrm{FC_t}, \mathrm{CO_{2eqt}}\} \therefore X_t \in \mathbb{R}^{B\times4\times N\times T}, Y_t \in \mathbb{R}^{B\times H}$
Parameters setting:		Econometrics; ML with DL model parameters; Systems optimisation
	Output:	Carbon emissions and fuel consumption for policy recommendation
1	Construct adjacency matrix: $\mathbf{A_t} = \mathbf{Self-Attention}(\mathbf{X_t}, \mathbf{W^K}, \mathbf{W^\varphi})$	
2	Normalise features using $\min-\max$ scaling: $\mathrm{X_t'} = \frac{\mathrm{X_t}-\min(\mathrm{X_t})}{\max(\mathrm{X_t})-\min(\mathrm{X_t})}$	
3	Check stationarity using **Augmented Dicky** $-$ **Fuller** (**ADF**) test	
	Check stationarity using **Phillips** $-$ **Perron** (**PP**) test **;** check stationarity using **Zivot** $-$ **Andrews** (**ZA**) test	
	Check staionarity using **Kwiatkowski** $-$ **Phillips** $-$ **Schmidt** $-$ **Shin** (**KPSS**) test	
4	Execute linear convolution on $\mathbf{X_t}$: $\mathbf{X_t} = \mathrm{Conv1d}(\mathrm{X_t}, \mathrm{F}, \mathrm{F_r}, (1,1)) \in \mathbb{R}^{B\times4\times N\times H}$	
5	Initialize skip connections: $\mathbf{Skip} = \mathbf{0}$	
6	**for** k in $\mathbf{K'}$ **do**	
7	Compute residual: residual $= \boldsymbol{X_t}$	
8	Apply activation functions: $\boldsymbol{X_t} = \mathrm{ReLU(skip)}$	
9	Perform final linear transformation: $\boldsymbol{X_t} = \mathrm{ReLU}\left(\mathrm{Conc1d}(\mathrm{X_t}, \mathrm{F_t}, \mathrm{F_r}, (1,1))\right)$	
10	Predict future values: $\boldsymbol{X_t} = \mathrm{Conv1d}(X_t, F_t, H, (1,1))$	
11	Solve econometric regression models:	
	Panel Quantile Regression (**QR**) for conditional distribution analysis: $\boldsymbol{Q_\tau(Y_t \parallel X_t)}$	
	Generalised Additive Models (**GAMS**) for non $-$ linear relationships: $Y_t = \propto + S_1(X_{1t}) + s_2(X_{2t}) + \ldots + s_n(X_{nt}) + \epsilon_t$	
	Dynamic Panel Data Models (**Arellano** $-$ **Bond GMM**) for endogeneity correction: $Y_t - Y_{t-1} = \beta(X_t - X_{t-1}) + \eta_t$	
12	Apply **LSTM** $-$ Attention for sequential CO_2 forecasting: $\widehat{CO}_{2eqt+1} = \mathbf{LSTM-Attn}(\boldsymbol{X_t})$	
	Formulate optimisation concern:	
	Objective Function: $\mathbf{min}\, \boldsymbol{X_t}\ \boldsymbol{\lambda_1 CO_{2eqt} + \lambda_2 FC_t}$	
	Constraints:	
	Urbanisation threshold: $\mathbf{0.72} \leq \boldsymbol{URB_t} \leq \mathbf{0.991}$	
	Passenger vehicle limit: $\mathbf{2.69M} \leq \mathbf{PV_t} \leq \mathbf{4.99M}$	
	Fuel consumption cap: $\mathbf{5.11B} \leq \mathbf{FC_t} \leq \mathbf{6.48B}$	
	Economic growth, GDP: $\mathbf{998,095}\boldsymbol{B} \leq \boldsymbol{GDP_t} \leq \mathbf{2,329,820}$	
14	Solve using **Mixed Integer Nonlinear Programming** (**MINLP**) with **CPLEX**	
15	**Return** $\boldsymbol{X_t}$ as optimised values for sustainable transportation policy	

4.2 Stationarity test outcomes

Ensuring stationarity in economic time series data is critical in this system econometrics in order to prevent spurious regression and ensure valid inference. The Augmented Dickey-Fuller (ADF), Phillips-Perron (PP), Kwiatkowski-Phillips-Schmidt-Shin (KPSS), and Zivot-Andrews (ZA) tests are applied to assess the stationarity of key parametric variables (from 2012 through 2023) in the transportation industry of Gauteng, South Africa. As illustrated in **Table 3**. CO_2-*eq* emissions exhibit weak stationarity, with ADF (-3.451, p = 0.0452) and PP (-3.322, p = 0.0516) marginally rejecting the null of a unit root, while KPSS (0.184, p = 0.0210) rejects stationarity. ZA (-4.932, p = 0.0398) confirms stationarity with structural breaks, necessitating trend adjustments. Nominal GDP is non-stationary, as ADF (-1.982, p = 0.6781) and PP (-2.021, p = 0.6400) fail to reject the unit root hypothesis, KPSS (0.422, p = 0.0031) rejects stationarity, and ZA (-3.509, p = 0.0741) indicates a structural break without sufficient stationarity evidence, necessitating first differencing as being performed in the background. Urbanization

also exhibits non-stationary, confirmed by ADF (-2.792, p = 0.2113), PP (-2.856, p = 0.1902), KPSS (0.612, p = 0.0009), and ZA (-4.018, p = 0.0495), requiring differencing. The parameter of passenger vehicle indicates non-stationarity, with ADF (-2.345, p = 0.4120), PP (-2.508, p = 0.3820), and ZA (-3.912, p = 0.0613) confirming a unit root, necessitating logarithmic transformation. Fuel consumption exhibits trend stationarity with structural breaks, as ADF (-3.092, p = 0.0871), PP (-3.218, p = 0.0748), and ZA (-4.698, p = 0.0412) confirm, requiring structural adjustments. The mixed stationarity necessitates Johansen cointegration and Vector Error Correction Models (VECM) for long-run equilibrium analysis, ran as scripted in the background as indicated in the algorithm. These findings reinstate the impact of regulatory shocks, policy interventions, and energy transitions, which further accentuate the need for structural modeling in transportation system.

Table 3: Econometrics stationarity diagnostic outcomes.

Variable	ADF	ADF	PP	PP	KPSS	KPSS	ZA	ZA
	Stat	*p*-value	Stat	*p*-value	Stat	*p*-value	Stat	*p*-value
CO_{2-eq} emissions	-3.451	0.0452	-3.322	0.0516	0.184	0.0210	-4.932	0.0398
Nominal GDP	-1.982	0.6781	-2.021	0.6400	0.422	0.0031	-3.509	0.0741
Urbanisation	-2.792	0.2113	-2.856	0.1902	0.612	0.0009	-4.018	0.0495
Passenger vehicle	-2.345	0.4120	-2.508	0.3820	0.271	0.0194	-3.912	0.0613
Fuel consumption	-3.092	0.0871	-3.218	0.0748	0.341	0.0135	-4.698	0.0412

4.3 Econometrics regression diagnostics

The econometric regression diagnostics as properly presented in **Table 4** indicate critical information into the correlation between urbanization, passenger vehicles, fuel consumption, and the nominal GDP in relation to GHG emissions in Gauteng, South Africa. The outcomes are deduced from three robust econometric techniques of Panel Quantile Regression (QR), Generalized Additive Models (GAMs), and Dynamic Panel Data Models (Arellano-Bond GMM) which ensure qualitative assessment of the interactions among these parametric variables. The results indicate that urbanization negatively impacts CO_2-*eq* emissions across different quantiles, with coefficients of -0.150, -0.100, and -0.050 at the 10th, 50th, and 90th quantiles, respectively. This indicates that as urbanization increases, emissions tend to decline, albeit at a diminishing rate. The Arellano-Bond GMM estimate (-0.080, $p < 0.05$) confirms this negative nexus, reinstating that urbanization fosters improved transportation efficiency and emission reductions.

Table 4: Systems econometrics regression diagnostics.

Variable	QR-0.1	QR - 0.5	QR-0.9	GAM	A-B GMM	*p*-value	95% CI (L)	95% CI (U)	R-*Squared*
Nominal GDP	-0.450	-0.500	-0.550	-0.480	-0.520	0.045	-0.480	-0.420	0.88
Urbanization	-0.150	-0.100	-0.050	0.120	-0.080	0.032	-0.180	-0.120	0.87
Passenger Vehicles	0.003	0.004	0.005	0.0025	0.0035	0.015	0.002	0.005	0.91
Fuel Consumption	1.250	1.350	1.400	1.300	1.280	0.001	1.200	1.450	0.89

In **Table 4**, the 95% confidence interval for urbanization (-0.180 to -0.120) supports the statistical robustness of this research findings. The passenger vehicle (PV) expansion as illustrated exhibits positive and significant effect on GHG emissions, with quantile regression coefficients of 0.003, 0.004, and 0.005 across the econometrics conditional distributions. The GAM estimate (0.0025) aligns with these findings, confirming that the rise in vehicle numbers contributes to higher emissions. The Arellano-Bond GMM estimation outcomes (0.0035, $p < 0.05$) further validates the strong statistical correlations. The confidence interval (0.002 to 0.005) ensures that this impact remains consistent within the systems. All these with limited but profound information are as only elaborated as here required.

4.4 Systems econometric visualization results

The econometric results visualizations provide critical interpretations into the correlations between GHG emissions and key explanatory variables (Nominal GDP, Urbanization, Passenger Vehicles, and Fuel Consumption) across different econometric models. The graphical representations illustrate coefficient estimates, statistical significance, confidence intervals, and model fit, ensuring a comprehensive evaluation of the robustness and reliability of the system econometric results. **Figure 1** presents the coefficient estimates of the key variables across the Panel Quantile Regression (QR-0.1, QR-0.5, QR-0.9), Generalized Additive Model (GAM), and Arellano-Bond GMM methodologies. Nominal GDP exhibits consistently negative coefficient estimates across all models, ranging from -0.450 (QR-0.1) to -0.550 (QR-0.9), confirming a significant inverse relationship between GDP growth and CO_2-*eq* emissions.

Figure 1: Coefficient estimates from system econometric models.

This indicates that as economic growth increases, improved energy efficiency and structural transformations in the province of Gauteng's economy contribute to emission reductions. Urbanization presents mixed effects. The QR estimates show negative coefficients at lower quantiles (-0.150 at QR-0.1 and -0.100 at QR-0.5), indicating urban expansion initially reduces emissions due to improved public transport and infrastructure. However, GAM indicates a positive association (0.120), implying that beyond a certain threshold, urbanization intensifies emissions due to increasing vehicular demand and energy use. Passenger Vehicles positively correlate with emissions across all models, with coefficients varying from 0.0025 (GAM) to 0.005 (QR-0.9), which further confirms fuel consumption as dominant driver to carbon emissions in the transportation industry.

Figure 2 illustrates the 95% confidence intervals (CIs) of the coefficient estimates, reinstating the precision and reliability of the econometric regression results.

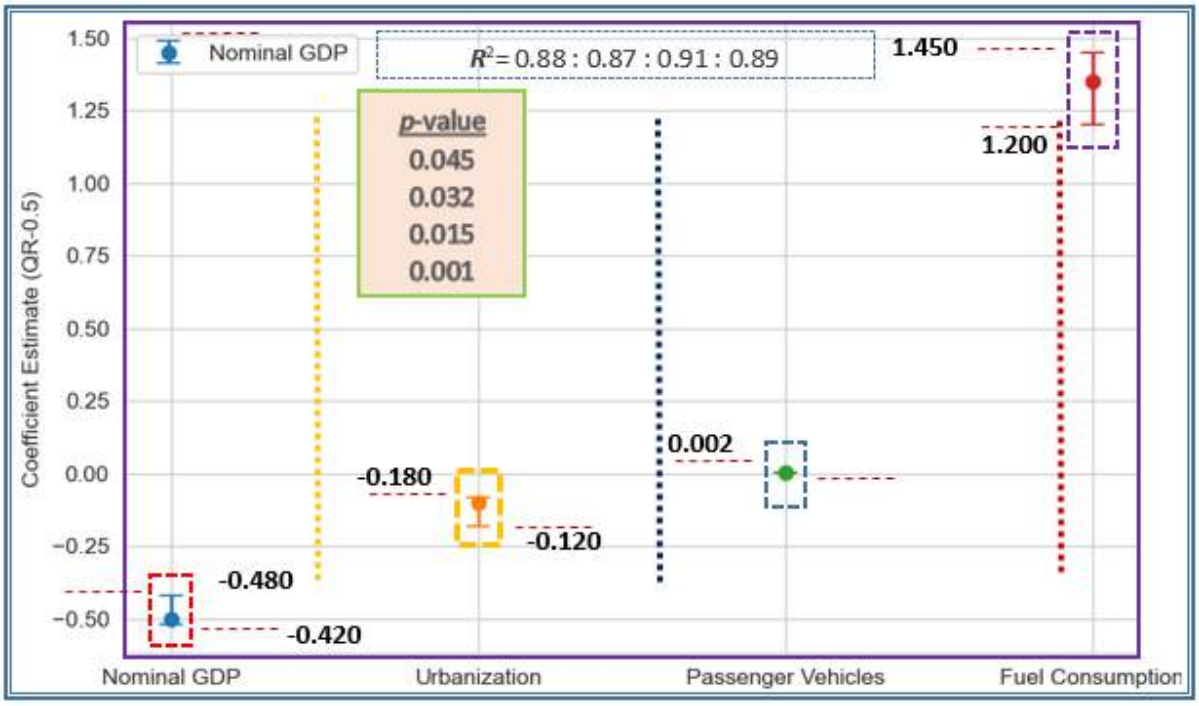

Figure 2: Confidence interval of parameter co-efficients estimations.

The coefficient for nominal GDP exhibits a narrow CI (-0.480 to -0.420) also indicating their *p*-value (0.045), reflecting high estimation precision and reinforcing confidence in its reflection of the negative correlation with GHG emissions. In contrast, urbanization presents wider CI (-0.180 to -0.120) with ***p***-value (0.032), this indicates greater uncertainty of a probable subjection, likely stemming from the complex and evolving interactions between urban expansion and transportation systems in the transportation industry of the province of Gauteng, South Africa. Passenger vehicles demonstrate highly precise estimates, with the lower bound of 0.002, confirming a small but statistically significant contribution to carbon emissions growth. Fuel consumption as illustrted in **Figure 2**, with a CI range of (1.200 to 1.450) also indicating their ***p***-value (0.001), further substantiates its dominant impacts on carbon emissions, exhibiting minimal estimation uncertainty. Collectively, these confidence intervals affirm the robustness of the system econometrics estimations, essentially for the nominal GDP and fuel consumption, while reinstating potential variability in the impact of urbanization on carbon emissions in the transportation industry. The robustness checks for the system econometric model confirm the reliability of the results. The multicollinearity assessment using the Variance Inflation Factor (**VIF**) indicates no severe collinearity concerns, as all independent variables exhibit VIF values below 5. Heteroskedasticity diagnostics, based on the Breusch-Pagan and White tests, yield ***p***-values of 0.038 and 0.042, respectively, indicating mild heteroskedasticity, which is effectively addressed using robust standard errors. The Durbin-Watson test statistic of 1.89 confirms the absence of strong serial correlation in the residuals. Furthermore, the Hausman test, with a ***p***-value of 0.029, establishes the fixed-effects model as the preferred specification over the random-effects model, ensuring robustness in addressing potential endogeneity concerns.

4.6 Optimization with modeled solver forecast outcomes

The optimization solver-driven forecast of GHG emissions and fossil fuel consumption in Gauteng's transportation industry from 2024 to 2040, as presented in **Table 5**, reveals the interdependent linkages among the parametric variables. These linkages indicate the energy requirements necessary for ensuring the efficient operation of the transportation industry

through 2050, while also demonstrating the potential for transitioning to cleaner energy sources.The model establishes strong positive correlation between fuel consumption and CO_2 *eq* emissions reflecting combustion dependent pattern of transportation fuels as depicted in **Figure 3** illustrating their interrelationship. In the absence of significant technological advan cements or regulatory interventions, increased fuel consumption proportionally drives higher transportation carbon emissions.

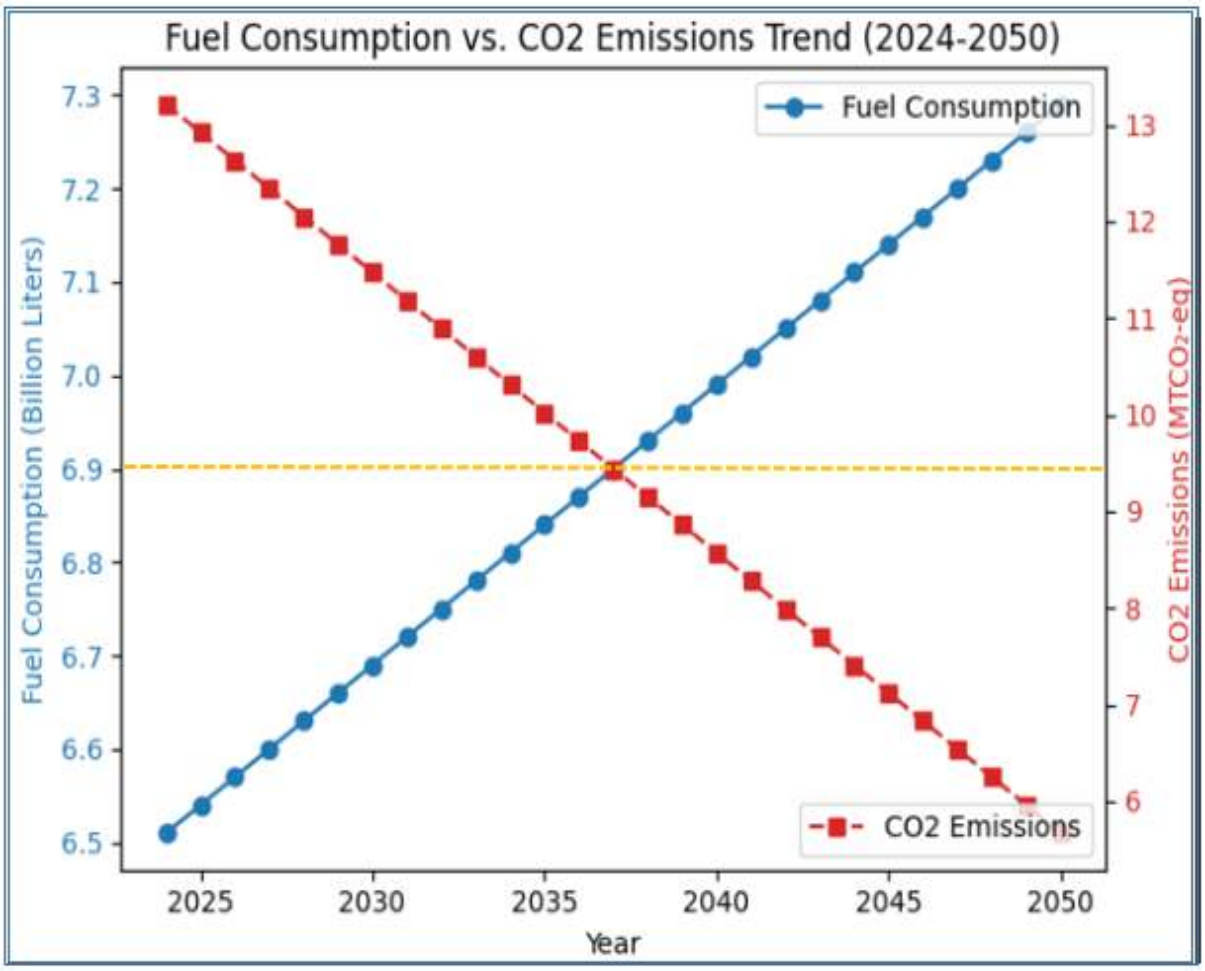

Figure 3: Forecasted fossil energy and emissions trend in Gauteng, South Africa transport.

However, the projected trajectory as impacted by advancements in fuel efficiency, the adoption of alternative fuels, and the implementation of transport electrification policies, collectively determine the extent to which emissions can be decoupled from fossil fuel consumption. Between 2024 and 2035, fuel consumption with shocks adjusments is projected to increase at moderate pace, driven by population growth, rising passenger vehicle ownership, and expanding transport activity. While carbon emission-reduction strategy are designed to be implemented during this period as indicated in **Table 6**, the overall growth in demand can offsets the initial decarbonisation efforts. However, beyond 20 35, distinct divergence emerges, with GHG emissions declining at steeper rate than fuel cons umption. This trend can reflect the increasing adoption of energy efficient transport technol ogies, the enforcement of stringent fuel economy regulations, and sustained investments in green transport mobility solutions. The optimzed parametric variable of urbanization, with

the descriptive mean statistics range between 0.72% and 0.991%, serves as dual-factor driver of transportation emissions.

Table 6: Optimized forecast for energy use and carbon emission mitigation 2024 to 2040.

Year	Nominal GDP (Billion ZAR)	Urbanization (%)	Passenger vehicles (million unit fleet)	Energy use (Required) (Mega Joule)	GHG emissions ($MTCO_2$-*eq*)
2024	2.350 ↑	0.930 ↑	4.997 ↓	236,964E6 ↑	13.21 ↓

5 CONCLUSION AND RECOMMENDATION

5.1 Conclusion

The research presents system-based assessments on the interplay between urbanization, passenger vehicle growth, fuel consumption, economic expansion, and CO_2-*eq* emissions in the province of Gauteng, South Africa's transportation industry. By leveraging system econometrics, machine learning-based forecasting, and optimization modeling, the research offers data-driven deployments to carbon emissions mitigation pathways and sustainable mobility solutions. The findings confirm that while economic growth and urbanization facilitate smooth mobility and economic development, they can also contribute to increased transportation related GHG emissions. However, strategic interventions can effectively decouple GHG emissions growth from economic expansion, reinforcing the feasibility of sustainable transport policies. The result outcomes indicate strong positive correlation among fuel consumption and CO_2-*eq* emissions, confirming that combustion-intensive energy sources remain the dominant driver of transportation emissions. However, long-term projections from 2024 and beyond 2040 indicate that GHG emissions can be reduced by 22.6% as here illustrated if sophisticated mitigation strategies are implemented. These include the adoption of hybrid and electric vehicles (HEVs), improvements in fuel efficiency, expansion of mass transit systems, and stringent carbon emissions regulations. The investigation further reinstates the dual impact of urbanization, where unregulated expansion exacerbates carbon emissions, while well-planned urban density can enhance fuel efficiency and reduce transportation's environmental footprint.

5.2 Recommendation

Based on the deduced findings, the research presents salient policy and strategic recommendations to facilitate a sustainable transition in the Gauteng, South Africa's transportation industry. Among others, the following recommendations from industrial and engineering management perspectives are designed for broader applicability to other rapidly urbanizing regions confronting peculiar GHG emissions concerns:

1. Transport Electrification for Sustainable Mobility: Electrical energy is essential for reducing carbon emissions and fossil fuel reliance in urban transportation. Policymakers can expand EV infrastructure, advance battery technology, and implement financial incentives to accelerate adoption. Public-private partnerships (PPPs) initiatives can be in line to develop fast-charging networks, enhance grid integration, and ensure renewable energy compatibility. Targeted policies, which include tax credits and subsidies, are essential for market expansion, technological innovation, and long-term sustainability.
2. Mass Transit Systems with Smart Mobility: Enhancing urban transport sustainability requires reducing car dependency by investments in high capacity public transit, thes e include Bus Rapid Transit (BRT), rail networks, and multimodal integration. Smart mobility solutions such as real-time transit analytics, adaptive traffic control, and dynamic ride-sharing can optimize efficiency and reduce congestion. Automated fare collection, demand-responsive transit, and intelligent transportation systems (ITS) further improve operational performance, facilitating the transition to low-emission, high-efficiency urban mobility systems aligned with global sustainability targets.
3. Data-Driven Policy Formulation and Technology-Based Emissions Monitoring: Real-time GHG tracking, technology-driven emission simulations, and geospatial transport data analytics can be integrated into policy frameworks to ensure evidence-based decision-making. Governments can establish open data platforms to facilitate cross-sector information sharing and optimize mobility planning.
4. Fostering Cross-Sector Collaboration and Policy Integration: Achieving long-term emission reductions requires synergized policies across energy, transport, and urban planning sectors. Policymakers can engage with industry stakeholders, academic researchers, and environmental organizations to design adaptive policies that respond to evolving transportation demands and global climate commitments.
5. Developing Green Logistics and Freight Optimization Policies: The freight and logistics industry can transition toward alternative fuel adoption, last-mile delivery efficiency, and intermodal transport systems. Policies should support eco-friendly freight corridors, improved rail freight integration, and low-emission transport hubs.

By aligning with international best practices and South Africa’s Paris Agreement commitments toward that of 2030, and the Net-Zero 2050 carbon neutrality for sustainability, these recommendations provide a scalable framework for GHG emissions mitigation in transportation sectors and industries globally. As urbanization intensifies in emerging economies, this study offers a policy blueprint for achieving low-carbon mobility, sustainable economic growth, and climate resilience. Future research can focus on real-time emissions monitoring, cross-border mobility policies, and adaptive transport resilience to enhance global climate action and long-term sustainability.

ABSTRACT

Agroecology presents a promising approach to agriculture, with the potential to restore soil health and sequester carbon, thereby contributing to climate change mitigation. However, farmers face considerable uncertainty when transitioning from conventional practices and selecting appropriate agro-ecological methods. This study develops a conceptual framework that synthesises the critical factors and their interdependencies required for a decision support system (DSS) to facilitate this transition. The framework consists of a data flow diagram and an adjacency matrix to guide the design of practical, farmer-centric DSS tools. A systematic literature review identifies relevant factors and considerations for DSS development, with the data analysed through an iterative thematic coding process. The resulting codes and their relationships inform the construction of the conceptual framework. Future research should focus on validating this framework in real-world settings to support the development of effective DSS solutions for agro-ecological transition.

Keywords: Agroecology, Decision Support Systems, Transition

1 INTRODUCTION

Climate change is projected to bring a tide of challenges in global agriculture: lower crop yields, higher food prices and declining household incomes. [1], accompanied by more frequent and intense extreme weather events [2]. Rising temperatures are expected to severely impact the cultivation of key food crops that supply much of the world's dietary energy [3]. Even a slight increase of 1°C could result in yield declines of about 6% for wheat, 7.4% for maize, 3% for rice, and 3.1% for soybeans, posing a serious threat to global food security [3]. A drop in food production is likely to drive prices even higher, worsening existing food security challenges [4]. In urban areas, high food costs remain one of the leading causes of food insecurity, as many households cannot afford enough nutritious food [5]. Concurrently, intensive farming practices are resulting in the unsustainable degradation of soils, decreasing its long-term food production capabilities [6]. Soil health is deteriorating due to multiple processes, including loss of organic content, increased greenhouse gas emissions, excessive fertiliser use, soil erosion, pollution, rising acidity, salinisation, and a reduction in genetic variation within soil ecosystems [6] It is, therefore, clear that a change in the agricultural industry is essential to secure food production, but the direction of this change remains uncertain.

Agroecology offers a holistic remedy that enhances the resilience of farming systems, safeguards the environment and sustains food production[7], yet farmers attempting this transition confront a flood of information and a steep knowledge barrier, leading to difficulties in determining which agro-ecological practices best fit their unique priorities and contexts. The inherent complexity of biological interactions and environmental variability magnifies this challenge.

Decision Support Systems (DSS) can help stem that tide by distilling complex data into guidance that is tailored for practical use. Tools like Decision Support System for Agrotechnology Transfer (crop simulation), Hydrologic (water management tool), Agricultural Production Systems Simulator (nutrient management) and InfoCrop (pest management) [8] illustrate DSS potential. Adoption has, however, been limited, which has been attributed to the lack of farmer involvement in DSS development [8]. The existing models lack comprehensive integration [8], as is demanded by agroecology, which highlights the research need. However, before an agroecology transition, DSS can be developed; the elements of such a model need to be determined.

Therefore, this study aims to develop a conceptual framework that synthesises the factors and interdependencies required for a DSS that can navigate agro-ecological transition. Such a framework will consist of a data flow diagram and an adjacency framework to guide the design of practical, farmer-focused DSS tools.

1.1 Terminology

This section defines two key terms: agroecology and decision support systems, as they are used in this paper, and provides the rationale for these definitions.

1.1.1 Agroecology

The definition of agroecology has changed significantly over time. Initially, in the 1980s, it was primarily defined as "the application of ecological concepts and principles to the design and management of sustainable agroecosystems, or the science of sustainable agriculture", focusing on the farm level [9], [10]. Since then, its scope has expanded to include the broader food system, framing agroecology as a "way of building relationship- based market systems that are equitable, just and accessible for all" [10], and as a means of "confronting the economic and political power structures of the current industrial food system" [10], [11].

These shifts reflect agroecology's three core dimensions as described by [10], [11]:

1. Scientific: applying ecological principles in sustainable agroecosystem design
2. Practical: incorporating local, empirical, and indigenous farming knowledge
3. Social change: challenging, advocating for alternative social structures and influencing policy change.

Each dimension has received varying levels of emphasis across agroecology's history, as shown in [11]. Table 1 was synthesised by combining the periods and historical focuses, as presented in [11], with the corresponding aspect of agroecology from [10], to illustrate how the focus has shifted over time.

Table 1: Aspects of agroecology that were focused on during different historical periods in the term's existence [10], [11]

Period	Historical focus	Corresponding aspects
1980's	Farm-level sustainability	Scientific & practical
1900's	Relationship-based market systems	Social change
2010's	Economic and political power structures	Social change

While the importance of integrating all three dimensions is widely acknowledged [10], [12], this study retains the original farm-level emphasis. It therefore centres on the scientific and practical aspects of agroecology. Broader sociopolitical factors, such as policy, governance and structural power dynamics, are only considered to the extent that they directly affect the farmer's decision-making. These external factors, which often fall beyond a farmer's control, lie beyond the scope of this research.

Agro-ecological transition, as used in [13], refers to the process of moving from conventional industrial agriculture towards more sustainable, biodiversity-based farming systems. This definition will be applied to this study.

1.1.2 DSS

A DSS (Decision Support System) is a computerised system for assisting decision-making processes, which integrates databases, modelling tools and multicriteria analysis methodologies to analyse and rank a set of alternatives, thereby enabling decision-makers to consider complex and interacting factors [14]. According to [14], DSS applications in agriculture have been increasing in the last decades, and the advantages of using a DSS are improved understanding of the process, identifying unexpected situations, improving communication, decisions and use of data and resources, as well as cost savings.

1.2 Paper structure

This paper is organised as follows: Section 2 outlines the research methodology. In particular, Section 2.1 describes the data gathering process, Section 2.2 details the data analysis procedures, and Section 2.3 explains how the validation for this study was performed. Section 3 presents the findings of the research, followed by the synthesised conceptual framework presented in Section 4. The paper concludes with Section 5, which summarises the key conclusions and Section 6, which offers recommendations for further research.

2 RESEARCH METHODOLOGY

2.1 Data gathering

For data gathering, a Systematic Literature Review (SLR) was applied since it uses

> *"…explicit, systematic methods to collate and synthesise findings of studies that address a clearly formulated question " [15].*

This method has been chosen for its comprehensiveness, to ensure all possible rigour and completeness in the resulting data. The aim of this SLR is to synthesise a conceptual framework integrating factors and interdependencies. The conceptual framework could be used in the

future to develop DSS models for agro-ecological transition, addressing the complexity of the problem and a gap in the literature.

The literature search was conducted between January and May 2025, and the following steps were used in this study [16].

1. Protocol: Define research question, scope, protocol and criteria for inclusion and exclusion (Section 2.1.1).
2. Search: Develop search string, select databases, conduct systematic searches (Section 2.1.2).
3. Appraisal: Select studies using inclusion/exclusion criteria and assess quality (Section 2.1.3).
4. Synthesis: extract and classify relevant data (Section 3).
5. Analysis: Evaluate synthesised data to extract a meaningful answer to the research question (Section 2.2) and Validation (Section 2.3).
6. Reporting: Reporting the study's findings in a transparent and detailed manner, and discussing the implications, limitations and suggestions for future research (Sections 4 and 5).

2.1.1 Protocol

The research protocol that was followed during this study is shown in Table 2.

Table 2: Research protocol followed in the SLR.

Purpose of the study	To identify the factors and their interdependencies involved in developing DSS models for agro-ecological transition, addressing a gap in the literature by integrating these elements into a conceptual framework, whether standalone or embedded in existing models or frameworks.
Keywords/search string	(DSS OR "decision support system*") AND (Agroecolog*) AND (transition* OR transformation*) AND (model* OR framework* OR factor*)
Search databases	ScienceDirect, Scopus, Springer, IEEE Xplore and Web of Science
Inclusion criteria	• Peer-reviewed, English-language studies on DSS in agriculture • Focus on agroecology practices involving the transition/transformation process • Present or discuss models/frameworks or defined factors for decision support • Full text available with transparent, reproducible methodology. • Articles published after 2005
Exclusion criteria	• Duplicates • Narrow Focus • Land-related topics • Climate change and sustainability (Broad) • Publication Type Issues • Tangential or brief keyword references • Full text unavailable
Quality assessment criteria	Studies should be published in English, and repeatable and reputable scientific research methods should have been followed, with adequate methodological transparency.

The inclusion criteria align closely with the objective of the study, and the reasoning behind the exclusion criteria is given below.

- Narrow focus: studies focused on isolated practices or technologies without a holistic or systems perspective, as required for agroecology.
- Land-related topics: studies related to land topics that are tangentially relevant but not of direct interest to the SLR's core focus.
- Climate change and sustainability: Broad sustainability or climate topics lacking a direct connection to agroecology.

- Publication type issues: non-peer-reviewed or insufficiently analytical formats (e.g. opinion pieces, data-only papers).
- Tangential or brief keyword references: studies that mention relevant terms superficially without addressing core research questions.

2.1.2 Search

To ensure that the SLR is conducted comprehensively and rigorously, multiple databases were selected based on their relevance, coverage and disciplinary scope. IEEE Xplore's comprehensive database of peer-reviewed literature in electrical engineering and computer science [17] makes it a promising resource for information on decision support systems and technological applications relevant to agroecology transitions. Scopus and Web of Science are widely acknowledged as authoritative multidisciplinary databases with high-quality resources, enabling broad coverage [18], while ScienceDirect and Springer provide extensive access to peer-reviewed journal articles and book chapters in environmental science, agriculture, and systems design [19], [20]- central to agroecology and DSS domains.

The search string was carefully designed to capture core concepts relevant to the design of DSS for the transition to agroecology, and consists of 4 key components, which are combined by Boolean operators, for clarity, and asterisk truncation, to allow variations:

- (DSS OR "decision support system*")- to capture all relevant literature referring to decision support systems.
- (Agroecolog*)- The term "agroecology" has been chosen for the search string, as it encompasses a wide range of other terminology that prioritise management of biodiversity [21].
- (transition* OR transformation*)- to capture shifts, changes or transformations in agricultural systems, addressing the dynamic process of change towards agro-ecological practices.
- (model* OR framework* OR factor*)- to focus on studies that identify standalone factors, as well as factors embedded in frameworks or models.

As the search was conducted, filters were applied to exclude all articles published before 2005, given the technological developments over the last 20 years, as well as a filter to limit the results to articles in English.

2.1.3 Appraising the literature

The literature was screened using the inclusion and exclusion criteria as discussed in Section 2.1.2. Figure 1 presents the PRISMA literature selection and reduction process, providing a detailed view of the number of articles that were excluded during the screening process, as per the reasons defined in section 2.1.1.

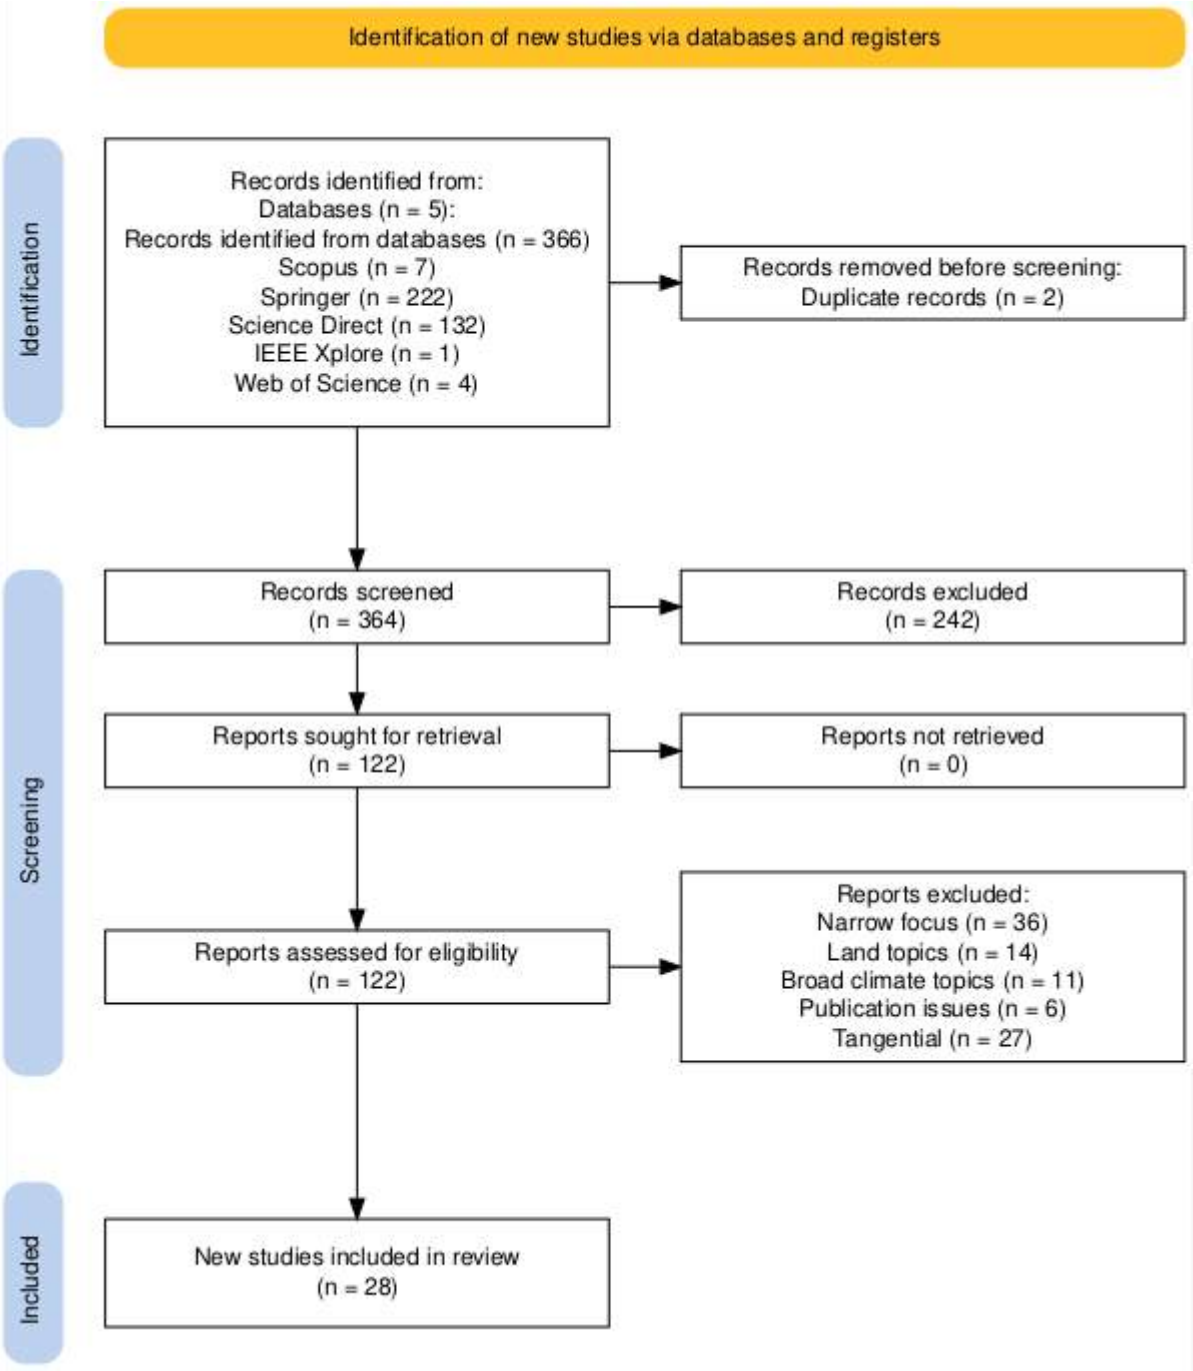

Figure 1: PRISMA literature selection and reduction process followed.

2.2 Data Analysis

The factors involved in designing a DSS to facilitate the transition to different agro-ecological systems were identified through an iterative process of qualitative coding and thematic refinement using Atlas.TI software (version 23), thereby following the qualitative synthesis methodology as established by [22], to protect the nuance and contextual understanding of the data, relevant quotations were revisited within their original source document, and the entire section was reviewed to minimise the risk of loss or data misinterpretation. A thematic iterative coding analysis methodology was chosen to systematically identify, code and

interpret patterns and relationships relevant to the adoption of agro-ecological practices at the farm level, as explained in

> *"Coding is an iterative, systematic, and meticulous process. Researchers often rely on both manual methods and qualitative data analysis software such as NVivo, ATLAS.ti, or MAXQDA. Each data extract is reviewed systematically, with relevant segments assigned concise codes" [23].*

The software enabled efficient management of the diverse data collected, particularly in terms of segmenting, coding and organising text across multiple sources. The process began by importing all references identified in Section 2.1.3. A bottom-up, inductive coding approach was initially applied, whereby relevant quotations were manually highlighted and assigned descriptive codes, which were either newly assigned or added to an existing code, allowing for the development of a comprehensive and growing codebook. To ensure rigour, coding decisions were documented throughout the process and incorporated into the code definitions, as each code represents an identified factor. The codes have been organised into code groups during the analysis phase, which is described in Section 2.3.

Relationships among factors were identified within quotations containing multiple factors (codes) and subsequently into three relationship types (detailed in Table 4). Each relationship type was assigned a specific code. A code co-occurrence table generated in ATLAS.ti was then validated by cross-referencing it with the relationship codes associated with each quotation, during which adjustments were made as necessary to ensure that the co-occurrence table accurately portrays relationships instead of simple code overlap.

2.3 Validation

The PRISMA framework validates the SLR conducted in this study, as it adheres to the following requirements:

1. Complete, transparent reporting that is in adherence to the PRISMA checklist [15].
2. This study has included a PRISMA flow diagram (Refer to Figure 1).
3. Measures have been taken to prevent bias and ensure that a pre-planned methodology was followed (Section **Error! Reference source not found.**).
4. The rationale and methodology in conducting the review, as well as the synthesised results (Sections 2 and 4, respectively), have been reported.

3 FINDINGS

The factors that were identified from the literature are presented in this section, and have been organised into four code groups, each reflecting their role within a future DSS:

- **Design requirements (Purple):** Functional and operational specifications that define how a DSS processes inputs to generate outputs.
- **Inputs (Orange):** Information required from the user to tailor the model's response.
- **Dual role factors (Yellow):** Factors that serve as both inputs and outputs, where the current state serves as an input, and the system returns improvement recommendations as output.
- **Outputs (Blue):** The resulting outputs or outcomes generated by the model.

Table 3 presents the factors involved in designing a DSS to facilitate the transition to a different agro-ecological system, their definitions, as used and developed during the iterative coding process, the desired DSS response, and the sources from where these factors have been found.

Table 3: Factors identified from the literature

Identified factor	Definition	How a DSS Should Respond	Sources
Adaptability	Adaptability & vulnerability of farming systems towards: •Environmental changes •Extreme weather •Flexible cropping •Early warning systems (improved response time) •Resilience •Wetland management	Support iterative reconfiguration and scenario adjustment in response to environmental or systemic change.	[8], [24], [25], [26]
Biodiversity	Diverse species & ecological interaction, to achieve polyculture and integration through multi-species management.	Identify opportunities and strategies to enhance on-farm biodiversity.	[24], [26], [27], [28]
Forecasting	Predictions & estimates for weather, climate & disaster (primary use), agronomy, pest & disease, weed population, socioeconomic & ecological scenarios.	Integrate external forecasts (e.g., weather, pest pressure) and simulate decision outcomes accordingly.	[24], [26], [29], [30], [31]
Information flow	Sharing agricultural data to improve response times, communication & record-keeping.	Allow data sharing and updates from multiple sources to ensure responsiveness and traceability.	[7], [8], [24], [25], [27], [28]
Outcome Measurement	Methods to quantify agricultural outcomes, as well as challenges experienced with measurements, which prominently feature challenges with measuring environmental impact.	Accept observed outcomes to support ongoing calibration and iterative improvement.	[7], [24], [25], [28], [29], [32], [33], [34], [35], [36], [37]
Participatory research	To co-design solutions with farmers, integrate local knowledge, farmer awareness, preferences, and tradition, and use on-farm experimentation.	Incorporate farmer input and validation loops to ensure contextual accuracy and trust.	[21], [24], [26], [27], [29], [33], [34], [38]
Priority	Priorities from literature and the incorporation of stakeholder opinions for agricultural decision-making and strategy.	Accept farmer-stated priorities and internally rank practices based on contextual fit and scientific evidence.	[24], [26]
Resource conservation	Practices to sustain resources.	Recommend context-specific opportunities to conserve natural resources.	[21], [24], [26], [31]
Species Interactions and Dependencies	Interactions and dependencies between species and systems.	Account for ecological synergies and interdependencies in the recommendation engine.	[24], [26], [28]
Disease resistance	Genetic traits enhancing resistance to diseases.	Capture species-level resistance traits to improve recommendation accuracy.	[7], [24]
Farmer capacity	Factors that are of importance to the individual farmer, like their ability to perform tasks, access capital, achieve self-sufficiency & make independent decisions	Tailor recommendations to the farmer's labour, financial, and operational capacity.	[8], [24], [26], [28], [39]
GIS	Geographic Information Systems for spatial analysis in agriculture.	Geolocate inputs and link them to relevant spatial datasets and constraints.	[8], [24], [28], [29], [30], [31], [37]
Social & Governance Structures	Relevant structures, at centralised (government) level, decentralised (community) level, and other sustainability-incentivising structures.	Incorporate regulatory and policy constraints that directly affect decisions.	[7], [24], [25], [26], [27], [28], [37], [40]

Identified factor	Definition	How a DSS Should Respond	Sources
Tools & Technology	Tools, including equipment, technology & infrastructure used to support agricultural activities- this includes information and decision-making tools.	Assess existing tools and technologies in use and adapt outputs accordingly.	[7], [24], [25], [26], [30], [31], [35], [38], [40], [41]
Topography	Physical features and land characteristics of a site, e.g. slope, altitude, field lengths, drainage, boundary management, terracing, alley cropping, contour bunds, raised beds, tied ridges, hillside farming, etc.	Incorporate topographical constraints into practical recommendations.	[7], [8], [24]
Trade opportunities	Prospects and market opportunities for trading & selling agricultural products.	Assess market access and opportunity levels to guide viable crop or product selection.	[24], [28], [39]
Animal Healthcare	Practices to maintain & improve animal health.	Identify improvement opportunities based on current practices.	[24]
Animal integration	Strategies for integrating & managing livestock.	Assess integration levels and suggest context-appropriate improvements.	[7], [24], [28], [31], [39]
Animal selection	Selection of animals based on morphology, body condition, and suitability.	Evaluate selection criteria and propose refinements.	[24]
Breeding	Processes to improve livestock or crop genetics, including advanced techniques and outcomes like high survival rates.	Analyse breeding strategies and suggest improvements or alternatives.	[7], [24], [25]
Chemical usage	Pesticides, insecticides, inorganic fertiliser, etc.	Evaluate chemical dependency and suggest safer or more sustainable alternatives.	[7], [24], [28], [30], [40]
Cover plants & Legumes	Used to improve soil health and nitrogen fixation.	Evaluate incorporation levels and recommend soil-enhancing strategies.	[24]
Crop diversification	Strategies like intercropping to enhance resilience and productivity.	Assess current species mix and suggest diversification strategies.	[7], [24]
Crop health	Monitoring and managing crop vitality.	Recommend targeted practices to improve or maintain crop vitality.	[7], [24]
Crop timing	Crop cycles, including life cycles, growing seasons, rotation, succession, flowering periods, pruning, etc.	Align crop cycles with climate, variety, and market demands for optimal outcomes.	[24], [28], [29]
Disease management	Strategies to prevent and control diseases in general.	Suggest context-specific disease prevention and control strategies.	[7], [24]
Diversify income	Its aim is to buffer agricultural systems.	Assess income streams and propose feasible on-farm diversification options.	[24]
Hygiene	Hygienic practices to maintain animal health, including proper disposal of dead animals.	Evaluate hygiene practices and recommend improvements.	[24]
INM	Integrated Nutrient Management to optimise nutrient use and soil fertility.	Evaluate nutrient strategies and suggest integrated, precision-based improvements.	[8], [24]
IPM	Integrated Pest Management for sustainable pest control.	Recommend pest control approaches that balance efficacy with sustainability.	[24]

Identified factor	Definition	How a DSS Should Respond	Sources
Long-term planning	The timeframe of long-term strategies, for example, land ownership/tenure duration is highly relevant for considering perennials.	Align recommendations with the stated planning horizon and land tenure strategy.	[24]
Nutrient management	Practices to enhance soil fertility and nutrient uptake, including nitrogen fixation, organic fertilisers, precision application, and addressing uptake complexities.	Assess nutrient strategies and propose scientifically validated improvements.	[7], [24], [29], [32], [39]
Organic fertiliser	Use of natural fertilisers like earthworm castings and organic manure.	Evaluate usage and suggest natural alternatives where applicable.	[24], [28], [39]
Organic pest management	Natural pest control methods like beneficial insects, biopesticides, organic chemicals, sterile insect techniques, trapping/confusing pests, transgenic insects and vector control techniques.	Suggest sustainable biological pest control methods.	[7], [24]
Pest management	Strategies to control pests and weeds.	Recommend integrated, context-sensitive pest and weed control strategies.	[7], [24], [28], [30]
Planting patterns	Arrangements to optimise crop growth and resource use.	Optimise planting configurations based on spatial and ecological inputs.	[24]
Raised Beds, Mulch & Shelters	Mulch protects soil and enhances agricultural outcomes, structures and raised beds protect crops from soil contact & waterlogging.	Recommend protective practices based on local soil and climatic conditions.	[24]
Risk & Insurance	Uncertainties faced & mitigations taken, which includes insurance.	Evaluate risk exposure and suggest mitigation strategies, including insurance.	[7], [8], [24], [26], [28], [39]
Seed planning	Selection, treatment, distribution, and delivery of seeds.	Support seed selection, treatment, and distribution based on local suitability.	[7], [24], [25], [35]
Soil characteristics	Soil properties like pH, runoff, temperature, colloidal minerals, texture/structure & productivity.	Integrate soil data to tailor practice recommendations.	[7], [24], [28], [35]
Soil health	Overall soil condition & fertility, microorganisms that contribute to soil health, and carbon sequestration practices.	Assess soil condition and suggest biologically informed improvements.	[7], [24], [29], [35], [39]
Soil moisture management	Aims to optimise water infiltration and soil-crop water balance.	Evaluate water balance and recommend moisture optimisation practices.	[7], [8], [24], [39]
Stress	Environmental pressures on plants and animals.	Diagnose stressors and propose adaptive response strategies.	[7], [24]
Tillage	Soil preparation methods.	Assess tillage methods and recommend regenerative or conservation alternatives.	[24], [31], [35]
Tree integration	Incorporating trees into agriculture.	Evaluate agroforestry practices and recommend improvements.	[7], [24], [39]
Varietal selection	Choosing crop varieties to optimise performance.	Assess crop variety suitability and suggest better-aligned alternatives.	[7], [24], [25]
Water management	Water optimisation strategies for delivery systems & scheduling, storage mechanisms & groundwater access.	Propose optimal water delivery and scheduling strategies.	[7], [24], [26], [31], [35], [39]
Quality Standards	Standard of agricultural products.	Estimate the quality of outputs based on current and proposed practices.	[21], [24]

Identified factor	Definition	How a DSS Should Respond	Sources
Viability	Farming venture profitability & financial sustainability.	Simulate financial outcomes to assess profitability and sustainability of the venture.	[7], [8], [21], [24], [25], [28], [31], [32], [37], [39]
Yield	Quantity of agricultural output	Simulate yield outcomes to support comparison of alternative practices.	[7], [8], [24], [29], [35], [39], [42]

4 CONCEPTUAL FRAMEWORK

This section presents the factors, as well as the relationships between them, as obtained from the thematic iterative coding analysis performed on the data obtained through the SLR.

Together, the data flow diagram (Section 4.1) and the adjacency matrix (Section 4.2) form a conceptual framework, as they illustrate the relationships between the factors or concepts under investigation, in accordance with the requirements for a conceptual framework outlined in [43]. This framework can inform the development of a decision support system (DSS) to facilitate the transition to agroecology.

4.1 Data Flow Diagram

Data flow diagrams are used to simplify designing DSSs, as they provide a view that simultaneously presents a high-level, while mapping the detailed factors [44]. Each factor in Table 3 was assigned to one of the four categories required for a data flow diagram: Input, Output, Design Requirements and Dual Role (factors that function as both inputs and outputs). The data flow diagram was then constructed by grouping the factors according to these categories and depicting the movement and processing of data through the model with directional arrows. Figure 2 presents the data flow diagram for a DSS model facilitating the transition to agroecology.

This data flow diagram can be used in the design of a future DSS. There is a clear emphasis on the need for collaborative research and stakeholder participation, as reflected in design requirements (top centre of the figure) such as "Participatory research". Important model inputs (positioned on the left side of the figure) include "Priority," where users specify their goals or areas of concern; "Farmer capacity"; and "GIS" data, which requires the farm's geo-location. Additionally, "Topography" (capturing site-specific features such as erosion, historical chemical use, and other relevant conditions) and "Trade opportunities" are critical components. Together, these elements significantly enhance the ability to tailor model outputs to the unique context of each user.

In addition to providing recommendations on agricultural practices for factors in the "Dual role" category (bottom centre), the model's output (top right) should also forecast the quality standards of the agricultural products, the financial viability of the venture- both short- and long- term-and the expected yield, presented in a format that allows users to compare projected future states with the current baseline.

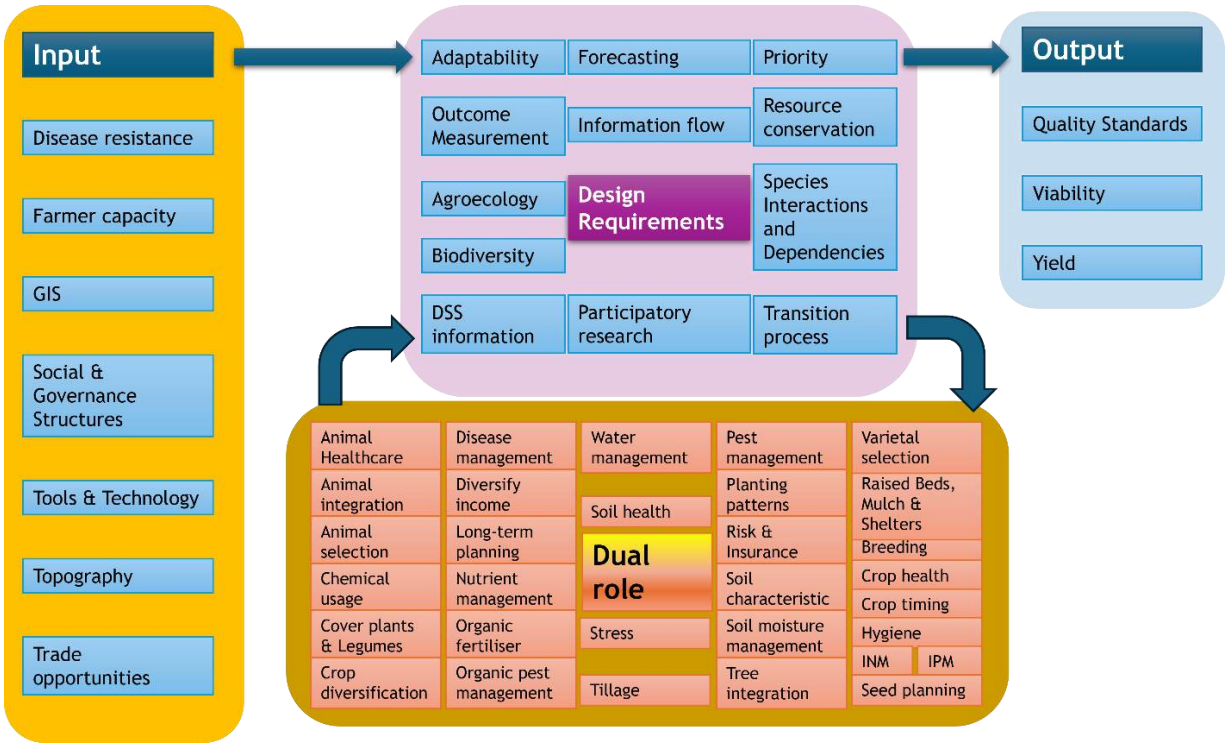

Figure 2: Data flow diagram for a future DSS model facilitating the transition to agroecology.

4.2 Adjacency matrix- Interdependencies and relationships between factors

Semantic relationships were observed from the identified factors and quotations, as found in the sources in the last column of Table 3. The key used in the adjacency matrix is presented in Table 4.

Table 4: Definitions and symbols for factor relationships or interdependencies

Relationship type	Symbol used	Colour used	Definition
Influences	I	Green	Both factors exert an influence on each other in a bidirectional relationship.
Is associated with	A	Blue	Factors are generally associated with each other, no directionality specified.
Opposing effect	O	Light red	One factor has an opposing or negative effect on the other, directionality specified on the table.

Figure 3 and Figure 4 shows the resulting adjacency matrix, which displays the relationships between factors. Blank rows and columns have been removed from the table in the interest of simplification. The colour key, displayed to the right of the table, includes two sub-categories:

1. The "Data flow role" corresponds to the established code groups, applied to the first row and column, and retains the same colour scheme as in Table 3.
2. The "Relationship" sub-category indicates the colour and symbol assigned within the matrix, excluding the first row and column, to represent each relationship type. The relationship definitions are presented in Table 4.

The directionality is indicated in the table, which should be interpreted by first considering the row variable, followed by the column variable. For example, adaptability, located in the first row, has an opposing effect on risk, indicating that as adaptability increases, risk decreases.

Figure 3: Adjacency matrix part 1

Factor Relationships	Animal Healthcare	Animal integration	Animal selection	Breeding	Chemical usage	Crop diversification	Crop health	Crop timing	Disease management	Diversify income	INM	Nutrient management	Organic fertiliser	Organic pest management	Pest management	Planting patterns	Risk & Insurance	Seed planning	Soil characteristics	Soil health	Soil moisture management	Stress	Tillage	Tree integration	Varietal selection	Water management	Colour code
Adaptability			I			I							A	O				I			A					Data flow role
Biodiversity							A	A					A					I								Design requirement
Forecasting													A		A											Input
Information flow		A											I	I	I											Dual Role
Outcome Measurement																										Relationship Type

The matrix is not symmetrical because some relationships are unidirectional, while others lack specified directionality due to the absence of that information in the literature that has been reviewed for this study. As seen in Figure 3 and Figure 4, there is a total of 190 relationships and interdependencies between the identified factors. There is a total of 105 "Influence" relationships, 69 "Association" relationships and 16 relationships that have opposing effects on each other. The adjacency matrix is a crucial component to incorporate into a future DSS, as the fundamental philosophy of agroecology depends on the relationships and interactions between different biological and non-biological parts of a farming ecosystem, encompassing both mutually beneficial exchanges and trade-offs within the ecosystem.

5 CONCLUSION

An SLR was performed to gather data on factors to consider during the transition to an agro-ecological approach to agriculture. Multiple factors have been identified from interdisciplinary sources. The following groups were used to classify these factors: Input (e.g., Farmer Capacity and Disease Resistance), Design Requirements (E.g., Adaptability and Biodiversity), Output (E.g., Quality Standards, Yield), and Dual Role (E.g., Animal Healthcare and Tillage). All factors have been brought together in the conceptual framework, which can be seen as a star

chart, guiding navigation through these waves of change amidst the storms of complexity and serving as a starting point for developing a future DSS.

6 FUTURE RESEARCH

The following limitations were identified during this study: Firstly, the conceptual framework is grounded on a synthesis of existing literature. The limited scope of only five databases may have excluded grey literature and studies indexed in other important regional or specialised databases. Future research should consider expanding the range of databases to improve the breadth of coverage.

Second, the interdisciplinary nature of agroecology and decision support system (DSS) design introduces a high degree of heterogeneity in study methods, contexts, and findings. This complexity is reflected in the large volume and diversity of the 190 identified relationships within the framework, which pose significant challenges for effective visualisation and generalisation.

Third, the conceptual framework remains unvalidated in real-world farming contexts. Future work should focus on empirical testing of the conceptual framework across diverse agro-ecological settings to assess its practical applicability, usability, and effectiveness. Additionally, co-design approaches that actively involve farmers and end-users in the development and refinement of the conceptual framework could enhance relevance and adoption.

In summary, this conceptual framework provides a foundational anchor for the emerging field of agro-ecological DSS design, derived exclusively from literature findings. The next critical step is to translate the conceptual framework into operational DSS models and validate them through participatory and applied research.

ABSTRACT

The execution of planned maintenance is one of the fundamental pillars of sound and progressive maintenance operating systems in automotive industries. An automotive industry was faced with an obstacle of bearing the inability to adhere to targeted planned maintenance schedule attainment which impacted parallelly on machine availability and the organization's cost drivers. Recurring schedule backlog, overtime cost of backlog recovery, and machine breakdowns on equipment that were not serviced within required mean time before failure, were the predominant phenomena impacting adversely on the efficient flow of operations. The paramountcy of the problem prompted the study to undertake to the utilization of the DMAIC (Define, Measure, Analyze, Improve, Control) methodology with the aim of circumventing the challenge and establish an improved streamlined maintenance planning process. The results of the study saw planned maintenance schedules being executed at targeted level, improved machine availability from 68.5% to 96.33%, and a significant cost reduction of backlog recovery.

Keywords: Maintenance planning, Machine availability, Schedule attainment.

1 INTRODUCTION

Maintenance planning is one of the fundamental strategic roles in automotive industries. With the industry characterized by various machinery and ever-shifting technological advancements, the upkeep of machinery holds core to the attainment of high efficiencies. Such upkeep of equipment requires a robust maintenance planning approach that is focused, chronological, and resource oriented. The plight of failing to plan maintenance effectively has seen maintenance departments in manufacturing organizations falling into the trap of reactive maintenance vicious cycles [1]. At the heart of the problem, is a failed maintenance strategic approach which impacts significantly on machine availability, preventive maintenance schedule attainment, and other departmental key performance indicators that are dependent on machine availability. The constituency of the magnitude of ineffective maintenance planning stems from excessive generation of preventive procedures, inconsideration to manpower and work content requirements, a scattered approach towards maintenance execution, and a lack of a streamlined approach to cement maintenance windows. Weeks *et al*.[2] added to this narrative by outlining that lack of planning expertise to integrate planning thought into computer maintenance management software (CMMS) is an integral part of planned maintenance failure. With resources overwhelmed by the number of schedules generated, and planned maintenance schedules lacking direction whereby procedures require machine downtime while at peak production targets, a phenomenon of planned maintenance schedules not being completed occurs. This does not only affect schedule attainment, but also the much-needed reverse equipment deterioration requirements to eliminate equipment breakdowns, quality defects as a result of failed equipment and inability to attain production targets. All these consequential phenomena are the bases to which overall equipment efficiency is measured in automotive industries. Substandard maintenance planning that is not aligned to the realities of the automotive operational sphere leads to the detriment of cost implications such as excessive overtime to catch up on missed production due to machine unavailability, excessive overtime for maintenance personnel to catch up on backlog schedules, and the cost of missed opportunity due to downtime. Given the gravity of this phenomenon, the DMAIC methodology is one such strategic approach to effect improvement in maintenance planning to enhance schedule attainment that uplifts equipment availability [25].

1.1 Objectives of the study

- To identify constraints that prevent the identified organization from meeting its intended planned maintenance schedule attainment.
- To analyze the current maintenance planning process and schedule generation through the organization’s computer maintenance management software.
- To utilize the DMAIC methodology to streamline and improve the maintenance planning process to attain targeted schedule attainment.
- To articulate the impact results of a structured maintenance planning process on equipment availability and subsequent cost reduction.

2 LITERATURE REVIEW

The DMAIC (Define, Measure, Analyze, Improve, Control) methodology is a strategic process improvement approach that is concerned with the drill-down of problems to develop solutions and the establishment of sustaining controls [3]. This methodology stems from the Six-Sigma philosophy and is predominantly utilized in automotive industries to drive identification of process abnormalities, elimination of waste, and productivity improvement. This is cemented by da Silver *et al*. [4] by outlining that the methodology is at the core of driving operational stability by ensuring that process abnormalities are addressed. This narrative bears significance in ensuring that the definition, measurement and analysis of maintenance

planning shortcomings that significantly impact on equipment availability capture the current problem faced by automotive industries, while simultaneously devising improvement solutions with controlled measures for sustainability.

Automotive industries are one of the major contributors of economic participation in various countries globally. With the sector expanding rapidly and new entrants to competitive participation emanating expeditiously, Javaid *et al*. [5] warned that high equipment efficiency has become the competitive baseline of these organizations. The propelling factor behind this narrative basis itself on the huge equipment investments to provide flexibility, ease of manufacturing, and a demand-based flow of operations. According to Sarvanka and Yawele [6] the success on the return of investment in these industries relies heavily on the outright performance of the equipment. This brings the paradigm of equipment availability to be a beacon of significance to hold firm competitive advantage. Arena *et al*. [7] asserts in this regard that maintaining high equipment availability extricates automotive industries from significant losses that come in the form of downtime, labor and overheads idle time, and revenue. These are critical elements of circumvention for any manufacturing industry to enhance overall profitability and operational continuity. Various strategies around the attainment of high equipment availability have been explored, and effective maintenance planning and execution is at the heart of driving the upkeep of such availability [8]. Available literature on various maintenance operating systems indicates limited pragmatic guidelines on effective maintenance planning at a functional level.

According to Pinto *et al*. [9] maintenance planning bears paramount significance in organizational maintenance departments through driving proactive actions that ensure the preservation of equipment health. The attainment of such preservation emanates from the development of equipment reverse deterioration procedures that are executed periodically. These periodic procedures are summarized by Yang *et al*. [10] as being periodic inspections, time-based maintenance, and condition-based maintenance. These are core procedural strategies that are facilitated to subdue forced equipment deterioration [11], unplanned equipment stoppages [12], and operation of unsafe equipment [13]. The ground development of planned maintenance procedures is primarily guided by original equipment manufacturers [14], equipment health assessments, available historical equipment failure data [15], root-cause analysis, and failure mode effect analysis. The benefits of an effective and thriving maintenance planning strategy warrants the attainment of reliable equipment, certainty of planning in the organization's supply chain, delivery to customer demands, and an overall safe manufacturing sphere. Wang [16] emphasizes that it is imperative for manufacturing organizations, particularly automotive industries, to safeguard the performance of their machines to ascertain generational handover and future investment.

One of the competitive strategies in the field of equipment maintenance is the need to drive preventive maintenance. This is a prevailing asset care approach that is measured through the attainment of an acceptable percentage of scheduled maintenance [17]. At a strategic and systemic level, maintenance managers and coordinators measure schedule adherence as a key performance indicator. The line of thought around this performance indicator is that of high or targeted schedule attainment must translate into targeted equipment availability. The are several factors that hinder schedule attainment which are given a synapsis by Shafiee and Sørensen [18] as being inaccurate scheduling, poor resource allocation, ineffective methods of communication, and lack of acclimatization of maintenance personnel to CMMS interactions. These hinderances are further recognized by Pasipatorwa *et al*. [19] as being the primary contributors to reactive maintenance as they negatively affect the execution of maintenance work on equipment within the require mean time before failure. The occurrence of the phenomenon of reactive maintenance brings a cycle of frustration and lack of direction in maintenance operating systems [20]. Spiraling equipment failures bring grave instability to

organizations and ultimately require great investment through consultation, training, and resource stabilization to revert to a preventive maintenance environment.

Planned maintenance is one of the most important pillars of efficient production flow in automotive industries. It is a critical approach to the establishment of proactive ways to enhance equipment availability [21]. As a baseline key performance indicator, equipment availability feeds directly into the performance indicator of other departments in any manufacturing supply chain. The dominance of equipment availability in this regard asserts that production output measures get affected when machines are not available, product quality gets affected when machine malfunction, safety score cards get affected when machines are not safe to operate, and supply chain planning experiences uncertainty when machines are not available. On the contrary, a shortcoming on each of the key performance indicators mentioned does not affect the availability score of equipment [22]. It is of paramount importance for manufacturing organizations to invest in preventive maintenance through extensive support to the role of maintenance planning to cement stability and productivity in the core pillars of their organizations.

3 METHODOLOGY

The process of streamlining maintenance planning for this study led to the employment of a mixed methodology of qualitative and quantitative results. The results were structured and presented utilizing the confines of the DEMAIC abbreviation. Primary data was extracted from the organization's CMMS and production monitoring system and manipulated in the various stages of the DMAIC approach to yield results. The development of project charter, histograms, root-cause analysis, schedule levelling and flow charts were some of the qualitative and quantitative techniques that were encompassed in the constructs of the DMAIC approach. The study outlined the approach accordingly as per the following narration:

3.1 DEMAIC approach

3.1.1 Defining the problem

This step was undertaken to develop and articulate an understanding of the wholistic problem that is faced by the industry. To attain this, a project charter was developed and the elements required to satisfy the charter were fulfilled. The first element of the charter was to clearly outline the problem that was being addressed. This was followed by stating the purpose of the study. The purpose is signifying in ensuring that the magnitude of the problem is cemented and the impact of the problem on the organization is outlined. On completion of stating the purpose, the business case was clearly outlined on the charter. This gave a wholistic synapsis of the need to undertake the project. The specific goal of the project, together with specific timelines and measurable results, was outlined. The charter was then concluded with an outline of the scope that is covered and what lies outside of the scope.

3.1.2 Measurements involved

The measurement phase was concerned with capturing theoretical and statistical attributes of the magnitude of the problem. This phase is primarily significant in outlining the critical factors that perpetuate the existence of the problem [23]. To fulfill this step, the study measured the current state of planned maintenance schedule attainment, the current equipment availability and outlined possible root-causes that could potentially lead to the problem. The current schedule attainment was captured for a period of seven months with a graphical articulation of the company's target. The equipment availability followed the same graphical depiction process. Through a process of verification, the real root-causes to the problem were identified utilizing an Ishikawa diagram.

3.1.3 Analysis of the problem

This phase of the methodology is concerned with establishing an in-depth understanding of the critical elements that contributed to the problem. This corresponds with Rana and Kaushik's [24] narrative that this step establishes the baseline to which opportunities for improvement can be identified. For this study, this step took a swipe into the analysis of the root-causes that have been identified in the measurement phase. Each of the root causes were supported with data extracts of the true state of abnormality. An in-depth outline of the contributory elements to the occurrence of the depicted analysis was then undertaken for each of the root-causes.

3.1.4 Improvement phase

The improvement phase of this study was concerned with the implementation of resolutions to the abnormalities that were identified and analyzed in the preceding phase. To accomplish this, the study explored different maintenance planning techniques relative to the abnormalities to subdue the current state. These techniques were focused on ensuring that resource allocation is carried out accordingly, planned maintenance procedures were allocated fairly amongst maintenance personnel, procedures were reviewed and accurate frequencies for the preventive maintenance procedures ware updated accordingly. A further plan to mitigate deadline constraints and to recover from scheduled maintenance backlog without compromising schedule adherence was outlined. The overall results on schedule attainment, equipment availability and cost reduction were outlined for a defined period.

3.1.5 Establish control

This phase of the DMAIC methodology bears immense significance in ensuring that improvements that have been implemented are sustained. In order to achieve this, the study drew the entire process of planned maintenance schedules using a flowchart. A procedure was then cemented from the flowchart. This procedure was to be followed to sustain and control activities that are centered around maintenance schedule attainment and ensure that executed plans translate into corrective action that enhanced equipment availability. This procedure was then followed by a training phase through a One-Point-Lesson that was given to all maintenance personnel in the maintenance department.

4 RESULTS AND DISCUSSION

4.1 Define phase

The results and descriptive articulation of the define phase were outlined in the project charter as per Table 1:

Table 1: Project overview and scope

Project overview	
Problem description	Incompletion of planned maintenance schedules timeously.
Project purpose	The maintenance department aims to achieve a schedule attainment of 95% from a low of 66% in line with the company objectives. Missed schedules have spiralled out of control, rendering the organization to invest in exorbitant overtime cost to recover from the backlog. This has had a negative impact on the attainment of plant equipment availability targeted at 95%.
Business case	Schedule attainment is currently below the required standard to enable the plant to attaint its equipment availability. Such has resulted in missed schedules for preventable equipment failures which is hindering delivery targets due to machines not being available. There is a strong need to drive effective maintenance planning to attain required schedule adherance and meet the service needs of equipment within their mean time to failure.
Project goal	By the 31st of January 2024, planned maintenance schedule attainment needs to be at 95% and above.
Scope of the project	
Scope covered	Maintenance planning process and schedule attainment.
Outside of the scope	Daily corrective maintenance.

4.2 Measurement phase

The study commenced with measuring historical data of the attainment of planned maintenance (PM) schedules. Data collected over a period of seven months (February 2024 to August 2024) as depicted by Figure 1 indicated that the plant was unable to meet its monthly target of 95%. Further to that, the results indicated that the plant had an allowable percentage loss of 5% which was exceeded over the period of seven months. On average, the plant had a schedule attainment of 66%. This entailed an exposure of 34%, which meant 34% of the equipment in the plant was not serviced according to their service intervals and functionality needs. This also entailed exposure to equipment failures that could have been prevented by the planned maintenance schedules. The plant had an average of 1800 planned maintenance schedules monthly across the seven months, 612 schedules were completed late.

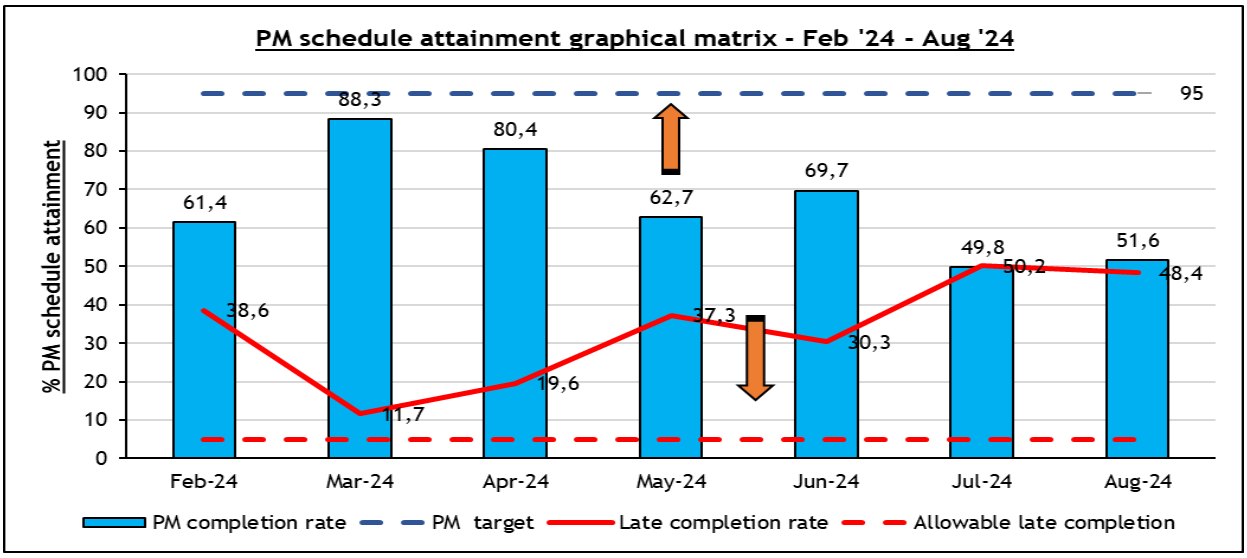

Figure 1: PM schedule attainment graphical matrix

The study went further to extract the correlation between the incompletion of planned maintenance schedules and machine availability. Figure 2 indicates a direct correlation between the two phenomena. On average across the seven months, the plant attained a

machine availability of 68,5%. This entailed all the schedules that were missed pulled down machine availability by 31,5%.

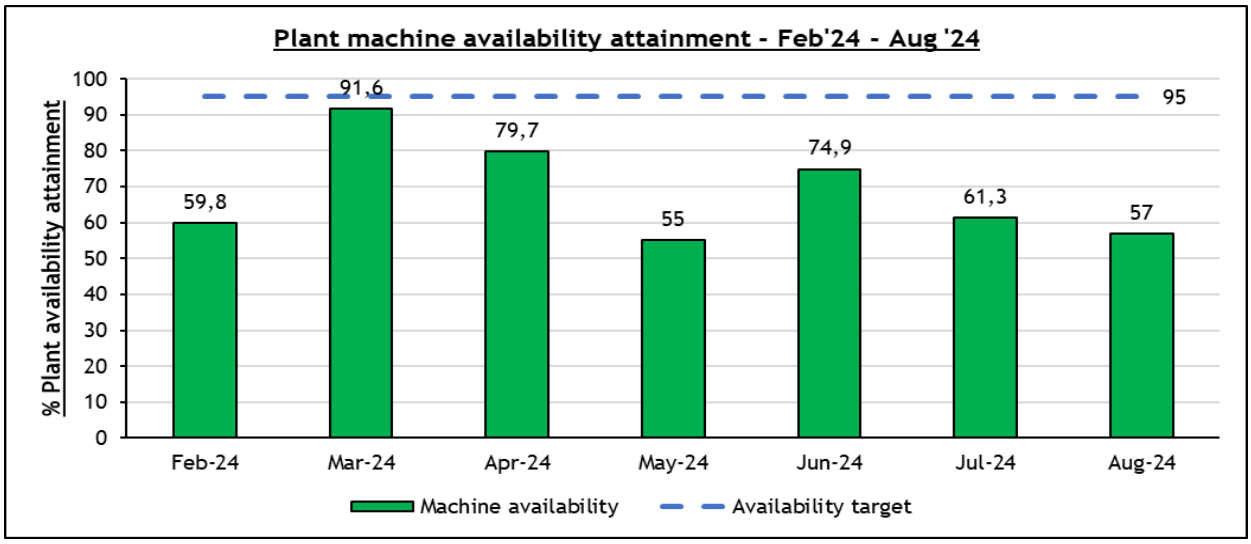

Figure 2: Plant machine availability attainment

Given the dynamics presented by Figures 1 and 2, the study embarked on determining the root-causes that contributed to the incompletion of planned maintenance schedules timeously. The root-causes were derived utilizing the Ishikawa diagram technique as depicted by Figure 3. Upon verification, the results of the techniques indicated that there were four root-causes that contributed immensely to the incompletion of schedules timeously. The root-causes are indicated by the red highlight in line with the legend in Figure 3. This root-causes became the base for an analysis scrutiny in line with the proceeding step of the DMAIC methodology.

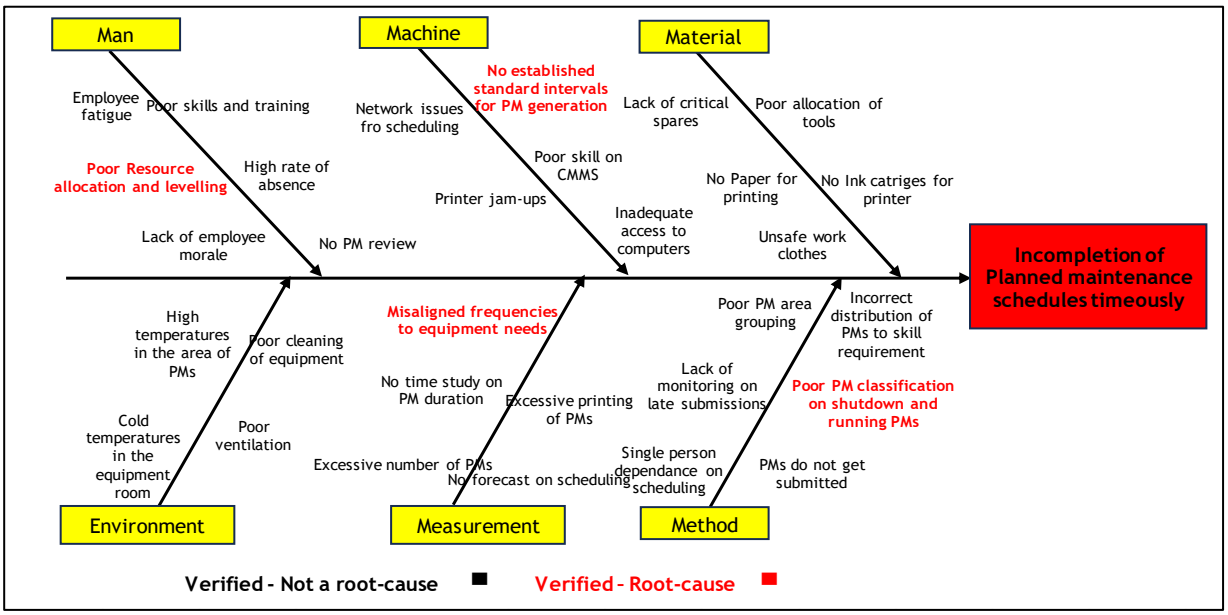

Figure 3: Ishikawa diagram - PM incompletion

4.3 Analysis phase

4.3.1 Misaligned PM frequency to equipment needs

Stemming from the historical data of equipment breakdowns and verification with the original equipment manufacturer (OEM) of the equipment, the study found that some of the equipment were set on a default one week schedule generation as opposed original equipment manufacturer recommendations. The default setting entailed an excessive number of schedules was generated when it was not required. The planned maintenance schedules warranted an over service of the equipment, when the default computer maintenance management system (CMMS) one-week schedule interval should have been altered. As per the depiction on the red highlight on Figure 4, the planned maintenance procedure for engine carriers was the default one-week as opposed to an OEM recommendation of four weeks.

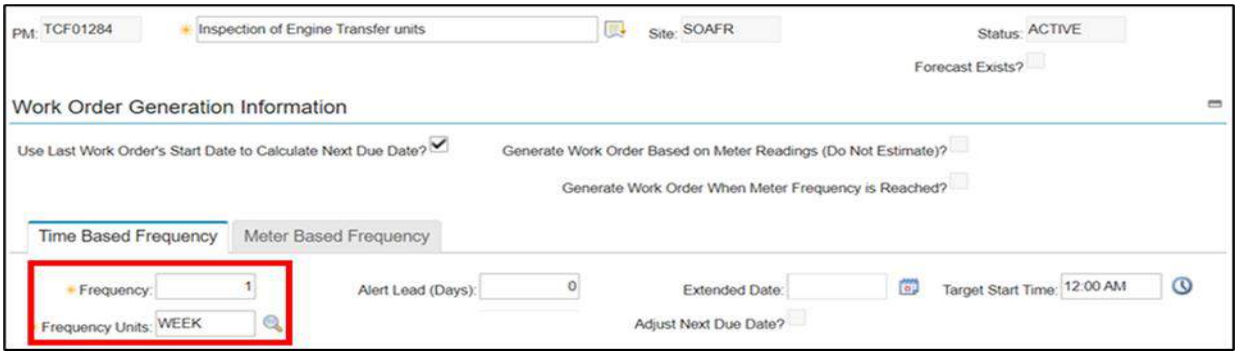

Figure 4: CMMS planned maintenance default setting

4.3.2 Poor resource allocation and levelling

The results of poor resource allocation and leveling indicated that there were maintenance technicians that were loaded excessively and those that were underloaded. Figure 4 is a depiction of the planned maintenance resource loading for one shift across a three-shift pattern. This presented the need to re-distribute planned maintenance workload accordingly and in line with technical skill and ability. This was attained through re-distributing the millwright PMs to electrical and fitter technicians in an endeavor to bring a polarized trend. The main reasons the millwright technicians were overloaded was due to their technical ability to carry out both electrical and mechanical fitter maintenance schedules. The total number of PMs in this shift was 575, with a manpower skill of 16 technicians. This entailed that on average, each technician needed to be allocated an average of 36 planned maintenance schedules.

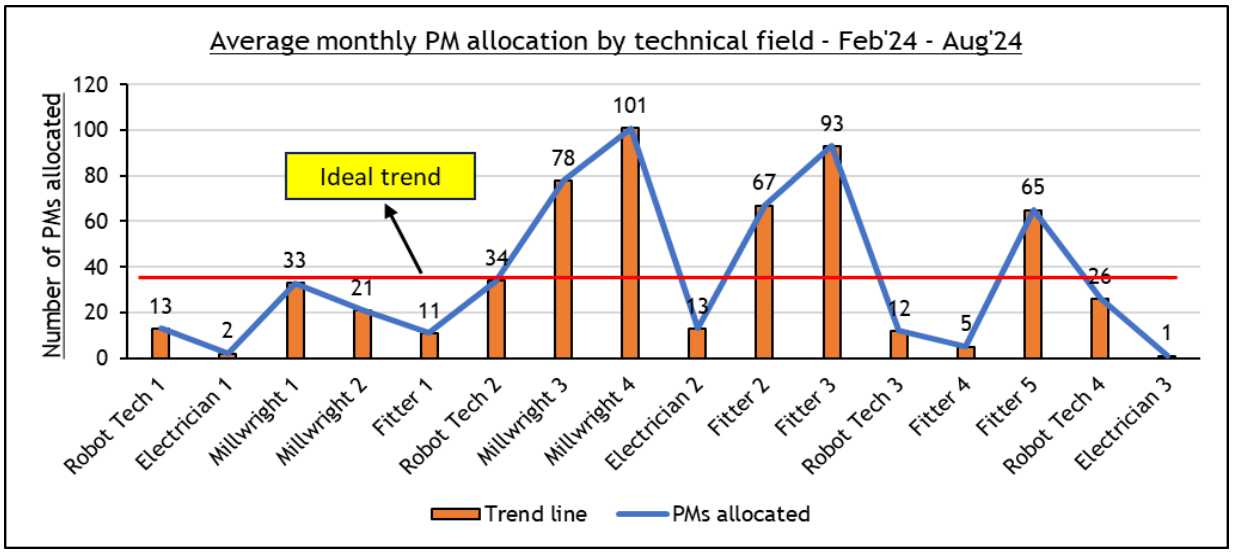

Figure 5: PM resource allocation

4.3.3 No established standard intervals of PM generation

This root-cause based itself on the generation of planned maintenance schedules not being fixed, thus hindering predictability and forecasting the exact number of schedules to be generated. Figure 5 on the red highlight indicates that there were planned maintenance schedules that were set to come out monthly. The number of days in a month varies, and this entailed schedules could come out randomly in any day. For example, a schedule that comes out on a Monday in a month could come out on a Saturday the following month. This presented a lack of control in establishing the exact number of planned maintenance schedules that were to be received daily. There was a need to change the 'monthly' generation of schedules to a more fixed period in the company's computer maintenance management system (CMMS).

Work Order No.	Date Created	22 - 06 - 2024	Type of work

Isolations:	FOLLOWED MACHINE LOCK OUT TAG OUT PROCEDURE		Maint. Category:	Mechanical/Electrical

Figure 6: CMMS interval scheduling snapshot

4.3.4 Poor classification of shutdown and running PMs

This was the major constraint and source of loss of direction towards planned maintenance schedule attainment. The highlighted lines on Figure 7 indicate equipment that required production downtime for their service. These types of planned maintenance schedules did not have a unique identifier and were generated randomly like schedules that could be executed while the equipment was running. The detriment of this phenomenon was that 38% of the planned schedules in the CMMS required downtime. With no fixed intervals as per subtitle 4.4.3, these schedules came out during machine running periods and could not be executed as the machines ran 24 hours a day, 5 days a week. This made them automatically late when they came out during the week as opposed to the weekend.

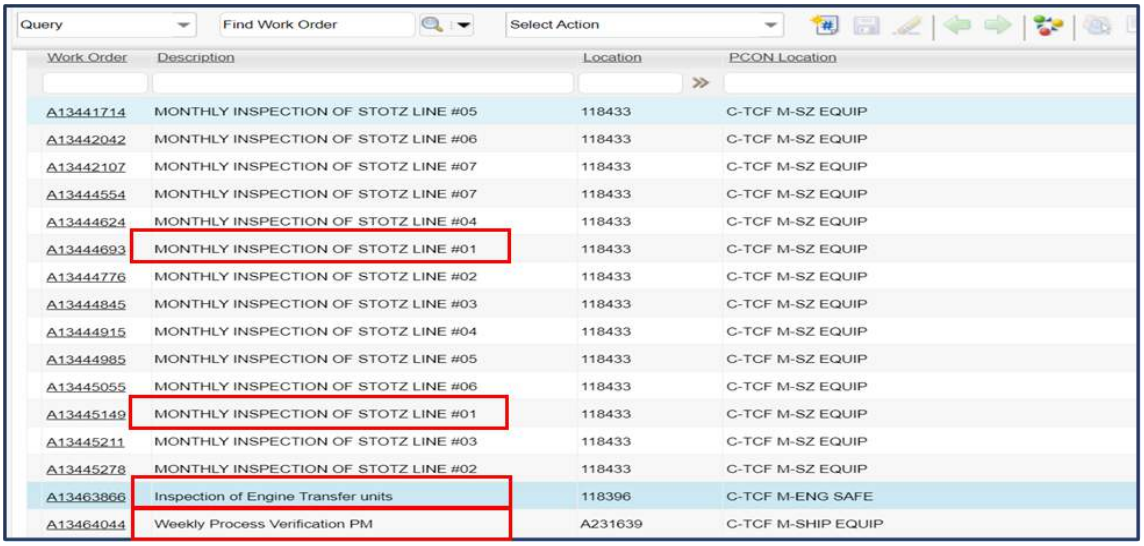

Figure 7: Shutdown maintenance segregation

4.4 Improvement phase

4.4.1 Frequency alignment of equipment needs

The improvement results of aligning the schedule frequencies to OEM recommendations reduced the number of schedules generated monthly from an average of 1800 to an average of 1200. There were 20 engine carriers which generated 80 schedules monthly. Shifting the frequency to 4 weeks as depicted by the green highlight on figure 8 reduced the number of schedules generated by 60 on average monthly. This process was replicated to other simile carriers across the plant and ultimately yielded a reduction of 600 schedules.

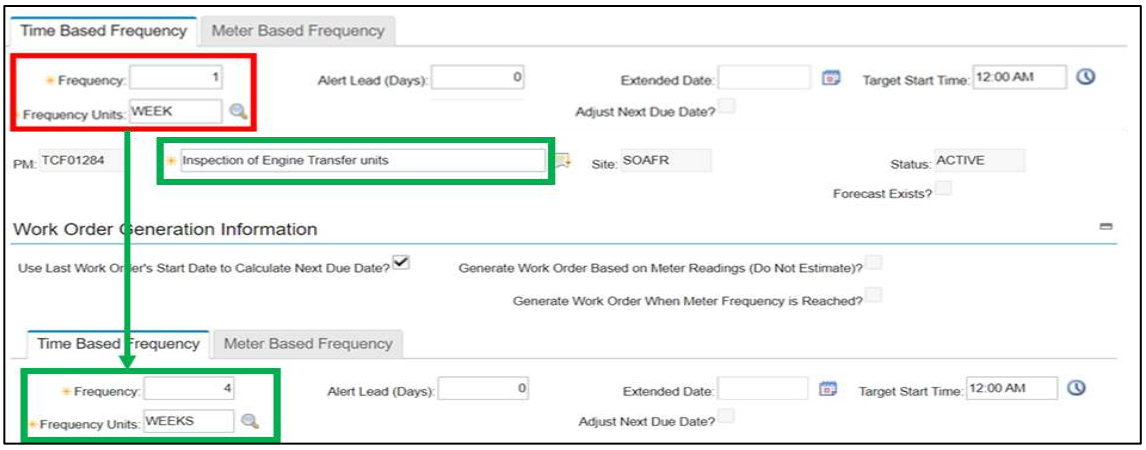

Figure 8: PM frequency alignment changes

4.4.2 Reallocation of PMs and levelling

Figure 9 indicates the results of the re-distribution of the average monthly planned maintenance schedules. The process saw a more balanced distribution with the highest allocation being 45 and the lowest being 28 planned maintenance schedules. This was in contrast with the previous allocation where the highest was 101 schedules and the lowest was 1 schedule. The trend line improved, indicating a more polarized distribution of schedules with no major spikes in allocation.

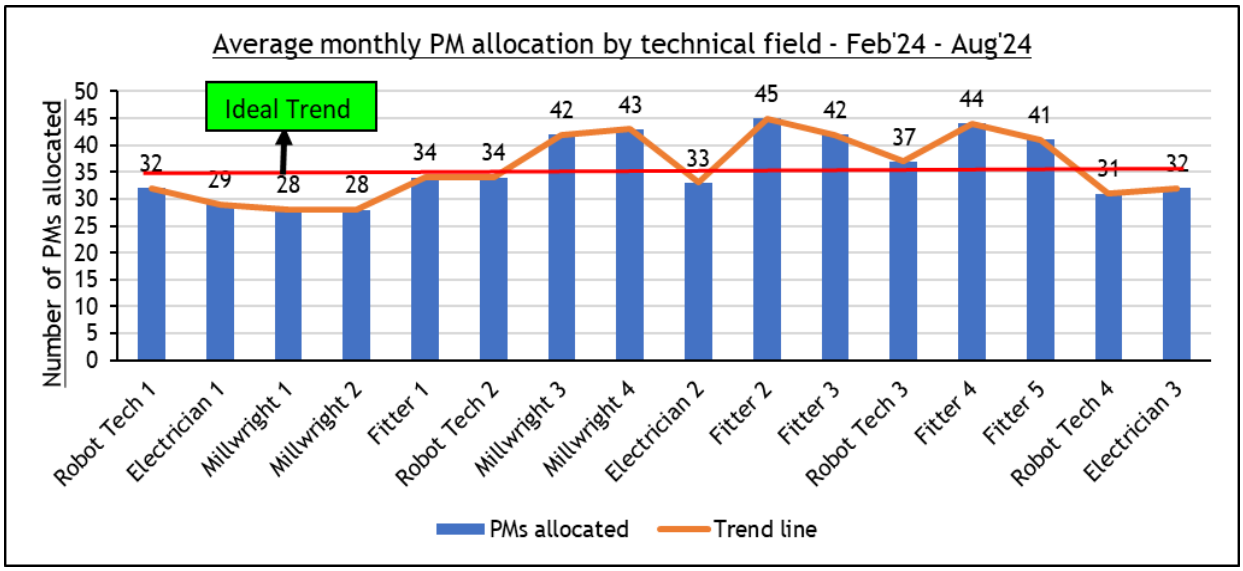

Figure 9: Improved PM reallocation and levelling trend

4.4.3 Standard fixed intervals with no generation overlap

The intervals were changed from using 'months' to utilizing 'weeks' as depicted by Figure 10. This ensured that there were no planned maintenance schedules that overlapped. Fixing the intervals through weeks entailed that when a planned maintenance schedule is set to come out on a Monday, it will not change as a week has a fixed number of days. This presented better control of allocation in that the exact number of planned maintenance schedules could be known and forecasted for each of the days of the week. This also provided simplicity of resource allocation for planned maintenance schedules and for line operation monitoring for each day of the week.

Work Order No.	Date Created	22 - 06 - 2024	Type of work

Work Instruction:	Change or Service or Inspect the machine/equipment as per the instructions below.		

Figure 10: Interval category change

4.4.4 Shutdown planned maintenance segregation

The segregation of shutdown planned maintenance schedules from running schedules presented a phenomenon where the schedules could not be filtered with simplicity from the CMMS system. Unique identifiers for non-running (NR) schedules were added to all procedures that required machine downtime as depicted by Figure 11. This provided ease of filtering in the CMMS and the ability to plan the maintenance schedules on production down days. This

eliminated the inability for maintenance personnel to complete the schedules due to machines running. Further to this, improved control over labor requirements to complete the schedules on overtime down days was attained. A standard requirement of 18 technicians to complete non-running schedules was established for each day of the weekend.

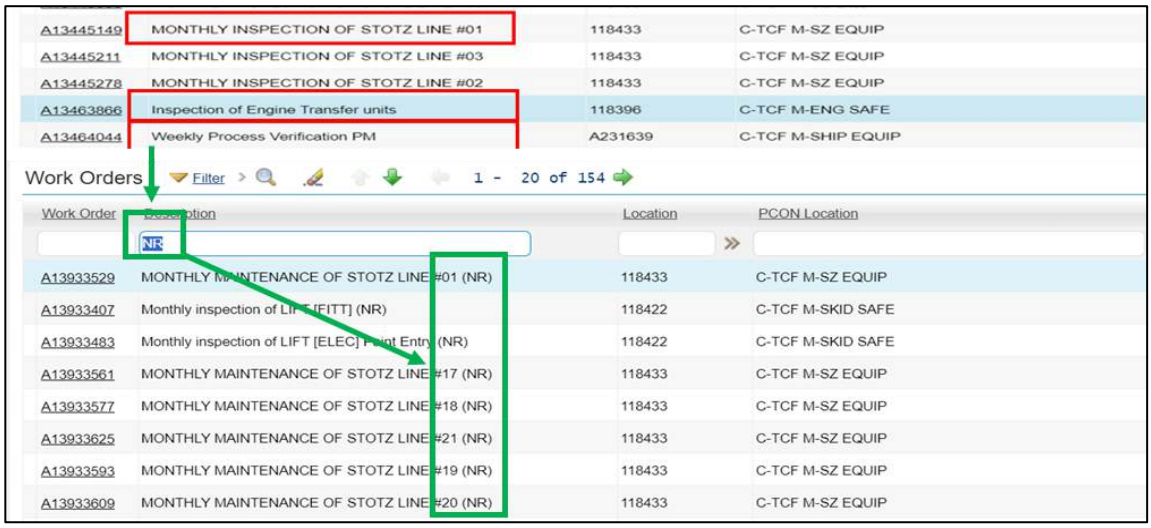

Figure 11: Segregation of downtime and running PMs

4.4.5 Overall improvement results

The interventions in this improvement phase yielded a positive result depicted by the breakpoint on Figure 12. The results indicate an attainment of 89% schedule completion and 93,1% machine availability attainment from the first month of implementation. The target for both planned maintenance schedule attainment and machine availability of 95% was achieved and was exceeded by an average of 2,25% and 1,33% respectively. This also indicated a positive correlation between the execution of planned maintenance procedures and machine availability.

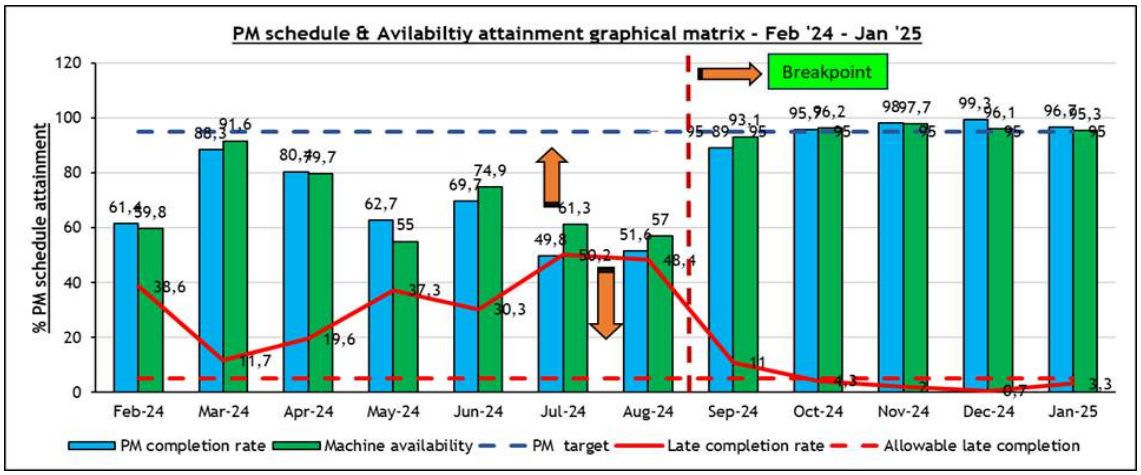

Figure 12: Improvement results - PM schedules and machine availability

Further to the attainment of the targeted planned maintenance schedule and machine availability of 95%, a significant reduction in the amount of overtime cost worked to recover from backlog was realized. Calculated at an average of R270.00 hourly renumeration rate, the average cost of overtime from February 2024 to August 2024 was R967 680.00 monthly. The calculation was based on 32 technicians working 8 hours at a Saturday and Sunday rate of 1.5 and 2 respectively for a monthly period of 4 weeks. With the establishment of control over

the planned maintenance schedules, the number of technicians required over weekends reduced to 18, which brought the overall monthly standard overtime cost to R544 320.00. This yieled to an average monthly cost saving of R423 360.00. This is depicted by Figure 13.

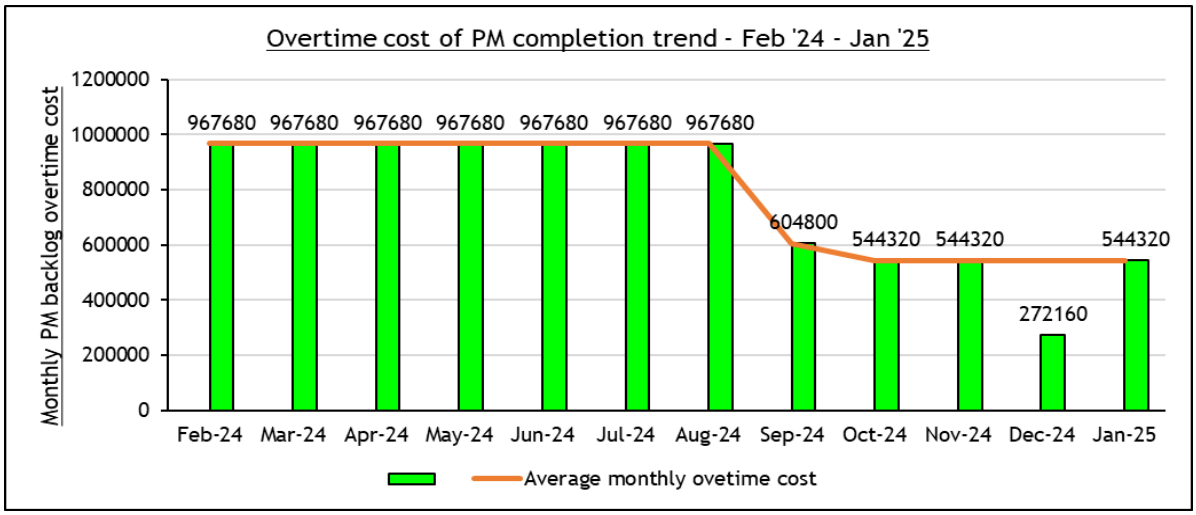

Figure 13: Improvement results – Overtime cost reduction

4.5 Control phase

The establishment of control on the interventions that were undertaken to bring about improvement remedies was attained through the development of a process flow. The process flow depicted the maintenance planning steps that were to be followed to ensure that sustainable results were maintained. The control measure detailed a responsibility flow and a review process to ensure that the integrity of the interventions is upheld. Figure 14 is a process flow chart that guides and summarizes the streamlined approach towards maintenance planning in this automotive industry. The process flow chart was issued to relevant maintenance personnel, training conducted and signed off as a one-point-lesson.

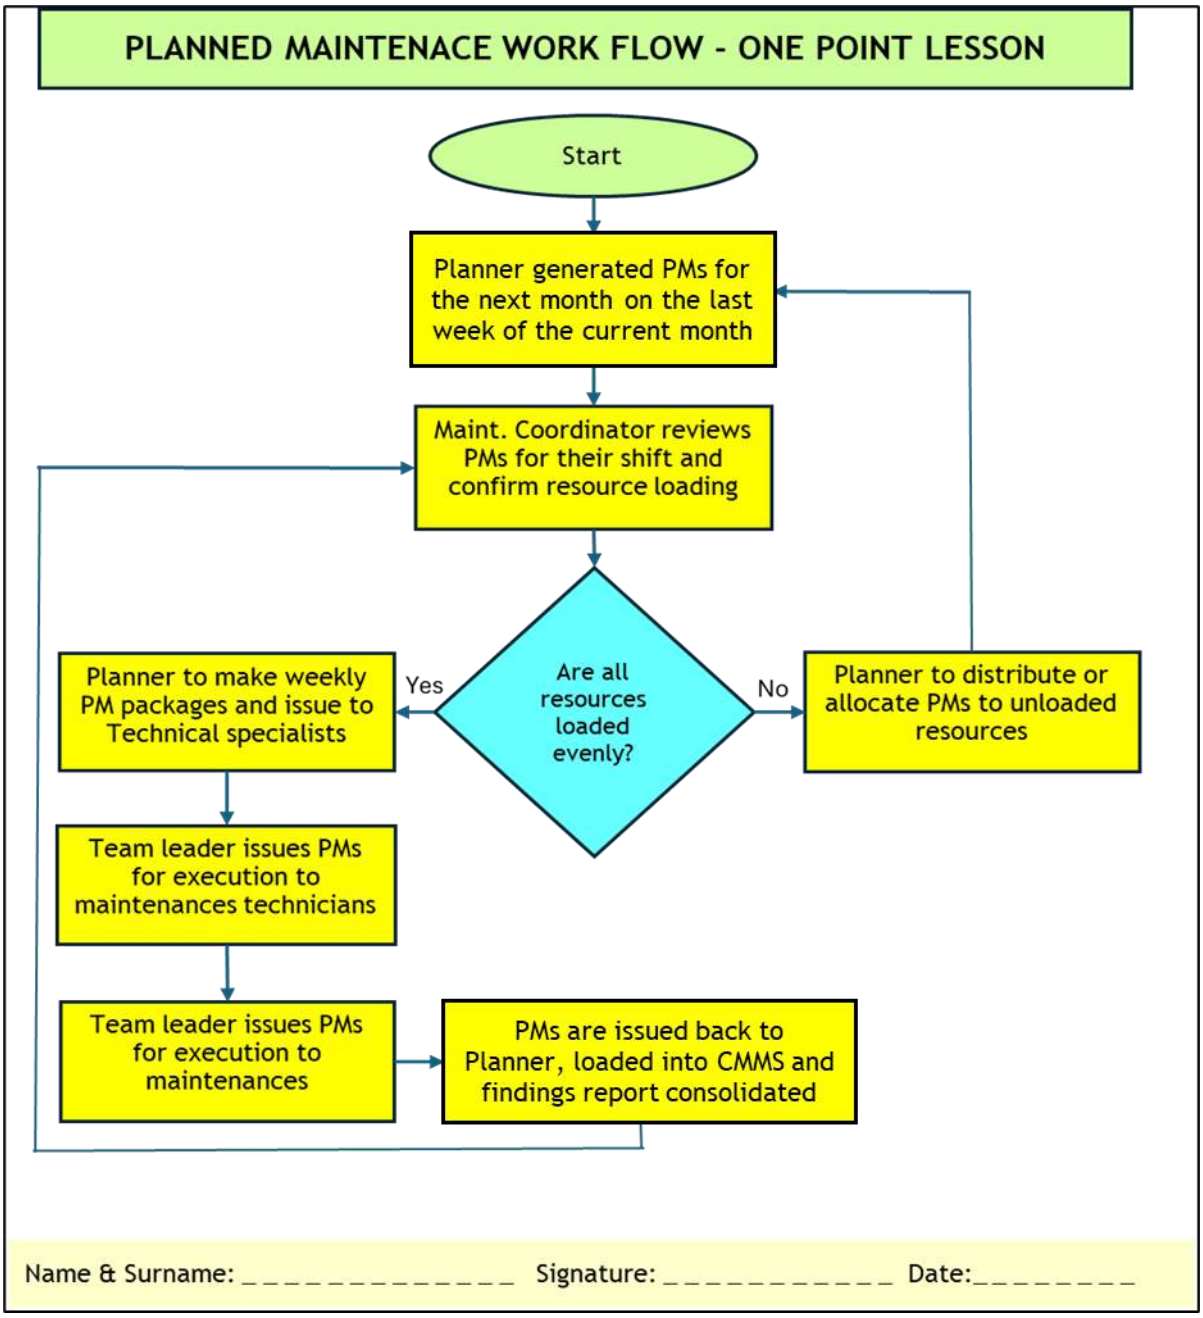

Figure 14: One-Point-Lesson – Planned maintenance

5 CONCLUSION

The study followed the DMAIC methodology which has proven to be a conquering tool in the implementation of a streamlined process towards planning for maintenance. The different phases of the methodology provided simplicity and ease of outrooting both the problems and resolutions that were contributing to a significantly low attainment of planned maintenance schedule execution, which ultimately impacted on machine availability. The first objective of the study was achieved through a detailed outline of the possible root causes through the Ishikawa diagram and the actual root-caused were identified through a verification process. This was followed by an extensive analysis of the root-causes through graphical and CMMS pictorial representations for each of the root-causes identified. This addressed the second objective of the study. The third objective of the study was encompassed by the entire

methodology of the study whereby the DMAIC approach was the core principle towards subduing the problem, through following and adhering to the details required in each step of the DMAIC approach. The fourth and final objective of the study was attained through a graphical outline of the impact of the improvement interventions. Such depicted the schedule attainment and availability to be above target, while significant cost reduction was also attained through the streamlined approach. There is vast literature that is centered around planned maintenance to attain zero machine breakdowns. What is lacking with the literature is pragmatic elements such scrutinizing CMMS interfaces and an overall on-the-ground practical guidelines on maintenance planning through a step-by-step pragmatic approach. The study paves a stream of further research towards shifting the paradigm of high-level maintenance principles to more pragmatic studies at an execution level.

DEVELOPING SYSTEMS ENGINEERING LEADERSHIP IN COMPLEX PROJECTS

T. Ramolete[1] and R. Oosthuizen[2*]

[1,2]Department of Engineering and Technology Management, Graduate School of Technology Management, University of Pretoria, South Africa
[1]u18382925@tuks.co.za, [2]rudolph.oosthuizen@up.ac.za

ABSTRACT

Systems engineering can assist in successfully managing complex projects through technical expertise and interdisciplinary collaboration. Both of these require effective leadership. Therefore, this study probes critical leadership attributes like communication, strategic thinking, and adaptability, vital to managing complex projects. It also found that robust communication shows the strongest positive correlation with project success, followed by strategic thinking and adaptability. The research also reveals apparent gaps in many current programs for developing leaders because they often overlook the specific needs of systems engineers. This paper proposes a tailored leadership development framework to respond to this in the context of systems engineering. It pushes structured training to equip the leaders with the necessary skills to navigate the complexities of multidisciplinary projects. The framework aims to enhance project outcomes and ensure long-term success by aligning leadership development with systems engineering demands.

Keywords: Systems Engineering, Leadership Development, Strategic Thinking, Communication, Adaptability

1 INTRODUCTION

Effective leadership is indeed critical within Systems Engineering (SE), which requires the management of technical aspects and cross-functional teams in a complex project scenario. Projects like these would always be multidisciplinary and likely involve subsystems and disparate technologies, which require bringing them together to reach the overall goals. The efforts of engineers, project managers, and other stakeholders must be aligned so that every component contributes to attaining success for the system to some extent. As Beasley et al. [1] state, experienced leadership is required to balance technical, budgetary, and timetable constraints. This intricate balancing act would depend on understanding technical and soft skills to manage teams and stakeholder expectations [2], [3].

Systems engineers must go deep into complicated technicalities yet present clarity and strategic alignment across all project layers. They have to transform the technical language for diverse audiences, some so that their buy-in is maintained, while others may see a person's potential upside or realise a commitment to cohesive teamwork. Communication failures have been associated with huge costs from delays and/or system failures, especially in cross-disciplinary contexts. Thus, leadership in SE includes the facilitation of alignment between the specialised knowledge and the shared objectives of the project. Effective communications are more than the transfer of information; they have a collaborative, clarifying, and engaging effect [1], [4].

Strategic thinking amplifies the potential of leadership effectiveness that extends to foreseeing risks, aligning with long-term goals, and making complex decisions. According to Alessandro and Jiju [5], SE leaders should be aware of the long-term implications of their choices of technology, risk trade-offs, and the footprint of their actions within the organisational strategy. Those equipped with strategic foresight deliver projects that are resilient, adaptive, and technically sound [6].

Leaders need to be flexible in their approach to changes in the scope of projects, changes in regulations, and new unaccounted costs. Adaptive leadership is required in the VUCA (volatile, uncertain, complex, ambiguous) environment, which most SE environments are characterised by, as pointed out by Abukalusa and Oosthuizen [7]. The speed at which leaders can react to new information or changes can be used to prepare individuals to steer their teams through challenges and uncertainties [8]. However, not recognising leadership as necessary enough is the primary nemesis for development programs tackling the disturbing challenges in SE. General management training tends to forget the fusion of technical skills and leadership in managing multidisciplinary teams [5]. This gap limits leaders' prowess in directing complex engineering projects.

There is a rising acknowledgement of and demand for the need for leadership development specific to SE [7]. Programs should emphasise appropriate competencies within the following categories: communication, strategic thinking, and adaptability. These are crucial skills to keep up with the field's extreme technical and organisational complexities. Such programs will create better-prepared leaders who lead multidisciplinary teams to successful results [7].

This paper investigates the leadership competencies required for successful SE in projects. It aims to examine the extent to which these competencies influence project outcomes and to identify gaps in current leadership development programs that often overlook the unique demands of SE. Furthermore, the study proposes a tailored leadership development framework that integrates conventional leadership theories with the specific technical and organisational complexities of systems engineering.

2 LITERATURE REVIEW

Bass [9] describes leadership as inspiring and motivating followers toward improved performance. This emphasises its role in shaping vision, fostering collaboration, and guiding collective effort. Therefore, leadership is how an individual influences a group of people to achieve a common goal. Bass [9] continues to describe transformational leadership as the capacity of the leaders to inspire and encourage teams to achieve better performance and innovation, which is the lifeblood for tackling the multidisciplinary nature of challenges in SE. Such leaders create collaborative environments, focusing all team members on the project's vision while stimulating creativity and motivating them to engage in creative problem-solving.

Transformational leadership can be particularly pertinent to SE in its individualised attention and intellectual stimulation. SE projects require not only technical competency but also the ability of leaders to enthuse teams toward critical thinking concerning the integration of the various subsystems in overcoming project obstacles [1]. These leaders must aspire to create a shared vision while supporting their team members' individual development needs.

Adaptive leadership becomes indispensable in SE, especially when managing VUCA environments [7]. Often, SE projects will be subject to changes in requirements, fast technological development, and unforeseen disruption. Environmental changes, rapid technological advancement, and even direct shocks frequently represent cases of SE's challenges. Adaptive leadership eventually provides the much-needed capability to change strategies or processes, thus ensuring effective responsiveness without losing sight of objectives. Adapting and changing direction in response to evolving knowledge or unforeseen challenges is a fundamental leadership competency, corresponding with the ever-changing character of SE [7].

Systems thinking is emerging as a holistic skill for leaders to understanding complex systems, enabling leaders to recognise interconnections among subsystems and anticipate how changes in one component may affect the whole [3], [10]. This perspective helps leaders manage technical and organisational complexities, ensuring cohesive and adaptive decision-making [2]. With systems thinking, a leader can see the network of influences from a project perspective. Hence, the judgment is consistent for what has been done and what should be done for both technical and organisational objectives [11]. This comprehensive view becomes crucial in SE since several subsystems must function together to achieve the project goal. It advances a leader's capacity to anticipate and proactively address potential problems [10].

Also, sustainable leadership has emerged as an excellent underpinning for SE, particularly in long-term projects, where environmental, social, and economic sustainability must be considered. Malik [12] recognises that sustainable leadership will increase the potential for engineering projects' immediate and prolonged effectiveness by including ethical, social, and environmental considerations as integral to leadership decision-making. Engineering Change Management is very relevant to SE, according to Serapelo et al. [13]. Here, the role of leadership becomes consequential in effectively handling project changes. SE executives must manage these processes effectively to minimise disruptions and achieve project timelines and goals.

Ultimately, transformational, adaptive, and systems-thinking leadership, grounded in sustainable leadership and engineering change management, creates a comprehensive system engineering leadership structure. Nonetheless, current research has indicated a severe lack of leadership development programs tailored to these needs. Urgent calls are made for more tailored training programs encompassing this leadership skill set, which is imperative to making leaders in SE more effective [8].

3 CONCEPTUAL MODEL

3.1 Overview

The conceptual framework aims to aid an SE leader in leading complex projects. The framework feeds into the larger discourse of leadership by suggesting actionable insights tailored to specific contexts and applicable to a wide range of engineering environments. Due to the dynamic nature of SE, traditional leadership models are often inadequate. This section delves into the junction of leadership and SE and stresses the need for leadership that can derive solutions from interdisciplinary, technologically challenging environments. Past research identifies leadership as an important critical success factor in this context [14], [15], [16]. However, implementing generic leadership theories without contextualization has been shown to mitigate the unique problems in SE [17], [18], [19].

This research addresses this gap by blending conventional approaches to leadership with the particular demands of SE. The value lies in solving the theory-practice gap by producing a framework that is theoretically sound and practically applicable. It will help to provide insights into how various leadership styles can be most effective in SE environments, thus advancing the understanding of what is considered effective leadership in this unique context [20].

3.2 Integration of Leadership and Systems Engineering Models

Integrating leadership models and SE concepts shows advancement in managing and executing complex projects [17]. The kind of leadership expected in SE is flexible and responsive since it is an interdisciplinary and integrative area. Though competent in conventional settings, conventional leadership styles are not comprehensive in addressing the specific problems posed by systems-engineering projects, such as the coordination of cross-disciplinary teams, high technical complexity, and the continuous demand for innovation [18]. Literature provides the following main leadership models relevant to SE and project management:

- **Situational Leadership**. Situational leadership emphasises the ability of leaders to adapt their style based on the situation, determined by the competence and commitment of their team members and the task demands [21]. This model assumes there is no best way to lead, and leaders must adjust their approach depending on the context. Within SE, this is applicable during project initiation phases, when teams are still forming and the project scope is being defined. White [18] highlights the importance of adaptability in complex environments, underscoring that leaders who adjust their style to dynamic project needs are better equipped to guide multidisciplinary teams effectively.
- **Servant Leadership**. Servant leadership prioritises the needs of team members and emphasises collaboration, empowerment, and shared responsibility [22]. Leaders must serve their teams by fostering trust, supporting professional growth, and encouraging creativity. Servant leadership is particularly relevant in SE contexts during the design phase, where innovation, cross-disciplinary collaboration, and inclusive problem-solving are essential. Servant leaders create an environment where individuals feel valued and motivated to contribute to complex technical solutions. Serapelo et al. [13] stress that such an approach to leadership enhances engineering change management and minimises project disruptions, making servant leadership a critical asset in maintaining cohesion and innovation throughout the project lifecycle.
- **Adaptive Leadership**. Adaptive leadership is designed for environments characterised by VUCA, which is typical of systems engineering projects [7]. This model emphasises flexibility, resilience, and continuous learning, allowing leaders to respond effectively to unforeseen changes in project scope, technology, or external regulations. Adaptive leaders guide their teams through uncertainty by encouraging experimentation, learning from setbacks, and reframing challenges as opportunities. When combined

with systems thinking, adaptive leadership equips leaders to adjust strategies dynamically without losing sight of long-term objectives [7]. This makes it a critical competency for managing evolving SE projects where unexpected disruptions occur.

- **Transformational Leadership**. Transformational leadership emphasises inspiring and motivating followers to achieve beyond expectations by fostering a shared vision, intellectual stimulation, and individualised support. Bass [9] describes transformational leaders as creating environments that encourage creativity, innovation, and long-term commitment from team members. In SE, transformational leadership is significant during testing and evaluation phases, where leaders must rally teams to maintain quality standards, embrace continuous improvement, and ensure integration of diverse subsystems [15]. Such leaders do not simply manage technical tasks; they inspire their teams to see beyond immediate challenges and contribute toward broader organisational and project goals.

This paper integrates these models within the SE framework. Integration enhances an efficient and successful project climate for work through cooperation, adaptation, and strategic decision-making. In particular, leaders in SE will have to investigate and implement this integration to manoeuvre the complexities of modern engineering projects effectively [19]. Figure 1 presents the concept framework integrating leadership models into SE project phases.

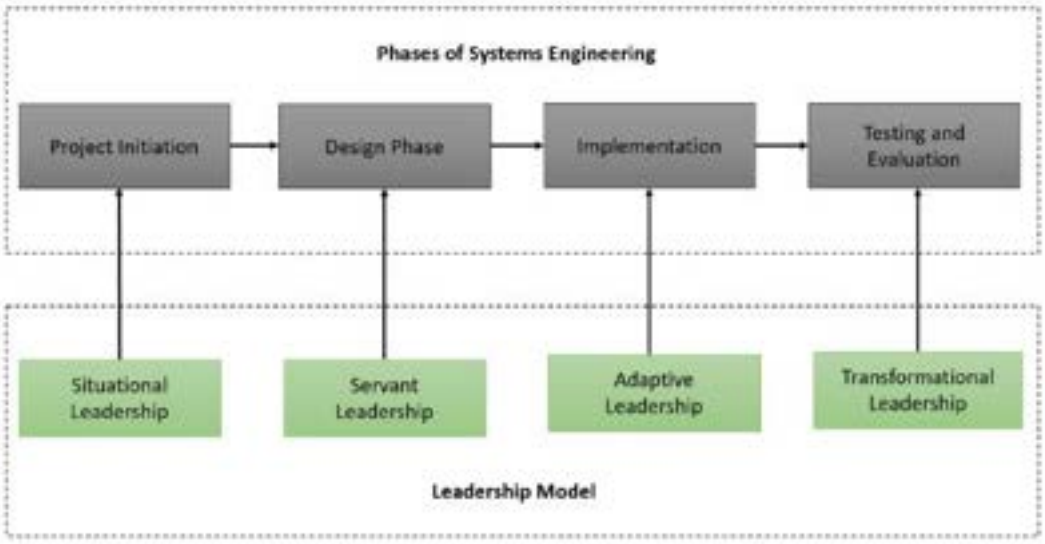

Figure 1: Integrating Leadership Models with Systems Engineering Project Phases.

Figure 1 contextualises several leadership models within phases of SE projects, each corresponding to the particular demands and challenges in the literature. Starting with situational leadership at project initiation, this model allows leaders to change styles according to the needs of the team and the situation; this is important for setting the direction and scope of a project. The adaptability and openness of this leadership model make it most effective in this early phase. The leader can establish a shared understanding and alignment, which are key to a successful project. Servant leadership will be envisaged for the design phases, emphasising the importance of attending to team needs and cooperation. As each stage of an SE project encompasses unique challenges with distinct demands from the leadership styles, the proposed framework links the set of leadership styles to any SE project phase. To be engaged at any of these stages, the dynamics in leadership must act as continuously required adaptive responses to ensure project success. The integration is achieved as follows:

- **Project Initiation – Situational Leadership**. Leaders must assess the team's competence and circumstances to adapt their leadership style accordingly and establish the course and extent of the project. This supports laying the project base for flexibility and responsiveness to early-stage planning and stakeholder alignment.
- **Design Phase – Servant Leadership**. Leaders can prioritise team collaboration and create an environment to develop teamwork and generate innovative solutions. Servant leadership is about serving the team while getting everyone involved, ensuring every voice is heard.
- **Implementation – Adaptive Leadership**. Leaders now must manage uncertainty and changing circumstances during the conduct of the project. This enables agile and robust conditions by amending plans and rerouting resources depending on prevailing constraints.
- **Testing and Evaluation – Transformational Leadership**. Transformational leaders encourage teams to surpass expectations by nurturing a shared vision and commitment to quality. They must foster a culture of continuous improvement and quality so the final deliverables meet and exceed intended objectives.

The leadership style has to adapt as the project traverses through its lifecycle. Each project stage presents unique challenges and demands specific leadership attributes. Therefore, effective SE leadership requires mobility between different types to complete each stage, guaranteeing the project's success from its inception to its conclusion. Based on the framework, the hypothesis developed is:

- **H1**: Leaders with elevated degrees of [leadership competency] demonstrate greater effectiveness in overseeing systems engineering projects.

3.3 Leadership Competencies in Systems Engineering

In discussing leadership competencies in SE, it is paramount to emphasise these in a contrastingly complex and diverse environment [23]. SE projects cut across multiple teams, complex technology integration, and constant change in requirements. Therefore, it becomes vital to design a distinct set of leadership competencies pertinent to SE [24]. These include, but are not limited to, the abilities of strategic thinking, technical knowledge, and communication. The steering of SE projects becomes constrained by favourable and detrimental components that fall within the aforementioned areas of potential [25]. Figure 2 presents a Conceptual Framework of Leadership Competencies in SE.

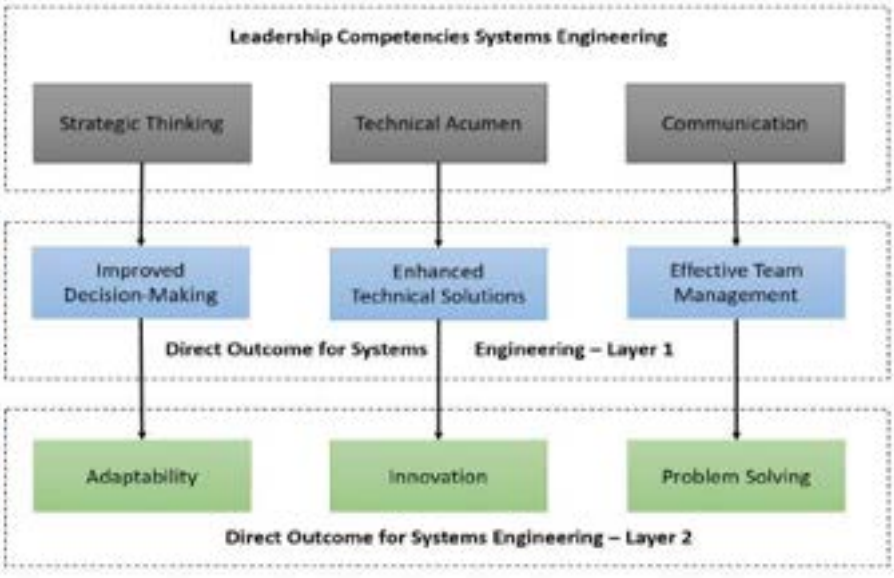

Figure 2: Conceptual Framework of Leadership Competencies in Systems Engineering.

The flow adheres to a conventional project management cycle, from planning and passing to technical execution and maintaining effective communication throughout the project. Each block represents an individual competence and resultant output within the SE environment. The arrows show the progress of these competencies and their interrelationship and influence on other characteristics of SE projects. Accordingly, the following hypothesis has been formed based on the framework mentioned above:

- **H2**: Systems engineering projects led by individuals with solid systems thinking skills have higher success rates.

3.3.1 Competency 1: Strategic Thinking

This is a technique that makes decisions through the effective management of projects. This skill improves an individual's decision-making capability, especially when faced with trying systems-engineering occasions [5]. This phase is critical to creating a project's vision, objectives, and strategies. Early project stages require strategic thinking to form the scope, goals, and approach. It demonstrates further the capacity to respond and adapt to changing situations and unanticipated difficulties. It ensures that the leadership plan remains flexible during projects and deals with unpredictable trials effectively [6].

3.3.2 Competency 2: Technical Acumen

Technical skills and technology are ever crucial in SE. The skills in question create better technological solutions for the complicated problems of engineering projects. Technical knowledge becomes important after strategy formulation. Interpreting the project's technical requirements, challenges, and limitations is needed [1]. The genius is in operationalising the strategic plan into concrete technical activities. Innovation means creating a culture of cleverness and continuous improvement within the team. It fosters the identification of new solutions and improvements in processes towards better project results [3].

3.3.3 Competency 3: Communication

Such communication is significant for the entire project, but becomes essential once it is up and running. Effective project management consists of collaborating with members of the team and stakeholders, co-managing issues, and ensuring that the project aligns with the vision and technical specifications [4]. This quality guarantees that the interaction between

such members is productive and sufficient and that communication is at all levels of the project. It will further pivot toward solving an identified problem, which is critical in identifying, understanding, evaluating, and addressing complex issues that may arise while the project is ongoing. Efficient problem-solving brings the smoothest implementation of projects [15].

3.4 Adaptive Leadership Model

The Adaptive Leadership Model is a contemporary leadership approach that acknowledges the rapidly altering environment of SE [7]. It embodies the real essence of leadership: empowering leaders to engage in challenging technical projects skillfully. The crux of this model lies in flexibility, whereby one believes that SE projects are often subject to unexpected changes and a dynamic environment [16]. The leader has to be able to adjust plans and approaches to meet the project's needs at any given time. Hence, continuing learning is threatened by the possible flux of technology and processes in SE. The leaders should continually update themselves with the current trends, innovations, and new avenues for making informed decisions and leading their teams productively [26]. Resilience is essential to recognising failure and obstacles in engineering projects. Leaders should be role models for staff to be resilient enough to overcome issues. These traits encompass all the abilities that enable leaders to navigate teams and projects within the changing environment and excel [27].

These will finally improve the success of projects, especially within the highly complex arena of SE. It indicates that the qualities of the Adaptive Leadership Model influence such factors associated with SE projects, eventually creating adaptive, resilient, and prosperous project results, as shown in Figure 3. The graphic depicts how the Adaptive Leadership Model incorporates adaptability, ongoing education, and a capacity to recover from setbacks. These characteristics impact several SE projects, enhancing team dynamics, well-informed decision-making, efficient problem-solving, and adaptability to swift technological advancements. It visually highlights the changeable nature of adaptive leadership and its positive effect on the success of projects in SE. Under the framework, the hypothesis deduced is:

- **H3**: Adaptive leadership practices positively correlate with completing complex systems engineering projects.

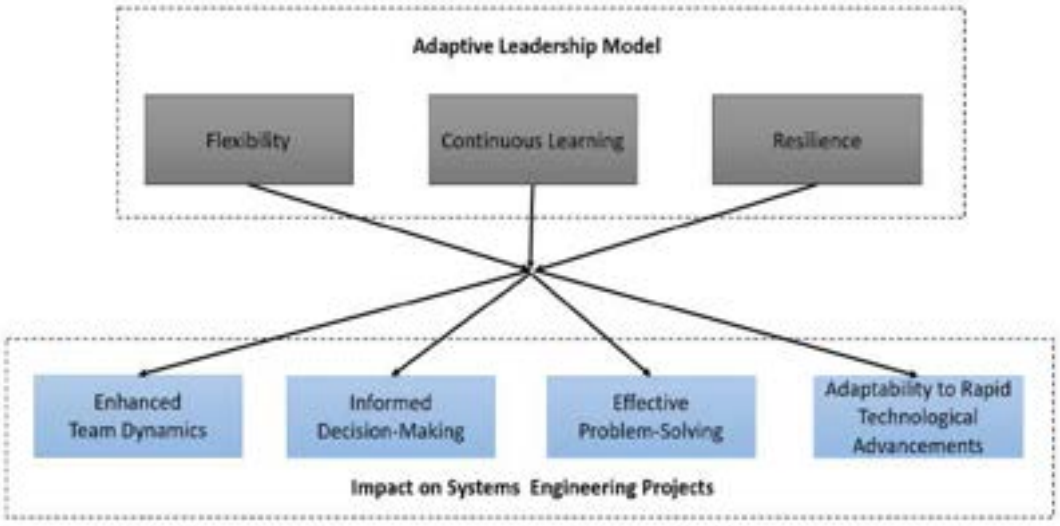

Figure 3: Adaptive Leadership Model Influence on Aspects of Systems Engineering Projects.

3.5 Adaptive Leadership Model Summary

The Integration of Leadership and SE Models integrates leadership theories with SE concepts to make a complete leadership approach for the specific leadership challenges in this arena. It acts as a conduit that connects leadership with technical capabilities. The program for Leadership Competencies in SE's competency framework delineates some essential constructs: strategic thinking, communicative abilities, and technical knowledge, which are vital for effective team and project management to achieve appropriate results in the SE profession. Adaptability, constant learning, and resilience were emphasised in the Adaptive Leadership Model for a systems engineer leader. It points out the dynamic nature of the projects and the demand for a leader to adapt and flourish amid change.

These conceptual models thus provide a backbone for good leadership. Their objective is to equip leaders with the required knowledge, abilities, and attitudes to traverse the complex, compelling, and ever-changing arena of SE. Throughout this research, these frameworks will act as guiding beacons, shedding light on achieving effective leadership in this dynamic and demanding sector. The whole integrated model of these three models is depicted in Figure 4.

4 RESEARCH METHOD

The study used quantitative and qualitative research to understand SE leadership competencies better. Implementing statistical validation and contextual understanding would account for effectively using a leadership model in SE projects. The mixed-method approach allows for a triangulated understanding of how leadership styles affect SE project success [28]. The quantitative side was suited to test specific hypotheses about the effectiveness of the various leadership styles. At the same time, the qualitative aspect would provide depth, context, and insight from practitioners that quantitative data could not reveal.

A structured questionnaire with open-ended and Likert scale questions was formulated and administered to professionals in SE working in project management and technical leadership positions in different areas of engineering. It assessed the perceived importance and application of selected leadership competencies in the conceptual framework and how they relate to project outcomes [29]. Respondents rated emphasis on leadership competencies, frequency of involvement in leadership development, and success of projects in which they were involved. They also rated the effectiveness of leadership models used (for example, adaptive or transformational) in different phases of projects.

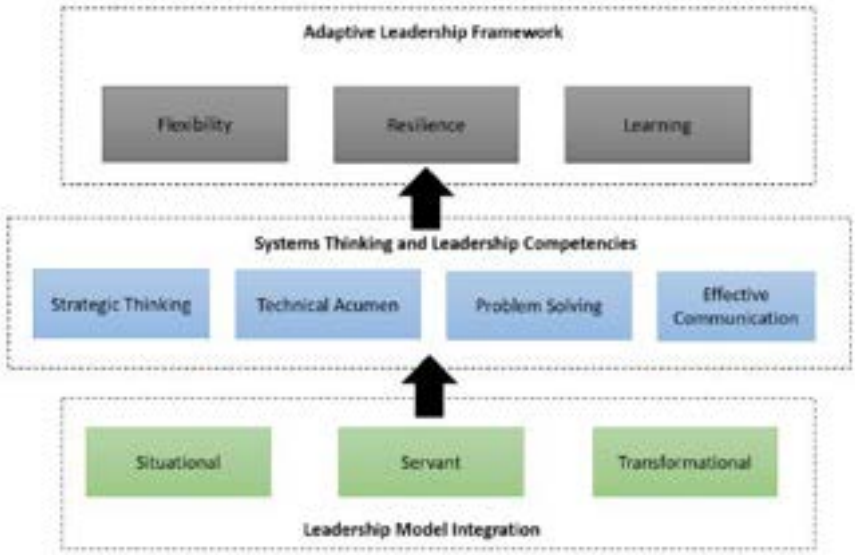

Figure 4: Holistic Integrated Conceptual Model for Leadership in SE.

In total, 30 respondents from different industries, including team leaders, systems engineers, and engineering managers, completed the questionnaire. Quantitative data were analysed using descriptive statistics and Chi-square tests to identify significant relationships (statistical significance) between leadership competencies and project success rates. Each hypothesis was analysed using observed and expected frequency tables to assess correlated statistical significance [30].

Semi-structured interviews were performed with a randomly selected subset of participants (n = 8) to investigate issues related to the practical application of leadership theories and models. Open-ended questions directed them to discuss issues surrounding adaptive leadership, giving their leadership practices and development needs, reasons for success in some areas, and adaptive uses of leadership styles in project phases. The interview transcripts were analysed thematically utilising a coding scheme ruled by the study's leadership constructs. During these analyses, exercises were synthesised, identifying patterns and recurring themes to yield insight into how leadership competencies interface with team dynamics, innovation, and project results [29]. The mixed-method approach yielded some insight; however, the small sample size in the quantitative phase (n=30) limits generalizability. Future research could increase the sample size and contemplate subgroup analyses (e.g., by industry, project type, and organisational maturity) for advanced insights.

5 RESULTS

5.1 Importance of Leadership Integration in Systems Engineering Projects

The study collected replies from 30 participants from May to July 2024, classified according to their positions in SE leadership. Table 1 presents the essential descriptive statistics in a summary format for roles, effectiveness and importance of leadership models. The role distribution is balanced across different leadership levels within SE projects. Most respondents (74%) rated leadership models as moderately or very effective, indicating strong buy-in for leadership integration in this field.

Table 1: Summary of Descriptive Statistics from Survey Responses – Part A

Category	Count	Percentage
Role Distribution		
Team Leader	10	33%
Manager	12	40%
Systems Engineer	8	27%
Effectiveness Leadership Models		
Very Effective	8	27%
Moderately Effective	14	47%
Not Very Effective	5	17%
Not Effective	3	10%
Importance of Leadership Models		
Adaptive Leadership	18	60%
Transformational Leadership	16	53%
Servant Leadership	12	40%
Situational Leadership	10	33%

The data suggests that leadership integration, defined as combining leadership principles with SE practices, is deemed critical for the success of projects. The consensus that leadership integration is important emphasises the need for a robust leadership approach in SE. As a result, adaptive leadership was identified as the most important model, with 60% of

respondents finding it adequate, followed closely by transformational leadership at 53%. Many respondents (40%) still consider servant and situational leadership important. These suggest that different leadership models may be helpful in different project environments or team dynamics. The relatively lower emphasis on situational leadership may indicate that respondents prefer a more dynamic and change-driven leadership style.

5.2 Impact of Leadership Adaptability on Systems Engineering Project Success

As part of the study, participants were asked to rate the extent to which leadership adaptability significantly impacts SE project outcomes. Figure 5 below illustrates the distributions of responses, highlighting how respondents view the importance of adaptability in leadership. The results reveal that a significant majority recognise adaptability as a crucial leadership quality for the success of SE projects. These results emphasise that 70% of the respondents believe adaptability significantly influences project outcomes. This finding aligns with the discussions of the importance of adaptive leadership, as highlighted in Table 1, where 60% of respondents rated adaptive leadership as the most essential leadership model for SE.

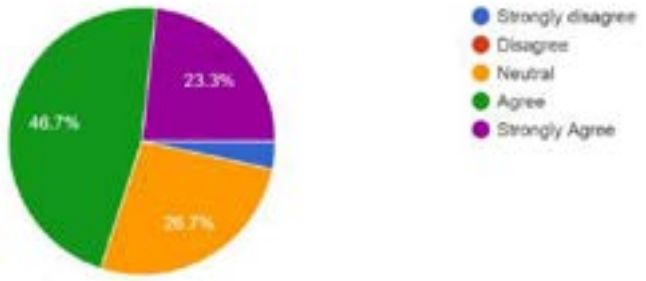

Figure 5: Impact of Adaptability in Leadership on Systems Engineering Project Outcomes.

5.3 Strengths and Weaknesses of Leadership Development Programs

Table 2 shows the respondents' perceived strengths and weaknesses of enhancing leadership development programs, particularly by incorporating soft skills and expanding their scope.

Table 2: Summary of Descriptive Statistics from Survey Responses – Part B

Category	Count	Percentage
Strengths and Weaknesses of Leadership Development Programs		
Perceived Strengths		
Technical Proficiency Emphasis	8	27%
Alignment with Industry Changes	6	20%
Tracking Progress and Updates	4	13%
Perceived Weaknesses		
Limited Scope and Availability	12	40%
Lack of Soft Skills Training	10	33%
Need for Research and Development	7	23%

Respondents identified technical proficiency, alignment with industry changes and tracking progress and updates as key strengths of leadership development programs. This suggests that the programs are well-designed to meet the technical and strategic demands of SE. Furthermore, the most significant weaknesses noted were limited scope and availability (40%) and a lack of soft skills training (33%). This highlights a gap in the focus of leadership programs on developing interpersonal and communication skills, which are critical for effective leadership, especially in managing cross-functional teams. The need for research and

development (23%) suggests that leadership programs may not be sufficiently forward-thinking or innovative in adapting to emerging trends in SE leadership.

5.4 Hypothesis Testing

The Chi-Square test assessed the association between leadership qualities (competencies, systems thinking, adaptive leadership) and project outcomes (success, completion). This test evaluates whether the observed frequencies in each category differ significantly from the expected frequencies under the assumption of no relationship (null hypothesis).

5.4.1 Hypothesis 1

- **H1**: Leaders with elevated degrees of [leadership competency] demonstrate greater effectiveness in overseeing systems engineering projects.

Table 3: H1 Observed Frequency Table

Leadership Competency	Successful	Unsuccessful
High Competency	10	2
Medium Competency	8	4
Low Competency	3	6

Table 4: H1 Expected Frequency Table

Leadership Competency	Successful	Unsuccessful
High Competency	7.64	4.36
Medium Competency	7.64	4.36
Low Competency	5.73	3.27

Chi-Square Calculations Statistic:

- Chi-Square statistic (X^2): 5.63
- p-value: 0.060
- Degrees of Freedom: 2

The Chi-Square test for Hypothesis 1 reveals that the relationship between leadership competency and project success is not statistically significant at the 95% confidence level ($p > 0.05$). While the observed and expected frequencies show some differences in Tables 3 and 4, the p-value of 0.060 is slightly above the 0.05 threshold, meaning the results do not provide strong evidence to confirm a significant association.

5.4.2 Hypothesis 2

- **H2**: Systems engineering projects led by individuals with solid systems thinking skills have higher success rates.

For Hypothesis 2, the relationship between systems thinking and project success is not statistically significant ($p = 0.173$). The observed and expected frequencies (Tables 5 and 6) do not differ significantly, and the p-value is above the 0.05 threshold. The available data suggest that systems thinking has no statistically confirmed impact on project success.

Table 5: H2 Observed Frequency Table

Systems Thinking	Successful	Unsuccessful
High Competency	9	3
Medium Competency	7	5
Low Competency	4	7

Table 6: H2 Expected Frequency Table

Systems Thinking	Successful	Unsuccessful
High Competency	6.86	5.14
Medium Competency	6.86	5.14
Low Competency	6.29	4.71

Chi-Square Calculations Statistic:

- Chi-Square statistic (X^2): 3.51
- p-value: 0.173
- Degrees of Freedom: 2

5.4.3 Hypothesis 3

- **H3**: Adaptive leadership practices positively correlate with completing complex systems engineering projects.

Table 7: H3 Observed Frequency Table

Adaptive Leadership	Successful	Unsuccessful
High Competency	12	3
Medium Competency	8	5
Low Competency	4	7

Table 8: H3 Expected Frequency Table

Adaptive Leadership	Successful	Unsuccessful
High Competency	9.23	5.77
Medium Competency	8.00	5.00
Low Competency	6.77	4.23

Chi-Square Calculations Statistic:

- Chi-Square statistic (X^2): 5.11
- p-value: 0.078
- Degrees of Freedom: 2

For Hypothesis 3, the relationship between adaptive leadership and project completion is also not statistically significant (p =0.078). Although a trend (Tables 6 and 7) shows some association between adaptive leadership and successful project completion, the p-value is slightly above the 0.05 threshold, meaning the results are inconclusive in confirming a significant relationship. However, the qualitative responses (Figure 11) strongly support the idea that adaptive.

5.5 Leadership Competencies in Systems Engineering

Effective communication emerged as the most critical competency, underscoring its significance in managing complex projects, as seen in Table 9. The survey highlighted the essential leadership competencies required in SE:

- **Effective Communication**: This was identified as the most crucial competency, acting as the linchpin for aligning interdisciplinary teams, exchanging technical information, and clarifying project objectives.
- **Strategic Thinking**: Second, most respondents emphasised the importance of strategic thinking in providing guidance and direction, particularly in complex project environments.

- **Technical Acumen**: While necessary, technical acumen was considered less critical than communication and strategic thinking, as effective communication can often bridge technical gaps.

Table 9: Descriptive Statistics – Leadership Competencies in Systems Engineering

Competence Importance	Count	Percentage
Effective Communication	14	47%
Strategic Thinking	10	33%
Technical Acumen	6	20%

5.6 Discussion

The findings demonstrated the importance of leadership integration in improving the success of an SE project. According to the respondents, complex project management is more successful for leaders who embrace systems thinking and can successfully combine managerial and technical elements. As technical leaders, systems engineers are strategic integrators who ensure that every aspect of a project aligns with the larger goals. This identified leadership roles and duties, especially when managing interdisciplinary teams. The findings show that systems engineers' integrative responsibilities go beyond simple technical supervision; they also need to control stakeholder expectations and ensure that various subsystems function as a cohesive unit.

It was discovered that one of the main factors influencing project success was the leaders' flexibility. The volatility and complexity that come with SE projects were considerably better handled by leaders who could modify their management approach according to the stage of the project. This was especially true for those who used transformational and adaptive leadership styles. This responds to research question two, which aimed to identify the abilities and proficiencies that distinguish successful leaders in SE. Leaders who exhibited adaptive leadership were better able to handle uncertainty and transition between technical problem-solving and team management. This outcome also supports research objective two, which states that technical knowledge and flexibility are essential leadership qualities in SE.

The data also identified significant shortcomings in the current leadership development programs, especially their incapacity to equip leaders for the particular difficulties presented by SE. Most respondents believed that current programs do not sufficiently address the technical integration and systems-thinking competencies needed in this profession and place an undue emphasis on general management skills. This result responds to research question three, which focused on the shortcomings and difficulties in systems engineers' leadership growth. Respondents emphasised that managing complex, interdisciplinary teams and navigating the ever-evolving technology landscape that systems engineers must contend with are rarely covered in leadership schools. This supports the idea that project managers with greater systems thinking skills are more successful. The results support a more specialised approach to leadership development in SE and validate research objective three to identify gaps in present leadership training.

The quantitative analysis's capacity to extrapolate the results to a larger population was somewhat constrained by the small sample size of 30 respondents. The respondents' detailed experiences and difficulties gave context and an explanation for the quantitative tendencies, which is where the qualitative analysis came in handy. Future research has a clear chance of expanding the sample size to support the quantitative analysis and enable more reliable statistical testing. Exploring subgroup analyses, such as variations in leadership effectiveness by industry or project type, might also be feasible with a larger sample.

In this study, the application of a mixed-method approach proved crucial. The qualitative data enhanced the comprehension of these findings by providing in-depth descriptions of how leadership issues manifest in real-world situations, and the quantitative data offered a glimpse of leadership competencies and project success. Given the limited sample size, this method made it possible to analyse the data more nuancedly than feasible with only quantitative data. By combining the two approaches, the study fully captured the range and complexity of SE leadership experiences.

6 CONCLUSION

The study's findings highlighted the role of leadership in SE, highlighting some key skills such as effective communication, strategic thinking, and flexible leadership. These attributes are strongly linked to project success, confirming leadership's critical and helpful function in guaranteeing project efficacy. Addressing the ever-changing issues that SE projects frequently face requires adaptive leadership. This approach enables leaders to effectively lead their teams through uncertainty and handle shifting circumstances. At the same time, systems thinking has given leaders a thorough framework for handling the intricacies of SE projects, allowing them to maintain a close eye on interconnected components.

According to the study's evidence, successful SE directors must combine technical expertise with advanced leadership characteristics to effectively manage their projects' interdisciplinary and frequently unpredictable nature. SE leaders can accomplish project objectives while adapting to limitations and changing demands by incorporating adaptive leadership styles and encouraging systems thinking.

For future research, the long-term impacts of leadership abilities on project outcomes over lengthy periods should be investigated further. Future research will be more credible and applicable if the sample size is increased and a greater variety of project scenarios are included.

PROJECT COMPLEXITY, PROJECT MANAGEMENT MATURITY AND PROJECT SUCCESS IN MINING ORGANISATIONS

K. Kotsane[1] and S. Pretorius[2*]

[1,2]Department of Engineering and Technology Management
University of Pretoria, South Africa

ABSTRACT

There is a common belief that higher levels of project management maturity lead to successful projects. This study focused on the mining industry. It examined the relationships between project complexity, project management maturity (PMM), and perceived project success. Based on survey responses from 40 project professionals, the results showed that PMM does not significantly moderate the effect of project complexity on perceived success. Three hypotheses were tested, and all three were rejected. A weak positive correlation between PMM and perceived success was found, but it was not statistically significant. The findings suggest that other factors may have a stronger influence on perceived project success and should be explored in future research.

Keywords: project management, project complexity, project management maturity, project success, mining industry

1 INTRODUCTION

Project Management Maturity (PMM) has been investigated across different industries because of its perceived potential to enhance project success rates [1]. Project management maturity models (PMMMs) provide a structured approach for measuring an organisation's PMM [2]. In emerging economies, where the mining industry significantly supports economic development, effective project management is necessary to manage challenges such as geological complexity, regulatory requirements, and sociopolitical influences [3]. This study investigates the relationship between project complexity, PMM, and project success in mining organisations, where successful project execution is crucial for organisational growth and sustainability [4].

In the mining sector, project complexity involves technical challenges, safety risks, environmental concerns, and market volatility [5], [6], whereas PMM reflects an organisation's capability to manage and execute projects efficiently and effectively [1]. PMM can influence project success by promoting best practices and standardised procedures, which are particularly important in the mining sector, where projects form the core of business operations [7]. Successful mining projects should achieve strategic goals, ensure environmental sustainability, and uphold social responsibility [8].

This study aims to address a gap in the literature by examining whether PMM helps manage project complexity to improve perceived project success in the mining industry. Given the mining sector's complexity, inherent unpredictability and the increasing focus on sustainable project delivery, understanding the role of PMM remains important [8], [9], [10].

2 LITERATURE REVIEW

2.1 Project complexity

Project complexity is an important and developing concept in project management, highlighting how traditional models often struggle to deal with the challenges and uncertainties of modern projects [11]). Some scholars argue that the focus on complexity is driven by trends in project management [12]. In contrast, others emphasise the need for a more practical understanding of complexity in dynamic and uncertain situations [13].

Another significant aspect in comprehending project complexity is the distinction between "complex" and "difficult", with "complex" often referring to something with numerous interconnected elements and intrinsic complexity [14], [15]. However, despite much debate, a unified definition of "project complexity" remains elusive [16] [17]. Complex projects are commonly acknowledged to be more than merely large or complicated ones, while there is no universal understanding of what defines them [18].

2.2 Project management maturity (PMM)

PMM refers to the incremental improvement of an organisation's project management skills. It reflects the current level of an organisation's ability to apply project management practices to achieve more successful outcomes consistently [19]. PMM is measured by PMMMs, and most PMMMs originated from the Capability Maturity Model Integration (CMMI) framework, which consists of five maturity levels (See figure 1). Level 1 is the lowest level of PMM, characterised by unstructured and inconsistent practices, while Level 5 is the highest level, defined by well-established and consistently applied methodologies. The five levels are [19], [20]:

- *Level 1:* Initial (Processes are spontaneous, *ad hoc* and strongly reliant on individual effort)
- *Level 2:* Managed: (Adds fundamental but inconsistent project management methods)

- *Level 3:* Defined (Standardises these procedures throughout the organisation, resulting in more predictable outcomes)
- *Level 4:* Quantitatively managed (Uses quantitative indicators to assess performance, integrated project management processes)
- *Level 5:* Optimising: (prioritise continuous optimisation, flexible, incorporating innovation and best practices to achieve project management excellence)

This organised progression emphasises the necessity of PMM in managing the rising complexity of modern projects, providing organisations with a deliberate roadmap for developing their PMM [19].

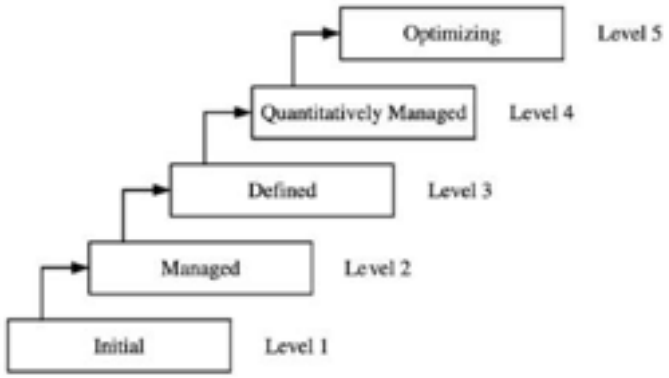

Figure 1: Five Organisational PMM levels [19]

2.3 Linking PMM to project complexity

Project complexity makes it difficult to understand, anticipate, and regulate project dynamics, which is caused by variables such as project scale and the interconnections of different project elements [17]. Several studies have found that higher levels of PMM can improve the management of complex projects [2], [17], [20], [21].

PMMMs are increasingly being used as a strategic tool to measure PMM. They offer a systematic framework for enhancing organisational project management capabilities [2]. The adoption of standardised processes is an essential aspect of PMM since it improves the management of complex projects by providing teams with clear approaches [22]. Additionally, a higher level of PMM implies better risk management, which allows organisations to identify and reduce risks associated with project interdependencies [21]. Higher levels of PMM could improve knowledge management and continuous learning, helping to reduce uncertainty and support informed decision-making in complex projects [23]. Maturity in project management enhances resource allocation, scheduling, and stakeholder communication, providing greater control over project processes [24]. It can also support a culture of ongoing improvement, allowing organisations to respond effectively to shifting project conditions [25]. These capabilities reflect the drivers of project complexity identified by Moza *et al*. [26], showing how higher PMM levels could contribute to more effective management of complex projects.

2.4 Project success

Traditional measures of organisational performance, which primarily rely on financial indicators, are increasingly seen as inadequate for evaluating long-term effectiveness in today's complex and rapidly evolving markets [27], [28]. In response, contemporary frameworks that offer a holistic picture of performance have been established, such as

Intellectual Capital and The Balanced Scorecard [29], [40]. However, there is no clear agreement on how to consistently measure project performance in project management, leading to scattered and incomplete indicators [31]. Operational success, which includes fulfilling deadlines, budgets, and specifications, is frequently given top priority by project managers [32]. However, this strategy might overlook important long-term effects, customer satisfaction, and larger corporate goals [33].

Recent studies recommend a multidimensional approach to project success that includes operational performance, customer satisfaction, and business outcomes [21], [34]. Measuring project success is difficult because different stakeholders, such as clients, developers, and end-users, often use other criteria to define success [35]. In addition, projects that are managed to support long-term company goals can improve overall performance, but these are less common because many projects focus on short-term results [35].

Scholars like Ingle *et al*. [32] suggest multidimensional success criteria, such as project efficiency, customer impact, business success, and future preparedness, to provide a more comprehensive evaluation technique. Technological uncertainty affects success assessment, with different project types (low-tech to ultra-high tech) requiring specialised methodologies [36], [37]. Recent studies support these ideas and encourage project managers to become strategic leaders who create value for the company beyond just meeting operational goals [1], [38].

This study evaluated the project's results as successful, challenged, or failed based on how interviewees perceived them. A successful project was completed on time and within budget while meeting all agreed-upon scope and quality requirements. A challenged project was one that was completed, but delivered late or over budget, or in which not all scope and quality objectives were met. Finally, the project was considered a failure if it was never completed or did not meet the project scope or quality requirements agreed upon by the customer and project manager [21].

2.5 Linking perceived project success with project complexity

Project success is a multidimensional concept that is closely related to project complexity, which can range from simple activities to very complex, innovative projects [33]. Understanding this link is important because project complexity has a significant impact on planning, execution, and outcomes [39]. Project complexity includes technological, organisational, and environmental elements that change over the project's lifecycle, making it difficult to manage and measure successfully [40]. The increase in the number of complex construction projects has resulted in more budget overruns and delays [41]. The classic "iron triangle" of time, cost, and quality is frequently prioritised, but the measure of the success of a project should also include stakeholder satisfaction and larger organisational goals [42], [43].

Several studies have shown a negative correlation between project complexity and construction project success [9]. Given the dynamic nature of complexity, particularly in mining projects, it is important to understand how project complexity develops and affects project success over time [9]. The demand for advanced project management approaches to handle complex projects continues to grow as organisations operate in increasingly dynamic business contexts [44].

2.6 The Influence of PMM on perceived project success

There is a lack of agreement among scholars on whether PMM significantly influences project success. Numerous studies have found no evident correlation between PMM and project success [45], [46], [47], [48], [49]. However, certain researchers argue that there is a relationship between PMM and project success [51], [52], [53]. They say that organisations

operating at the lowest level of PMM are more likely to experience project failure. In contrast, higher maturity levels are associated with a greater likelihood of project success [50], [54], [55], [56].

The relationship between PMM and perceived project success remains unclear. Some studies suggest a positive link, while others find no connection. Findings continue to differ, and no shared conclusion has been reached.

3 RESEARCH HYPOTHESES AND CONCEPTUAL MODEL

This study tested the following hypotheses, each supported by the literature cited beneath the respective hypothesis:

H1: PMM positively moderates the relationship between project complexity and perceived project success.

Prior research indicates that increased project management maturity is associated with more effective management of complex projects [2], [17], [20], [21].

H2: Project complexity significantly negatively impacts perceived project success.

A study by Hartono et al [9] showed a negative correlation between project complexity and construction project success.

H3: There is a significant positive relationship between PMM and perceived project success.

Several authors agree that higher levels of maturity are linked to an increased probability of achieving project success [50], [54], [55], [56].

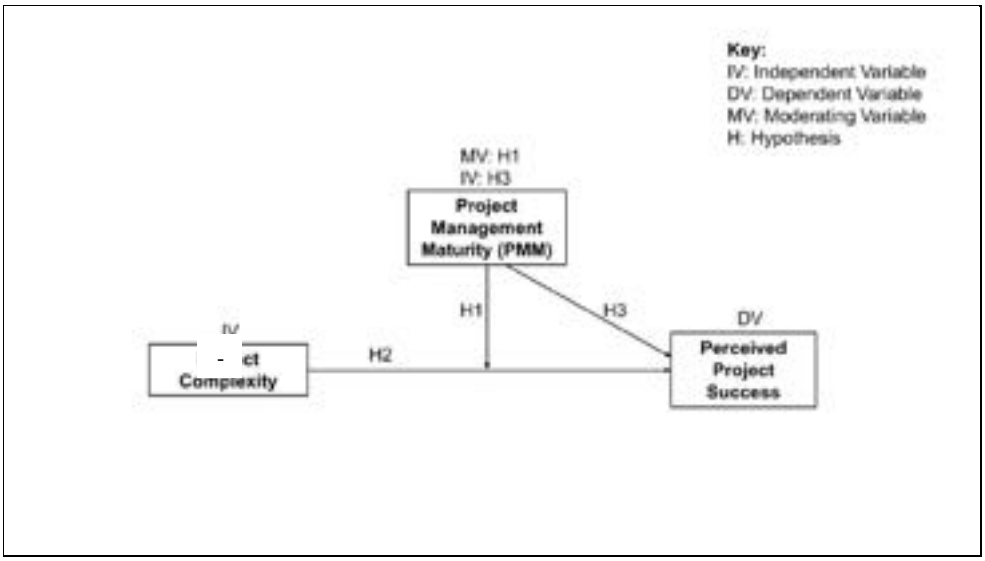

Figure 2: Conceptual Model

The three hypotheses informed the development of the conceptual model shown in Figure 2.

4 RESEARCH METHODOLOGY

A quantitative approach was used to examine the relationship between project complexity, PMM, and perceived project success in the mining industry. A structured questionnaire was developed based on the study's research questions and hypotheses, informed by the theoretical foundations and empirical findings discussed in Section 2. Project success was self-defined by respondents to capture context-specific interpretations, however, definitions of project success and PMM levels were provided within the questionnaire to ensure a shared understanding of the constructs.

The questionnaire was distributed through the Qualtrics XM Platform™ using purposive sampling. This sampling technique was chosen to ensure that respondents with specific expertise and experience relevant to the research objectives were chosen, thereby enhancing the relevance and quality of the collected data.

Responses were obtained from 40 project professionals in the South African mining industry. It included project managers, team leaders, and executives, based on their involvement in projects. Each respondent was requested to report on the projects that they were working on or had worked on in the recent past, as relevant to the study's scope. This approach enabled the collection of data on multiple projects from a single respondent where applicable, thereby providing a broader dataset while maintaining respondent-level context. In total, the respondents reported on 161 projects. Allowing respondents to report on more than one project did not introduce bias, as each project was treated as a separate observational unit in the analysis.

The Qualtrics XM Platform™ was used to collect and process survey responses, reducing the need for human intervention and minimising potential bias. Data preparation included cleaning and coding in SPSS, followed by descriptive statistics to summarise central tendencies and variability in the three variables. Hypothesis testing assessed the statistical significance of the observed relationships.

A regression analysis was conducted using Andrew and Hayes' PROCESS macro to determine how PMM moderates the association between project complexity and perceived success. This study investigated both direct and interaction effects to see whether PMM influences the link between complexity and perceived success [57], [58]. Moderation analysis emphasised PMM's importance in improving project outcomes under increased complexity.

Implementing metrics such as Cronbach's alpha for internal consistency, component analysis for construct validity, and cross-validation techniques ensured the reliability and validity of the survey results. These methods were vital for obtaining reliable and dependable findings. The research was approved by the Ethics Committee of the Faculty of Engineering, the Built Environment and Information Technology at the University of Pretoria.

5 RESULTS AND DISCUSSION

The Qualtrics survey results examine how PMM moderates the relationship between project complexity and perceived project success in the mining sector. This section analyses the responses from 40 participants, all experienced project professionals within the mining industry. Respondents represent a range of operations, including hard rock and soft rock mining, as well as mining consultancy. Each participant has at least two years' experience managing mining-related projects, offering substantial domain expertise and practical insight into project management dynamics in this context.

5.1 Reliability Analysis

Cronbach's alpha is a statistical measure that evaluates the internal consistency of a survey or test items, commonly used to determine its reliability. It assesses the degree of correlation between items in a questionnaire, thereby indicating the reliability or consistency of the instrument used for collecting data. In this study, Cronbach's alpha was used to assess the reliability of the survey items measuring the constructs of Project Complexity, Project Management Maturity, and Project Success.

Table 1: Descriptive statistics

*Sr.	Variable name	Cronbach's Alpha	**N of Items
1	Project Complexity	0.770	3
2	Project Management Maturity	0.755	3
3	Project Success	0.791	2

** Sr. – Serial number of the variables listed*

*** N – The number of observations*

Overall, the Cronbach's alpha values for all three variables (refer to Table 1), project complexity (0.770), PMM (0.755), and project success (0.791), show good to very strong internal consistency. These results confirm that the survey items employed in the study are reliable and effectively measure their respective constructs. The data produced from these items can be regarded as dependable, providing a firm platform for subsequent statistical analysis and interpretation in the study.

5.2 Descriptive analysis

This section investigates the descriptive statistics for the critical variables in the study. Descriptive statistics describe the key properties of the data, including measures of central tendency (mean), variability (standard deviation), and the shape of the distribution (skewness and kurtosis). By evaluating these statistics, a better grasp of the overall patterns and distributions of the variables is critical for interpreting the data and sets the basis for more sophisticated analysis. Tables 2 and 3 below present the findings from examining the data.

Table 2: Descriptive statistics

Variable	Mean	Std. Deviation	Skewness	Kurtosis
Project Complexity	3.29	0.59527	-0.627	-0.601
PMM	3.65	1.02657	-0.278	-0.994
Project Success %	58.47	27.310	-0.351	-0.111

N=40

5.2.1 Project complexity

The average project complexity score is 3.29 on a scale of 1 to 4, indicating that the sampled mining projects are generally complex. The standard deviation of 0.60 indicates that complexity scores are rated similarly across the sample. A skewness of -0.627 indicates a slight negative skew, suggesting that some projects are viewed as less complex. A kurtosis of -0.601 implies a flatter distribution with fewer outliers (See Table 2). These findings indicate that mining companies operate on rather challenging projects, with some variation in complexity levels.

5.2.2 Project management maturity (PMM)

The mean PMM score on a scale of 1 to 5 is 3.65, indicating that the participating organisations have a relatively high level of PMM. The larger standard deviation of 1.03 implies significant diversity in PMM levels among organisations, emphasising inequalities in project management approaches. The skewness of -0.278 reveals that most organisations cluster around higher maturity levels, whilst the kurtosis of -0.994 indicates a diversified distribution with fewer outliers (See Table 2). These findings show that, while many mining companies have well-established project management techniques, there is still significant room for standardisation and development.

Table 3: Project complexity, PMM and perceived project success

Project Complexity				
Level	**Frequency**	**Percent**	**Valid Percent**	**Cumulative Percent**
1. 1-2	2	5.0	5.0	5.0
2. 1-3	12	30.0	30.0	35.0
3. 1-4	26	65.0	65.0	100
Total	**40**	**100**	**100**	
PMM				
PMM Level	**Frequency**	**Percent**	**Valid Percent**	**Cumulative Percent**
1	0	0	0	0
2	7	17.5	17.5	17.5
3	9	22.5	22.5	40.0
4	15	37.5	37.5	77.5
5	9	22.5	22.5	100
Total	**40**	**100**	**100**	
Perceived project success				
	Frequency	**Percent**	**Valid Percent**	**Cumulative Percent**
0 - 20%	4	10.0	10.0	10.0
21 - 40%	5	12.5	12.5	22.5
41 - 60%	13	32.5	32.5	55.0
61 - 80%	12	30.5	30.0	85.0
81 - 100%	6	15.0	15.0	100
Total	**40**	**100**	**100**	

5.2.3 Perceived project success

The average project success rate is 58.47%, with a standard deviation of 27.31%, demonstrating significant diversity in project results. The skewness of -0.351 and kurtosis of -0.111 indicate a roughly symmetric distribution of perceived success rates, with no substantial skewness or severe outliers (See Table 2). Of the 161 projects sampled from 40 survey respondents, 29% were challenging, 13% failed, and 58% were considered successful (Table 4). This distribution highlights the mining sector's different outcomes, with more than half of projects meeting their objectives and a significant minority facing major obstacles or failing to meet expectations.

Table 4: Sampled projects

	Number of Projects	Percentage
Successful Projects	94	58%
Challenged Projects	46	29%
Failed Projects	21	13%
Total Sampled Projects	161	

5.2.4 Overall interpretation

The descriptive statistics show that mining projects are generally difficult, yet well-managed. However, the difference in PMM and perceived project success rates indicates discrepancies in how organisations manage complexity and fulfil project objectives. The balanced distribution of project complexity and the high average PMM levels show that mining organisations are well-equipped to manage moderately difficult projects. Yet, variations in maturity levels highlight areas for future improvement. Furthermore, the success rate dispersion emphasises the need for better project management methods to improve overall project outcomes.

These descriptive insights are important for understanding the operational dynamics of the mining industry and serve as the foundation for more advanced analyses, such as correlation and regression, to investigate the relationships between project complexity, PMM, and perceived project success.

5.3 Regression analysis

5.3.1 Linear regression analysis

This study used linear regression analysis to investigate the links between project complexity, PMM, and perceived project success in the mining industry. The study found a slight positive correlation ($R^2 = 0.035$, $p = 0.246$) between project complexity and perceived project success. However, complexity only explains 3.5% of the variance and is not a meaningful predictor [58]. PMM had a moderate positive link with perceived project success ($R^2 = 0.074$, $p = 0.089$), indicating that higher PMM levels may improve project outcomes. The relationship did not achieve statistical significance. The unstandardised beta coefficients showed that higher project complexity and PMM are linked to slight increases in perceived project success, with a weak effect from complexity and a stronger impact from PMM [58]. These findings suggest that while PMM can improve perceived project performance, project complexity alone does not substantially impact perceived success. This shows the importance of considering other factors, like team dynamics and resource use, to better understand what affects project success in the mining industry. The nearly significant p-value for PMM suggests that the link might become statistically significant with more data or more complete information.

5.3.2 Regression analysis (Andrew and Hayes)

This analysis used the Andrew and Hayes PROCESS macro model to investigate the moderating effect of PMM on the relationship between project complexity and perceived project success [58]. The interaction term's coefficient (-0.1451) suggests that as PMM increases, the relationship between project complexity and perceived project success weakens slightly. However, with a p-value of 0.6399 and a t-value of -0.4718, the interaction effect was found to be statistically insignificant. The confidence interval (-0.7688 to 0.4786) includes zero,

indicating that PMM does not have a meaningful moderating effect on the relationship. These findings suggest that, contrary to expectations, PMM does not significantly strengthen the link between project complexity and perceived project success. This challenges the idea that PMM acts as a moderator in managing complexity to improve outcomes. Other variables may play a more important role in influencing perceived success.

5.3.3 Hypothesis testing

Hypothesis testing is a basic statistical method used to make conclusions about a population based on sample data [58]. The process usually involves creating an alternative hypothesis (H1), which shows what the researcher expects, and a null hypothesis (H0), which assumes no effect or difference. Researchers can use statistical tests such as regression analysis, F-tests, and t-tests to evaluate the likelihood that the observed data will occur under the null hypothesis [58]. This approach allows for objective decision-making on whether to accept or reject hypotheses, ultimately contributing to the validation or creation of theoretical models in various study areas [58].

The following are the proposed research hypotheses and their related null hypotheses:

H1: PMM positively moderates the relationship between project complexity and perceived project success.

- **$H0_1$ (Null):** PMM does not positively moderate the relationship between project complexity and perceived project success.

H2: Project complexity has a significant negative impact on perceived project success.

- **$H0_2$ (Null):** Project complexity has no significant impact on perceived project success.

H3: There is a significant positive relationship between PMM and perceived project success.

- **$H0_3$ (Null):** There is no significant relationship between PMM and perceived project success.

By considering important statistical statistics such as the Coefficient of Determination (R^2), F-statistic (F), beta coefficient, t-test, and p-value, inferences regarding the validity of the proposed hypothesis can be drawn (See Table 5).

Table 5: Hypothesis testing

	R^2	F	B (Coeff)	t test	p	Status
H1	0.0985	1.3112	-0.1451	-0.4718	0.6399	Rejected
H2	0.035	1.387	0.371	1.178	0.246	Rejected
H3	0.074	3.056	0.313	1.748	0.089	Rejected

The study found no statistically significant results for the three tested hypotheses. The R^2 values less than 0.7 suggest that other factors might influence the dependent variable that the model is not capturing (See Table 5).

The interaction between project complexity and PMM on perceived project success was not significant, indicated by a high p-value (>0.05). H1 was rejected, and the null hypothesis ($H0_1$) was accepted. PMM did not show a meaningful moderating effect on the relationship. Higher PMM levels did not lead to better perceived outcomes in complex projects within this sample.

The regression analysis showed that project complexity did not significantly affect perceived project success. The p-value was not significant (>0.05). The null hypothesis ($H0_2$) was accepted, and H2 was rejected. A positive beta coefficient was found, suggesting a weak positive link, though not statistically meaningful. This goes against the view that more complex projects usually face more problems, which leads to lower success rates. The

difference between this result and earlier studies suggests that other factors may influence the link between complexity and perceived success in mining projects.

The study showed a positive link between PMM and perceived project success, but the p-value was slightly above the standard level for statistical significance (0.05). H3 was rejected, and the null hypothesis ($H0_3$) was accepted. This means the results suggest a possible link, but the data is not strong enough to confirm it in this study.

6 CONCLUSIONS AND RECOMMENDATIONS FOR FUTURE RESEARCH

The rejection of all three hypotheses shows that the tested factors may not fully explain perceived project success. The results were unexpected, but still show that more research is needed. Other factors, not included in this study, may have a more substantial effect, or the links between them may be more complex. The findings show the need to better understand what leads to project success in mining. The results challenge some common ideas about complexity and maturity. They also suggest that well-known models may not work the same in a complex and fast-changing industry like mining.

Limitations of the study include a sample size that may have been too small to detect subtle relationships among the tested variables. Data was based on perceptions, which may not fully reflect actual project performance or outcomes. Limiting the scope to a specific sector reduced the generalisability of the results to other industries or contexts. The complexity and dynamic nature of the mining sector may have resulted in some relevant industry-specific influences not being captured.

Recommendations for future research are:

Broader Research Scope: Future studies should include larger and more varied samples to improve the strength and relevance of the results. A bigger sample can help show clearer patterns and give a better understanding of how project complexity and PMM affect project success.

Explore More Variables: Project complexity and PMM alone may not fully explain project success. Other factors like team dynamics, resource use, company culture, and external conditions could also play an important role. How these factors interact with complexity and PMM might help explain project outcomes more clearly.

Context-Specific Factors: Future studies should consider the unique nature of the mining industry. Challenges in mining may affect project outcomes in ways that differ from other sectors. These specific factors can lead to more valuable insights and practical advice.

Longitudinal Studies: Future research could track projects over time to better understand how project complexity and PMM influence success at different stages of the project lifecycle. This may reveal time-based patterns that are not visible in cross-sectional data.

In conclusion, although the study did not find significant results on how project complexity and PMM affect perceived project success, it highlights important questions that deserve further attention. The limited sample size may have impacted the findings. These results offer a starting point for rethinking common assumptions about the role of complexity and maturity in project performance.

The limitations of the study are:

- The sample size may have been too small to detect subtle or complex relationships among the tested variables.
- The data was based on perceptions, which may not fully reflect actual project performance or outcomes.

- The study was limited to a specific sector, reducing the generalisability of the results to other industries or contexts.
- The mining sector is complex and dynamic, and the study may not have accounted for all relevant industry-specific influences.

ABSTRACT

The advancement of conventional metal casting has given Rapid Sand Casting (RSC) increasing recognition. RSC involves rapidly prototyping sand moulds and cores through binder jetting for metal casting. This process has successfully minimized many challenges encountered in traditional methods of producing sand moulds and cores. However, RSC has not yet been widely adopted for manufacturing high-tech products in industries such as biomedical or aerospace. Therefore, assessing the capacity, feasibility, consistency, efficiency, and reliability of RSC products for high-tech applications is essential. Statistical analyses, including descriptive methods (mean, standard deviation) and inferential methods (ANOVA), are employed to examine the variability of the mechanical properties of the parts, including strength, dimensional accuracy, and hardness. Understanding the variability of Additive Manufacturing sand moulds can lead to improved process control, enhanced product quality, and broader adoption in high-tech industries.

Keywords: Binder Jetting, Rapid Sand Casting, and Statistical Analyses

1 INTRODUCTION

Additive manufacturing (AM) has emerged as a monumental development in modern industry, transforming how parts are designed and manufactured. As a foundation of the Fourth Industrial Revolution, AM builds three-dimensional objects layer by layer, providing incomparable design freedom and flexibility [1, 2]. Firstly, in the early 1990s, this technique was regarded as Rapid Prototyping (RP); this technology allowed manufacturers to create prototypes directly from CAD data, consequently minimizing the production routes and speeding product development [3]. Presently, AM is hugely applied across diverse areas, such as aerospace, construction, automotive, and biomedical engineering [2, 4].

One AM technique that has received recognition is Binder Jetting, which develops sand moulds and cores by selectively depositing a binder onto a sand bed, layer by layer. This technique has opened the route for Rapid Sand Casting (RSC), a modernized method to traditional sand casting [2-4]. RSC minimizes some of the inadequacies related to conventional methods, like time-intensive pattern-making, extensive material usage, lengthy mould preparation times, and high labour costs, making it an attractive option for industries prioritizing speed and cost-effectiveness [5]. In spite of these advantages, RSC is yet to attain widespread adoption in high-tech industries, including biomedical and aerospace sectors [3]. Since, these sectors require exceptionally high standards in aspect of dimensional accuracy, mechanical strength, and overall reliability, factors that remain difficult for RSC to consistently meet [6, 7]. One of the vital challenges surrounding RSC is the lack of qualification of the mechanical properties of the produced parts, such as strength, hardness, and geometric precision, in order to determine their consistency, dependability, reliability, and variability [8]. In high-performance applications, even slight inconsistencies can immensely affect product safety and reliability [2, 8].

Previous works on binder jetting have looked closely at how printing parameters and post-processing steps can be fine-tuned to improve the quality of the final parts. For example, Lores et al. (2019) thoroughly review the materials and process aspects of binder jetting, underscoring its strong potential for metal additive manufacturing [5]. Building on this, Huber et al. (2021) studied how changes in sintering temperature and hold time influence the densification, mechanical strength, and microstructure of binder jet 3D printed 17–4 PH stainless steel, offering practical insights that help optimize the process for better performance [9]. Also, several studies have delved into the optimization and performance of binder jetting to ensure quality and high performance across different materials and applications [2, 10].

Despite these innovative works, there remains a gap in this field to completely harness the RSC potential, where a thorough examination of its efficiency to offer consistent, high-quality parts is paramount. An important part of this evaluation involves statistical analysis of data obtained from RSC-manufactured parts, which gives insights into the variability of mechanical properties and their overall performance. Descriptive statistical methods, including mean and standard deviation, would help establish a foundational understanding of property distribution and consistency. Also, inferential statistical methods, like Analysis of Variance (ANOVA), ensure a deep study of variations across production batches. These analytical tools are vital in recognizing critical process parameters that impact mechanical performance, allowing for refinements that improve product quality and process stability [11].

Furthermore, managing and understanding variability in AM-based sand moulds is integral to ensuring reproducibility and reliability. By methodically addressing these complications, RSC has the capability as one of the techniques to emerge into a viable and hugely accepted solution for manufacturing high-precision components. As industries search to enhance production efficiency without compromising quality, refining RSC procedures becomes

increasingly important. Therefore, this study aims to contribute valuable insights into the feasibility, efficiency, and reliability of RSC, offering a pathway toward broader adoption in advanced manufacturing sectors. To the best of my knowledge, no prior work has been carried out to determine the qualification of the parts produced from binder jetting. Moreover, there remains a lack of sufficient data on how mold orientation in binder jetting affects the integrity and final properties of cast components. Hence, the findings of this research will play a crucial role in leapfrogging the knowledge base surrounding RSC and its application in high-tech industries. By identifying key factors influencing mechanical performance and establishing effective process control measures, this study seeks to bridge the gap between RSC's efficiency and its practical implementation in demanding environments. Through incessant research and optimization, RSC could eventually redefine how precision parts are produced, leading to more effective, sustainable, and scalable production solutions.

2 METHODOLOGY

2.1 Mould and Core Production

Fifteen sand moulds were manufactured using Binder Jetting Additive Manufacturing technology by the Voxeljet VX1000 system. Each mould comprises a core and a drag, making a total of 15 cores and 15 drags. The moulds have a design with dimensions specified in Figure 1. With silica sand combined with a furan-based binder, the core and drag designs were digitally designed and printed. This procedure ensured precise, smooth surfaces and shapes, ensuring the moulds are well-designed for casting aluminium alloy components. Table 1 shows the processing parameters consistently applied to produce moulds across various orientations. Furthermore, the workflow from the fabrication process to data interpretation and analysis is depicted in Figure 2.

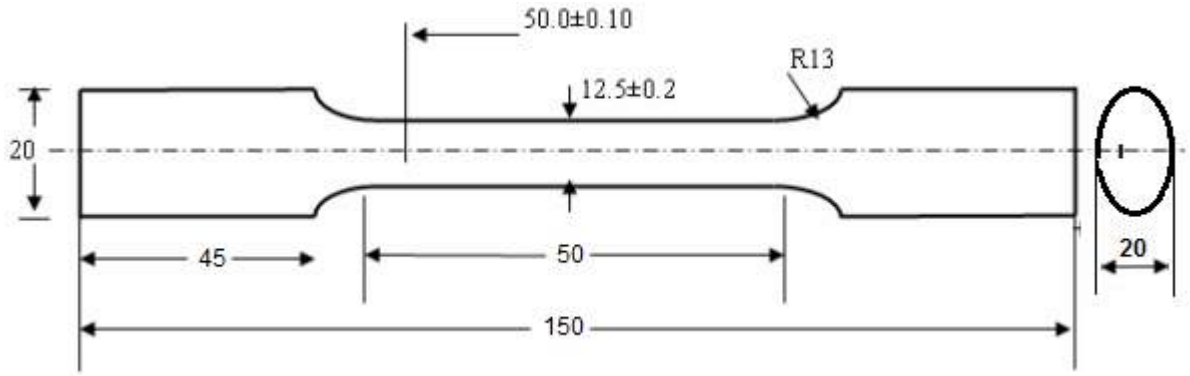

Figure 1: The dimensions of the specimen cast from the moulds

Table 1: Printing parameters for the mould printing

Parameter	Typical Value
Layer Thickness	0.30 mm
Binder Saturation	70%
Printhead Speed	0.72 mm/s
Curing Time / Temperature	Air cool for 12 hours

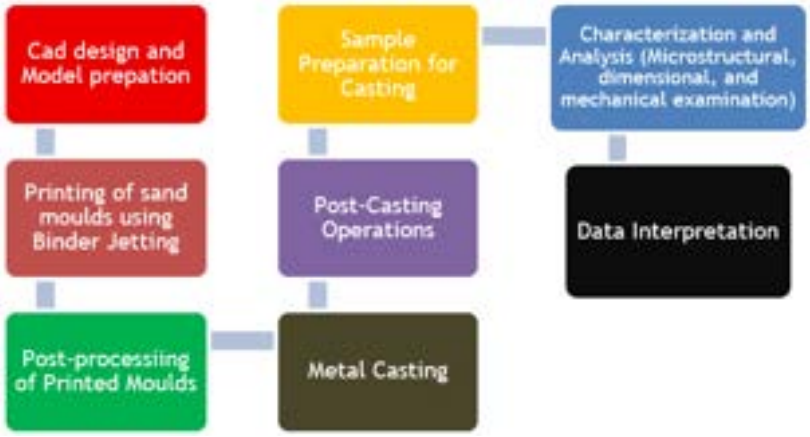

Figure 2: Step-by-step workflow illustrating the fabrication process through to data interpretation and analysis

2.1.1 Mould Orientation Strategy

In evaluating the impact of mould orientation on casting performance and quality, the moulds were classified based on their build orientation during printing:

- M1–M5: Horizontally arranged moulds
- M6–M10: Vertically arranged moulds
- M11–M15: Mixed-orientation moulds (combination of horizontal and vertical features)

A schematic diagram of the above is depicted in Figure 3. The categorization was designed to examine how orientation from a Voxeljet VX1000 system influences dimensional accuracy, mechanical properties, and entire casting integrity. The moulds were fabricated in batches, arranged sequentially across the build platform during the printing process.

A sample size of 5 per orientation group was selected in line with standard practice for pilot or exploratory experimental designs, where sample sizes typically range between 5 and 20 [12]. This choice also reflects the balance between obtaining preliminary, reproducible insights and managing practical limitations in fabrication, material usage, and testing resources [13, 14].

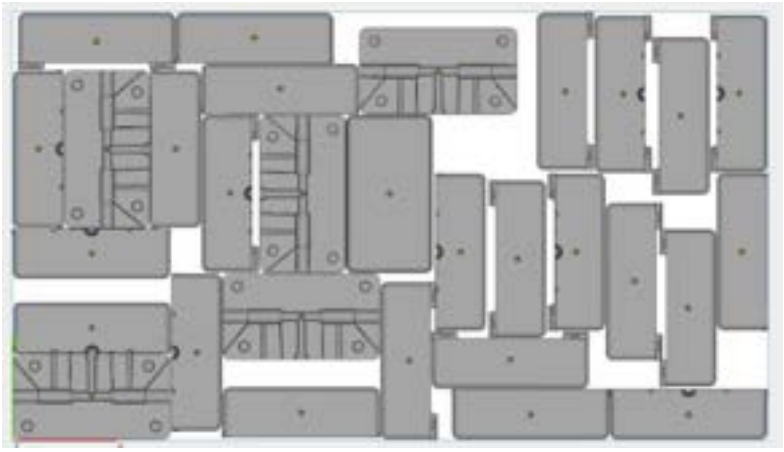

Figure 3: Schematic illustration of the Build Orientation of the Tensile Specimen Mould in the build platform

2.2 Metal Casting Process

The moulds were applied to cast LM25 aluminium alloy, a commonly used casting alloy with excellent mechanical features and corrosion resistance. The chemical composition of LM25 is presented in Table 2. The alloy was melted in an induction furnace and poured into the moulds under regulated conditions to ensure uniform filling and solidification. After solidification, the castings were cleaned and prepared for testing. The following examinations were carried out:

- Optical microscopy: The samples were sectioned, ground, polished, and examined under an optical microscope to determine their surface morphology and microstructural features based on mould orientation
- Dimensional Accuracy Evaluation: A digital vernier calliper was employed to measure the manufactured samples precisely. This tool ensured high-resolution and precise readings, determining dimensional deviations from the intended CAD geometry. This thus aids in validating the consistency and fidelity of the manufacturing process.
- Hardness Testing: Vicker's hardness assessments (HV 0.5) were introduced on representative surfaces of the cast specimen for 15 seconds.
- Tensile Testing: Standard tensile specimens were cut from each casting, and tensile tests were performed according to ASTM E8/E8M to evaluate the maximum load the sample can sustain before breaking or fracturing. This restriction was aimed at determining the comparative assessment of fracture load response among the samples printed from a variety of mould orientations

2.3 Data Analysis

To show the interrelationship between printing orientation, casting quality, and mechanical behaviour, giving a good understanding of RSC for high-tech applications. The data from the dimensional and mechanical tests were subjected to descriptive and inferential statistical analyses. Methods including mean and standard deviation calculations, and Analysis of Variance (ANOVA) performed using Microsoft Excel (Microsoft 365, version 2307) were applied to evaluate:

- The consistency of properties across mould orientations
- The statistical significance of orientation effects
- The reliability and repeatability of the Binder Jetting–Casting process

Descriptive statistics (mean and standard deviation) successfully summarized data trends and variability within and between orientations; however, they do not indicate statistical significance. ANOVA offered a thorough inferential context to establish whether observed differences were unlikely due to chance, thus providing statistical confidence in the effects of mould orientation. The combined use of these methods enabled clear data interpretation and reliable conclusions regarding process performance.

Table 2: Composition of LM25 aluminium alloy

Elements	Fe	Si	Ti	Mg	Cu	Mn	Al
percentages	0.387	7.46	0.038	0.326	0.071	0.047	Remaining

3 RESULTS AND DISCUSSION

3.1 Microstructure examination

The microstructural evaluation of the samples was carried out to show how the sand-printed moulds' orientation could influence the shape, distribution, and size of grains within the aluminium alloy samples. In all samples examined, the anticipated microstructure of cast LM25 Al alloy was detected, consisting a primary dendritic α-Al (aluminium) matrix intermingled with eutectic silicon particles. This structure is typical for this category of aluminium-silicon

alloy (hypoeutectic) and is influenced by the solidification parameters. While this entire structure remained stable, there were observable variations in how the features appeared from one sample to another. The differences, particularly in the size and distribution of the silicon particles, appeared to rely on how the sand moulds were oriented during the 3D printing process, signifying that the build direction and orientation can impact how the metal (tensile specimen) solidifies and takes shape. Figure 4 depicts the morphology of the samples according to their positional arrangement. In the horizontally arranged moulds (M1-M5), the samples cast from them depicted a uniform grain structure with moderate dendritic growth. Their surfaces were smoother and more stable due to the even layering of sand during the printing process. The silicon phases were more evenly dispersed throughout the aluminium matrix, indicating that solidification happened under steady and favourable conditions [15]. While the vertically oriented moulds (M6-M10), the samples cast from them exhibited slightly coarser microstructure with glaring directional solidification patterns running along the build direction. In some areas, non-uniform grain and micro-porosity were detected, which is likely a possible challenge related to vertical printing, namely inconsistent binder infiltration and layer compaction in vertical builds [16, 17]. These variations may have led to localized differences in heat transfer during casting, affecting the mechanical and morphological properties of the final parts. Lastly, the samples cast from mixed-orientation moulds (M11-M15) exhibited an interesting blend of features from both vertical and horizontal orientations, signifying transitional features. In some regions, the metal had bonded smoothly, depicting strong cohesive bonds. Although other regions showed weaknesses in bonding and irregular silicon segregation, implying inconsistent thermal gradients during the metal flow and solidification [15].

In general, the surface of the aluminium castings differed with mould orientation. Horizontally built moulds gave a better microstructural uniformity and more consistent as-cast surface texture, making them more applicable in areas necessitating consistent mechanical performance. In contrast, vertical and mixed type orientations brought different microstructures and surface features that may influence fatigue and strength life. These discoveries pinpoint the important role of mould orientation procedure in binder jetting-based rapid sand casting.

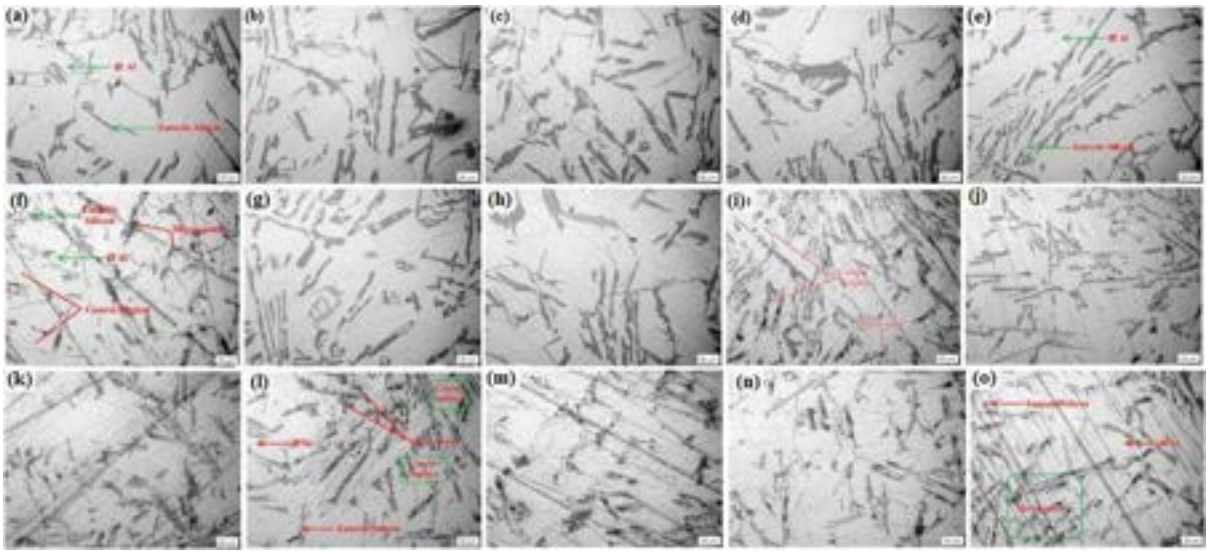

Figure 4: Microstructures of the aluminium samples cast from moulds arranged in (a-e) horizontal, (f-j) vertical, and (k-o) mixed build orientations.

3.2 Dimensional Accuracy – Length of Tensile Specimen

The dimensional accuracy of the tensile specimens was assessed by measuring their actual lengths and comparing them with the nominal design length of 150 mm. Across all specimens, a general trend of undersizing was observed, indicative of shrinkage during metal solidification and cooling. However, the extent of deviation varied noticeably depending on the orientation of the 3D-printed sand moulds used during casting, highlighting the influence of build direction on dimensional precision in rapid sand casting (RSC).

Figure 5 reveals the diagrammatic representation of the sample's length from different moulds. Specimens cast from horizontally built moulds exhibited the most accurate dimensions, with measured lengths ranging from 148.39 mm to 149.07 mm. The average length across the horizontal group was 148.73 mm, translating to an average deviation of −1.27 mm or approximately −0.85% from the nominal length. This relatively high-dimensional fidelity can be attributed to the more uniform layer deposition and compaction achievable in the horizontal printing orientation, which promotes even heat dissipation and consistent binder distribution during the mould printing process [18].

In contrast, specimens from vertically oriented moulds showed the largest deviations from the nominal value. Their lengths ranged from 147.99 mm to 148.43 mm, with an average of 148.18 mm, corresponding to an average dimensional error of −1.82 mm or −1.21%. The greater variability in vertical builds may be linked to factors such as gravity-induced compaction inconsistencies, directional solidification effects, and less uniform binder infiltration, all of which can impact the dimensional outcome of the cast parts [19, 20].

Specimens from moulds with a mixed orientation (vertical and horizontal features) exhibited intermediate results. Their measured lengths ranged from 148.17 mm to 148.70 mm, with an average of 148.51 mm. This equates to an average deviation of −1.49 mm or −0.99% from the nominal. The observed variability within this group likely reflects the combination of favourable and unfavourable characteristics from both vertical and horizontal builds, resulting in transitional dimensional performance [21].

Overall, the results demonstrate that mould orientation has a tangible effect on the dimensional accuracy of cast components produced via binder jetting-based RSC. Horizontally oriented moulds yielded the most consistent and accurate results, suggesting their suitability for applications requiring higher geometric precision. Conversely, vertical and mixed orientations introduced more dimensional variation and may require compensation strategies or post-casting adjustments to meet strict tolerance requirements.

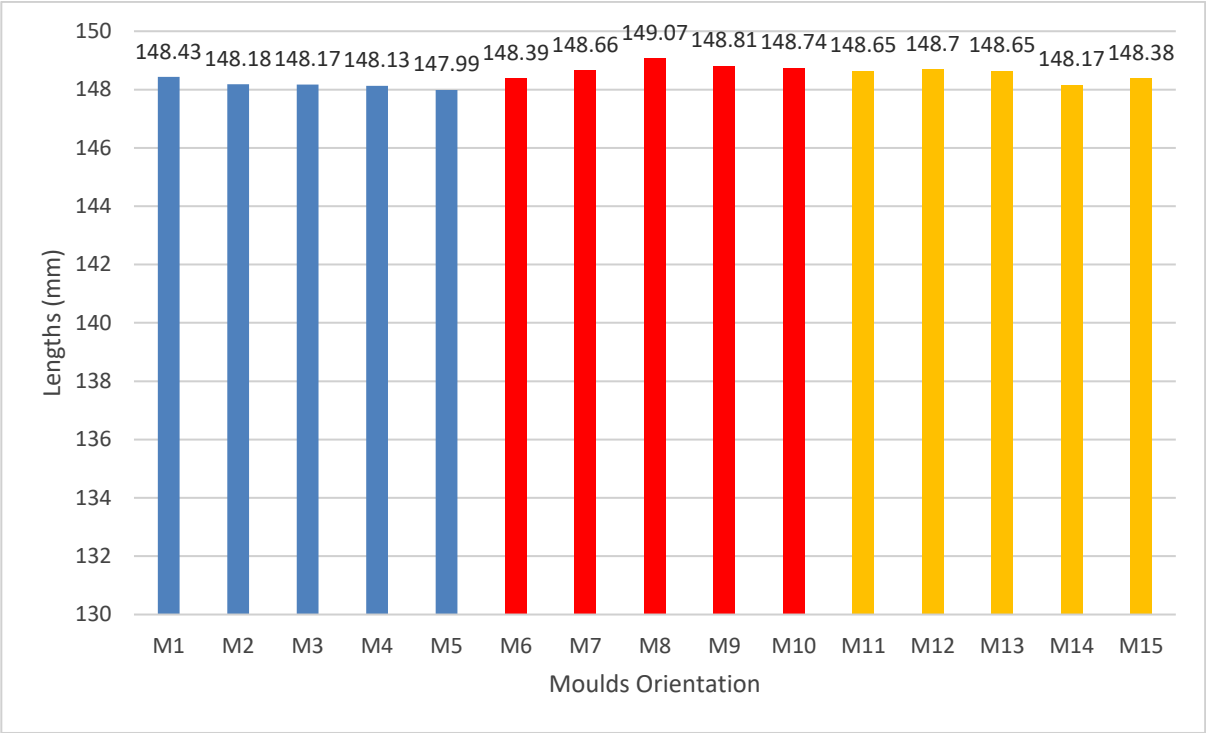

Figure 5: Dimension accuracy of the tensile samples length casted from the moulds arranged in vertical (M1-M5), horizontal (M6-M10), and mixed build orientations (M11-M15).

Table 3: Sum, average, and variance of the cast specimen lengths from different orientations

Groups	Count	Sum	Average	Variance
Vertical	5	740.90	148.180	0.0253
Horizontal	5	743.67	148.734	0.0606
V & H	5	742.55	148.510	0.0520

Table 4: ANOVA outcome of the tensile specimen length

Source of Variation	SS	df	MS	F	P-value	F crit
Between Groups	0.777	2	0.3883	8.4492	0.005127	3.885
Within Groups	0.552	12	0.0460			
Total	1.328	14				

Where, SS – Sum of Squares, df – Degrees of Freedom, MS – Mean Square, F – F-statistic, P-value – Probability Value, F crit – Critical Value of F.

Furthermore, a one-way ANOVA was conducted to evaluate whether the orientation of sand-printed moulds (Horizontal, Vertical, and Vertical & Horizontal) had a statistically significant effect on the length dimension of the cast tensile specimens. The results stated in Tables 3 and 4 depicted observable differences in variance across the different mould orientations. The Horizontal group has the highest variance (0.06063), followed by the Vertical & Horizontal group (0.05195), and lastly in the Vertical group (0.02530), indicating that dimensional consistency varied slightly across orientations.

The ANOVA analysis from Table 4 yielded an F-statistic of 8.45 and a p-value of 0.0051. Since the p-value is less than the standard significance level of 0.05, the differences in mean lengths among the three groups are statistically significant. This means that the mould orientation had a measurable impact on the dimensional accuracy of the specimens.

3.3 Hardness of the Tensile Specimens

Figure 6 reveals the hardness results of the tensile specimens cast using different sand mould orientations, Horizontal, Vertical, and Mixed (V & H), depicting a measurable impact of build orientation on the mechanical response (hardness) of the aluminium alloy, particularly in relation to the underlying microstructure developed during solidification.

The horizontal mould orientation developed samples with the most consistent and generally higher hardness values, ranging narrowly between 74.2 and 74.9 HV 0.5. This performance is closely linked to the relatively uniform grain structure and well-dispersed silicon particles observed in the microstructure of horizontally cast samples [5, 22].

The smoother and more stable sand layering associated with horizontal 3D printing likely facilitated more uniform heat flow during casting, supporting steady solidification conditions. This contributed to the consistent hardness values observed and a reduced presence of casting defects. Such reliability makes horizontally built moulds better suited for applications demanding mechanical uniformity. In contrast, specimens produced from vertically oriented moulds showed a wider variation in hardness, with values ranging from 72.6 to 74.8 HV 0.5. This spread reflects the influence of vertical build orientation on thermal gradients and compaction, which may introduce microstructural inconsistencies and localized porosity [19, 23].

These defects possibly compromised the local resistance to plastic deformation, leading to the observed variability and reduced hardness values. In particular, the uneven compaction and inconsistent binder distribution characteristic of vertically printed moulds may have introduced areas of localized weakening. The mixed-orientation (V & H) samples demonstrated moderate hardness values, ranging from 73 to 75 HV 0.5, which reflects the hybrid influence of horizontal and vertical build directions. These specimens demonstrated a combination of well-fused and less uniform regions, consistent with their transitional microstructures. Variations in thermal gradients during solidification likely caused uneven silicon particle dispersion and matrix heterogeneity, resulting in a more fluctuating yet intermediate hardness profile [20].

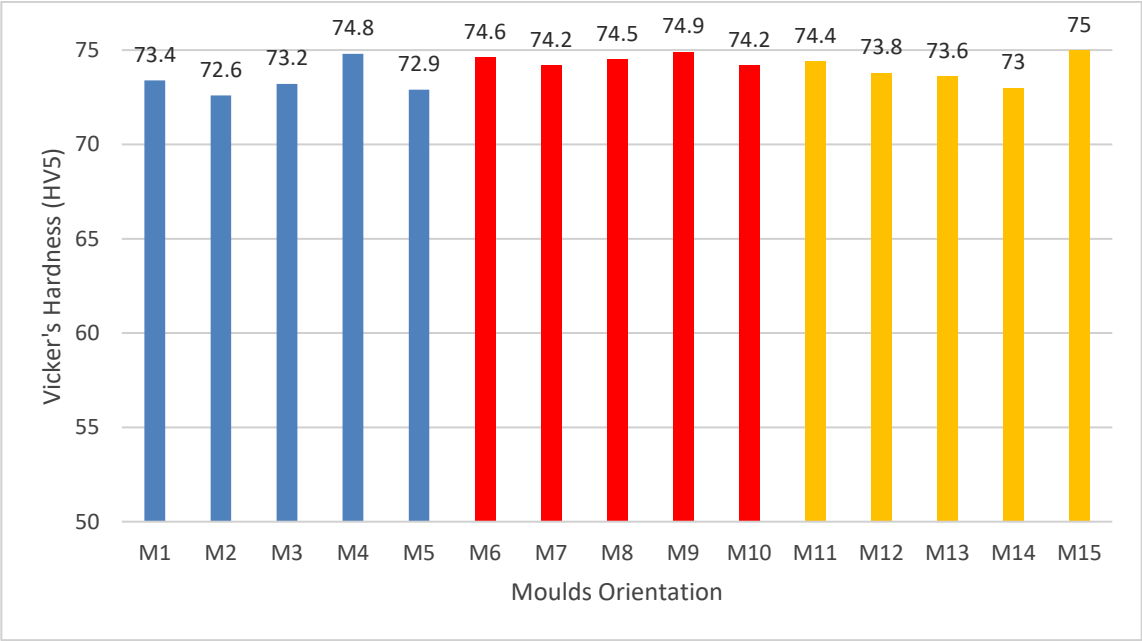

Figure 6: Hardness of the tensile samples cast from the moulds arranged vertically (M1-M5), horizontally (M6-M10), and in mixed build orientations (M11-M15).

Table 5: Depicting the sum, average, and variance of the cast specimen hardness from different orientations

Groups	Count	Sum	Average	Variance
Vertical	5	372.4	74.48	0.087
Horizontal	5	366.9	73.38	0.722
V & H	5	369.8	73.96	0.588

Table 6: ANOVA Table of the specimen hardness tests

Source of Variation	SS	df	MS	F	P-value	F crit
Between Groups	3.028	2	1.514	3.251	0.0744	0.0515
Within Groups	5.588	12	0.466			
Total	8.616	14				

Based on the ANOVA results (Tables 5 and 6) for the hardness values of the tensile specimens produced using different mould orientations (Vertical, Horizontal, and V&H), there is no statistically significant difference at the 95% confidence level (p-value = 0.0744) standard. Although the Vertical orientation showed slightly higher hardness on average than the others, the observed differences in hardness values across the groups were not sufficient to be considered statistically meaningful. This suggests that while mould orientation may influence hardness to some extent, likely due to differences in cooling rates and resulting microstructures, the variation observed in this case remains within a range that can be attributed to normal process variability.

Therefore, the mould orientation influences the hardness of cast aluminium by affecting microstructural features like grain uniformity and porosity. Horizontally built moulds produced the most consistent and higher hardness values due to uniform sand layering and better heat distribution. Vertical and mixed orientations introduced variability from inconsistent compaction and directional solidification. While ANOVA showed the differences were not

statistically significant, the trend highlights the importance of mould orientation in achieving reliable mechanical properties in rapid sand casting.

3.4 Tensile Performance and Orientation Effects

The tensile performance of the cast aluminium specimens was noticeably influenced by the orientation of the sand moulds during 3D printing. Specimens produced using horizontally printed moulds consistently showed the highest and most uniform maximum load values, ranging from 17.38 to 21.77 kN (as depicted in Figure 7 and Table 7). This enhanced performance appears to be linked not just to microstructural refinement, but also to more favourable thermal parameters and better binder saturation attains through horizontal layering. These combined factors possibly added to the enhanced mechanical consistency observed in the horizontally cast samples [24].

On the other hand, moulds built in a vertical orientation showed greater variation and generally lower tensile strengths, ranging from 14.61 to 21.78 kN. This reduced performance may be ascribed to layer-wise anisotropy affecting binder distribution and compaction density. Vertical layering can also limit gas permeability and modify how entrapped air or decomposition gases escape, which increases the chances of internal defects or porosity that compromise strength. Also, the vertical direction of heat flow during solidification may lead to uneven cooling, resulting in localized stresses, potential solidification cracks, or zones of segregation that further weaken the material [22, 23].

The mixed-orientation (vertical and horizontal) samples showed a huge range of tensile strengths, from 16.26 to 22.83 kN, including the highest individual value recorded across all groups. However, their average strength was still comparable to that of the horizontal group. This suggests that blending orientations leads to varied solidification behaviour; some regions benefit from the stability of horizontal layering, while others are impacted by the weaknesses associated with vertical layering. The inconsistent heat extraction and non-uniform layer bonding likely contributed to the more varied mechanical performance observed in these samples [24, 25].

Therefore, these outcomes indicate that the orientation used during sand mould 3D printing impacts more than just the grain structure; it plays a crucial role in shaping the thermal and mechanical conditions during casting. Factors such as gas entrapment, cooling rates, and shrinkage behaviour are all influenced by how the layers are oriented. This highlights mould orientation as a practical and effective lever for enhancing the mechanical reliability of cast aluminium components, particularly in rapid manufacturing settings where performance consistency is essential.

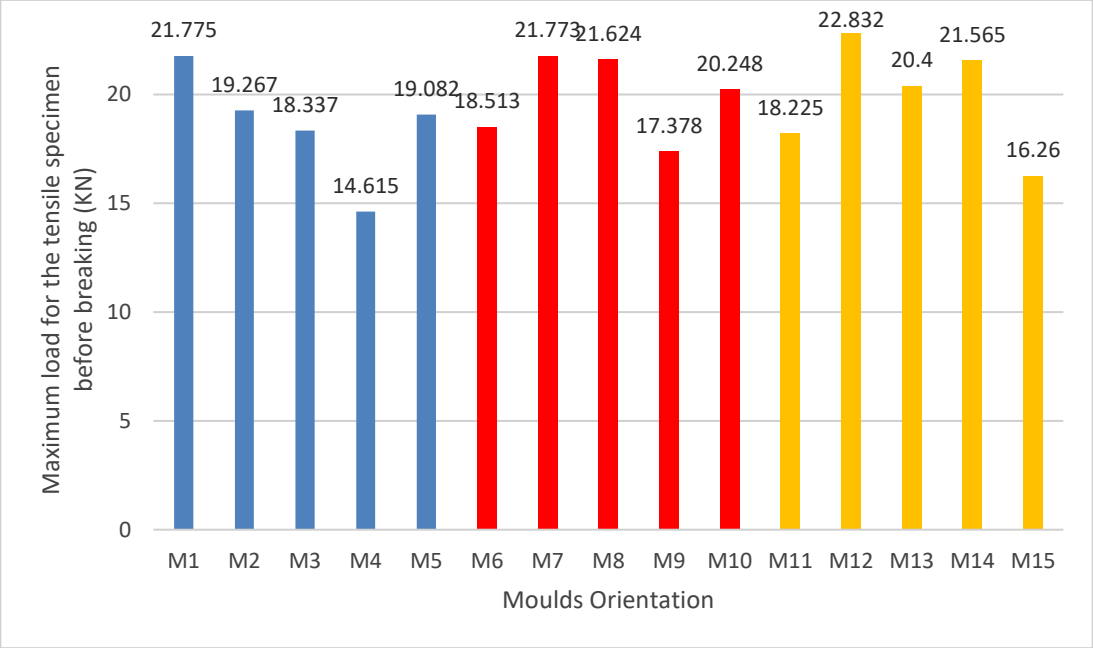

Figure 7: Maximum load for the tensile specimen before breaking, from the moulds arranged in vertical (M1-M5), horizontal (M6-M10), and mixed build orientations (M11-M15)

Table 7: Sum, average, and variance for the maximum load of the tensile specimen before breaking

Groups	Count	Sum	Average	Variance
Vertical	5	93.076	18.6152	6.916
Horizontal	5	99.536	19.9072	3.721
V & H	5	99.282	19.8564	6.677

Table 8: ANOVA Table for the maximum load of the tensile specimen before breaking

Source of Variation	SS	df	MS	F	P-value	F crit
Between Groups	5.354	2	2.677	0.464	0.640	3.885
Within Groups	69.256	12	5.771			
Total	74.610	14				

To further determine the consistency of the cast specimen in the different mould' orientations, a one-way ANOVA was carried out. Table 7 depicts that the horizontal group exhibited the highest average tensile strength (19.91 kN), followed closely by the mixed group (19.86 kN), while the vertical group showed the lowest mean value (18.62 kN). In terms of variability, the horizontal group also demonstrated the lowest variance (3.72), indicating more consistent performance, whereas the vertical and mixed groups showed higher variances (6.92 and 6.68, respectively).

The ANOVA results are shown in Table 8. The calculated F-value was 0.464 with an equivalent p-value of 0.640, immensely greater than the standard alpha level of 0.05. These results indicate no statistically significant difference in tensile strength between the three mould orientation groups. Although the horizontal orientation yields slightly higher and more uniform tensile strength, the statistical analysis reveals that these differences are insignificant at the 95% confidence level. This suggests that while mould orientation may influence tensile

strength trends, it does not exert a strong enough effect to be considered statistically reliable within the scope of this experimental dataset.

4 CONCLUSION

This investigation clearly pinpoints that mould orientation during 3D sand printing significantly influences the structural and mechanical behaviour of cast aluminium components.

- Horizontally oriented moulds produce samples with refined microstructures, more uniform dimensions, higher hardness, and greater load capacity, reflecting enhanced thermal management and binder distribution during casting.
- Vertically oriented moulds show greater variability in geometry and performance, likely due to layer-wise anisotropy, reduced gas permeability, and uneven heat extraction.
- Mixed orientation samples exhibit the highest individual load but inconsistent overall performance due to the complexity of heat flow and bonding behaviour in non-uniform orientations.

Generally, optimizing mould orientation stands out as a practical and cost-effective strategy for improving the mechanical reliability and dimensional consistency of components produced through rapid sand casting methods. This technique holds potential for manufacturing parts that provide competitive and comparative advantages in the high-tech industries, including biomedical, automotive, and aerospace. Future research should explore how mould orientation impacts fatigue life, internal stresses, and hidden flaws in cast parts, specifically parts produced from horizontal moulds, because they have the best outcomes from this research and can be optimally optimized to minimize their variations. Applying tools like CT scanning and thermal simulations could give a deeper understanding and assist in optimizing the mould design and casting quality across different alloys.

THE ROLE OF THE PROJECT TECHNICAL MANAGER WITHIN THE PROJECT MANAGEMENT FRAMEWORK

N. Scribante[1]

[1]Department of Engineering and Technology Management
University of Pretoria, South Africa
nscribante@npsc.co.za

ABSTRACT

For a project to be delivered on time, within budget and meeting the technical requirements, the project and technical management processes must dovetail into one another on many levels, like a precision clock. In a previous paper, a new Project Management Framework was presented, along with an initial examination of the various roles and responsibilities. One crucial role that was defined but not described in detail was that of the Project Technical Manager within the integrated project management framework. This paper will explore this role of the Project Technical Manager in more detail by examining its various dimensions, including the roles and responsibilities.

Keywords: Project Management, System Engineering, PM-SE Integration

1 INTRODUCTION

1.1 Background

A combined project management framework aimed at the successful delivery of complex projects was presented in a previous paper [1]. The paper focused on identifying the central elements required for successful project delivery and how to integrate them into a single framework that combines the management requirements from the project management discipline with those of the systems engineering discipline [1]. The paper also described a generic project team setup, as shown in Figure 1, that can be used to implement the new project management framework. Within this generic project team, two core management responsibilities have been identified. These are the project management function, which has overall responsibility for project delivery, and the technical management function, which reports to the project manager function and is responsible for the successful delivery of the project's technical aspects.

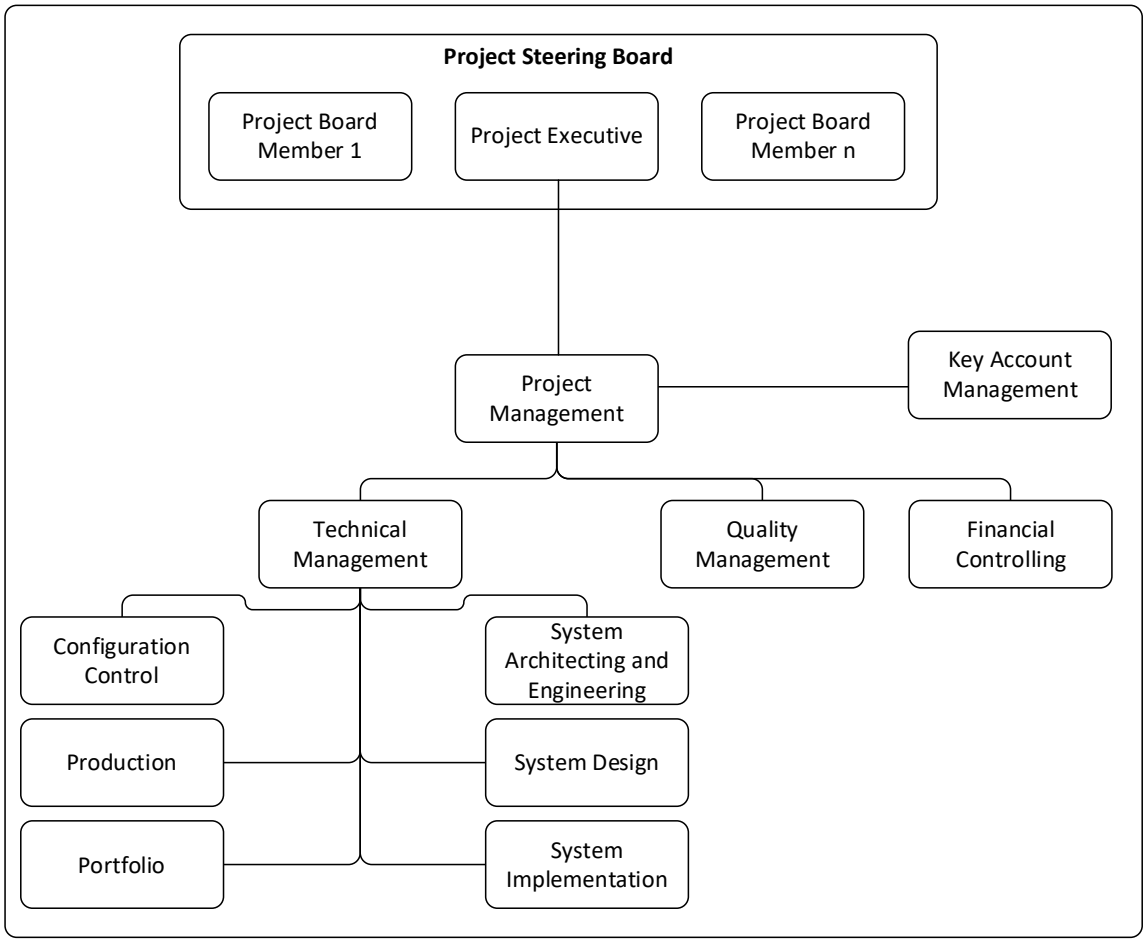

Figure 1: Generic Project Team Setup [1]

The project management framework within which the project team operates is shown in Figure 2.

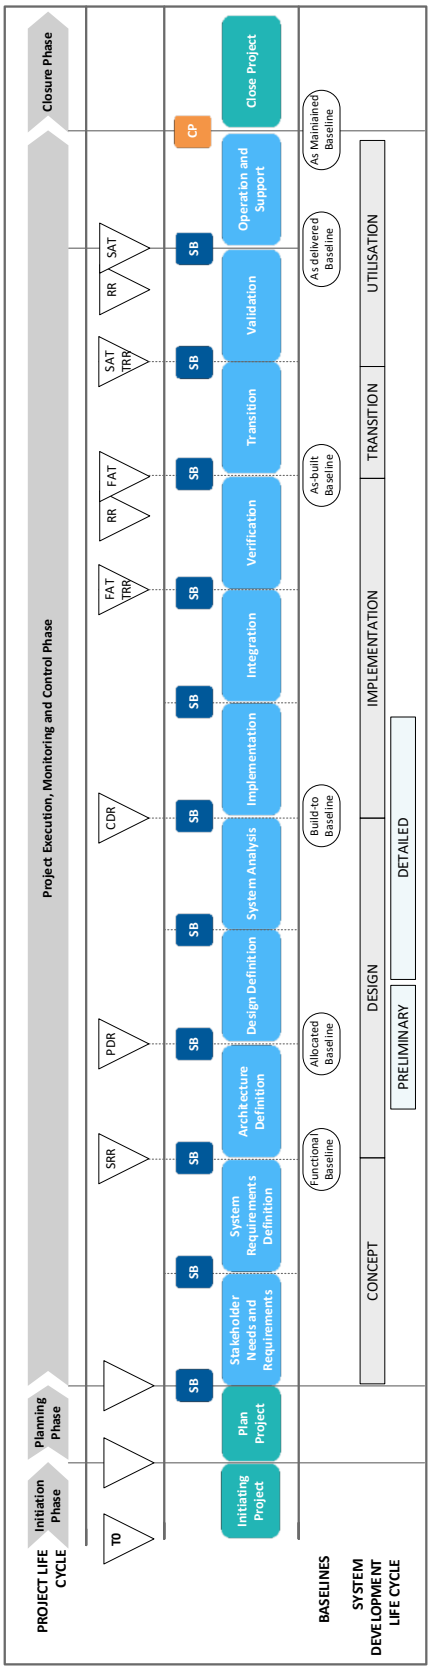

Figure 2: Combined Project and System Development Life Cycle [1]

The project management function is responsible for managing the project through its various phases, including project initiation, planning, execution, monitoring, and control, as well as project closure. The technical management function, on the other hand, is responsible for managing the technical delivery of the project throughout the complete system development lifecycle.

1.2 Research approach

This paper presents the second part of a case study that focuses on the pragmatic integration of project management and systems engineering environments for use in the delivery of complex projects. The primary research approach employed is a mixed-methods research approach. This research approach integrates quantitative and qualitative methods to address complex research questions. The research process followed builds on the work presented in the previous paper by refining the problem statement and reviewing and analysing the literature for new insights. This paper also includes insights from the author's 35 years of experience in the field of Systems Engineering and the delivery of complex problems.

The layout of the paper follows a typical case study approach. [2]:

- Section 1 - Introduction (This section)
- Section 2 – The need for a technical management function
- Section 3 – Roles and responsibilities of the technical management function
- Section 4 – Project Technical Manager versus Technical Project Manager
- Section 5 – Conclusion and recommendations

During the implementation phase, the actual outcome will be compared with the desired outcome, and corrective actions will be identified and implemented to move closer to the desired outcome. The intention is to capture the results of the overall exercise report in future papers.

2 THE NEED FOR A TECHNICAL MANAGEMENT FUNCTION

For any project to succeed, it must achieve its cost, time, and technical performance targets. In a complex or high-technology environment, the management and achievement of the technical performance targets is the responsibility of the technical management function [3].

In practice, the cost, schedule, and technical performance targets are tightly interconnected and interrelated. The net result of this interconnectedness is that the project management function has a direct influence on the technical performance or technology aspects of the project. Conversely, the technical management function has a direct impact on the time and cost aspects.

The project manager is responsible for the project management function. The role and responsibilities of the project manager are well-defined and form the topic of numerous publications, such as the Project Management Body of Knowledge (PMBOK) [4], training courses, and professional certifications, including the PMP* Certification, among others.

* https://www.pmi.org/certifications/project-management-pmp

Similarly, the technical management function can be executed by the systems engineer assigned to the project. The role and function of the Systems Engineer are also well understood and described in various publications, such as the Systems Engineering Handbook [5] or the Guide to the Systems Engineering Body of Knowledge (SEBoK) [6]. Different training courses are available, and INCOSE offers certification through its SEP† program.

The role of the systems engineer is not a simple one to define since this person can fulfil different roles within the project environment. Sheard [7] identified the various roles that the systems engineer can potentially fulfil during the project lifecycle, as summarised in Table 1. These roles may be assigned to one or more individuals, depending on the project's size and complexity. Overall, the systems engineer is considered the technical leader within the project organisation and has the authority to speak for and commit the systems engineering team [3].

Table 1: Various Systems Engineering Roles [7]

Nr	Role
1	Requirements owner
2	System Designer
3	System Analyst
4	Verification and Validation Engineer
5	Logistics or Operations Engineer
6	Interface Engineer
7	Customer Interface Engineer
8	Technical Manager
9	Information Manager
10	Process Engineer
11	Coordinator

One challenge encountered in real-life projects is that the project management function and the technical management function can easily devolve into two operational silos, where interaction is limited to progress meetings and similar events. The risk this poses is that the project may fail since the tight interconnections between cost, schedule, and technical elements are broken and thus no longer kept in balance.

A bridging function is thus required to link the project management function and the systems engineering function. The need for this bridging function stems from the continuously increasing complexity and interdependence experienced in projects, particularly those that can be classified as complex, socio-technical projects. This bridging function can be identified as the technical management function identified in Table 1. The roles and responsibilities of this technical management function will be explored in the following sections of this paper.

3 ROLES AND RESPONSIBILITIES OF THE TECHNICAL MANAGEMENT FUNCTION

One possible way to visualise the Project Technical Manager and the associated technical management function is to view it as the bridge between the Project Manager and the Systems Engineer. This is conceptually shown in Figure 3.

† https://www.incose.org/certification

Figure 3: Project Technical Manager as the bridge between the Project Manager and the Systems Engineer

Forsberg et al. [8] identify this bridge as being required to manage the business, budget, and technical baselines, with the primary objective of aligning these baselines. The function within this overlapping region is identified as belonging to the systems engineering management or technical management functions [9], [10].

3.1 Split between Technical Management Functions and Systems Engineering Functions

The identification of activities allocated to the technical management function versus the systems engineering functions is vital to ensure that there is no overlap and that nothing is missed. The INCOSE Systems Engineering Handbook identifies the Technical Management process versus the Technical Process, as shown in Figure 4 and described in more detail in Sections 2.3.4 and 2.3.5 of the INCOSE Systems Engineering Handbook [5].

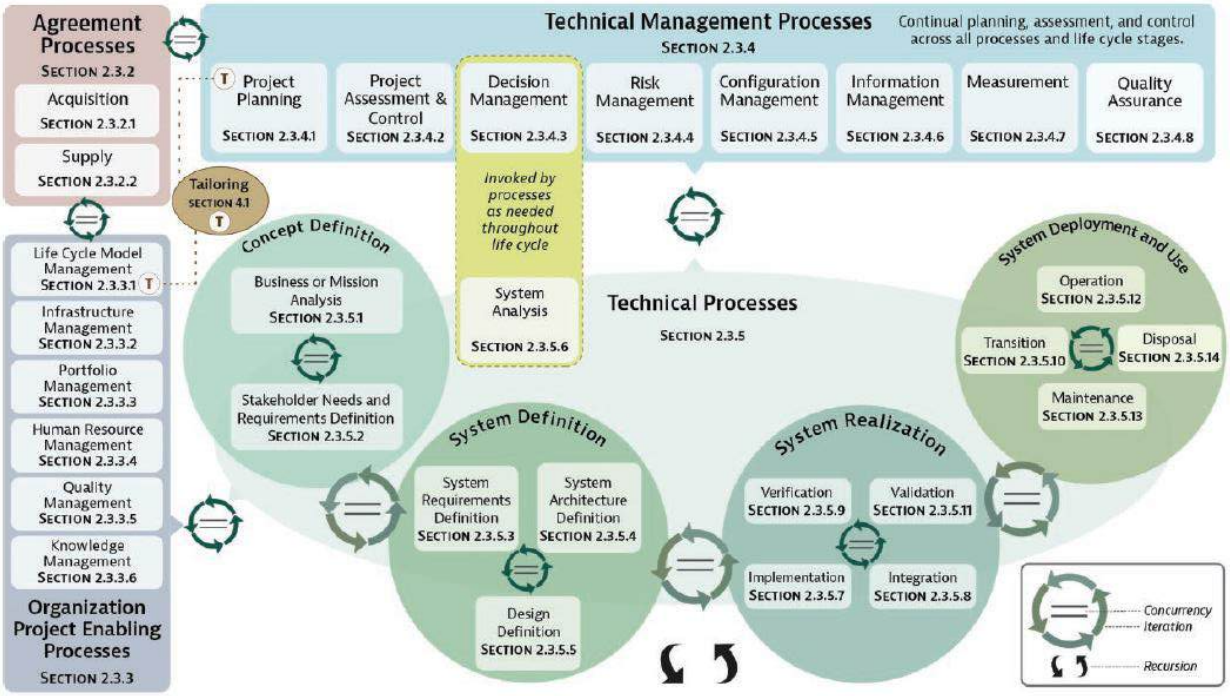

Figure 4: Technical Management Processes vs Technical Processes [5]

An alternative way of visualising the functions that form part of the technical management bridge versus the systems engineering pillar is to consider which activities are executed sequentially, i.e., the next activity depends on the previous activity, versus parallel activities, i.e., they occur concurrently throughout the project.

3.1.1 Sequential activities

The systems engineering activities tend to be more sequential – i.e. there is a logical progression from one step to the next. The progression from one step to the next is controlled by gated events, such as the Systems Requirements Review (SRR) and Preliminary Design Review (PDR), among others. These gated events are a powerful aspect of the systems engineering process, as they ensure a smooth transition from one phase to the next.

The sequential activities identified in the Systems Engineering Handbook [5] are shown in Table 2.

Table 2: Sequential Activities

Nr	Activity
1	Business or mission analysis
2	Stakeholder needs and requirements definition
3	System requirements definition
4	System architecture definition
5	Design definition
6	System analysis
7	Implementation
8	Integration
9	Verification
10	Transition
11	Validation
12	Operation
13	Maintenance
14	Disposal

3.1.2 Parallel activities

The technical management activities, on the other hand, are more parallel in the sense that they can occur concurrently and, in certain instances, last the entire period of the project.

The parallel activities identified in the Systems Engineering Handbook [5] are shown in Table 3.

Table 3: Parallel Activities

Nr	Activity
1	Project planning
2	Project assessment and control
3	Decision management
4	Risk management
5	Configuration management
6	Information management
7	Measurement
8	Quality Assurance

3.2 Alternative Viewpoint

Van Gemert [10] described an alternative viewpoint on the sequential and parallel activities. This viewpoint is shown in Figure 5. While there are common activities between this view and the activities identified by the INCOSE Systems Engineering Handbook [5], certain activities are absent from this view. These activities include project planning, project assessment and control, and information management, among others.

3.3 Consolidated view of the technical management processes

Although the activities identified by the INCOSE Systems Engineering Handbook [5] appear to be complete, the author's opinion is that certain activities are missing from that definition. These activities are shown in Table 4.

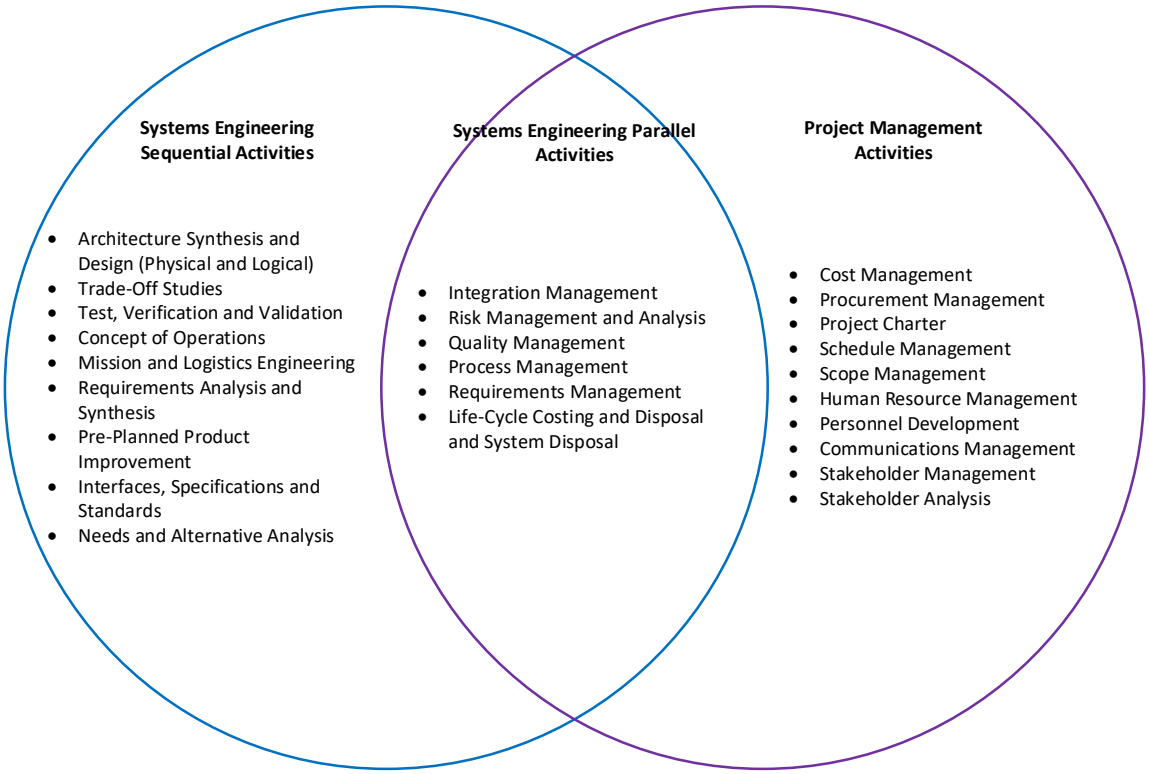

Figure 5: Sequential and Parallel Activities (Adapted from [10])

Table 4: Missing Activities and Description

Nr	Activity	Description
1	Technical process tailoring	1. Tailoring can be defined as the modification, addition, or deletion of outcomes, activities, tasks, typical inputs, or typical outputs.[6] 2. Tailoring can also be defined as the process of designing the processes for the Creating System, where the Creating System is the organisation that develops the Created System [11].
2	Managing the technical process	This is seen as the effort whereby the projects are advanced through the System Development Lifecycle in an orderly and controlled manner. This stands in contrast to the management of project processes, including planning, execution, monitoring, control, and finally, project closure.
3	Leading the technical team	It is assumed that the line managed function of the technical team is separate from the project execution activities. This activity involves leading and guiding the technical team within the project context, encompassing aspects such as coaching and mentoring.
4	Identification of the applicable systems engineering toolset	This can be seen to form a subsystem of the process tailoring activity, whereby the applicable systems engineering toolset is selected to match the project size and complexity. This can include tools such as the specific requirements management tools that will be used, or whether model-based systems engineering principles will be used.

4 PROJECT TECHNICAL MANAGER VS TECHNICAL PROJECT MANAGER

Terminology and definitions are fundamental in any field to ensure that all stakeholders understand the same concept. This raises one question that still needs clarification regarding the job title assigned to the person performing the technical management function. There

seem to be two options: the first is “Technical Project Manager,” and the second is “Project Technical Manager.” While both titles imply technical expertise within project management, there are subtle but important distinctions between a Project Technical Manager and a Technical Project Manager. While the final selection of the name remains the responsibility of the organisation implementing the project, it will still be essential to decide on an appropriate name and define the responsibilities clearly.

4.1 Project Technical Manager

The focus of the title is on the technical aspects of the management within the confines of the project. This indicates a primary concern with the technical execution of the project, focusing on aspects such as overseeing technical execution, managing risks associated with technology implementation, and guiding team members toward successful deliverables.

4.2 Technical Project Manager:

The focus of this title is on project management skills, combined with in-depth technical knowledge. The role oversees the entire project lifecycle from initiation to closure, leveraging their understanding of technology to manage scope, budget, timelines, and resources effectively [4]. They are the "technical leader" who drives both execution and delivery.

5 CONCLUSION AND RECOMMENDATIONS

Within the context of the project organisation, the need for the technical management function was identified. This technical management function aims to bridge the divide between the project management function and the systems engineering function. The typical activities associated with this technical management function were identified, along with some activities that are considered significant from an industry viewpoint but have not been explicitly identified in the literature yet.

A final aspect that was touched on was the job title that will be assigned to the incumbent of this technical management function. While no specific title was identified, the importance of selecting and communicating the expectations within the project environment was highlighted.

The following steps in this research journey will involve implementing this generic process within the organisation and evaluating its effectiveness in projects that involve complex, high-technology solutions. The results of this evaluation process and optimisation activities will be reported in a future paper.

ABSTRACT

This study evaluates the effectiveness of a multidisciplinary team approach in managing burn injuries, with emphasis on improving outcomes and streamlining care. In South Africa, 1.6 million burn injuries occur annually, with 3,200 patients requiring specialised services. Severe burns are among the most devastating forms of trauma survivable, and their complexity makes multidisciplinary treatment crucial for functional survival. Systems thinking, widely applied to complex problems, offers a holistic lens to understand interconnected components and dynamic interactions. Advanced burns care encompasses resuscitation, pain management, wound care, surgery, infection control, nutrition, rehabilitation, and psychological support. Using systems thinking and a grounded theory approach, this article develops a conceptual causal loop diagram to model the impact of multidisciplinary care. The model and systems archetype demonstrate how interdisciplinary management reduces intervention delays, improves wound healing, and lowers secondary complications compared to conventional care, supporting MDT protocols as essential for effective burns management.

Keywords: systems thinking, burns care, multidisciplinary team, casual loop diagram, system archetype

* Corresponding Author

1 INTRODUCTION

The World Health Organisation (WHO) regards Burn injuries as one of the most severe types of trauma that a patient can experience while still maintaining the possibility of survival [1]. In 2018, the WHO also declared burn injuries a serious public health problem, with an estimated 180,000 people succumbing to their burn injuries annually. Also, most of these injuries occur in low- and middle-income countries [2]. Burns constitute a significant public health issue in South Africa, leading to considerable morbidity and long-lasting physical disabilities [3]. It is estimated that annually, 1.6 million people suffer burn injuries, and as many as 3200 patients require specialised burn care in South Africa.

Severe burns represent one of the most catastrophic types of trauma. It is widely acknowledged that well-equipped specialised burn centres provide the best care for these patients. In these facilities, contemporary burn treatment has evolved into a complex, meticulously coordinated and targeted approach that encompasses resuscitation, infection management, critical care, surgical wound treatment, pain management, nutritional support, and both psychosocial and physical rehabilitation [4]. Specialised burn units have proven crucial in enhancing survival rates in high-income nations [5]. Improving safety and quality of care for burn injury patients is most needed in Low- and Middle-Income Countries, especially in sub-Saharan Africa, where mortality rates of burn injuries can be seven times higher than in high-income countries [6].

The patient's response to a burn injury can be characterised as complex, as is how to provide care for it [7]. Managing burns necessitates a joint effort from a multidisciplinary team (MDT), as no individual discipline alone can sufficiently handle the complexities of caring for a patient with severe burns [5]. Since multidisciplinary burns care is a complex problem, systems thinking may provide a perspective, language and a set of tools to understand the influences of the various elements of multidisciplinary burns care on functional patient outcomes and each other.

Systems thinking is an approach to help model complex health challenges by providing a holistic lens emphasising healthcare systems' interconnectedness and dynamic interaction [8], [9]. This promotes stakeholders' understanding of how multiple components, such as clinical care, policy, and community engagement, play into health outcomes. Systems thinking is thus well suited to handle something so complex as burn injuries and health systems in general, for it looks at relationships, feedback loops, and dynamic behaviour over time [8]. Other linear approaches may fail to capture the nonlinear relationships and delays characterising complex clinical environments [10]. In contrast, systems thinking enables a holistic understanding of how interventions in one part of the system may produce consequences (intended or unintended) elsewhere, which contribute to developing better policy and operational decisions [11].

Specifically, in burn care, one could argue that since clinical pathways overlap with various psychosocial, logistical, infrastructural, and other variables, systems thinking could facilitate scenario analysis, identify leverage points for improvement, and create cross-cutting silos between disciplines [12]. Its application can help design more resilient and adaptive care models, particularly in resource-constrained settings where optimising care delivery is crucial.

This paper applies systems thinking to model the workings of an MDT in burns care to support the development of more effective clinical processes, policies, and operating procedures. Mapping the dynamic interactions between various professional roles, systemic constraints, and treatment phases should uncover the underlying structures influencing care quality and patient outcomes. The systems thinking lens allows a deeper understanding of interdependent and feedback processes defining performance by MDTs, offering insightful leverage points toward improved coordination, resource allocation, and decision-making. The output models

can support understanding how best to design interventions that would integrate and tailor into the available systems possible components of resilience, efficiency, and patient-centeredness in burns care delivery, even in resource-constrained settings.

2 METHOD

Systems thinking is a transdisciplinary approach that offers frameworks and tools to understand the structure and behaviour of complex systems, which are often found in healthcare [13]. It provides a holistic perspective on multifaceted challenges by integrating across the traditional boundaries of social, health, and natural sciences [14]. In the context of this research, systems thinking addresses the MDT as a system comprising tangible (clinical roles, procedures, etc.) and intangible (communication patterns, institutional culture, etc.) components working towards a common goal [15], [16]. Instead of analysing components in isolation, systems thinking focuses on how relationships and interactions within the team and between the team and its external environment cause behaviours and outcomes that can be emergent or unexpected [10], [17], [18].

Burns care also exemplifies a "wicked" or "messy" problem, a complex situation shaped by social, political, infrastructural, and regulatory contexts. Solving these kinds of problems requires multiple perspectives and a framework to connect seemingly unrelated events or processes into conceivable high-impact interventions [19]. Adopting a systems approach in health service delivery generates dialogue and discussion, encouraging health professionals to question prejudices and mental models that may inhibit innovation or service improvement [20].

By focusing on whole systems, systems thinking enables problem solvers to uncover the structural causes behind the observed and recurring behavioural patterns [19], [21]. It applies stakeholder mental models, which are their implicit assumptions, beliefs, and values, to derive the causal structures driving system behaviour [17]. Such modelling of structures helps simplify complexity through feedback loops and cause-and-effect relationships by clarifying leverage points for change [22]. Viewing burn care as a system can help articulate a shared understanding, guide strategic decision-making, and develop sustainable policies and processes to improve patient outcomes [23].

This study models the complex and interconnected nature of a multidisciplinary burns care system, using a Systemigram to construct a high-level narrative representation. The systemigram is illustrative of a storyline that captures the system's essential elements, actors, and objectives that come into interrelation across various domains, such as clinical care, communication, logistics, and infrastructure [24]. Through a holistic yet interpretable view of the system, all stakeholders can develop a shared understanding of and leverage points, feedback loops, and bottlenecks along the patient care pathways. This enables mapping socio-technical systems in healthcare, where the tangible (e.g., the personnel, resources) and the intangible (e.g., flows of decision, culture) factors influence outcomes [16].

A Causal Loop Diagram (CLD) was developed from the systemigram to capture the dynamic interdependencies, feedback loops, and cause-and-effect relationships between critical variables within the burn care system. CLDs are valuable systems thinking tools for modelling nonlinear behaviour and reinforcing or balancing feedback mechanisms that can lead to improving or degrading care quality. In this context, variables such as communication efficiency, pain management, rehabilitation engagement, staffing levels, and complication rates will be linked to identifying reinforcing loops (e.g., early rehabilitation improves recovery, which enhances team morale) and balancing loops (e.g., resource limits reduce service delivery). The CLD will be informed by the insights from the systemigram and supported by literature and expert input to ensure its relevance and accuracy. This dual

modelling approach enables the development of actionable strategies for system improvement and highlights points where small interventions could yield [16], [25]

Another output of the systems thinking process is identifying the primary system archetypes present in the situation, as shown in Figure 1. These are commonly recurring behaviour patterns in complex systems rooted in the underlying structure of feedback loops. Senge and Wolstenholme describe high-level models that help explain why systems often behave in predictable but counterintuitive ways [25], [26]. In multidisciplinary burn care, these archetypes can help identify dysfunctional patterns—such as coordination breakdowns or unintended consequences of well-meaning interventions—that emerge from systemic structures rather than individual errors [27].

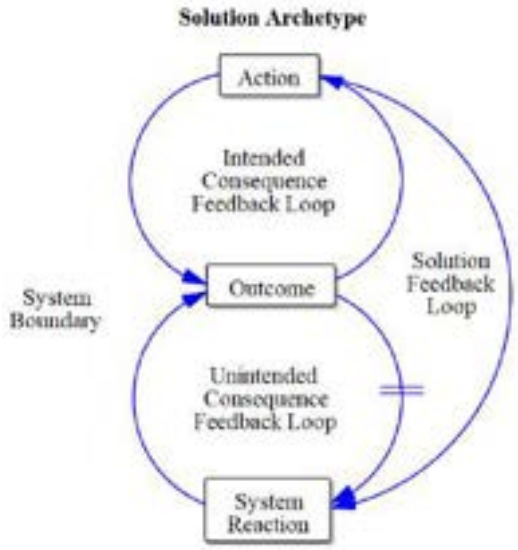

Figure 1: Generic Systems Thinking Archetype

Rather than big and thorough models, simple archetypal models capture system behaviour and lead to improvement quite well [28]. These often include unintended consequences alongside supposed benefits to give stakeholders some understanding of how actions in one part of the system can trigger adverse outcomes elsewhere, sometimes after a delay in visibility or outside the perceived system boundary [29]. By diagnosing such patterns, archetypes help identify leverage points in the system where small changes can yield substantial impact. Although not consistently rigorous in a theoretical sense, system archetypes offer a practical and communicable tool for understanding systemic issues, supporting strategic decision-making, and informing the development of more effective processes and policies in burns care delivery [30].

Figure 2 shows an elementary system thinking process that implements modelling with the help of system archetypes [31]. As applied in this paper, the first step is to capture information about the system through a thematic literature survey. The literature study used the thematic synthesis [32]. Data regarding burn pain management were extracted from the available literature and analysed by a transdisciplinary team. Factors influencing an MDT's operation to rehabilitate a burn patient were extracted. These factors were combined into themes: advanced clinical care, optimal conditions for wound healing, hospital-acquired complications (HACs), functional survival, MDT vigilance and communication, rehabilitation, nutritional support, pharmacovigilance, surgical intervention, and PC.

The retrieved literature was analysed to identify and describe the system and extract issues that cause unexpected or unwanted system behaviour. This paper uses a systemigram as a rich picture to graphically determine the critical variables in the problem situation or system.

System archetypes provide a template or guideline to identify the underlying problematic aspects [31]. Using the identified system archetype, the variables from the systemigram are used to develop a CLD to model the causal relationships and feedback loops. The CLD should include the impact of various interventions and their unintended consequences. The system archetype helps identify the basic system structure (variables and interconnectivity), behaviour and possible leverage point(s) to develop a dynamic hypothesis.

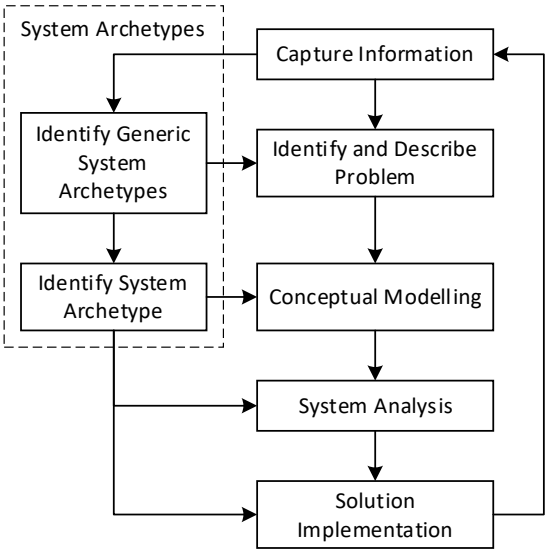

Figure 2: System Thinking Modelling Process using System Archetypes

3 MULTIDISCIPLINARY BURNS CARE

Burn care is a complex and comprehensive process involving multiple factors and approaches, requiring the collaboration of an MDT to enhance patient outcomes [33]. The complexity of advanced burns care, which involves resuscitation, pain management, infection control, and nutritional and psychosocial support, necessitates coordinated multidisciplinary interventions [34]. Multidisciplinary care for burn injury patients involves a coordinated team of healthcare professionals from various specialities, such as nurses, surgeons, dietitians, physiotherapists, pharmacists, psychologists, occupational therapists and social workers, working collaboratively to address the comprehensive psychological, physical, and social needs of burn patients throughout their recovery journey, from acute treatment to rehabilitation and reintegration into the community [34].

There have been remarkable improvements in burn care outcomes since World War II. It results from deliberate efforts to develop and sustain high-performing MDTs. These teams include clinical experts who address burn patients' complex physical and emotional needs and researchers who drive progress through basic and applied science. Continued collaboration of this kind is essential for future advancements in burn treatment and offers a valuable model for addressing other complex medical challenges [35].

The treatment of burn injuries likely exemplifies the surgical speciality that incorporates the highest degree of collaboration among healthcare professionals, benefiting significantly from genuinely multidisciplinary care. This integration has arisen due to the intricate nature of burn injuries, which demands a wide array of skills for optimal contemporary treatment. It is unreasonable to expect any specialist to have the comprehensive knowledge, skills, and stamina needed for the quality care of a burn patient. Instead, a team of specialists has been relied upon to deliver coordinated care through creative organisational strategies [36]. The burns unit manages burn injury patients in a team of nurses, physiotherapists, dietitians, and

general surgeons. A clinical pharmacist is involved in antimicrobial stewardship and pharmacological and nutritional support. 'The response to a burn injury is very complex, and so is the approach to its care' [7].

3.1 Advanced Clinical Care

In the past, patients with burn injuries were often grouped together in a section of a surgical ward. Due to the unpleasant appearance of their wounds, associated odours, and the difficulties of pain management, many healthcare providers were hesitant to treat this complex group of patients [34]. Extensive burns demand more significant resuscitation efforts because of their widespread systemic impact, highlighting the need for an accurate and efficient assessment of burn size. Additionally, outcomes are better for burn patients when they receive care in specialised facilities equipped to deliver advanced burn treatment [34].

Significant progress in burn care encompasses several key areas, including prompt excision, fluid resuscitation protocols, closure of burn wounds using grafts or skin substitutes, management of sepsis, the use of topical antimicrobials, nutritional support strategies, infection control measures, pharmacological management of the hypermetabolic response, and maintenance of thermally neutral environments. These advancements have led to better wound healing, decreased inflammation and energy requirements, reduced hypermetabolism and muscle breakdown, and ultimately, lower rates of morbidity and mortality in patients with severe burns [36].

As in other areas of healthcare, having appropriate infrastructure, a committed interdisciplinary team, and strong family support is crucial for helping burn survivors return to functional, well-adjusted, and meaningful lives. Consequently, it is widely acknowledged that patients who meet specific clinical criteria achieve the best outcomes when treated in a specialised burn centre. Ideally, such a centre offers a comprehensive, self-contained setting with dedicated, isolated beds staffed by plastic and general surgeons with sub-speciality expertise. A MDT delivers care focused solely on burn patients, including nurses skilled in wound and intensive care, specialised dietitians, social workers, physiotherapists, occupational therapists, and consultants from various medical disciplines [4].

3.2 Optimal Conditions for Wound Healing

Every aspect of burns care should aim to create optimal conditions for wound healing while preventing typical HACs [7]. Enhancing wound healing involves providing hemodynamic support during the initial stages—such as fluid resuscitation and, when necessary, vasopressor therapy, ensuring adequate nutritional support. Using pharmacological agents can also reduce the effects of hypermetabolism and encourage tissue repair [7].

3.3 Hospital Acquired Complications

Care should aim to prevent common HACs, such as stress ulcers, venous thromboembolism, ventilator-associated and hospital-acquired pneumonia, and infections related to urinary or bloodstream catheters [7]. The link between HACs and long-term, patient-reported quality-of-life measures shows that these complications have a lasting negative impact on the well-being of adult burn survivors. Conditions such as kidney failure, urinary tract infections, pulmonary embolism, and venous thrombosis are particularly associated with lower physical health scores.

Individuals who experience HACs may face ongoing challenges related to treatment side effects, frequent medical monitoring, and additional interventions—all of which can detract from their physical health and overall quality of life. HACs are linked to long-term patient-reported quality of life declines. This underscores the importance of preventing these complications. Additionally, the results suggest that burn survivors face challenges with

functional recovery for up to two years following their injury. When a patient is admitted with severe burns, minimising the risk of HACs is crucial [7].

3.4 Functional Survival

In high-income countries, reduced mortality rates from burns are no longer the primary quality improvement measure. Instead, the focus has shifted to successful reintegration into family and society as a key indicator of progress. There is still potential to reduce mortality rates in resource-limited settings, but a more progressive approach would simultaneously prioritise reintegration through enhanced rehabilitation efforts [34]. Being admitted to a specialised burn critical care unit is linked to a notable improvement in survival outcomes. This benefit is partly attributed to the comprehensive care delivered by a well-coordinated MDT [37]. Incorrect management at any stage can negatively influence the progression of the injury and hinder the recovery of bodily functions and reintegration into daily life [38].

3.5 Multidisciplinary Team Vigilance

MDTs are involved early upon hospitalisation to ensure a focus on 'functional survival' [7]. Caring for critically ill burn patients is highly complex and involves multiple interconnected aspects, including advanced wound care, sedation, respiratory support, pain control, nutritional management, and skilled nursing. In specialised burn critical care units, closely coordinated teams of experts from various disciplines work together on-site, conducting daily multidisciplinary ward rounds and delivering continuous, around-the-clock critical care as a unified MDT [37].

A MDT should support burn care management, which includes surgical, medical, nursing, intensive care, occupational therapy, physiotherapy, social work, dietetics, psychiatry, psychology, pharmacy, speech therapy, and technicians. All burn team members interact throughout the patient's management, from admission to discharge, to support the patient and family in reintegration [39]. Effective communication is critical to ensuring the team functions successfully, in interactions among team members and engagements with patients and their families [36].

3.6 Rehabilitation

Primary burn survivors often face long and difficult recoveries, with the potential for chronic impairments that keep them below their baseline levels of function. Factors that cannot be changed, such as age and gender, along with disease characteristics like burn size and associated physical, physiological, and psychosocial consequences, play a role [40].

Rehabilitation is a crucial component of burn treatment. "Burns Rehabilitation" encompasses physical, psychological, and social aspects. Burn patients often experience difficulties in one or all of these areas following a burn injury. Burns can result in severely debilitating and deforming contractures, which can lead to significant disability if left untreated. The goals of burn rehabilitation include minimising the adverse effects caused by the injury, maintaining the range of movement, reducing contracture development and the impact of scarring, maximising functional ability, enhancing psychological well-being, and promoting social integration [41].

The multidisciplinary physical rehabilitation of burn patients is an ongoing process of active therapy. No distinction should be noticeable between an "acute phase" and a "rehabilitation phase", as therapy needs to start from the day of admission. It is essential to begin physical rehabilitation from day one of admission, whether the patient is on bed rest and immobile or ambulant and well. Maintaining a consistent approach from all MDT members is crucial to ensure ongoing education and rehabilitation [7].

Physiological factors impacting physical rehabilitation outcomes in burn patients include burn severity (total body surface area burned), age, gender, location of burns, presence of complications like infection, fluid loss, hypothermia, respiratory issues, impaired mobility due to contractures, pain levels, nutritional status, and the body's healing response. All these factors can positively or negatively influence the patient's ability to participate in rehabilitation exercises and achieve functional independence [42].

3.7 Nutritional support

Proper nutrition plays a vital role in burn care. Although weight loss following burn injury is mainly unavoidable, a key objective of comprehensive burn care is to limit the extent of this loss during recovery. Achieving this requires detailed initial and ongoing evaluations of nutritional status and estimating daily caloric needs. It is widely anticipated that early initiation of tube feeding enhances clinical outcomes by mitigating post-burn hypermetabolism and modulating the immune response, thereby minimising weight loss and reducing the incidence of infections [34].

While many patients can eat by mouth, those with burns covering more than 20% of their body surface area often need additional support through tube feeding due to their elevated calorie requirements. Early initiation of tube feeds is advised, along with consultation from a dietitian to ensure appropriate nutritional management [43]. Patients with severe burns often experience acute malnutrition due to extreme hypermetabolism and increased protein breakdown. Accurately evaluating their nutritional needs and adjusting energy and protein intake according to their condition's stage has proven outcomes [44].

Nutritional status is crucial in affecting multiple organ systems, though these effects may be subtle or confused with physiological alterations secondary to burn injury. However, the price of not addressing nutritional care is dire, with inordinate susceptibility to infections, unfettered catabolism, and death from malnutrition [34].

3.8 Pharmacovigilance

Pharmacovigilance, which is the science of monitoring, assessing, and preventing adverse drug reactions, is essential in burn care, where patients often undergo complex, multi-drug treatments [45]. Burn injuries can significantly alter drug pharmacokinetics and pharmacodynamics, affecting absorption, distribution, metabolism, and elimination. These changes necessitate vigilant monitoring to prevent therapeutic failures or toxicities [46]. Pharmacists play a critical role in achieving pharmacovigilance during burn treatment. Their responsibilities include dispensing medications, monitoring therapy, detecting adverse drug reactions, and advising the MDT on safe medication use. Proactive involvement should enhance patient safety and support adherence to evidence-based protocols [47].

Electronic health records with automated adverse reactions or drug interaction alerts enable real-time surveillance and improve clinical decision-making. Therefore, pharmacovigilance is indispensable in burn care to minimise harm and enhance therapeutic outcomes. It ensures that drug use remains effective, appropriate, and tailored to the physiological changes in burn patients [48].

3.9 Surgical Intervention

A well-trained, well-prepared, and adequately equipped burn care team is crucial for a facility managing severe burn injuries requiring excisional surgery. Surgical debridement and skin grafting are key components in effectively treating patients with a substantial percentage of deep burns (%TBSA). Even when skin grafting is not performed, patients can still experience notable improvements in their recovery and overall outcomes. However, grafting full-thickness burns significantly accelerates wound healing, promotes quicker recovery, and helps prevent or lessen contractures [49].

The gold standard in burn treatment highlights early excision to eliminate the source of potential infection, reduce the hypermetabolic response, and lower the risk of burn wound sepsis. Following this, early autografting by closing the wound with healthy skin from another area of the patient's body enhances these benefits. This further minimises the risk of infection, reduces pain, and supports quicker mobilisation [7].

Gentle washing is also a crucial part of burn wound cleansing. Exposed areas should be covered using a closed dressing method. Biologic dressings generally offer better outcomes compared to non-biologic options. The choice between temporary or semi-permanent dressings and how often they change depends on the wound condition and dressing material availability [49].

3.10 Infection Prevention and Control

Maintaining a clean hospital environment and upholding strict hygiene standards are essential to preventing healthcare-associated infections, particularly in burn units where patients are uniquely vulnerable due to the loss of skin integrity [49]. Fundamental yet straightforward infection control measures, such as hand hygiene, remain highly effective. Improved hand hygiene protocol compliance has consistently been associated with lower infection rates in burn care [50]. Continuous staff education, monitoring, and behavioural audits ensure these interventions are sustainable and effective [39].

Given the heightened risk of infection in burn patients, especially from multidrug-resistant organisms, implementing an antimicrobial stewardship program is essential. These programs guide antibiotic selection, dosing, and duration to optimise outcomes while minimising resistance [51]. Pharmacovigilance also plays a vital role in antimicrobial stewardship to support the rational use of antibiotics based on local resistance patterns and microbiological surveillance. Integrating antibiograms and culture results assists clinicians in tailoring therapies, avoiding unnecessary use of broad-spectrum agents that drive resistance [50]. Beyond antibiotic optimisation, pharmacovigilance ensures medication safety through the early detection of adverse drug reactions. By combining stewardship with active pharmacovigilance, pharmacists and clinicians can deliver safer, more personalised therapy in burn care, reducing antimicrobial resistance and improving patient outcomes [39].

4 SYSTEMS THINKING MODELS OF MDT BURNS CARE

4.1 Systemigram

Systems thinking focuses on the active interplay, coordination, and unification of individuals, processes, and technology [20]. In resource-limited settings, it is essential to prioritise investment in key burn care personnel and the facilities they work in. At the very least, essential burn care team members, such as burn nurses, surgeons, occupational therapists and physical therapists, are vital for delivering a basic standard of effective burn treatment [34].

As seen in Figure 3, the systemigram provides a high-level visual representation of the interdependent components within multidisciplinary burn care and reveals several critical insights into how various functions and interventions interact to influence patient outcomes. Advanced Clinical Care is at the model's core, which acts as the central node influenced by multiple upstream factors, including pharmacovigilance, surgical intervention, infection prevention and control (IPC), nutritional support, and rehabilitation. The systemigram demonstrates that improvements in these areas do not operate in isolation; they converge synergistically to enhance clinical outcomes, ultimately improving functional survival and reducing HACs. The key supporting elements are:

- MDT Vigilance: Central to the system; improves all other functions. It directly enhances Advanced Clinical Care.

- Surgical Intervention, IPC, Nutritional Support, Rehabilitation, and Pharmacovigilance: These elements are tightly interconnected. All directly or indirectly improve Advanced Clinical Care.
- Rehabilitation: Depends on nutritional support. Enhances functional survival and wound healing.
- Functional Survival and Optimal Conditions for Wound Healing: Advanced clinical care, rehabilitation, and nutritional support improved outcomes. Functional survival is a significant success metric.
- Hospital-acquired Complications: This is the primary undesirable outcome. Reduced by enhanced clinical care and other system elements.

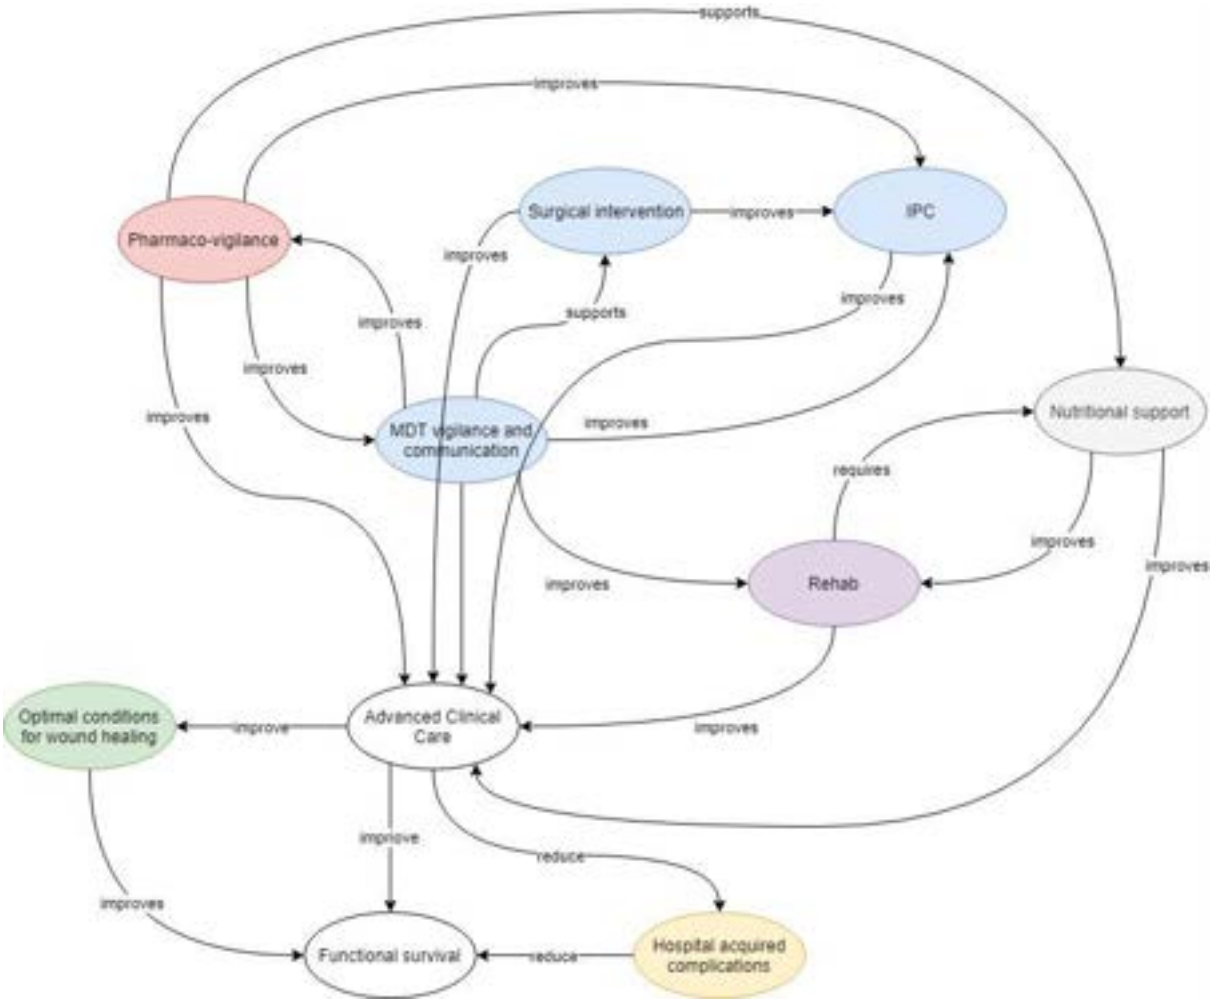

Figure 3: Systemigram of the Functions of a MDT in Burns Care

One of the most critical insights from this systemigram is the centrality of MDT vigilance and communication, which is pivotal in reinforcing the effectiveness of almost every domain in the system. It directly enhances pharmacovigilance, surgical decision-making, and IPC practices while indirectly supporting optimal wound healing and rehabilitation. This highlights the need for tightly integrated teamwork, shared decision-making, and real-time information flow among the multidisciplinary team. Without such coordination, the effectiveness of individual interventions may be compromised, leading to fragmented care and suboptimal outcomes.

The systemigram also reveals valuable feedback pathways, such as how rehabilitation is improved by nutritional support and clinical care and loops back to enhance overall clinical outcomes and reduce complications. Similarly, optimal conditions for wound healing and functional survival are outcomes of multiple reinforcing factors, illustrating that successful burn care depends on addressing physical, procedural, and systemic variables in tandem. These insights underscore the value of systems thinking. By visualising dynamic interactions, leverage points such as nutritional support and MDT communication can be prioritised for targeted interventions that yield widespread improvements across the system.

4.2 Systems Archetype

The systems archetype proposed for the situation in the Systemigram of Figure 3 is named "Shifting the Burden." This archetype describes a situation where a problem is addressed by its symptomatic solution rather than a fundamental one. This can lead to dependency on the symptomatic solution and neglect of the root cause. In this case, the symptomatic solutions include surgical interventions, and IPC responds to immediate threats but does not address the root causes of poor clinical outcomes alone. Pharmacovigilance deals with medication safety issues after the fact.

The fundamental solution can be MDT vigilance and communication, which are foundational as they coordinate care, anticipate risks, and enhance decision-making across all areas. This strengthens all systemic responses (e.g., rehabilitation, nutritional support, and surgical decision-making). The risk of falling into the Shifting the Burden archetype is that without robust MDT engagement, the system may rely on reactive interventions (e.g., more surgeries, antibiotics and pain medication). This can increase complications, creating a dependency loop on corrective measures instead of proactive care planning. Recommendations to break out of the “Shifting the Burden” archetype include the following:

- Prioritise strengthening MDT vigilance.
- Invest in proactive, integrative care approaches (e.g., rehabilitation and nutritional support).
- Reduce dependency on symptomatic interventions by enabling early detection and prevention through team-based vigilance.

Identifying the systems archetype forces you to ask different questions about the system, adding other elements and interactions to the system's model. This will be seen when developing the CLD below.

4.3 Causal Loop Diagram

The CLD in Figure 4 developed for multidisciplinary burn care clearly reflects the dynamics of the “Shifting the Burden” systems archetype. This archetype describes a common systemic pitfall where an organisation or system relies heavily on symptomatic solutions that offer immediate relief while neglecting fundamental solutions that address underlying structural causes. In the case of burn care, the recurring problem symptoms are poor functional survival and the prevalence of HACs, both of which significantly diminish long-term outcomes for burn patients.

The symptomatic solutions in this system include surgical intervention, IPC, rehabilitation, nutritional support, and pharmacovigilance. These essential clinical responses often mitigate acute threats or support patients in crisis. For example, surgical debridement and grafting can quickly reduce infection risks, and IPC protocols help control the spread of healthcare-associated pathogens. Likewise, nutritional support addresses hypermetabolic responses, and rehabilitation tackles mobility and scarring. While these interventions are medically necessary, they operate primarily downstream—they respond to problems once they have emerged rather than preventing them at their root.

In contrast, the fundamental solution is found in MDT vigilance and the broader development of optimal conditions for wound healing and advanced clinical care. These systemic practices enhance coordination, promote early detection of complications, and enable a proactive rather than reactive approach. MDT vigilance fosters shared situational awareness across clinical disciplines, streamlines decision-making, and ensures that each specialist's efforts are synergistic rather than siloed. As a result, patient care is more cohesive and responsive, ultimately reducing the likelihood of complications and improving long-term functional survival. This balancing loop—where enhanced team communication improves care, reducing complications—represents a more sustainable and preventive approach to complex clinical challenges.

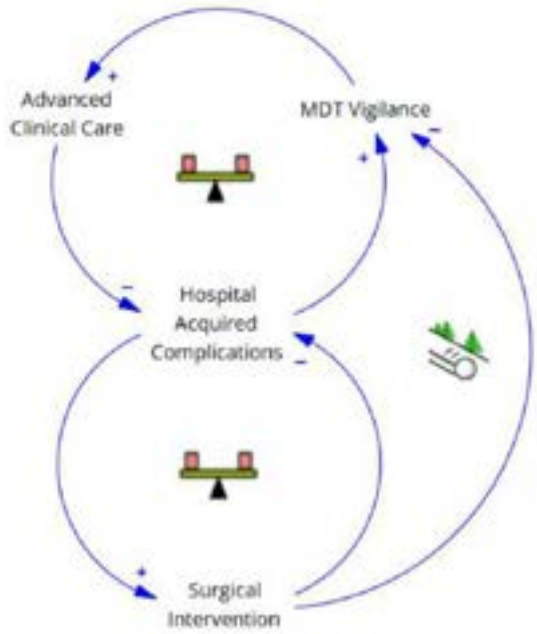

Figure 4: Causal Loop Diagram of MDT in Burns Care

However, the diagram also reveals a reinforcing loop of unintended consequences—an essential characteristic of the Shifting the Burden archetype. As pressure mounts to deliver quick results, symptomatic interventions such as surgery and intensive IPC measures become increasingly prioritised. Over time, this can divert attention, funding, and institutional focus from MDT development and systemic prevention. The health system, therefore, becomes more reliant on reactive measures, such as escalated pharmacological responses or repeated surgical procedures, to address recurring complications. This dependency not only undermines the effectiveness of the fundamental solution but also contributes to systemic fatigue, increased costs, and potential burnout among care providers. It becomes a cycle of "fix and repeat," where the root causes of poor outcomes remain unaddressed.

Breaking out of this archetype requires deliberate and strategic action. The paper identifies several key recommendations: First, MDT vigilance must be prioritised. This includes structured multidisciplinary rounds, investment in team-based training, and real-time data sharing to enhance situational awareness. Second, proactive and integrative care approaches must be emphasised, particularly those focusing on patient-centred outcomes like rehabilitation, nutritional support, and psychosocial care. When implemented as part of a coordinated system rather than isolated disciplines, these interventions help shift the focus upstream. Lastly, the system must actively reduce dependency on symptomatic interventions by building capacity for early risk detection, anticipating complications, and embedding team-based problem-solving.

The CLD encapsulates a critical tension within burn care delivery: the balance between treating symptoms and addressing causes. By mapping the system's feedback loops, it becomes evident that sustainable improvement hinges on technical excellence and the structural integrity of care coordination. Investing in the foundational capacities of MDTs and creating conditions for optimal healing are not just operational choices—they are strategic imperatives for breaking the cycle of dependency and shifting the burden toward long-term resilience in burn care systems.

5 CONCLUSION

This study highlights that a MDT approach is fundamental to achieving optimal functional survival in burn patients. The analysis demonstrates that coordinated care across disciplines significantly reduces intervention delays, enhances wound healing, and lowers the incidence of secondary complications. By integrating expertise in resuscitation, surgical intervention, infection control, nutritional support, physical rehabilitation, and psychological care, MDT protocols address burn patients' complex and multifaceted needs more effectively than conventional care models.

The models suggest that the success of MDT care lies in its ability to combine diverse perspectives, structured communication, and shared decision-making. These elements enable the team to respond more holistically to patient needs, improving clinical outcomes and patient and family support throughout recovery. However, while the results provide compelling evidence, they remain context-specific. Variations in healthcare resources, staffing, and system capacity may influence how similar outcomes can be replicated elsewhere.

Limitations of this study include reliance on retrospective data and a conceptual systems model that requires validation across multiple care settings. Future work should therefore focus on prospective, multi-site studies that test the causal relationships proposed in the model and measure long-term patient outcomes. Further research could refine the systems-thinking framework, ensuring its adaptability across healthcare environments. Expanding this evidence base will help strengthen the argument for embedding MDT frameworks as a global standard in advanced burns management.

ABSTRACT

Cement is essential in construction, yet dust emissions from packaging plants present serious environmental issues. This study examines the factors behind excessive dust, particularly the shortcomings of dust suction and filtration systems. Employing a case study approach, experimental and historical data was analyzed to evaluate how operational parameters pressure, temperature, cement particle size, and gas flow rate affect dust filtration efficiency. A multivariable regression model was employed, with the concentration of dust at the plant outlet as the primary performance indicator. Findings revealed that pressure was the only variable significantly affecting outlet dust emissions. The Taguchi optimization process revealed the optimal suction pressure to be 7.16 mbar, with specific damper settings. The model demonstrated a high R^2 value of 92.42% and a P-value of 0.000, indicating robust statistical significance. Ultimately, these optimizations led to a substantial reduction in dust concentration to 14.292 mg/m^3, highlighting the critical role of pressure management in improving environmental performance and achieving regulatory compliance in cement packaging operations.

Keywords: bag house, cement dust, dust emission, environmental pollution, optimization,

1 INTRODUCTION

Dust control involves a range of techniques aimed at minimizing airborne particles and reducing their impact on air quality. Cement packaging plants are specialized facilities where cement is processed and packaged for distribution. However, cement production is notorious for generating significant amounts of dust and other pollutants, which pose serious risks to both environmental health and human well-being. Within these plants, baghouse systems are essential dust-extraction mechanisms that effectively filter particulates from the air. Furthermore, pressure management is crucial for optimizing the performance of these systems by regulating airflow, ensuring efficient dust capture, and maintaining compliance with environmental standards. The primary airborne pollutants associated with cement production include both dust and fumes emitted during the manufacturing processes of cement and clinker.

Dust consists of solid particles that become airborne as a result of being entrained by process gases, often directly from the materials being handled or processed. These dust particles vary significantly in size, ranging from 0.1 microns to 10 mm in diameter, with some being relatively large [19]. Fumes, on the other hand, are solid particles formed by the condensation of vapours through processes such as sublimation, distillation, calcination, or other chemical reactions. Common fume constituents include sulfur and silicon oxides, which are produced during the high-temperature calcination process of clinkerization. The diameter of fume particles typically ranges from 0.03 to 0.3 µm [19]. Together, these pollutants pose significant risks to air quality, public health, and the surrounding ecosystems, underscoring the need for effective control measures in the cement industry.

Emissions of cement dust are rigorously managed through the implementation of dust-extraction systems in loading areas, cement silo filter systems, and stringent controls on powder-blowing pressures. Additionally, high-level silo alarm systems are in place to enhance safety [9]. The cement factory selected for this study operates two identical packing lines, each fitted with baghouses that feature multiple suction ducts strategically located at critical points, including the tops of the bucket elevators, vibrating screens, packer bins, rotary packers, packer discharge points, and bag cleaners.

The primary function of the filtration system is to capture dust particles and divert them into downstream hoppers while allowing clean air to be released into the atmosphere. However, despite these measures, the plant continues to face challenges with discharging air that has a high dust concentration ($\geq$15 mg/m^3). This persistent issue necessitates further investigation to identify the underlying cause, as it remains unclear why contaminated gas is still being emitted.

The inadequacy of the current filtration system to maintain dust concentrations within permissible limits presents a significant operational and environmental concern. Despite implementing advanced filtration technologies and adhering to regulatory standards, the facility is unable to consistently achieve acceptable air quality parameters due to an unidentified failure in the filtration process. This discrepancy indicates a critical gap in understanding how various operational parameters—such as airflow rates, particle size distributions, and filter maintenance protocols—affect filtration efficiency and dust emissions. Moreover, the high levels of dust released into the atmosphere not only jeopardize compliance with regulatory standards but also pose health risks to workers and surrounding communities, thereby undermining the sustainable operational objectives of the facility. Therefore, addressing the inefficacies of the dust filtration system is essential for improving air quality and ensuring compliance with environmental regulations.

The objective of this study is to assess the impact of operational parameters on the quality of the process gas released into the atmosphere. The findings will contribute to the development of a comprehensive model designed to establish operational guidelines aimed at minimizing dust emissions. While the study will indirectly enhance the overall packaging process, the primary focus is on optimizing dust suction and filtration. This targeted approach will facilitate the effective treatment of dust emissions, ensuring compliance with air quality standards.

2 LITERATURE REVIEW

Dust emissions in cement manufacturing plants arise from diverse sources, including mining, raw material handling, grinding mills, clinker coolers, storage silos, and packaging operations. Research indicates that the primary contributors to dust emissions are the movement and transfer of cementitious materials, particularly during loading, unloading, and packaging [20] [4], [16]. A study by [25] determined that total dust concentrations ranged from 4.20 mg/m^3 in crushers to 15.20 mg/m^{3}in packaging areas, surpassing exposure limits in the latter and raw mill areas. Contrary to the common belief that raw mills, kilns, and cement mills generate the most dust, [17] found higher geometric means of total dust exposure in cranes (38.64 mg/m^3), packing plants (21.30 mg/m^3), and crushers (13.48 mg/m^3) compared to the cement mill (3.23 mg/m^3), kiln (2.87 mg/m^3), raw mill (1.85 mg/m^3), maintenance (1.16 mg/m^3), and administration block (0.29 mg/m^3). Such disparities underscore the need for detailed analysis to identify areas for improving dust emission control. Additionally, [16] highlighted that dust emissions in cement packing plants primarily originate from transfer points along the packaging line, conveyor belts, and rotary packers.

Airborne dust particles from cement plants contribute to significant environmental pollution and health hazards. Exposure to cement dust can result in various respiratory problems, including bronchitis and asthma, as noted by [4], and other health complications affecting workers and local communities [15]. Moreover, dust deposition poses ecological risks, leading to soil degradation and water contamination [6]. Environmental protection agencies mandate that all cement plants implement effective dust control measures. Various techniques exist for dust removal, such as bag filters, electrostatic precipitators (ESPs), wet scrubbers, and dust collectors. Bag filters, particularly effective for capturing particles sized between 0.1 and 1 µm, use impaction, direct interception, and diffusion to remove dust when gas stream passes through filter fabric [24].

The baghouse, a crucial component of dust filtration, comprises a metal vessel containing fabric bags designed to capture dust. Bag selections depend on operating conditions such as temperature and pressure. Typically, the bags measure between 2 to 10 meters in length and can have diameters of up to 0.4 meters. Baghouses can house between 100 to over 1000 bags depending on the specific process gas being treated [2].

The filtration process begins as dusty gas enters the dust collector, where coarse particles are separated due to inertia, falling into a hopper. The gas then passes through fabric bags, where dust accumulates on their surfaces. With a filtration velocity of approximately 0.3-2 m/min and a pressure loss of 1-2 kPa, clean gas travels upward until it exits through the outlet tube, while dust is cleaned by mechanical shaking, reverse pressure, or pulse jet methods. A pulse valve activates when a specified dust layer thickness is reached, releasing compressed air to dislodge collected dust. Standard fabric filters exhibit dust collection efficiencies above 99%, necessitating regular cleaning and maintenance for optimal performance [22].

A standard baghouse dust filtration system consists of ductwork, the baghouse unit, and a suction fan. Effective design and operation hinge on four key parameters: inlet temperature, system pressure, gas flow rate, and filtration wind speed. High temperatures can compromise filter bags' longevity, while pressure fluctuations can indicate leaks or fan issues, ultimately affecting system performance [11], [10].

Monitoring gas flow rates is essential, as variations impact dust loads and overall filtration capacity. Efficiency can be optimized by adjusting wind speeds according to specific conditions such as particle size and humidity levels. Reducing leakage and maintaining appropriate cleaning intervals are critical for enhancing dust collection efficiency and prolonging equipment lifespan [13]. For example, [7] explains that when the dust accumulates on the fabric bag, the filter drag is described by the following basic filtration equation.

$$\frac{\Delta P_f}{v_f} = S_f = S_E + K_2(W - W_R) \quad \textbf{(1)}$$

Where ΔP_f is the pressure drop across the filter bag, v_f is the filtration velocity, S_f is the filter drag, S_E is the effective drag of residual dust, K_2 is the specific resistance coefficient of the dust cake, W is the mass per unit area of the dust cake and W_R is the residual dust mass per unit area.

While substantial research has been conducted on dust generation during loading and packaging, a significant gap remains in studies focused on optimizing baghouse systems through systematic performance evaluations. Recent investigations have primarily concentrated on health impacts, dust generation, and the design and initial setup of fabric filter systems in baghouse installations, rather than on operational improvements aimed at reducing emissions.

For instance, [35] highlight the health effects of cement dust exposure and the necessity for effective mitigation measures. Similarly, [36] discuss preventative strategies that have proven limited in effectiveness due to regulatory and technical challenges. Although these studies emphasize existing filtration systems, they do not delve into comprehensive optimization methods for enhancing baghouse performance.

Research has identified various dust emission sources, such as transfer points and conveyor systems, underscoring the need for systematic analyses to improve baghouse functionality. Current findings indicate high dust levels in packing areas, emphasizing the urgency for optimization, yet specific data often remain scarce. Many studies focus on initial setups without addressing troubleshooting for ineffective systems, highlighting the need for targeted optimization efforts.

Furthermore, while diverse dust extraction technologies exist, the optimization of these systems through pressure management remains underexplored. Operational parameters, such as pressure fluctuations and airflow velocity, are critical for enhancing dust capture efficiency but require further investigation. Understanding the impact of pressure drops across filters is essential for improving overall baghouse performance.

In summary, existing literature highlights health implications and dust generation in cement production but lacks a dedicated focus on optimizing baghouse systems. Future research should aim to fill this gap by prioritizing operational assessments and performance enhancements to meet air quality standards and improve system efficacy. Given the pressing environmental and occupational health concerns related to excessive dust emissions from cement plants, thorough assessments of operational and design deficiencies affecting dust filtration efficiency are crucial. This study seeks to address these gaps by enhancing the performance of existing fabric filter systems, ultimately aiming to reduce the environmental and health risks associated with cement dust emissions and contribute to improved air quality and safer working conditions.

3 METHODOLOGY

This study investigated the performance of baghouses at a cement packing plant. The methodology encompassed a two-pronged approach: an analysis of historical operational data and a series of on-site assessments to determine the current efficiency of the baghouse

system. Initial evaluations were conducted using historical performance data of the baghouse to understand trends and identify any past operational issues. This data included past records of pressure variations, temperature readings, and dust concentration levels. Following the historical analysis, comprehensive on-site assessments were performed to evaluate the current operational state of the baghouse. These assessments focused on the physical design and functionality of the baghouse, closely resembling the layout depicted in Figure 1, which features bags with a length of 4.2 meters. The baghouse was assessed under specific operating conditions, where the recommended temperature range was maintained between 45°C and 65°C, with an associated pressure range of 0.2 mbar to 8 mbar. To facilitate measurement and data collection, the ductwork was labelled sequentially from 1 to 9, with dampers designated as D1 to D3 and measurement points indicated as IP1 to IP6, as shown in Figure 2. Multiple strategically located measuring points were established throughout the system to accurately capture pressure variations. This strategic placement ensures a comprehensive understanding of airflow dynamics and performance across the baghouse.

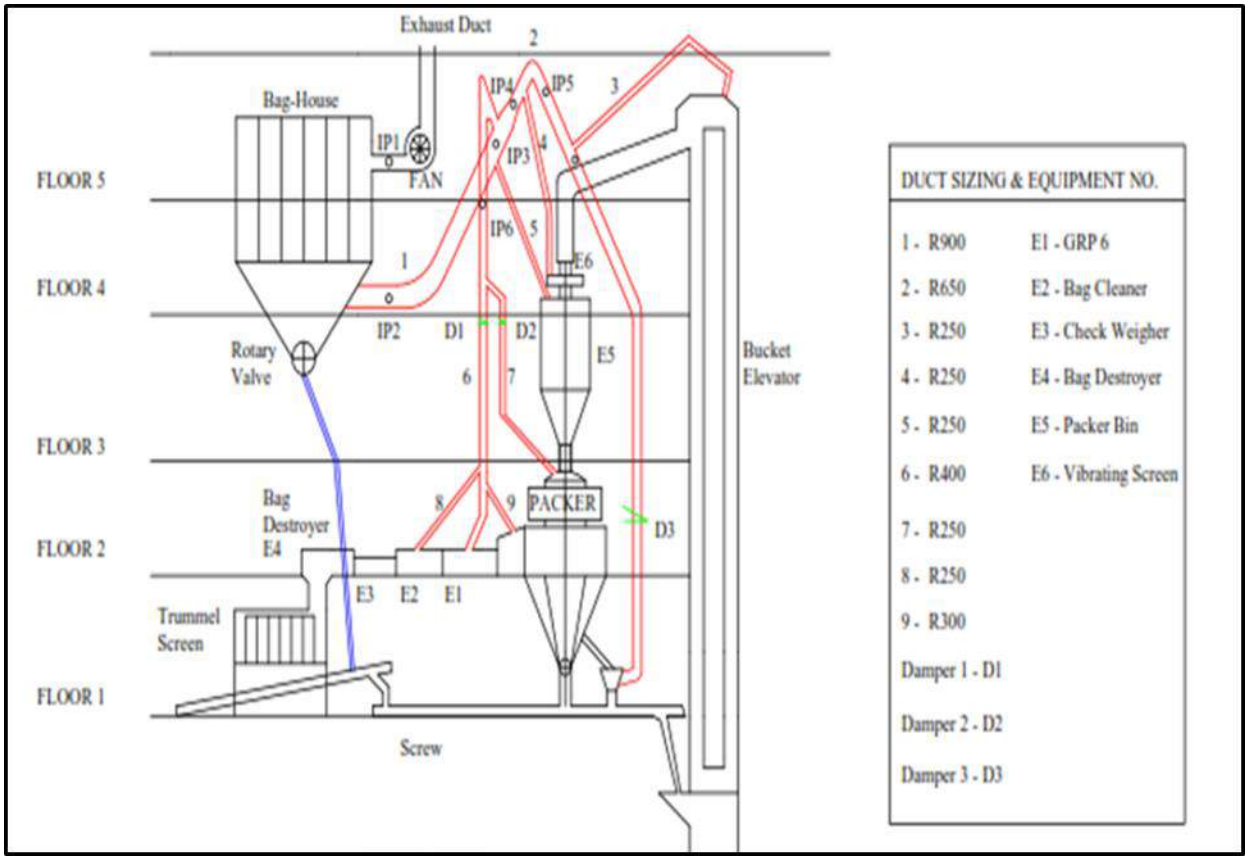

Figure 1: Diagram of baghouse filter system and sampling points

3.1 Data Collection

The study monitored several key performance indicators (KPIs) to evaluate the baghouse's operational efficiency, including static and dynamic pressure measurements were used to assess the resistance within the system and identify any potential inefficiencies. Continuous temperature monitoring was conducted to ensure that the baghouse operated within the optimal range, as temperature significantly influences filtration performance. Both inlet and outlet dust concentration levels were measured to evaluate filtration efficiency. Changes in dust concentration were vital for understanding the effectiveness of the baghouse in capturing particulate matter.

To assess airflow efficiency, the study calculated the differential pressure, defined as the difference between fan suction pressure and duct static resistance, following the methodology presented by [2]. Using temperature and dynamic pressure data, airflow rates into the baghouse were determined. These calculations facilitated an understanding of the relationship between airflow and the operational efficiency of the baghouse. The effectiveness of the baghouse in filtering dust was evaluated through the analysis of inlet and outlet dust concentration changes. A decrease in outlet concentration compared to inlet concentration indicated effective filtration performance.

3.1.1 Static and dynamic pressure measurements

To ensure accurate measurements of dynamic and static pressure in the filtration network, a systematic approach was employed involving meticulous preparation and procedural execution. The pitot tube was thoroughly cleaned using a blower to eliminate any dust blockages that could affect readings. Following this, the digital manometer was calibrated to ensure measurement accuracy. Then, the L-type pitot tube was connected to the digital manometer via connecting pipes, ensuring that the positive (+) port of the manometer was linked to the total pressure port of the pitot tube and the negative (−) port to the static pressure port. Furthermore, the digital manometer was tared to establish a baseline reading of 0, ensuring precise measurements when the pitot tube is inserted. After the pitot tube was inserted into the duct through the static pressure port, oriented to face the direction of airflow. To obtain representative measurements, the area around the pitot tube was sealed with mutton cloth to minimize airflow disturbances. The digital manometer was allowed to stabilize for 30 seconds, followed by the collection of dynamic pressure readings at 30-second intervals over 5 minutes [11]. This process was repeated to account for any temporal variations in pressure. In total, 10 readings were captured from each of the 6 measuring points, with the average recorded as the dynamic pressure in mbar.

After completing the dynamic pressure assessment, the connection on the total pressure port (+) was detached, leaving only the static pressure port (-) connected to the digital manometer. The digital manometer was tared again, and the Pitot tube was cleaned to remove any internal dust residue before it was inserted into the duct to measure static pressure. Similarly, the Pitot tube was allowed to stabilize for 30 seconds before taking static pressure readings at 30-second intervals for 5 minutes [11], A total of 10 static pressure readings were recorded from each of the 6 measuring points, with the average noted as static pressure in mbar

3.1.2 Temperature measurements

The temperature measurement process involved the careful use of a thermocouple probe to ensure accurate readings within the duct system. The thermocouple probe was inserted into the duct to obtain the temperature reading. Prior to insertion, the thermocouple thermometer was checked to confirm that it was accurately displaying the ambient temperature. Following the recommendations from [11], the thermocouple thermometer was allowed a stabilization period of 30 seconds after insertion into the duct. This step was crucial for ensuring that the temperature reading reflects the true conditions within the duct environment. After the stabilization period, temperature readings were recorded at 30-second intervals over a duration of 5 minutes. This method provides a consistent approach to capturing temperature fluctuations and ensures comprehensive data capture. To account for temporal variations, the measurement process was repeated multiple times. A total of 10 temperature readings were taken from each of the 6 measuring points for each sampling session. The average temperature from the 10 readings at each measuring point was calculated and recorded as the duct temperature in degrees Celsius (°C)

3.1.3 Dust Concentration Measurements

The study employed a hand-held dust monitor to assess dust concentration levels within the baghouse system's inlet and outlet ducts. The dust monitor was securely positioned at IP2, the inlet duct of the baghouse, ensuring it was properly oriented to capture the incoming dust-laden air. After activation, the monitor was allowed a 30-second stabilization period to adjust to the ambient conditions. Once stabilized, dust concentration readings were recorded at 30-second intervals for a total duration of 5 minutes, following the method outlined by [11] This process was repeated to account for any temporal variations in dust levels. A total of 10 readings were taken at IP2, and the average concentration was calculated and documented in mg/m^3. The dust monitor was then relocated to IP1, the outlet duct of the baghouse. Similar to the inlet measurement, it was securely mounted and oriented to capture the purified air stream. After a 30-second stabilization period, dust concentration readings were again recorded at 30-second intervals over 5 minutes. This process was repeated for consistency, resulting in 10 readings from IP1, which were averaged and recorded as the outlet dust concentration in mg/m^3. The same methodology was applied to the remaining measuring points (IP3, IP4, IP5, and IP6) to assess dust concentrations throughout the system. In conjunction with dust measurements, visual inspections were conducted at each sampling point to identify primary sources of dust generation and potential leaks within the ductwork.

3.2 Data Analysis

To evaluate the performance trends of the baghouse, a thorough analysis of historical data from previous years was conducted. This historical context is essential for identifying trends, detecting anomalies, and assessing the long-term effects of operational changes on the baghouse system. By integrating this historical data with the measurements collected during the current study, a comprehensive understanding of the system's behaviour and overall performance was achieved.

Dust filtration efficiency was specifically analysed using weekly operational data from the plant. The detailed equation derived from the multivariable regression analysis is provided in Equation 1. To refine the regression model, the P-value was employed to eliminate insignificant variables, utilizing a threshold of 5% at a 95% confidence level, in accordance with the methodology proposed by [12]. Variables with P-values exceeding 0.05 were excluded from the model, and the analysis was iteratively re-evaluated, retaining only those variables that demonstrated statistical significance (P-value < 0.05) in the final regression equation. The multivariable linear regression analysis was conducted using Minitab Statistical Software ©2022, ensuring robust statistical evaluation.

$$Y = X_0 + \alpha X_1 + \beta X_2 + \delta X_3 + \varepsilon X_4 \quad \textbf{(2)}$$

Where: $\alpha, , \delta, \varepsilon$ represent coefficients
Y - dust emission concentration in mg/m^3
X_0 - constant
X_1- baghouse inlet gas flow rate in m^3/h
X_2 - baghouse inlet temperature in ℃
X_3 - baghouse inlet pressure in mbar
X_4- cement residue in wt%

Mathematical modelling was applied to optimize critical variables impacting dust emission concentrations. Using the Taguchi method and Minitab software, suction fan damper settings were systematically adjusted to maximize suction pressure in the dust filtration system. The experimental design utilized a comprehensive L25 orthogonal array, testing three fan dampers across five levels, resulting in 25 experimental runs as shown in Table 1. Measurements of suction pressure were recorded and analysed for robustness using signal-to-noise (S/N) ratios.

This approach identified the optimal damper settings, yielding the highest suction pressure for effective dust filtration. Confirmation tests were conducted to validate the reliability of the results, reinforcing the effectiveness of the optimization process in enhancing cement dust filtration systems.

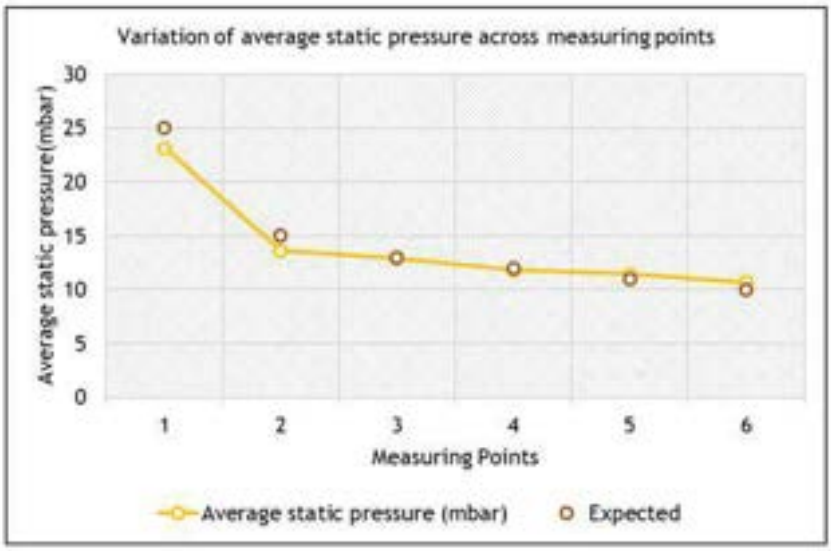
Table 1: Factors for the L25 orthogonal array in Minitab

	Factors (Damper Opening Setting)			Response
Levels	Damper 1	Damper 2	Damper 3	Suction Pressure
1	0	0	0	
2	25	25	25	
3	50	50	50	
4	75	75	75	
5	100	100	100	

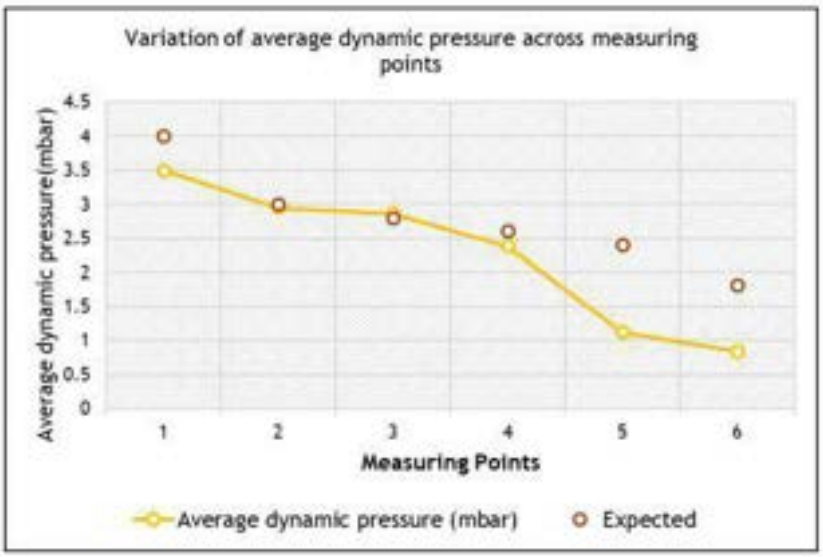
4 RESULTS

This section presents the findings from the study, structured into three key sections. The first part details the evaluation of the unit processes within the dust filtration system, assessing their performance based on various operational metrics. The second section examines the influence of packing plant operating parameters on the concentration of dust at the outlet. Finally, statistical analysis software was used to optimize these operating parameters, aiming to achieve the desired outlet dust concentration as informed by experimental observations.

The performance of the unit processes in the dust filtration system was analysed through variations in both measured operating parameters—such as static pressure, dynamic pressure, temperature, and dust concentration—and calculated parameters like gas flow rate. The experimental values were then compared against established industry standards and equipment manufacturer recommendations [3]. The results of this analysis are illustrated in the graphs Figures 2-4



(a)



(b)

Figure 2: Measurements of static and dynamic pressure

4.1 Variation of average static and dynamic pressure

The average static pressure starts at 23 mbar at the first measuring point and gradually decreases to 11 mbar at the sixth measuring point, as shown in Figure 2(a). The expected static pressure values, also depicted in Figure 2(a), follow a similar decreasing trend. A significant drop in static resistance is anticipated from point 1 to point 2, where the baghouse is located. The gradual decrease from point 2 to point 6 indicates resistance in the duct system, which is typical for airflow in filtration systems [1]. The small difference between average and expected static pressure suggests a strong correlation, indicating that the system is performing as designed.

In contrast, the average dynamic pressure begins at 3.5 mbar at the first measuring point and decreases through subsequent points. This pressure is generally lower than expected and

notably below industry standards [14]. A steep decline in average dynamic pressure is observed between points 4 and 5, indicating significant changes in system characteristics. From points 5 to 6, the dynamic pressure continues to decrease, albeit at a more gradual rate. This trend suggests that the dust filtration system operates effectively, with pressure dropping as air flows through filters and components. However, the measured dynamic pressures do not align with findings from other studies [10], [8], [16], which reported dynamic pressures ranging from 3 to 6 mbar.

4.2 Variation of average temperature

The average temperature starts at 59°C at the first measuring point and steadily decreases from point 1 to point 6, as illustrated in Figure 3. A significant drop occurs between points 1 and 2, where the baghouse is located. Beyond this point, duct temperatures gradually decrease as the distance from the suction fan increases. This trend indicates effective heat dissipation from the suction fan as air flows through the duct.

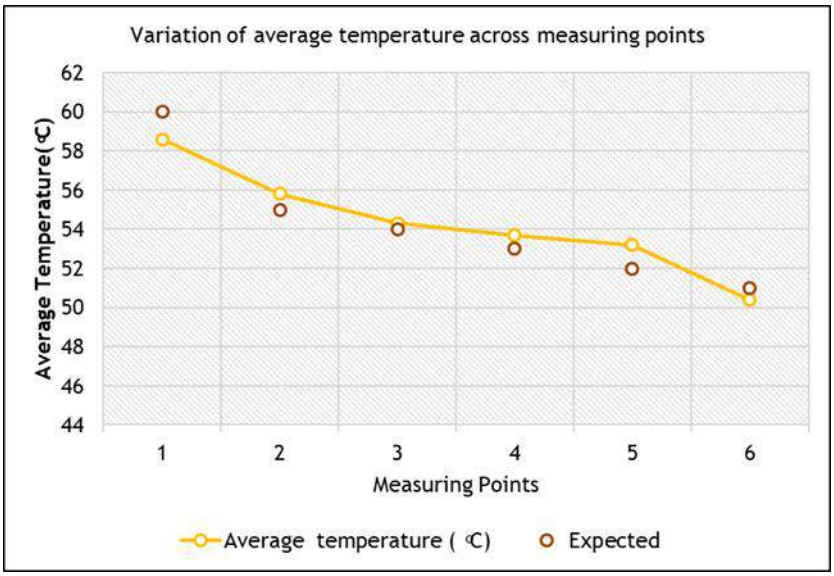


Figure 3: Measurements of temperature across sampling points

This temperature behaviour aligns with findings by [18], suggesting proper functioning of the dust filtration system, where the temperature drop correlates with energy dissipation and heat transfer during filtration. The pronounced decrease in temperature between points 1 and 3 indicates that the initial stages are where most heat removal occurs due to the filtering process. The measured temperatures generally align with expected values, confirming the system's effectiveness.

The gas flow rate through each duct was calculated using various duct characteristics, including duct configuration, gas properties, gas density, thermodynamic properties, barometric pressure, and energy above ambient. These data were provided by duct manufacturers and plant operators. The measured static and dynamic pressures and temperatures were integrated with these characteristics to derive the gas flow rates, as shown in Figure 4.

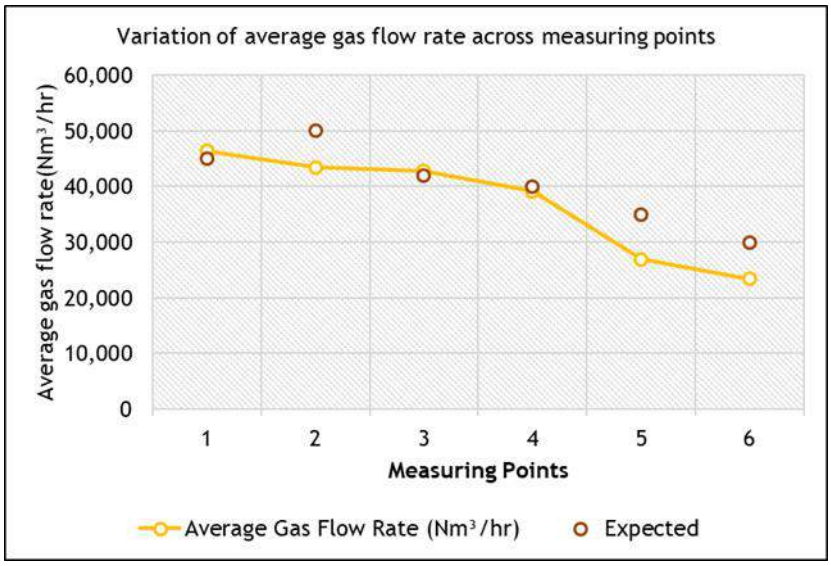

Figure 4: Measurements of temperature across sampling points

5 DISCUSSION

The analysis of static and dynamic pressures measured at various points within the filtration system reveals significant insights into operational efficiency and airflow performance. The average static pressure recorded at 23 mbar at the initial measuring point and decreasing to 11 mbar by the sixth point demonstrates an expected trend that aligns closely with predicted static pressure profiles. This close correlation suggests that the filtration system operates effectively and within acceptable limits, as indicated by the minimal disparity between measured and expected values [27]. The noticeable drop in static pressure from point 1 to point 2 corresponds with the presence of the baghouse, where an initial significant resistive force is anticipated due to the filtration media itself. Subsequent measurements from point 2 to point 6 indicate resistance contributed by the duct system, a behaviour consistent with established airflow dynamics in filtration systems, where resistance occurs as air travels through ductwork and filter media [31].

In contrast, the analysis of dynamic pressure indicates more complex behaviour. The initial average dynamic pressure at 3.5 mbar shows a consistent decline through the measuring points, reaching levels notably lower than expected values, particularly when considering industry standards that typically range from 3 to 6 mbar. The steep decline between points 4 and 5 displays an abrupt change in the dynamic characteristics of the system, reflecting either a sudden increase in resistance or a modification in airflow patterns as air continues to traverse through the filters and ducts. This observation is critical, as it validates the hypothesis that conditions within the system may fluctuate due to factors such as filter saturation or turbulence induced by airflow speed [33].

Furthermore, the gradual decrease from points 5 to 6 reinforces the notion that the filtration mechanisms are intact, allowing the system to function as designed with effective dust capture and pollutant removal. However, the lower than expected dynamic pressures compared to findings from other studies indicates an area for further investigation, particularly concerning how specific design parameters of the filtration system influence performance metrics. The disparity suggests that while the system operates effectively under current configurations, optimization efforts could further enhance performance by aligning with and possibly exceeding standards established by previous research [30]. These differences highlight the importance of contextualizing operational metrics within the broader landscape

of filtration research to comprehensively assess effectiveness and identify potential improvements.

The results of the temperature measurements taken at various points in the duct system showcase a clear pattern of thermal dynamics, indicating operational mechanics in the dust filtration system. The average temperature drops from an initial 59°C at the first measuring point to lower values as the distance from the suction fan increases, with a significant decline observed between points 1 and 2, where the baghouse is situated. This observation aligns with the finding of [26], who noted that the geometry and configuration of ducts can influence heat transfer and airflow characteristics.

The notable temperature reduction at the initial measuring points suggests that primary heat dissipation occurs early in the airflow process, which is likely correlated with the nature of particulate filtration. As noted by [34] flow characteristics alongside thermal dynamics significantly influence the performance of filtration systems. This trend is promising, as it indicates that the system efficiently removes heat from the air, which is essential in preventing overheating that can lead to diminished filter performance and unplanned operational disruptions.

As the air progresses through the ductwork, a gradual cooling trend is evident, commonly attributed to laminar flow and convective heat transfer mechanisms within the duct system [29]. The calculated gas flow rates further substantiate the relationship between duct characteristics and thermal performance, derived from accurate metrics such as duct configuration, gas properties, and energy above ambient pressure, all of which are crucial in understanding dynamic thermal behaviour [32]. The systematic integration of static and dynamic pressures with temperature data enhances insights gained from the temperature profiles and predictions about system efficiency.

While the measured temperatures show a good alignment with expected values, the reliability of the filtration system's design is reinforced by this consistency. The expected values closely matching the recorded temperatures suggest that the system operates effectively within its intended parameters, as supported by the observations made by [28] regarding thermodynamic efficiency within forced convection systems.

In summary, the observed temperature profiles within the ductwork provide evidence of the effective heat management characteristics of the filtration system, demonstrating its capability to sustain operational efficiency under prescribed conditions.

6 CONCLUSION

This paper provides a thorough exploration of the interrelated dynamics of static pressure, dynamic pressure, temperature, gas flow rate, and dust concentration within a dust filtration system. The findings demonstrate the intricate relationships among these parameters and their critical influence on effective dust management. Through comprehensive graphical analysis and multivariable regression, we quantitatively assessed the impact of each variable on dust concentration, revealing that static and dynamic pressures play pivotal roles, with static pressure emerging as the most significant factor.

To leverage these insights for practical optimization, the study utilized the Taguchi method, employing Minitab software to methodically minimize dust concentration at the plant outlet by fine-tuning the operational settings of the suction fan dampers. The results confirmed that duct temperature and static pressure levels remained consistent with expected performance benchmarks; however, dynamic pressure, gas flow rate, and dust concentration displayed notable inconsistencies, particularly at measurement points 5 and 6. Observations indicated that dust build-up could obstruct dust movement towards the baghouse, a problem stemming

from design limitations within the ductwork and insufficient suction pressure, exacerbated by fully closed dampers during the experiments.

The regression analysis provided a robust mathematical model for the dust filtration process, reinforced through analysis of variance (ANOVA), which demonstrated the appropriateness of the model with a significant P-value (less than 0.05) at a 95% confidence level. The derived predictive equation specifies the relationship between various operational parameters and dust concentration, allowing us to optimize damper settings effectively. Our empirical analysis identified optimal damper configurations—100% for dampers 1 and 2 and 50% for damper 3—yielding a suction pressure of 7 mbar at point 6, closely aligning with industry standards and maintaining a minimal error margin of 3.8% between predicted and measured values.

Further complications arose from the presence of sharp edges within the ductwork, contributing to turbulent airflow and subsequent pressure loss, thus highlighting the necessity for design improvements. This study recommends implementing smoother transitions or filleted edges to enhance airflow efficiency and dust suction, particularly in high concentration zones such as the packer area. Ongoing monitoring and analysis of operational parameters are imperative to compare actual performance against established industry best practices—ensuring timely identification of inefficiencies and adaptive modifications.

Although the study focused on key factors such as pressure, temperature, particle size, and gas flow rate, it did not explore additional elements like filter maintenance and aging, which could significantly influence system performance. The optimization methods used, such as the Taguchi method, might not capture the full complexity of the filtration process. As a result, the effectiveness of the suggested solutions may differ across various operational settings.

In conclusion, an adaptive control strategy that dynamically adjusts damper settings based on real-time operational data can be integrated into the process, thereby ensuring consistent airflow regulation and significantly enhancing dust separation performance. By integrating cutting-edge technologies such as Artificial Intelligence (AI), the Internet of Things (IoT), and advanced data analytics into cement dust filtration research, we can achieve remarkable improvements in operational efficiencies, predictive capabilities, and adherence to stringent environmental standards. The implementation of these technologies not only serves to optimize dust filtration systems but also plays a crucial role in promoting a more sustainable cement production process.

Moreover, further research should investigate the impact of cement particle size on baghouse efficiency, which could refine filter media selection and bolster overall dust collection effectiveness. While static pressure readings currently meet satisfactory levels, the insights gained from examining dynamic pressures reveal substantial opportunities for performance enhancement within the filtration system. Future studies focused on duct geometry, airflow rates, and dynamic thermal behaviours are essential for optimizing heat management and ensuring that operational effectiveness is sustained in line with recognized industry standards.

ABSTRACT

Industry-University Collaboration (IUC) is a way to leapfrog innovation, and benefits both sectors, with industry partners contributing resources like equipment, expertise and data in exchange for intellectual property (IP) access. However, establishing IP agreements in the context of the South African IPR Act is complex and challenging regarding data valuation in the context of hard-to-value tangibles. Without a proper framework, both parties risk legal and financial challenges. This research aimed to develop a data valuation framework that ensures compliance with the IPR Act. The 7-Step Soft Systems Methodology is used, incorporating semi-structured interviews with relevant stakeholders. Preliminary findings highlight strengths and shortcomings of current data valuation methodologies and propose a more effective approach to a framework artefact as a solution, which could encourage investment in university research by providing clear valuation mechanisms and drive innovation by facilitating knowledge transfer through fair agreements, ultimately strengthening collaborations between universities and industry.

Keywords: data valuation, intellectual property, innovation

1 INTRODUCTION

Industry-University Collaborations (IUC) refer to joint efforts between universities and industry aimed at exchanging knowledge, resources, and expertise for mutual benefit. IUC is essential for integrating theoretical research with industrial applications, and promoting entrepreneurship and commercialisation of innovations [1]. With a growing emphasis on data science at universities, opportunities for collaboration with industry are increasing. Industry is keen to engage in research projects, offering in-kind contributions such as mentorship, access to equipment, and data, which are sought after by universities. In return, they seek access and rights to use the intellectual property (IP) generated by the university. Establishing contractual agreements on IP access rights involves several considerations, including relevant IP laws and the monetary and in-kind contributions by the parties, which often require the valuation of data, the latter posing a significant challenge. Without an appropriate data valuation methodology in the context of IUC, universities and industry are exposed to risks of non-compliance with the South African Intellectual Property Rights from Publicly Financed Research and Development Act ("IPR Act") [2].

This study is positioned within the field of Industrial Engineering, which is inherently concerned with the optimisation of complex systems and decision-making at the intersection of people, processes, and technology. As data becomes a critical asset in modern engineering systems, Industrial Engineers are uniquely placed to contribute to the development of systematic, stakeholder-aligned valuation frameworks. This is also highly relevant to Research and Development (R&D) management, where the ability to fairly and accurately value data supports better resource allocation, IP planning, and innovation commercialisation strategies.

Data is at the heart of data valuation and has a different outlook depending on its use case. Data is a new asset class [3] that is intangible, which companies can exploit to gain more value from it [4]. In the context of finance, data is defined as digitised information, which can have various use cases, including forecasting. The data is generated from economic transactions that give a picture of the consumers' behaviour and other digital footprints that companies can use for a competitive edge [3]. In the context of R&D conducted by institutions such as universities, data can be the result of R&D activities and can hold considerable value.

Data typically does not hold significant value on its own; instead, it serves as an input for analytics, often integrated into software programs to derive insights that can be translated into content-based information products like scientific reports or business intelligence. Data primarily functions as intermediate goods, intended for integration and transformation to generate various information goods [5]. The transformation of data into information and subsequently into knowledge closely mirrors the principles of data valuation. In its raw state, data consists merely of unstructured signals or symbols. However, when contextualised, this data acquires meaning and becomes valuable information. Further integration of information into organisational processes facilitates the development of actionable knowledge, enhancing decision-making and operational clarity [6].

Figure 1: Value creation from progressive utility of processed data [6]

Figure 1, indicates that as data progresses from raw input to insight, its utility and economic value increase. Therefore, effective data valuation must account for the data's current use and its latent potential to generate knowledge and drive enterprise value [6]. But what if the latent potential is not yet fully conceivable at the time that the data valuation transaction must be finalised? And what if there is IP creation linked to the increased value of data as it progresses from raw input to insight? This leads us to considering data as a hard-to-value intangible, defined as "intangibles or rights in intangibles for which, at the time of the transaction, no reliable comparables existed and projections of future cash flows expected to be derived from the transferred intangible or assumptions used in valuing the intangibles were highly uncertain" [7, p. 1]. In the context of concluding a research contract governing a research project, it is essential to understand the complexity of valuing data as well as IP and the rights linked to data and IP, to ensure fair contract negotiations and compliance with IPR Act [2].

1.1 Problem statement

This leads to the **Problem Statement**: *The lack of a standardised data valuation methodology in IUC poses significant risks for both sectors in terms of non-compliance with the IPR Act and equitable IP access rights.*

1.2 Research objectives

The **Key Research Objective** is creating a Data Valuation Framework artefact as a solution for use in IUCs that comply with legislative frameworks.

Through providing a Framework for data valuation, industry and universities will be guided towards making informed decisions on which existing data valuation methodologies (if any) are appropriate for a specific situation. Where no suitable methodology is available, the Framework will assist in providing shared principles and understanding and alignment across various methodologies, to achieve a suitable solution in an agile manner [8].

To achieve the Key Research Objective, several Sub-Objectives are defined:

1. Explore and evaluate the existing data valuation methodologies and their use cases.
2. Identify the key challenges and merits of these methodologies.
3. Determine key requirements by stakeholders for the proposed Data Valuation Framework through the conduct of interviews with universities and industry.

4. Determine the key legislative requirements for data valuation to ensure compliance with the IPR Act and the Exchange Control Regulations.
5. Evaluate the existing data valuation methodologies for suitability in the IUC context by considering the key requirements from stakeholders (Sub-Objective 3) and legislation (Sub-Objective 4).
6. Design a suitable Data Valuation Framework for IUCs which would give guidance for informed decisions on the most appropriate existing data valuation methodologies (if any) for a specific situation, or provide shared principles, understanding and alignment across various methodologies, to achieve a suitable solution.
7. Verify the suitability of the proposed Framework (Sub-Objectives 6) through interviews with stakeholders (industry and universities) and legislative regulators (National Intellectual Property Management Office (NIPMO)). A case demonstration will be used as part of the verification step.
8. Validate that the Framework has fulfilled the requirements through expert interviews.

A systems thinking approach is used for the creation of a Data Valuation Framework, satisfying the requirements of industry, universities and legislators (NIPMO). All these requirements will be compiled, verified, and validated within the Data Valuation Framework artefact, which makes it unique for IUC, where valuation of data is required before access to IP rights in a research agreement can be concluded. For the scope of this paper, sub-objectives 1, 2, and 4 are completed, and 3 and 5 are in process.

2 TOWARDS AN INDUSTRY-UNIVERSITY COLLABORATION DATA VALUATION FRAMEWORK

Data is increasingly recognised as a critical intangible asset that significantly influences enterprise value in the digital economy [6], therefore, a tendency to measure its value in monetary terms. As an intangible asset, data can be valued in ways beyond its financial impact; however, with significant difficulty [9].

2.1 Importance of data valuation in the context of IUC

Data valuation is important for regulatory compliance, especially with data protection and IP laws, and industry-specific regulations.

In the context of IUCs, the IPR Act (See Section 2.5) by default assigns IP rights to the university where public funding is used to create IP because of a research contract between industry and the university, and certain IP transactions will be subject to NIPMO approval. However, Section 15(4)(a) of the IPR Act states that "any research and development undertaken at an institution and funded by a private entity or organisation on a **full cost basis** shall not be deemed to be publicly financed research and development and the provisions of this Act shall not apply thereto". [2] To determine whether the contribution by the industry complies with the full cost basis, especially where the contribution is partially in-kind (in this scenario, through providing access to valuable data to the university for R&D), it is critical to determine the value of the data, which this study aims to achieve.

2.2 Data Valuation as part of good practice and governance

Valuing data helps organisations demonstrate accountability, transparency, and responsible data stewardship practices required by regulatory authorities [9].

Data valuation is crucial in risk management by assessing the potential risks and liabilities associated with data assets, such as data breaches, privacy violations, regulatory non-compliance, and data quality issues [3]. Valuing data helps organisations prioritise data security measures, implement data governance frameworks, and mitigate risks effectively [4].

Organisations that effectively value and leverage their data assets gain a competitive advantage in the market. Valuable data enables better decision-making, innovation, customer insights, operational efficiency and agility, which positions organisations for success and differentiation in a data-driven economy [4].

In the context of mergers, acquisitions, or partnerships, data valuation becomes critical for assessing the value of data assets owned by potential partners. Data valuation helps in due diligence processes, negotiations, and determining the overall value and synergy potential of combining data assets from different entities [4].

Venture capital (VC) represents a type of private equity funding and involves providing equity capital to companies not publicly traded on stock markets. This is particularly relevant for young companies that have innovative ideas and growth potential but lack established business models and a track record. Venture capitalists take on the risk of investing in these new or growing businesses with the expectation that some of them will become successful in the long term. Therefore, when VC investors put money into big data companies, it reflects their assessment of the future revenues generated by these companies' data assets. In this way, VC investment serves as an indicator of the value of their data [9].

Assigning monetary value to data is important for financial reporting, accounting, and valuation purposes, especially for organisations that consider data as a valuable intangible asset on their balance sheets [3]. Data valuation methodologies can help organisations comply with accounting standards and accurately reflect the value of data in financial statements [9].

Valuable data assets can be monetised through various means, such as selling data to third parties, licensing data for analytics or research purposes, creating data products or services, and leveraging data for targeted marketing or personalised experiences. Data valuation helps organisations identify monetisation opportunities and optimise revenue generation from data assets [4].

2.3 Data characteristics and challenges

Although benefits of data valuation are recognised, implementation of effective valuation practices is hindered by the inherent characteristics of data. A systematic examination of these characteristics is essential, as it may provide critical insights into the development of an appropriate and robust methodology for data valuation.

2.3.1 Data are (in general) non-rival

The concept of rivalry is used to describe whether the consumption of a good by one individual/entity diminishes its availability or quality for others. Data are non-rivalrous by nature because they can be accessed by multiple parties simultaneously [10]. For example, an online article can be viewed by multiple users without any degradation in the content. However, data can become rival because of legal contracts around the infrastructure, technologies and resources used to process, store and transmit data that restrict access to data [3, 9]. This is known as excludability.

2.3.2 Data has spillovers

This refers to the unintended or indirect effects of data that benefit or disadvantage other companies. Spillovers can be positive or negative. Positive spillovers from data-driven industries such as research sectors can contribute to job creation and foster a conducive environment for innovation and entrepreneurship. Knowledge sharing can also enhance problem-solving capabilities across industries. Negative spillovers can pose privacy risks if sensitive information is leaked to unauthorised parties. Market distortions are also possible when certain parties gain access to valuable data resources that are not equally accessible to others, leading to monopolistic practices [9, 10].

2.3.3 Data has low specificity

Data can be used for unforeseen purposes other than intended. That unpredictable change in context makes it difficult to value data [9], but can provide possible monetisation opportunities and alternative use cases [4].

2.3.4 Data has network effects

The value of data increases as more users access, contribute to, or interact with it. Social media platforms, for example, derive value from network effects as more users join and engage with the platform, creating a larger network of interconnected data and interactions. The Organisation for Economic Co-operation and Development (OECD) describes this as synergies [9].

2.3.5 Data has increasing returns to scale

This refers to a concept in economics and business that describes a situation where increasing the scale of production leads to a more than proportional increase in output or efficiency. Increasing returns to scale imply that larger firms or organisations can produce goods or services more efficiently and cost-effectively than smaller entities. This can lead to competitive advantages, higher profit margins, and market dominance for firms that achieve economies of scale in their operations. Veldkamp refers to this as the data feedback loop [3]. It is often associated with economies of scale, occurring when the average cost of production decreases as the level of output or scale of operations increases. This can be due to various factors such as specialisation, better utilisation of resources, efficient production processes, bulk purchasing discounts, and spreading fixed costs over a larger output, all made possible through the effective use of data [9].

2.3.6 Data can depreciate

Data about the previous day's conditions is less pertinent to the current situation due to the rapid pace of change in the environment. Additionally, it is observed that extensive reservoirs of knowledge tend to lose value more rapidly compared to smaller reservoirs. To calculate the depreciation of data accurately, it is essential to understand its intended purpose. It is also important to understand how volatile and persistent the environment is [3]. This is supported by the views of Deloitte in stating that: “Data is perishable, but not depletable” [4].

2.3.7 Data are an experience and credence good

An experience good is a type of product/service whose quality or value can only be fully assessed by the consumer after they have used or experienced it. A credence good is a type of product/service whose quality or characteristics are difficult for consumers to evaluate even after purchase and use. Unlike experience goods, where quality can be assessed through consumption, credence goods require trust in the seller's expertise or third-party certification to determine their true value or effectiveness [5]. Examples include medical services, legal advice, and certain types of dietary supplements, where consumers may not be able to verify the quality or outcomes directly. In the context of data, it may be difficult to assess their usefulness or accuracy until they are compared to similar data sets [5].

2.4 Data as a “hard-to-value” intangible

As mentioned in Section 1, data can be considered as a “hard-to-value” intangible, as it shares one or more of the typical characteristics [7], namely:

- It is partially developed at the time of transfer
- Commercial exploitation might only take place several years after the transaction
- It could be an integral part of the development of other hard-to-value intangibles

- Due to the expectation of novel exploitation, it is difficult to compare it with reliable past projections of similar transactions
- Transfer of the hard-to-value intangible to another enterprise is done under a lump-sum agreement
- It is used or developed under a cost contribution or similar arrangements.

From the described IUC context, many of these mentioned characteristics can be assigned to data.

2.5 Legislation impacting data valuation and IUC

To come up with a reasonable Data Valuation Framework in the context of IUC, it is important to consider the legislation that could govern data within the context of the use case of the data. Assessing the importance of data's value within the economy is crucial for informing discussions on understanding the potential hazards linked to personal data usage and managing cross-border data exchanges [9]. Compliance with these laws will shape organisations' data strategies, risk management practices, and approaches to data monetisation, affecting how they assess and assign value to data assets. As a result, companies must adopt more expensive measures to handle personal and sensitive data, which can increase its value [10].

The most prevalent laws and regulations considered in this research for South African universities are mentioned below. However, there are other legislations which would be considered on a case-by-case basis. As an example, if the industry is from the European Union (EU) and shares personal data from EU citizens with a South African university, then the General Data Protection Regulation **(GDPR**) of 2018 [11] must be considered in addition to the relevant South African laws described below. As it is an offshore company, not only the Intellectual Property Rights from Publicly Financed Research and Development (IPR Act) (No.51 of 2008) [2], but also the South African Exchange Control Regulations (1961, with their Amendments 2012) [12], must also be considered. This paper only focuses on the most relevant legislation within the IUC in South Africa, but considers other legislations as per Sub-Objective 4, which are not mentioned here.

In South Africa, the main legislations governing IP rights and data having a bearing on this study include:

The Intellectual Property Rights from Publicly Financed Research and Development (IPR Act) (No.51 of 2008) addresses the ownership and management of IP rights arising from publicly financed R&D activities. The Act aims to promote innovation, technology transfer, and the commercialisation of research outcomes while ensuring fair and equitable treatment for all stakeholders involved, including researchers, institutions, and the public. The IPR Act is particularly of interest as it governs all IP rights created through public universities and science councils in South Africa. It is critical to be able to value data where it forms part of the industry partner's contribution towards a research project governed under the IPR Act, to ensure that fair IP access agreements can be negotiated [2].

The South African Exchange Control Regulations (1961, with their Amendments 2012), are designed to control the flow of foreign exchange into and out of the country. These regulations aim to manage the country's foreign currency reserves, stabilise the economy, and prevent illicit financial flows. They are governed by the South African Reserve Bank (SARB). In the context of this study, for any IP or other forms of assets (such as data) to be transferred to offshore entities, the SARB's approval is required in terms of the Exchange Control Regulations. One of the considerations for approval is whether the South African entity charged a market-related fee for the transfer of the IP, hence, the valuation of IP (and data in this study's context) becomes critical to the transaction [12].

The Protection of Personal Information Act (No. 4 of 2013), POPIA, is a comprehensive data protection law that aims to safeguard the privacy and personal information of individuals in South Africa. The Act applies to the processing of personal information by public and private entities, outlining principles and requirements for the lawful and responsible handling of such data [13].

2.6 Data valuation methodologies

There are insufficient tools available to adequately study the modern data economy [3]. Determining a structured approach or set of procedures to determine the worth of data assets is still a challenging task. According to Fleckstein et al., data valuation approaches can be grouped into three models: market-based, economic and dimensional models [10].

2.6.1 Market-Based Models

Market-based models are an expansion of valuing physical assets. Much like tangible assets, data can be evaluated based on its cost, its market value for sale, or its potential to generate income [10]. The value is derived from the principle of supply and demand.

To further establish the idea of market-based models, Deloitte highlighted a method called **the market approach**. As companies keep using their data and creating models to trade it, these trades can help show their market value. Like other assets, comparing values will be tricky at first, but as the market grows and trading methods improve, Deloitte expects data trades to become a common way to value data [4].

The **cost approach** uses the replacement cost as an indicator of value and considers the cost of acquiring a new asset or factor of production, including any associated expenses such as transportation, installation, and training. This approach is used to gauge the economic value of an asset by considering the cost of replacing it rather than its original purchase price or historical cost [4]. Veldkamp further explains this cost approach as a **barter trade system**. If a company wants to increase the number of entries in its dataset, it needs to lure more client transactions. It can do so by introducing loyalty programs or offering discounts where clients trade their transactional behaviour for this benefit. If financially feasible, the ideal strategy for the company might entail initially setting prices below cost during its early stages, as this acts as an expensive yet beneficial investment in data and transactions that will yield valuable data. If one can quantify what it costs the company to attract these additional client transactions, the cost-based approach could be used to assess the value of data [3]. According to the OECD report, the **sum-of-cost approach** 'consists of measuring the value of output by summing the costs of production: intermediate consumption, compensation of employees, consumption of fixed capital used in production, a net return to fixed capital used in production (also known as "mark-up") and taxes (minus subsidies) on production' [9, p. 29].

2.6.2 Economic Models

The economic model values data by looking at the financial estimates of economic benefits, assessing the value of making data public and its impact on policy legislation [10].

Deloitte explores the **multi-period excess earnings method (MPEEM)** as a valuation approach under economic models. It is commonly applied to valuing intangible assets where there is significant future income expected from these assets. Future earnings are typically estimated multiple periods into the future, and then the excess earnings are calculated by subtracting a reasonable return on tangible assets (such as physical assets or working capital) from the total earnings. The excess earnings are attributed to the intangible asset being valued. The estimated excess earnings are discounted back to their present value using an appropriate discount rate. This discount rate accounts for the time value of money and the risk associated

with receiving future earnings. The present values of the excess earnings for each forecasted period are summed up to arrive at the total value of the intangible asset [4].

Another approach that can be considered under the economic model is the **Relief from Royalty method,** which is commonly used to value IP and intangible assets. The royalties are calculated by estimating what would be paid if the owner did not own the asset but instead licensed it from a third party. These royalties represent the cost savings or relief that the owner gains by not having to pay for the use of the asset. The estimated royalty payments are discounted back to their present value using an appropriate discount rate. The present value of the estimated royalty savings represents the value of the intangible asset [4].

2.6.3 Dimensional Models

Dimensional models value data by looking at other dimensions of data that are not market-based or economic. It focuses on the intrinsic characteristics of the dataset and the context within which the data is used [10].

Deloitte proposes the **With and Without method**. The value of the business, with all its data assets, is estimated. This is to assess how data will change cash flows. The business is then valued without the data assets to account for the absence of data benefits. The difference between the two scenarios is calculated and represents the incremental value attributable to the data assets [4].

Fleckstein et al. [10] developed a model that is straightforward, efficient, and accessible to a variety of stakeholders. The serves as a preliminary assessment tool to identify areas for further exploration depending on the use case of the data. It can reveal the relative value of a dataset, identify potential risks, and support informed decision-making. For this study, it will be called the **Data Dimension method** and Table 1 shows the set of dimensions used.

Table 1: Data valuation dimensions [10]

Dimensions used to value data	Description
Ownership	Addresses outright data set ownership plus licensing restrictions and service agreements
Cost	Addresses the cost of data set acquisition, maintenance, and replacement
Usage	Addresses dataset mission criticality, ability to integrate, usage scope, usage frequency, metadata, additional resources, expected increase in demand, and diminishing value
Age	Addresses refresh rate and available history
Privacy	Addresses whether the dataset contains sensitive data such as Personally Identifiable Information (PII) and Protected Health Information, and meets privacy standards
Data Quality	Addresses completeness, accuracy, currency, consistency, duplication, trustworthiness, and timeliness
Volume & Variety	Addresses the number of records, scope of information for each record, and ability to answer needed questions

3 RESEARCH METHODOLOGY

The Soft Systems Methodology (SSM) will be the main methodology used in this study. It is a seven-step method for addressing complex, disordered situations of all types. It is an action-focused process of investigating problematic scenarios, enabling users to progressively learn and move from comprehending the situation to implementing actions for improvement [14].

Figure 2 illustrates the seven-step SSM.

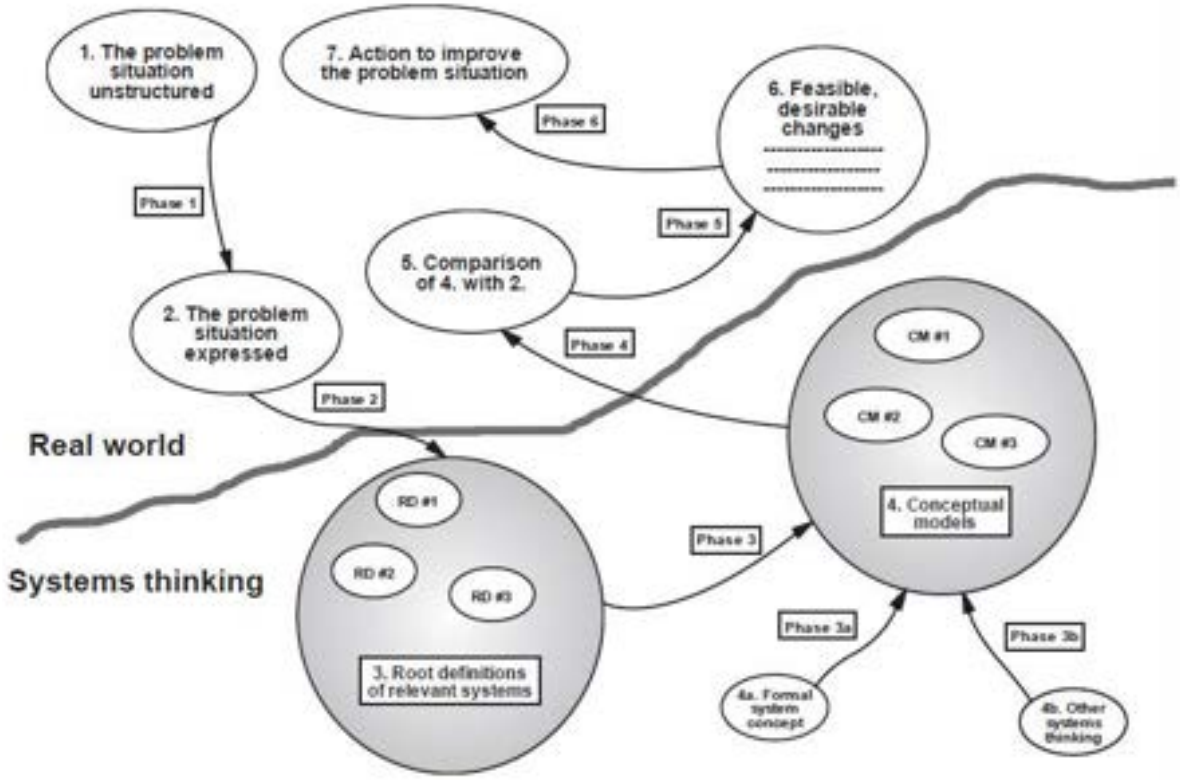

Figure 2: Checkland's soft system methodology [15]

***Step 1**: The problem situation unstructured*: In this step comprehensive information about the problem situation is gathered without imposing any structure [14]. For this study, there will be semi-structured interviews with the main stakeholders, such as industry partners, universities, and the legislative body (NIPMO) and a review of the existing literature, including an evaluation of existing data valuation methodologies. Different interview questions are aimed at industry, universities and NIPMO, and for each of these, pilot interviews were conducted to test the suitability of the interview questions.

***Step 2**: The problem situation expressed:* In this step, the objective is to visually and descriptively represent the problem situation to capture its complexity. Drawings, symbols, text, and diagrams that capture elements, interactions, and perspectives to facilitate understanding and communication among stakeholders are used. A Rich Picture is one such collaborative tool that gives a shared understanding of the problem [16]. This will be based on the outputs from Step 1. The problem statement aims to express the core of the problem situation, as already captured in Section 1.

***Step 3**: Root Definitions of relevant systems*: In this step, concise descriptions of the relevant systems are developed within the problem situation. A root definition is used to capture the essential purpose of the relevant system and is always described as a transformation process, where the input is changed into a new form, resulting in the output. The CATWOE analysis is used for this, and it stands for:

- Customers: These are the beneficiaries of this transformation process e.g. universities in the context of this research
- Actors: These are the individuals who do the transformative work
- Transformation: The process that changes the input to an output
- Worldview: A broader view that makes the system meaningful

- Owners: The individuals with the power to control the system
- Environmental Constraints: External factors that are beyond the control of the system [14].

For this study, the root definitions will give the key requirements of the proposed Data Valuation Framework.

Step 4: *Conceptual Models:* In this step, models are created that represent the ideal operation of the systems defined in the root definitions [14]. These models represent the activities that need to occur within the system to achieve the defined purposes. The Data Valuation Framework design will be the output of this step.

Step 5: *Compare models with the real world:* In this step, gaps and discrepancies between the conceptual models and the actual situation are identified. To ensure that the designed model aligns with the real-world experiences and needs of the stakeholders, a verification and validation process is undertaken. This process involves comparing the model against the actual situation and the stakeholders' perspectives to confirm that it meets the intended objectives and is suitable for its purpose. Verification checks if the model is correctly constructed, while validation ensures that it accurately represents reality and addresses the stakeholders' requirements [14]. Verification and validation for the proposed Data Valuation Framework will be done using expert interviews and an IUC case study.

Step 6: *Feasible and desirable changes*: In this step, changes that are realistic, acceptable to stakeholders, and beneficial for the system are proposed. Changes can be to any of the objects of the process or to the process itself. There are three types of change: in structure, in procedures, and attitude [15].

Step 7: *Action to improve the problem situation:* An action plan is developed and implemented based on the proposed changes. Planning, examining, and evaluation occur. Communication is deemed very important to have stakeholder buy-in [14].

4 ARTEFACT DESIGN OPTIONS

Currently, there are two approaches identified towards building Conceptual Models, which will be further investigated during the interviews with industry, universities and NIPMO.

Approach #1:

The Data-Information-Knowledge-Wisdom (DIKW) pyramid [17] can serve as a useful foundation for a Data Valuation Framework, because it offers a conceptual lens to understand how data gains value as it is contextualised and applied [6]. In this study, the pyramid can provide a shared language between industries and universities. Universities may bring in technical expertise by focusing on data and information layers with the goal of building foundational understanding and providing theoretical models. Whilst industries may bring strategic priorities by focusing on the knowledge and wisdom layers, with the goal of solving practical problems and driving innovation and competitiveness. The DIKW provides a layered view of responsibilities, enabling each side to understand how their work contributes to the broader outcome [17].

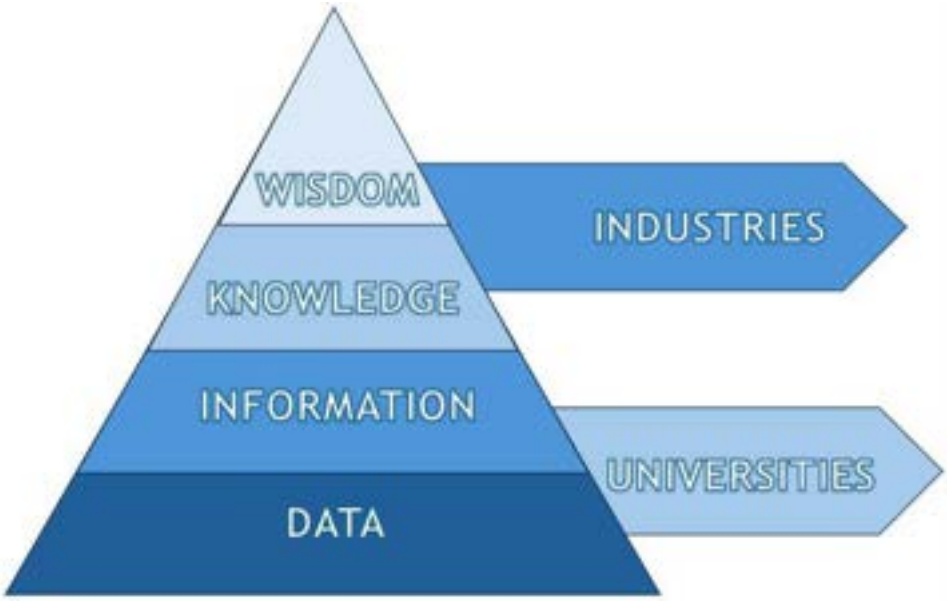

Figure 3: Data-Information-Knowledge-Wisdom pyramid in the IUC context

Approach #2:

Another approach would be to lean on enterprise architecture to conform to already existing industry standards. Hafner et al. [18] proposed the Data Valuation Business Capability (DVBC) Taxonomy, structured into four layers, namely Information, Resources, Roles and Processes, as illustrated in Figure 4. These layers align with enterprise architecture principles from The Open Group Architecture Framework (TOGAF). Each layer contains key dimensions, which are further broken down into characteristics that represent specific aspects of data valuation [18].

The information layer focuses on what data is being valued and why. In IUCs, the motivation could be for compliance or product innovation. The resource layer focuses on tools, models, and theories used for valuation. This aligns expectations on how data will be assessed, secured, and leveraged. The role layer looks at who is involved in data valuation and decision-making, and would also include a neutral body (e.g. NIPMO) to ensure fairness and transparency. The process layer focuses on how valuation is done, tracked, and used [18]. This approach transforms data from a point of contention into a shared strategic asset.

Layer	Dimension	Characteristics							E/N*
Information	Purpose	Qualitative Data Valuation			Quantitative Data Valuation			Combination	E
	Data Valuation Object	Bundled Data				Non-Bundled Data			E
	Data Value Driver	Business Utility	Cost	Data Durability and Lifetime	Data Quality	Data Security and Privacy	Sentiment and Perception	Others	N
Resources	Data Valuation Theory	Economic	Cooperative Game Theory	Non-Cooperative Game Theory	Decision Theory	Query-Based	Index-Based	Proprietary	N
	Data Valuation Tooling	Interpersonal Elaboration			Model and Application			Combination	E
Roles	Value Determination Stakeholder	Internal		Internal and External (with Intermediary)		Internal and External (without Intermediary)		External	E
	Value Auditing Stakeholder	Internal Data Value Auditor			3rd Party Data Value Auditor			Not Existing	E
Processes	Component	Data Value Assessment		Data Value Allocation		Data Value Prediction		Data Value Monitoring	N
	Result	Specific Absolute Data Value			Approximate Absolute Data Value			Relative Data Value	E

* E = Exclusive *N = Non-Exclusive

Figure 4: Data Valuation Business Capability (DVBC) taxonomy [18]

5 CONCLUSION AND FUTURE WORK

Data valuation is core to complex contractual negotiations, especially in the context of IUCs, where compliance with legislation as well as a fair and beneficial value proposition to all parties is critical. This study contributes to addressing this challenge by proposing some options towards the development of a stakeholder-informed Data Valuation Framework, grounded in systems thinking. For Industrial Engineers, the implications are significant. By applying structured, context-sensitive valuation methodologies, Industrial Engineers can facilitate more effective technology transfer processes, ensuring that innovation derived from public–private collaboration is equitably recognised and rewarded.

Preliminary requirements for developing the framework need to be elicited, e.g. the framework should support more transparent and compliant intellectual property (IP) management, particularly under South Africa's IPR Act. It should position Industrial Engineers to play a strategic role in shaping institutional data strategy policies by embedding valuation principles into research management, governance, and contract development processes. Ultimately, this study indicates that Industrial Engineers should also manage intangible assets, negotiate complex stakeholder environments, and enable data-driven innovation ecosystems.

ABSTRACT

This study explores the causal factors influencing capital structure decisions in JSE-listed industrial, resources, and technology firms. While traditional theories like the trade-off and pecking order offer some guidance, they fall short on causal clarity. Using a model-agnostic framework with SHAP analysis, the study identifies key drivers, showing that the debt ratio has the strongest influence, supporting the trade-off theory. Asset turnover and enterprise value also show importance, aligning with the pecking-order view. To test time-based influence, Granger causality was applied and confirmed that changes in Debt-to-Assets Ratio and Cashflow Interest Cover precede shifts in the Debt-to-Equity ratio. This supports the idea that firms respond to past leverage levels and internal cashflow signals when adjusting capital structure. Together, machine learning and statistical tools provide a clearer, data-driven view of how firms manage financing decisions.

Keywords: Causal Inference, SHAP Analysis, Granger Causality, Explainable Machine learning

1 INTRODUCTION

The pursuit of an optimal capital structure remains a central challenge in corporate finance, drawing significant interest from scholars and practitioners worldwide. Despite decades of extensive research and debate, a comprehensive understanding of the factors influencing firms' financing decisions remains elusive [1]. Traditional statistical models have predominantly been used to analyze variations in debt ratios across firms, focusing on identifying key determinants of capital structure. However, limited research has explored the use of non-linear models as alternative predictive tools for capturing the dynamic nature of capital structure decisions [2].

Understanding the determinants of capital structure and identifying the optimal leverage level is vital for firms aiming to maintain solvency and long-term sustainability. Highly leveraged firms, for example, may be compelled to reduce employee-related costs when facing financial distress [3]. Although various theories attempt to explain the composition of debt and equity in firms, cross-sectional and time-series variations in capital structure remain challenging to interpret [1]. The Trade-off Theory, Pecking Order Theory, and Market Timing Theory are the most prominent frameworks guiding discussions on capital structure decisions. Yet, empirical studies have struggled to clearly differentiate the strengths and limitations of these theories, leaving the determinants of capital structure an ongoing subject of inquiry [4]. Furthermore, there is no universally accepted method for determining a firm's target leverage [5].

This study addresses this gap by employing causal inference methods to uncover the relationships between capital structure and financial variables. The foundational work of [6] initiated the exploration of capital structure's impact on firm value, emphasizing the trade-off between debt and equity financing [6]. Their theorem highlighted the appeal of debt financing due to tax advantages [7]. Building on this foundation, the Trade-off Theory suggests that firms balance the tax benefits of debt with the risk of bankruptcy costs [8]. However, this theory has been criticized for its assumptions about debt discipline and agency problems.

In contrast, the Pecking Order Theory focuses on firms' financing preferences, driven by information asymmetries between firms and investors [9]. This theory suggests that firms prioritize internal financing over external debt to mitigate risks associated with asymmetric information. Additionally, the Market Timing Theory posits that firms strategically time their financing decisions based on market conditions, opting for equity issuance when stock prices are high and debt issuance when equity is undervalued to minimize the cost of capital [10].

Despite these theoretical models, empirical evidence remains inconclusive in identifying dominant drivers of capital structure across different markets. Recent studies emphasise the importance of exploring non-linear models and machine learning techniques to capture the complex and dynamic factors influencing capital structure. Techniques such as artificial neural networks and support vector machines offer promising alternatives for uncovering hidden patterns and nonlinear relationships within financial data [11].

While several studies have examined capital structure determinants, most rely on linear modelling techniques and often fail to establish causal relationships. This research addresses that gap by integrating causal inference methods with explainable machine learning techniques. Specifically, it employs the Granger Causality Test to identify features with statistically significant causal relationships to the debt-to-equity ratio and applies Shapley Additive Explanations (SHAP) to interpret feature importance in model predictions. This dual approach ensures a comprehensive understanding of both association and causality in the factors influencing capital structure.

The theoretical foundation of this study is anchored in Modigliani–Miller, Trade-Off, and Pecking Order theories. While Agency Theory and Signalling Theory are acknowledged as

important extensions—highlighting agency conflicts and information asymmetry issues, respectively—they are not explicitly incorporated. The research focuses intentionally on the primary causal mechanisms of financing decisions rather than managerial incentive problems or market signalling dynamics.

The contributions of this study are threefold: First, it applies advanced machine learning algorithms to identify a broader and non-linear set of capital structure determinants. Second, it integrates causal inference (Granger causality) and explainable machine learning (SHAP) to assess both causal relationships and feature contributions. Third, it explores the potential influence of Environmental, Social, and Governance (ESG) factors on capital structure decisions, offering new insights within an emerging market.

2 REVIEW OF THE LITERATURE:

2.1 BACKGROUND OF CAPITAL STRUCTURE THEORIES

Capital structure theory examines the principles and frameworks that guide how firms determine the proportion of debt and equity in their financing mix. Foundational perspectives—such as the Modigliani and Miller irrelevance proposition, the trade-off theory, the pecking order theory, and market timing theory—have shaped decades of empirical and theoretical inquiry into financing decisions [5]. These frameworks offer contrasting explanations of how capital structure choices influence firm value, cost of capital, and risk exposure. Subsequent research has extended these theories to account for firm-specific characteristics, market conditions, and institutional environments, revealing that no single theory fully explains observed financing patterns across industries or time periods. This diversity of perspectives underscores the complexity of capital structure decision-making and provides the basis for examining more recent methodological developments, such as machine learning approaches, in capturing its dynamic and non-linear determinants.

Three principal theories attempt to explain the factors influencing a firm's capital structure: The Trade-off Theory, the Pecking Order Theory, and the Market Timing Theory. Despite extensive empirical studies, a consensus on the dominant theory remains elusive [1], with findings often varying across different global markets.

Modigliani and Miller's ground-breaking research in 1958 revolutionized the understanding of capital structure's impact on firm value. Initially suggesting that capital structure is irrelevant in perfect capital markets, their subsequent work incorporated tax considerations, advocating for the increased use of debt financing [6].

The Trade-off Theory posits that a company's capital structure strikes a balance between the benefits of debt, such as tax advantages, and the costs of potential bankruptcy. Although it has faced criticism, this theory remains a widely accepted framework for understanding corporate decisions regarding capital structure [8].

In contrast, the Pecking Order Theory suggests that firms follow a financing hierarchy, prioritizing internal funds over external debt. This theory highlights the role of information asymmetry between firms and investors in shaping financing choices [9].

The Market Timing Theory, introduced by Baker and Wurgler in 2002, argues that firms strategically time their financing decisions based on market valuations. According to this theory, companies issue debt when stock prices are high and equity when undervalued, thereby minimizing their cost of capital [10].

Empirical studies conducted by [13] have explored the complex determinants of capital structure, identifying key variables like firm size, assets, and growth prospects [13]. Similarly, [1] emphasised factors such as industry leverage, asset tangibility, and expected inflation as critical drivers of capital structure decisions.

Machine learning techniques including artificial neural networks and support vector machines offer alternative methodologies for analysing capital structure dynamics, their ability to uncover nonlinear relationships within datasets presents exciting opportunities for future research [11].

2.2 THE EXPLAINABLE AI: ENHANCING TRANSPARENCY, ACCOUNTABILITY, AND FAIRNESS IN MACHINE LEARNING SYSTEMS

Explainable AI (XAI) is a branch of machine learning focused on leveraging transparent models or generating post-hoc explanations for opaque predictions to improve interpretability [14]. Recent advancements in artificial intelligence have led to widespread adoption across various industries, with machine learning systems demonstrating exceptional performance in a wide range of tasks. However, this increased performance often results in heightened model complexity, transforming these systems into "black boxes" [15]. As a result, understanding the decision-making processes of such systems has become increasingly challenging.

XAI addresses this challenge by providing users with transparent explanations of system decisions [16]. These explanations are vital for ensuring algorithmic fairness, identifying biases in training data, and validating the performance of algorithms. Regulatory frameworks, such as the European General Data Protection Regulation (GDPR), have further intensified the demand for transparent decision-making in AI systems [15]. The GDPR mandates the auditability of decisions made by intelligent autonomous systems, significantly impacting businesses worldwide [17].

The rise of AI has also sparked concerns regarding accountability and the potential biases embedded in decision-making processes. For instance, questions arise about holding AI system owners accountable for automated decisions, particularly when these decisions may be based on unethical grounds [18]. Discriminatory biases, such as gender and racial biases in credit scoring algorithms, have garnered considerable attention, highlighting the importance of addressing fairness in AI systems [19]. These concerns underscore the critical role of interpretability and explainability in AI, ensuring that systems operate ethically and justly.

Interpretability refers to the ability to extract relevant information from machine learning models regarding the relationships between data or the patterns learned by the model, while explainability translates this information into human-understandable language [20]. Both interpretability and explainability are foundational components of XAI, enabling a deeper understanding of AI decision-making processes and ensuring transparency, accountability, and fairness in their application [21].

In conclusion, XAI plays a pivotal role in enhancing the transparency, accountability, and fairness of machine learning models. As AI continues to advance and become integrated into diverse industries, the demand for interpretable and explainable systems will increase, driving further innovation and development in the field of XAI.

2.3 CAUSAL INFERENCE AND ITS APPLICATION TO CAPITAL STRUCTURE DYNAMICS NETWORK

Causality plays a fundamental role in our understanding of the world and its phenomena. It is essential for establishing cause-and-effect relationships, which are central to many scientific inquiries and decision-making processes [14]. In the context of model interpretation, it is critical that a model not only provides accurate predictions but also offers explanations that are meaningful to decision-makers. These explanations must clearly outline the reasons behind the model's decisions and offer a coherent understanding of the causal relationships at play [17].

Currently, XAI models, particularly those designed to interpret complex, pre-trained models (often referred to as "black boxes"), focus on offering local explanations. These post-hoc,

model-agnostic approaches attempt to approximate the behaviour of these black box models by providing insights into the specific features influencing individual predictions [17].

Identifying causal relationships in observational data is a complex and vital task in understanding the underlying factors influencing predictions. In observational studies, the counterfactual framework is often employed, assuming the existence of well-defined causal states that can transparently explain the outcomes for individuals in the population being studied [22]. Causal effects are typically elucidated by comparing outcomes based on exposure to alternative causal conditions.

For instance, when investigating the capital structure of firms, the target variable (Y) represents the financial structure in question. The goal is to establish clearly defined causal situations that allow for an in-depth understanding of how different factors influence the outcomes. In this framework, potential outcomes are identified for each individual in the population, where these outcomes are defined under different causal conditions.

For binary causal variables, the potential outcomes can be represented as Y_ (0) and Y_1 corresponding to the treatment and control states, respectively, for individual i. These notations capture the individual-level causal effect of the treatment. To assess counterfactuals accurately, a causal model must include all relevant information regarding the antecedents that lead to changes in the outcomes. The individual-level causal effect can be understood as the difference between the potential outcomes, which allows for a deeper analysis of the impact of causal factors on specific individuals.

The reviewed literature highlights the evolution of capital structure theory from foundational models, such as Modigliani–Miller, to more nuanced frameworks like the trade-off, pecking order, and market timing theories, each offering partial explanations for observed financing behaviours [6,7,10]. Empirical studies demonstrate that capital structure decisions are influenced by a complex interplay of firm-specific factors, market dynamics, and broader macroeconomic conditions, with no single theory providing a universally applicable model. This gap underscores the need for approaches capable of capturing non-linear relationships and sector-specific dynamics, particularly within engineering-based industries where long-term solvency and project feasibility are critical. By integrating advanced AI techniques, such as SHAP-based causal analysis, this study addresses the identified limitations in prior research and provides a novel lens for understanding and optimising the funding structures of firms operating in industrial, resources, and technology sectors.

2.3.1 SHAP method

The SHAP method, introduced by [29], leverages concepts from game theory to provide explanations for individual predictions. Rooted in the Shapley values from economics and game theory, SHAP enables equitable distribution of a prediction’s "payoff" among the features that contribute to it. Essentially, each feature in a prediction task acts as a "player" in a collaborative game, working together to achieve a final prediction. The outcome of this "game" represents the difference between the Shapley value of a prediction and the average Shapley values of all the features in that instance.

One of the key aspects of SHAP is its ability to assign importance values to each feature for a specific prediction. These importance values offer insights into how much each feature influences the final prediction. SHAP also introduces an additive feature importance measure, providing a mathematical framework that guarantees a unique solution with desirable properties for interpreting model predictions [17].

In simple terms, SHAP explains a prediction by decomposing it into the individual contributions of each feature. For example, consider a prediction $\hat{y}$ where each feature contributes incrementally to the final prediction. The overall prediction can be expressed as:

$$\hat{y} = \phi_0 + \sum_{j=1}^{n} \phi_j \quad \textbf{(1)}$$

Where ϕ_0 represents the average prediction and ϕ_j is the Shapley value for feature for j. The Shapley value quantifies how much each feature contributes to the difference between the actual prediction and the average prediction across all instances.

SHAP relies on four core fairness principles to ensure the equitable assignment of feature contributions:

1. **Additivity**: The sum of all individual feature contributions equals the total prediction. This ensures that the explanation is consistent with the overall outcome.
2. **Symmetry**: If two features contribute equally to a prediction, they should receive the same Shapley value.
3. **Efficiency**: The total contribution of all features should match the final prediction, ensuring that the model is fully accounted for in the explanation.
4. **Dummy**: Features that do not influence the prediction should be assigned a Shapley value of zero, ensuring that only meaningful features are attributed to the model's output.

In conclusion, SHAP offers a powerful method for interpreting machine learning models by attributing contributions to individual features, offering transparency in decision-making processes while adhering to core fairness principles.

2.3.2 Granger Causality and SHAP-based Engineering for Causal Interpretation

To complement the counterfactual framework discussed previously, this study incorporates two methodological approaches for uncovering causal signals in capital structure dynamics: Granger causality and SHAP engineering [29, 33]. Each method offers a unique lens for exploring cause-and-effect relationships within complex firm-level financial systems.

Granger causality, a statistical concept rooted in time series analysis, tests whether lagged values of one variable provide predictive information about another. A variable $\boldsymbol{X}$ is said to Granger-cause variable $\boldsymbol{Y}$ if past values of $\boldsymbol{X}$ improve the prediction of $\boldsymbol{Y}$ beyond what is possible using only past values of $\boldsymbol{X}$. This is formally tested through the following comparison of predictive models:

$$Y_t = \alpha_0 + \sum_{i=1}^{p} \alpha_i Y_{t-i} + \varepsilon_t \quad \textbf{(2)}$$

$$Y_t = \beta_0 + \sum_{i=1}^{p} \beta_i Y_{t-i} + \sum_{j=1}^{q} \beta\gamma_i X_{t-j} + \nu_t \quad \textbf{(3)}$$

Where ε_t and ν_t are error terms. If model (2) significantly reduces the prediction error compared to model (1), then of $\boldsymbol{X}$ Granger-causes $\boldsymbol{Y}$. In this study, Granger tests are applied to macro-financial time series (e.g., tax rates, profitability ratios) to reveal temporal causal influences on capital structure metrics.

While Granger causality captures temporal precedence, it lacks sensitivity to nonlinear dependencies and individual-level variation. To bridge this, we utilize SHAP engineering, a technique that decomposes machine learning model outputs into additive feature contributions. Given a model prediction $f(x)$ the SHAP explanation assigns a value $\phi_i$to each feature $x_i$such that:

$$f(x) = \sum_{i=1}^{n} \phi_i \quad \textbf{(4)}$$

Where $\phi_i$is the expected value of the model output over the training data. These $\phi_i$values approximate the marginal contribution of each feature to the final prediction. SHAP values

are computed locally (per instance) but can be aggregated across observations to derive global importance rankings and visualize how factors like firm size, earnings volatility, or market-to-book ratio contribute to the capital structure outcome $\boldsymbol{Y}$.

By integrating both techniques, this work constructs a causal inference network where Granger causality informs *temporal directionality*, and SHAP engineering captures *structural attribution*. This hybrid approach enhances the interpretability of machine learning models and provides actionable insights into how financial and operational factors causally shape firm capital structures.

3 DATA AND METHODOLOGY:

3.1 DATA

The study utilised secondary market data obtained from IRESS [34], a financial data provider, covering listed companies in the industrial, resources, and technology sectors. The dataset includes firm-level financial metrics, market performance indicators, and capital structure variables. As this is publicly available listed market data, it does not involve primary data collection. The dataset was randomly split into training and testing sets with a 70-30 ratio. The training set was used to train the models, while the testing set was kept aside for model evaluation. This split was performed using the train_test_split function from the sklearn.model_selection library, with a random seed set to ensure reproducibility of the results.

The dataset is divided into a training set (X_{train}, y_{train}) and a test set (X_{test}, y_{test}), with X_{train} containing $r \times m$ samples and X_{test} containing (1 − r) × m samples, where r is the chosen ratio. The unseen data set X_{unseen} is kept aside and used later to evaluate the model's generalizability on new, unseen data.

in practice, a common split ratio might be $r = 0.7$, meaning 70% of the data is used for training, 15% for testing, and 15% for unseen evaluation. The splitting of the data can be done using a random shuffling approach, ensuring a representative distribution of features in each subset.

3.2 TRAINING MODEL CONSTRUCTION

The model is trained using the Random Forest algorithm, which is an ensemble method that constructs multiple decision trees and aggregates their predictions. The process begins by configuring the model with key hyperparameters, such as the number of trees in the forest $n$estimators and the maximum depth of each tree Max$depth$.

A Random Forest Regressor model was employed, with key hyperparameters such as the number of estimators, maximum tree depth, minimum samples required for splitting, and bootstrapping settings being defined. To optimize these parameters, a randomized search cross-validation (CV) approach was used, enabling the exploration of various hyperparameter combinations through the cross-validation process.

3.2.1 SHAP Analysis: Proxy for Causal Attribution

To interpret model predictions, SHAP values were computed. SHAP assigns each feature an importance value based on its marginal contribution to the model's output. While not causal in the temporal sense, SHAP serves as a proxy for causality within the model framework, identifying variables that meaningfully influence predicted capital structure outcomes. This interpretability aligns with economic intuition and enhances the transparency of the machine learning process.

Although SHAP does not imply temporal or structural causality, it serves as a proxy for causal influence within the model's learned relationships. Features with higher SHAP values are

interpreted as being more impactful in explaining the variance in the dependent variable, under the assumption that the model has captured meaningful economic relationships.

3.2.2 Granger Causality Tests

To complement the SHAP analysis and formally assess temporal causality, we conducted Granger causality tests [33]. This time series method tests whether lagged values of an independent variable can significantly predict the current values of the dependent variable, conditional on past values of the dependent variable itself.

Each explanatory variable was tested against the Debt/Equity ratio using a maximum lag of 3. A feature was classified as Granger-causal if the test returned a p-value < 0.05, suggesting statistically significant predictive power over the capital structure dynamics.

By integrating SHAP values and Granger causality results, we constructed a combined view of variable influence:

- SHAP values quantify each feature's average marginal impact on model predictions.
- Granger causality identifies whether features temporally cause changes in capital structure.

The overlay analysis helps distinguish features that are not only influential in the model but also exhibit statistically significant predictive causality. These features are visually represented through bar plots (SHAP) and heatmaps (Granger) and further explored through scatter plots for deeper diagnostic insight.

4 RESULTS

4.1 Causal Inference on Capital Structure: SHAP-Based Explanatory Attribution

The SHAP-based approach is highly effective for exploring the determinants of capital structure because it quantifies the influence of different factors on a model's predictions, allowing for a clearer understanding of how specific variables contribute to a firm's financing decisions. In the context of capital structure, relevant features might include financial ratios, profitability metrics, market conditions, and industry-specific factors. SHAP values help assess the impact of each feature on the overall decision-making process.

For example, if the debt ratio feature has a high SHAP value, it indicates that this factor plays a significant role in determining the model's prediction of a firm's capital structure. Similarly, SHAP analysis can identify how industry-specific factors, such as asset turnover or market value, influence capital structure decisions in various sectors like industrial, resources, and technology.

This method helps reveal proxy causal relationships by showing which features contribute the most to a firm's financing choices. It offers an interpretable approach to understanding the complex interplay of factors that shape capital structure decisions, making it a valuable tool for understanding the key drivers behind financing strategies.

Figure 1. Summary of the predictive variables extracted using Shap Feature importance.

The results shown in Figure 1 highlight the key factors that influence a firm's capital structure, distinguishing between actionable and non-actionable variables. The debt ratio emerges as the most influential determinant, accounting for 39 percent of the feature importance. This ratio, which represents the proportion of a company's assets financed through debt, is an actionable variable, offering management the opportunity to adjust the firm's debt-to-asset ratio strategically.

Next in importance are asset turnover and enterprise value (EV), which rank second and third, respectively. EV, a holistic measure of a company's total worth, incorporates market capitalization, debt, and cash holdings. While it reflects the overall financial health of a firm, EV's impact is largely non-actionable, influenced by market conditions rather than direct managerial decisions.

The prominence of debt as the leading factor in determining corporate leverage aligns with the trade-off theory of capital structure, which suggests that companies increase debt when tax incentives, such as favourable interest rate tax deductions, encourage borrowing. This finding is consistent with previous research by [8], [23], [24], and [17]. Furthermore, the significance of asset turnover and EV supports the pecking order theory, which posits that profitable firms with strong growth prospects rely less on debt financing. This theory is echoed in the studies of [25], [26], and [27].

Other factors show a limited influence on capital structure decisions, with the focus primarily on actionable variables to assess their effect on the dependent variable, capital structure.

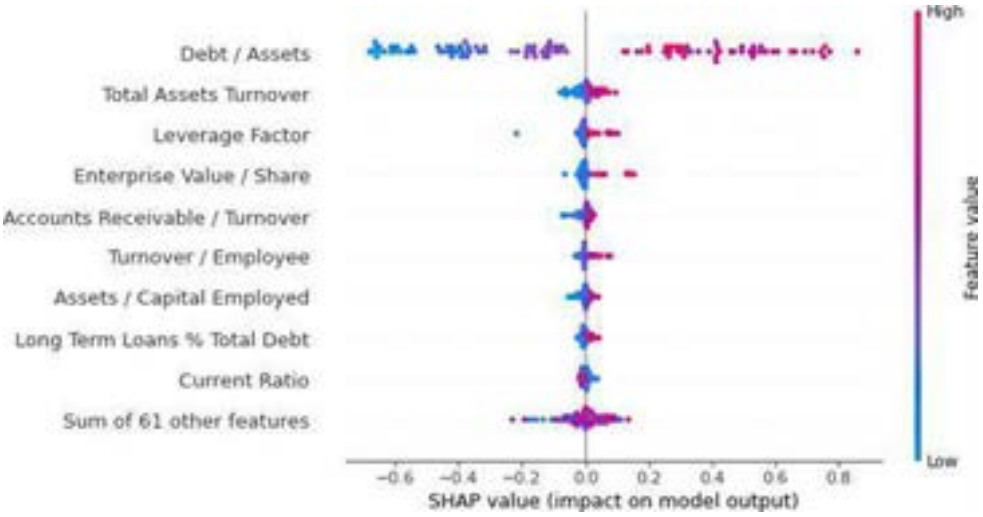

Figure 2. SHAP beeswarm plot summary.

SHAP feature engineering in Python was utilized to examine the influence of both actionable and non-actionable variables on capital structure levels, focusing on the impact of both low and high feature values. Figure 2 offers valuable insights into the relationship between feature values and capital structure predictions, visualized through a SHAP beeswarm plot. The plot highlights the relative importance of each feature, with the Debt-to-Asset ratio emerging as the most significant predictor, followed by Total Asset Turnover and Enterprise Value per share [23].

It is essential to note that the default feature ordering, based on mean absolute SHAP values, may not entirely capture the influence of extreme feature values on capital structure predictions. For instance, the Debt-to-Asset ratio analysis shows that lower or negative values correspond to lower capital structure levels, indicating a low-leverage company. In contrast, higher values are associated with higher capital structure levels, suggesting a highly leveraged company. While high leverage may present growth opportunities, it also increases financial risk, especially in terms of the challenges involved in servicing debt and meeting capital commitments [25].

Similarly, the asset turnover ratio, which reflects a company's efficiency in generating revenue from its assets, demonstrated a significant effect on capital structure decisions. Higher asset turnover ratios were linked to higher capital structure levels, suggesting effective asset utilization. Conversely, low asset turnover ratios indicated internal challenges, leading to greater reliance on debt financing, in line with the trade-off theory [26].

Enterprise Value (EV) per share, which reflects the market's valuation of a firm, also emerged as a key determinant of capital structure. Higher values of EV per share were associated with higher capital structure levels, indicating that positive market sentiment regarding the company's growth prospects influences its capital structure decisions. This observation is consistent with the pecking order theory, which underscores the preference for equity financing over debt financing to support sustainable growth [27].

Furthermore, the leverage factor, which measures the proportion of capital provided through debt, exhibited a direct relationship with capital structure levels. Low leverage factors were associated with lower capital structure levels, aligning with the pecking order theory's emphasis on internal funding and equity over debt. Conversely, a leverage ratio above 1 indicated increased risk for investors, highlighting the need for careful and strategic financing decisions [28].

In conclusion, the SHAP beeswarm importance plot provided critical insights into the impact of various financial metrics on capital structure decisions. By analysing both low and high values of actionable and non-actionable variables, firms can make more informed decisions about their financing strategies, carefully balancing growth opportunities with the associated financial risks.

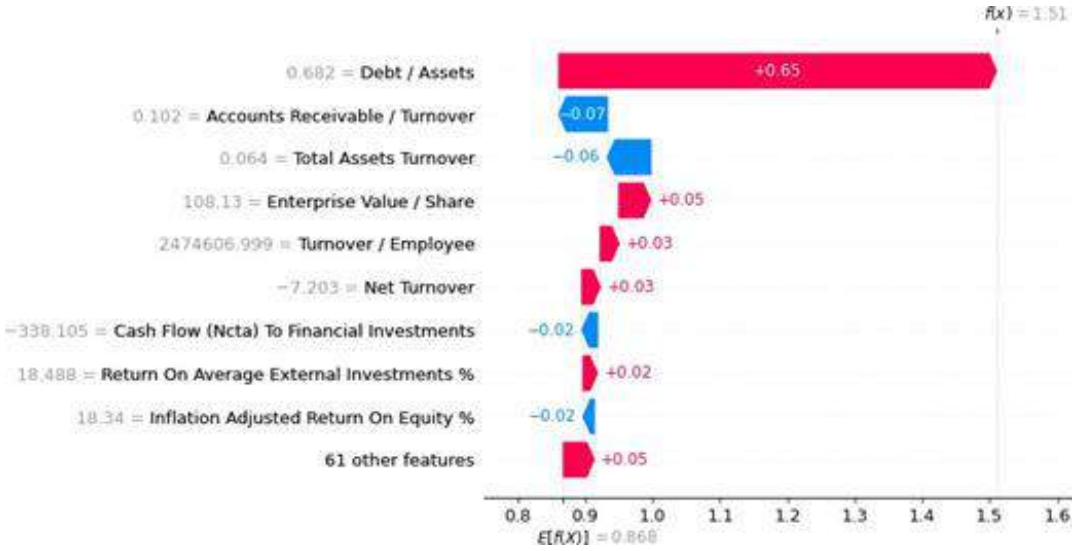

Figure 3. SHAP waterfall plot.

The results were further visualized using a waterfall plot in Figure 3. This illustrates how the SHAP values of each feature, or independent financial variable, influence the model's output in relation to prior expectations based on the background data distribution. Features are ranked by the magnitude of their SHAP values, with smaller values grouped together at the bottom of the plot when the number of features exceeds the maximum display parameter [29].

The waterfall plot offers an additional perspective to the SHAP beeswarm plot by demonstrating that the sum of all SHAP values corresponds to the difference between the predicted value $(f(X))$ and the expected value $(E(X))$. In alignment with the beeswarm plot findings, the Debt to Asset ratio remains the most significant predictor, followed by Total Assets Turnover. Interestingly, Accounts Receivable Turnover emerges as the third most important variable, surpassing Enterprise Value in terms of influence.

The prominence of Accounts Receivable Turnover aligns with its crucial role in evaluating a company's profitability, supporting the pecking order theory. This ratio indicates the frequency with which a business collects its average accounts receivable within a year, reflecting its ability to efficiently extend credit to customers and collect payments promptly. Companies with a higher accounts receivable turnover are better positioned to reduce debt levels and enhance their capital structure.

4.2 Causal Inference on Capital Structure: Granger Causality

This section presents a comparative causal analysis to investigate the determinants of the capital structure, particularly the Debt-to-Equity (D/E) ratio, in JSE-listed firms across the industrial, resources, and technology sectors. The analytical approach combines traditional time-series econometric techniques with contemporary interpretable machine learning frameworks to uncover both lagged (temporal) and contemporaneous influences.

4.2.1 Granger Causality Findings

The first method employed is the Granger causality test, illustrated in Figure 4. This method is an established econometric tool for identifying whether the historical values of an independent variable significantly improve the prediction of a dependent variable, over and above its own history. The analysis was conducted using a lag structure of up to three periods. Prior to testing, stationarity of all-time series was verified using the Augmented Dickey-Fuller (ADF) test to ensure methodological validity.

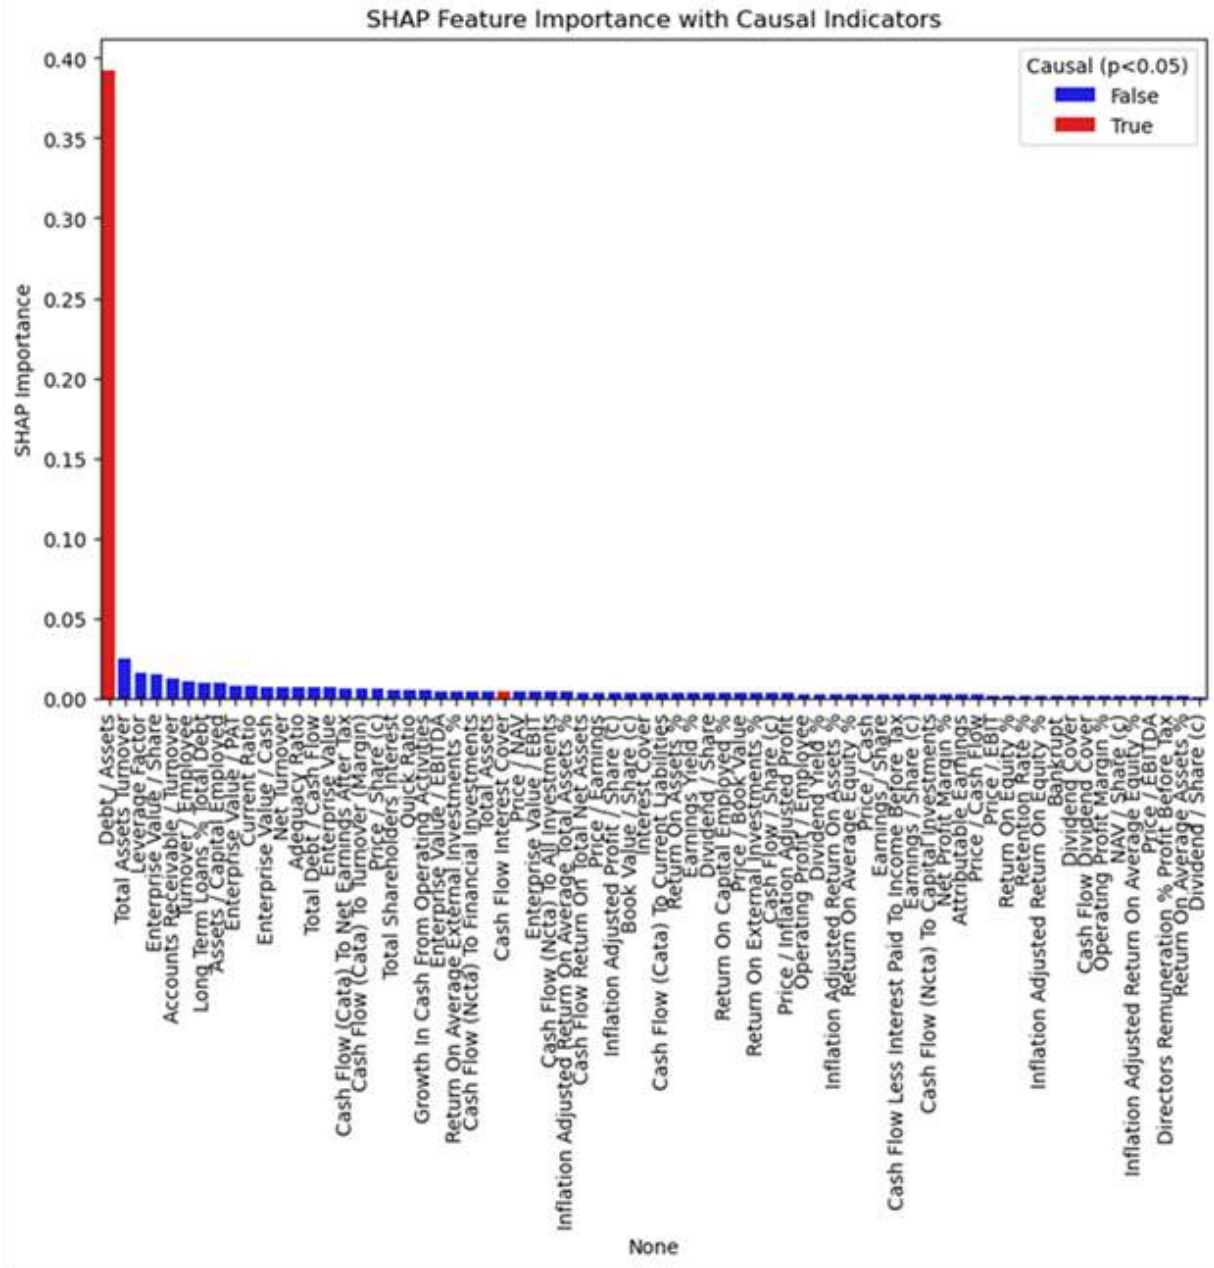

Figure 4. Granger Causality plot.

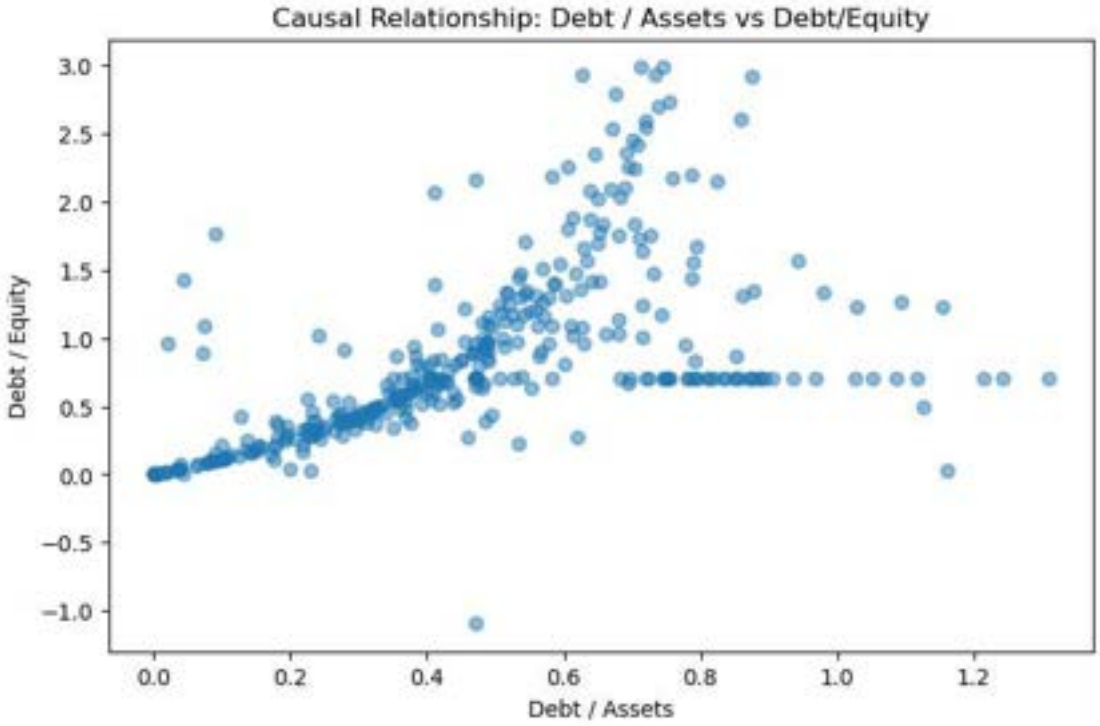

Figure 5. Granger Causality plot: Debt/Assets vs Debt/Equity.

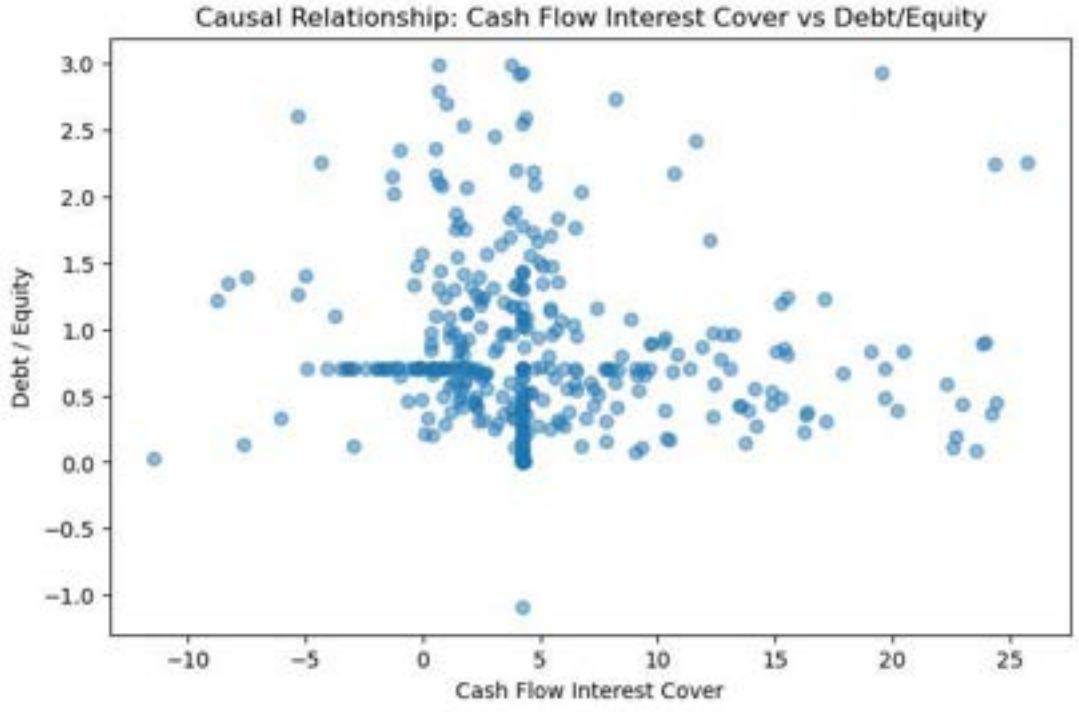

Figure 6. Granger Causality plot: Cash Flow Interest Cover vs Debt/Equity.

Among all the candidate explanatory variables, only two variables emerged as statistically significant Granger causes of the Debt-to-Equity ratio at the 5% significance level. These are:

- Debt to Assets Ratio and
- Cashflow Interest Cover

Past changes in the Debt to Assets Ratio and Cashflow Interest Cover significantly predict shifts in a firm's Debt-to-Equity (D/E) ratio, indicating that firms adjust their leverage decisions based on prior changes in their leverage structure and internal debt-servicing capacity, illustrated in Figures 5. and 6. respectively. These results support dynamic trade-off theory, where firms actively monitor their leverage to maintain an optimal capital structure aligned with their risk thresholds.

The Cashflow Interest Cover also influences D/E decisions, reflecting how firms adjust leverage based on internal liquidity. When debt-servicing capacity weakens, firms may increase equity financing, and when cash flows improve, they may take on more debt. These findings show that firms manage capital structure dynamically, responding to shifts in balance sheet risk and liquidity metrics.

4.3 Reconciling the divergence between SHAP analysis and Granger Causality test results.

This divergence in results between Granger causality and SHAP analysis can be attributed to fundamental differences in methodological scope and causal assumptions:

- Granger causality is restricted to identifying lag-based temporal causation under the assumption of linear dynamics and strict stationarity. It tests whether one variable preceding another in time improves forecasting accuracy.
- SHAP, on the other hand, captures predictive relevance within the model at a point in time, and can identify non-linear and contemporaneous influences, including interactions between variables. However, SHAP does not infer temporal or policy-relevant causality in the strict econometric sense.

In this context, SHAP can be viewed as revealing “proxy causality” or structural relevance—where variables may not have a lagged effect, but still materially shape the model’s decision boundary due to underlying correlations, economic structure, or immediate firm-level signals. Such variables may reflect real-time decision-making criteria used by managers or lenders, even if they do not satisfy formal temporal causality.

5 CONCLUSION

This study explored the causal determinants of capital structure decisions in JSE-listed firms across the industrial, resources, and technology sectors. By integrating Shapley Additive Explanation (SHAP) analysis within a model-agnostic framework, the study provided a deeper understanding of how key financial variables influence firms' capital structure decisions, bridging the gap left by traditional capital structure theories.

The research aimed to (i) evaluate the relevance of capital structure theories—specifically the trade-off and pecking order theories—in the context of JSE-listed engineering firms, and (ii) uncover the behavioural financing dynamics and determinants that shape firms' capital structure decisions.

The findings identified the debt-to-asset ratio as the most significant predictor of capital structure, reinforcing the trade-off theory, which emphasises balancing the benefits of debt financing (such as tax shields) against the risk of financial distress [8], [23], [24]. Additionally, asset turnover and enterprise value per share emerged as influential factors, aligning with the pecking order theory that suggests firms prioritize internal financing over external debt [25], [26], [27].

Further analysis revealed that declines in revenue and profitability increase a firm's reliance on debt, raising the capital structure ratio. This behaviour supports both the pecking order theory—highlighting limited internal funding—and the trade-off theory—where higher leverage introduces greater financial risk [24], [26], [27]. Notably, accounts receivable turnover also

demonstrated a significant impact, suggesting that firms with efficient cash flow management are better positioned to manage debt levels [28].

To strengthen the causal interpretation beyond static associations, the study employed Granger causality tests to assess temporal precedence between financial indicators and changes in capital structure. The results revealed that only the Debt to Assets Ratio and Cashflow Interest Cover Granger-cause the Debt-to-Equity ratio at the 5% significance level, indicating that firms systematically adjust their leverage in response to prior shifts in overall balance sheet risk and internal debt-servicing capacity. This integration of SHAP and Granger causality strengthens the validity of the explanatory model by demonstrating both feature importance (via SHAP) and temporal predictive influence (via Granger), thereby offering a more robust and time-aware causal interpretation of capital structure dynamics.

The study concludes that the capital structure decisions of JSE-listed firms in the industrial, resources, and technology sectors are best understood through the combined lens of the trade-off and pecking order theories [30]. SHAP-based causal analysis effectively captured the complex relationships between financial predictors and capital structure dynamics, offering actionable insights for firms seeking to balance growth opportunities with financial risk [31].

These findings contribute to a more comprehensive understanding of financing behaviour in key economic sectors, providing valuable guidance for corporate managers, investors, and policymakers in making informed capital structure decisions [32].

TOWARDS A SOUTH AFRICAN KELP FARMING INDUSTRY: A SYSTEMATIC LITERATURE REVIEW

C.M. Wilcox[1], M. Roopa[2] and J. Bekker[3]

[1,2,3]Department of Industrial Engineering
Stellenbosch University, South Africa
[1]25554883@sun.ac.za, [2]meelanroopa@sun.ac.za, [3]jb2@sun.ac.za

ABSTRACT

An interest in kelp has grown in the Western world for its ability to sequester carbon, high regeneration rates, and its low nutrient requirements. In the wave of new and sustainable technologies for the future, opportunities exist to create bio-based plastics. However, globally, kelp is not being sustainably harvested in sufficient quantities for this use. South Africa is no exception to this with fragmented private harvesting facilities. This paper uses a systematic literature review to enable a future functional analysis of the kelp farming value chain in South Africa. The review identified three main themes in the literature about geospatial analyses, farming techniques and social and environmental impact. The results will aid companies in selecting an ideal location to set up operations for commercial kelp farming, navigating the turbulent waters of sustainability and economic viability within a business context.

Keywords: kelp farming, geospatial analysis, farming techniques, social impact, environmental impact, industrial engineering, South Africa

1 INTRODUCTION

An interest in seaweed has swelled in the Western world over the last few years due to its ability to sequester carbon and its application in bio-based plastic production among other products [1], [2], [3]. Its appeal has grown because of its fast regeneration, use of no cultivated land area, and its natural polymers that allow for easy manufacture of plastic films for packaging. Seaweed is a marine macroalga, with red, green, and brown groups, with kelp falling under the brown macroalgae [4]. With the South African coastline that boasts large natural kelp forests, this points to the possibility of commercial-scale kelp farming to create jobs and contribute to the global drive of plastic alternatives [5]. Seaweed farming has a complicated supply chain that consists of many interconnected activities and so the lack of commercial kelp farms in South Africa can be seen as a systems engineering problem. Effective facility planning must be undertaken to ensure the best placement of kelp farming operations, and best farming practices relevant to the species being cultivated.

1.1 Research statement

Against this background, there is little research on kelp farming in South Africa, or on how to begin farming operations with the local kelp species. This study investigates on a global scale how other countries are finding suitable farming areas and cultivating different seaweed types. The first step to establishing the industry is to analyse and synthesise the literature which is the main theme of this article.

1.2 Research Aim

The aim of this research is to analyse and then synthesise available literature on kelp farming site selection and operations for the creation of South African commercial kelp farming. This includes the various socio-economic and environmental effects that farming poses.

1.3 Research Questions

The following specific research questions are addressed:

1. How are researchers performing geospatial analyses for seaweed farms, if any?
2. What are the farming and harvesting methods used all around the world for seaweed and kelp?
3. What are the socioeconomic effects that kelp farms have on the nearby coastal communities?

1.4 Methodology

The chosen methodology is a Systematic Literature Review (SLR). The aim of an SLR is to answer specific research questions by including all related research in such a way that it can be reproducible and unbiased [6]. As the knowledge frontier is pushed, it is based on past research, and so SLRs have gained popularity in academic research for their structured and rigorous approach to exploring literature [7]. Literature reviews can be one of two types: either 1) a background review to justify design decisions or give the research context, or 2) embody a freestanding review to synthesise and clarify existing literature by summarising and aggregating literature. This SLR follows that of the latter.

The SLR methodology was chosen to specifically map out the research on the current state of the kelp farming industry's farming methods and how geospatial analyses are done to plan for aquaculture, such as seaweed and kelp farming. Furthermore, efforts are made to understand the current impact of these farms on nearby communities, socioeconomically and environmentally, to assess the feasibility of farming.

2 SYSTEMATIC LITERATURE REVIEW RESULTS AND FINDINGS

This section begins with the application of the chosen methodology, followed by a thematic examination of geospatial analyses, farming techniques and socioeconomic impact of seaweed farming. Following the aforementioned method in section 2.2 of [5], the first step was to formulate the review question to decide on the utility of the SLR and which questions needed to be addressed. Once formulated, a search protocol table was set up to define inclusion and exclusion criteria as well as the search string to be used in the databases that align with the research question. This can be seen in Table 1.

Table 1: Search protocol table used for SLR

Research Elelment	Details	Justification
Keywords:	Kelp farming, seaweed farming, South Africa, geospatial, location, planning, mariculture, aquaculture, marine.	These keywords were chosen as they cover the primary Research Aim.
Search Strategy:	("kelp farming" OR "seaweed farming") AND (location OR planning OR spatial OR geo*) AND (aquaculture OR mari*).	Chosen to include all keywords to account for variation in wording.
Timeframe:	2015 - 2025	Chosen to avoid potentially outdated research.
Databases:	Scopus, Web of Science, EBSCOhost (GreenFILE, Africa-Wide Info).	Chosen for the popularity and prominence of each database.
Inclusion Criteria:	Explicit mention of Must be about seaweed farming operations, or identifying locations (how to do so), and the impact on coastal communities.	Chosen to align with, or avoid straying from the research questions. Chosen to avoid straying from research questions
Exclusion Criteria:	Not relevant if it does not include seaweed or kelp farming, focuses on the biology of seaweed and comparison of different species' growth, focus entirely on carbon sequestration, or specific to the cosmetic industry.	Chosen to align with, or avoid straying from the research questions.

The search string used in each database was slightly modified from the search strategy in Table 1 and the search included, title, abstract, authors for each database. The strings are as follows:

- Scopus: ("kelp farming" OR "seaweed farming") AND (location OR planning OR spatial OR geo*) AND (aquaculture OR mari*))
- Web of Science: ALL=("kelp farming" OR "seaweed farming") AND ALL=(location OR geo* OR spatial OR planning OR facility) AND ALL=(aquaculture OR mari*)
- EBSCOhost: (kelp farming) OR (seaweed farming) AND (location OR facility OR spatial OR geo*) AND (aquaculture OR mari*)

A PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram is a flowchart used in systematic reviews and meta-analyses to visually represent the process of identifying, screening, and including studies [8]. This framework was used for this literature study and Figure 1 shows the PRISMA diagram for this SLR following the criteria set out in Table 1. By consistently applying the inclusion and exclusion criteria to the set of literature, selection bias was minimised as the screening process was more objective [8].

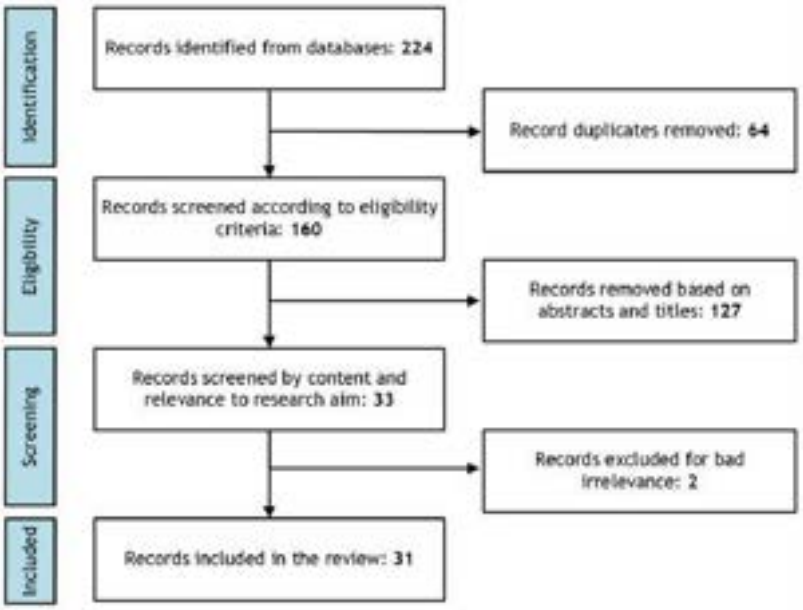

Figure 1: PRISMA diagram of included literature

Once selected, the 31 included records were grouped into 3 themes of geospatial analysis, kelp farming methods and socioeconomic effects of kelp farms through a thematic analysis. A thematic analysis is a method used to interpret and organise the textual data from an SLR into predefined themes [9]. Figure 2 visually depicts where the included papers come from across the globe, and shows the fragmented nature of the publications. South Asia had the most publications, with Indonesia totalling 6, 2 from the Philippines and 1 from China.

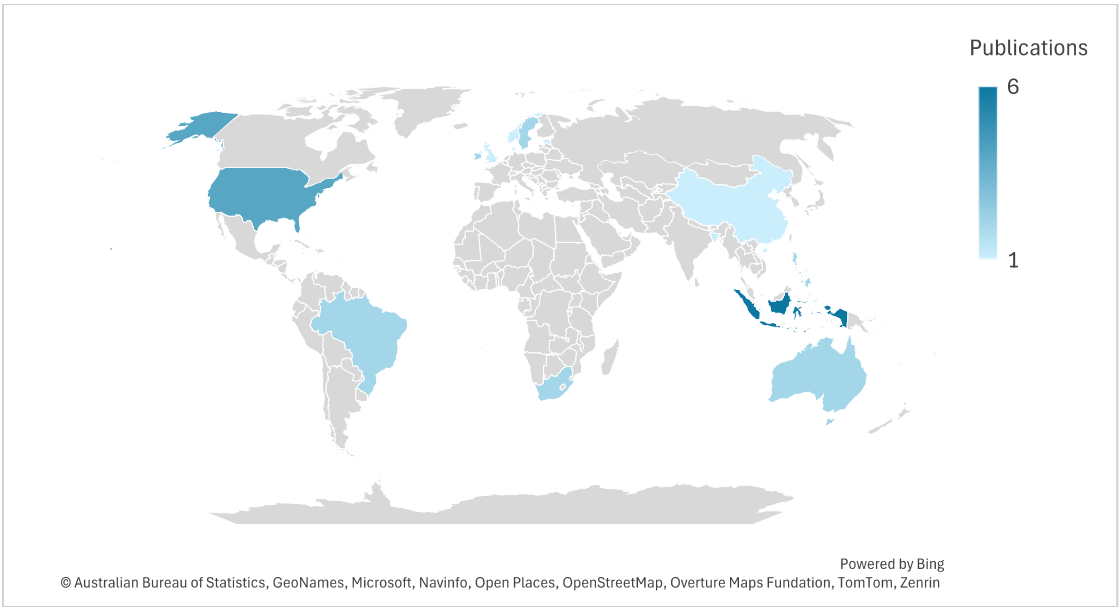

Figure 2: Global distribution of publications

Figure 3 shows the number of publications which appears to have a cyclical trend. However, the drop in publications in 2021 is most likely due to the Covid-19 pandemic in 2020, and only 2 publications in 2025 as the records were only collected in March.

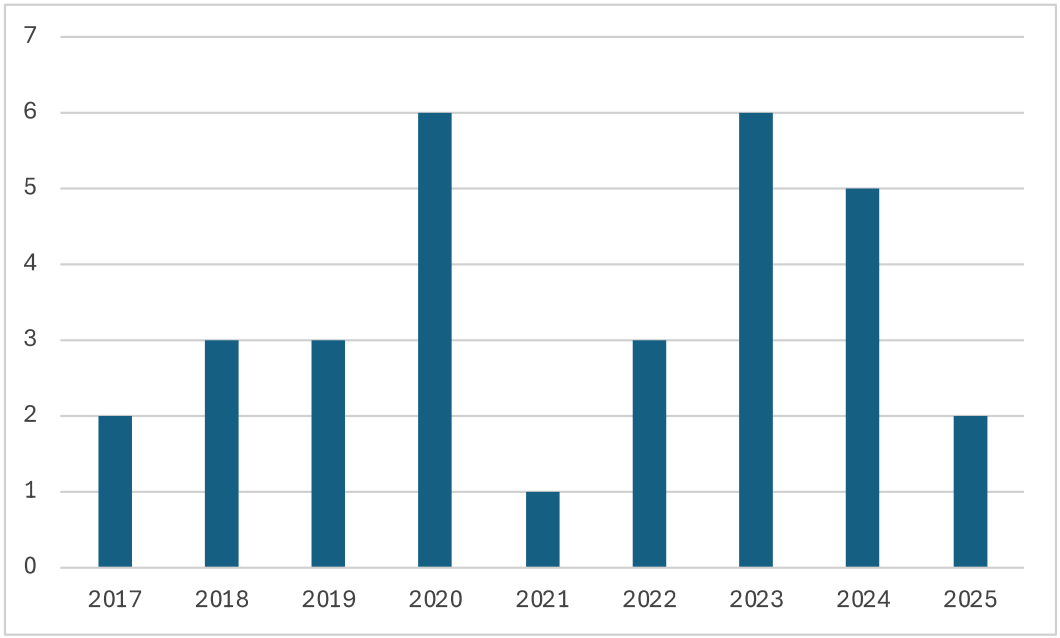

Figure 3: Yearly distribution of publications

Table 2 sorts all included records from the SLR by year published and indicate which of the three themes they explore. The number of citations each paper received along with their publication type have also been included.

Table 2: Records used in SLR and themes discussed, ordered by publication year

Number	Year	Title	Citation	Publication type	Number of citations	Geospatial analysis	Farming Process	Impact
1	2017	Production Efficiency of Seaweed Farming in Tarakan North Borneo	[10]	Journal	3		x	
2	2017	Spatial Analysis to Evaluate the Suitability of Seaweed Farming Site in Lampung Bay, Indonesia	[11]	Journal	18	x		x

2.1 Geospatial Analysis

A geospatial analysis is a method that most often uses Geographical Information Systems (GIS) to process, analyse and visualise data with geographical components [2], [5], [16], [30], [36]. The aim of this type of analysis is to find areas well suited for seaweed farming based on chosen characteristics related to the surrounding environment through data from empirical maps, numerical models and remote sensing data [5], [11], [35], [38]. Tasks involved in such an analysis are data aggregation, overlaying, conversion and finally map generation. This is an essential first step, especially in the case of Marine Spatial Planning (MSP), as it provides a tool to aid in spatial decisions to find near-optimal locations for seaweed farms [16].

From the 13 papers of the 31 from the SLR that performed geospatial analyses, a variety of methods were used. GIS was the most common tool, with software such as ESRI ArcGIS [36], [16], ESRI ArcMap [5], the free Quantum Geographical Information System (QGIS) [30], and Idrisi [16] to layer and analyse spatial data.

Another popular tool was Multi-Criteria Decision Analysis (MCDA), which was often used in conjunction with GIS to determine site suitability. Two methods were used in [16], namely a Weighted Linear Combination (WLC) and a Boolean Overlay. The first method assigned weights to different criteria layers based on the importance and linearly combines them to create a suitability score for each criterion before combining each layer to form a suitability map. The second method uses a binary approach whereby a location is suitable or not based on it meeting all criteria or avoiding all constraints. A hybrid approach was used in [28] whereby a WLC was used for the primary criteria and a Boolean overlay for the secondary criteria to produce a result that is easily readable, allowing for quick site selection. This hybrid approach was called a Multi-Criteria Analysis Site Selection (MCASS). As mentioned by [2], geospatial and environmental suitability analyses are important to optimise seaweed farming and mention suitability matrices can be created using Analytical Hierarchical Process (AHP) or models like TOPSIS and Multi-Criteria Evaluation (MCE). A Generalised Additive Model (GAM) was used by [35]. GAMs are an effective method for conducting non-linear regression analyses and are commonly used in environmental science research to assess the non-linear relationships between covariates. It involves two main steps: data fitting and spatial prediction, which fitted in-situ seaweed biomass data with environmental variables to generate highly accurate spatial predictions and habitat suitability maps [35].

Remote sensing involves data that is acquired indirectly from the area being studied, either by satellite or by an Unmanned Aerial Vehicle (UAV). Several papers used remote sensing data to aid in their geospatial analyses. A dataset of kelp forests along the South African coastline was used by [5], and [38] used multiple satellite sources to evaluate site suitability from multiple environmental parameters. These parameters were chlorophyll-a, sea surface temperature and sea surface salinity, total suspended matter, dissolved oxygen, pH, and bathymetry.

Despite the differing approaches to finding suitable areas for seaweed and kelp farming, there were a few common environmental parameters used. The most common parameters across the 13 geospatial focused papers are summarised in Table 3. Some variation in parameters was found, namely in nitrate levels where some papers stated the parameter as nitrates, others as mean nitrates, or nitrogen concentration.

Table 3: Common geospatial analysis parameters

Parameter	Citation

2.2 Kelp Farming Methods

The majority of the papers used in the SLR pertain to seaweed farming, rather than kelp farming found in [5], [19],[22]. Kelp is a type of macroalgae much like seaweed and so growth and harvesting techniques can be similar. Indonesia was the country with the most publications found in the SLR, as seen in Figure 2, and was the largest producer of seaweed species like *Eucheuma cottonii* and *Gracilaria* in 2011. In 2014, Indonesia and China together accounted for 81% of global production, and in 2020 where worldwide seaweed production reached almost 30 million tonnes China and Indonesia were still the major contributors [20], with kelp accounting for 45.16% of total global production [22]. The predominant farming methods used are longline systems, floating rafts and off-bottom systems. Longline systems involve long ropes in parallel attached to buoys and anchored to the seabed with seaweed attached to the ropes at regular intervals, and can be positioned at different depths [35],[21]. Net cultivation is similar to longline, in that there are long lines of nets with the seaweed propulgates attached to the nets and can be anchored and placed at different depths. Most often the buoys used are empty plastic bottles, and these lines can be placed in deeper waters [31]. The longline method is also a viable option for offshore kelp farming as mentioned in [5] which noted successful trials of large-scale cultivation of *Saccharina latissima* offshore and near-shore in the Faroe Islands.

Floating rafts commonly have seaweed attached to nets or lines that are connected to a raft [35]. A variant was explained in [14] which uses a 3x100m raft made from PVC pipes with 18 5.5m sections with tubular netting across which the seaweed is planted. This method was employed in a seaweed farm in Brazil that made use of a seaweed monoculture system, a biculture systems with oysters and another with mussels, which used a spacing of 0.4m between lines [14]. The outputs of the monoculture system was 24,192 t/ha/year and 13,506 t/ha/year for the biculture systems combined compared to 12.65 t/ha/year for a monoculture equivalent and 7.15 t/ha/year for a biculture equivalent in Indonesia, where spacings of 1m between lines were used. Another technique known as depth-cycling was experimented with in [24].

Other popular methods are off-bottom longline and off-bottom nets that are also deemed ‘semi-floating systems’ as at low tide they lay exposed on the seabed [35]. These two techniques were used in the GAM model in [35] for the geospatial analysis along the Bangladesh coastline. Off-bottom techniques are also implemented in intertidal seaweed farms in Zanzibar, although in [34] no specific techniques were mentioned. A drawback with these off-bottom techniques is that intertidal zones tend to be muddy which can be a hindrance to expansion of such farms, and so methods like floating raft longlines were tested [35].

Technical Efficiency (TE) of seaweed farms was looked at in [29] and [10], primarily using quantitative methods to assess how efficiently inputs were converted into outputs, and what factors affected this. An advanced statistical technique called double bootstrap Data

Envelopment Analysis (DEA) was employed in [29] to assess the TE, sampling 63 small-scale farms in the Philippines, and revealed that bias-corrected TE scores showed inputs could be reduced by 55% to achieve the same output level.

Excluding more obvious factors such as whether the farmers' primary occupation is farming or whether they have access to finances, key factors were found to be the number of farms owned or managed, the farm location, and whether a particular type of seaweed was sold. More farms managed were found to have an inverse relationship to TE, and farms that were located in deeper waters were more technically efficient as the crops were more protected from diseases because of stronger currents. It was also found that it is more efficient to sell both wet and dry seaweed. Another technique known as Ordinary Least Squares (OLS) was used in [10], which sampled 100 farmers in Indonesia. The average TE of these farms was 92%, and found that inputs such as farm area, seed, and labour positively and significantly impacted the seaweed production. It was also noted that TE varied depending on whether the farm was located in a secure or insecure location, as set out by local government criteria, but was not explicitly described. Farming experience was also found to be an important factor regarding TE, as the more experienced the farmer, the more efficient their farms [10].

2.3 Social and Environmental Impact

With East Asia and Southeast Asia being the predominant producers of seaweed, a large portion of this section has a focus on these areas. While seaweed farming has many benefits, such as supporting coastal livelihoods and global food security [15], it also has many negative impacts, with a large amount of research on the environment and marine biodiversity [32].

2.3.1 Environment and Ecosystems

First, looking at the environmental effects, seaweed farming has a positive effect on water quality by reducing the levels of nutrients such as nitrogen and phosphorus and increasing DO, which mitigates eutrophication [32][17], hence its importance in geospatial analysis criteria. Another reason which has become more popular as the world looks to find ways of reducing carbon is that farming can sequester it [1], and the expansion of seaweed farming will allow for the capture of large quantities of carbon dioxide (CO_2) [32]. The CO_2 is absorbed and accumulated in living and decaying biomass during photosynthesis before sinking to the sea floor [35].

Three main ecosystems emerged in the research, those being seagrass bed, benthic communities and coral reefs. Seagrass bed impact was negative, as most research showed that farms placed directly on beds, due to ideal water quality, caused shading and trampling, leading to a reduction in biomass [18]. It was noted then that seagrass beds should be removed before establishing a seaweed farm to avoid the seagrass and seaweed competing for nutrients. Benthic communities are an assemblage of organisms that live on, in, or near the seabed [26]. A negative impact would be on these communities from large-scale farming operations, especially near estuaries, noted by [18]. Coral reefs can be negatively affected by seaweed farming operations, as fragments of seaweed from overgrowth can cause smothering of nearby coral reefs and lead to a decline in coral cover [18]. A positive impact however can be found in the sediment resettlement due to changing water flows that can protect the coral [32].

2.3.2 Fish and Megafauna

Fish in surrounding environments are affected in various ways. Seaweed farms largely have a negative effect on fish communities and can change fish community composition [18], [27], [32]. Fish abundance can increase if the seaweed farm offers a more complex habitat than originally, and lower fish abundance if the farm offers a less complex habitat. In a study noted in [18], it was hypothesised that seaweed farms can enhance fish populations more than areas

that had been blast fished, but found that instead fish biomass was less in seaweed farms in comparison with Marine Protected Areas (MPA). Farms tended to favour small invertivores, such as fish that consume crustaceans and insects, and had lower diversity, whereas MPAs tended to favour large herbivores. Little research has been done on the impacts of other megafauna. However, issues have been found with dugongs in the Philippines being killed by getting entangled in farming lines [18]. Issues between green turtles and seaweed farmers have also arose as turtles graze on seaweed. In the Marshall Islands, an effort was made to reduce shark grazing on experimentally cultivated seaweed, but had an unfavourable effect, but was not specified in [18].

2.3.3 Livelihood and Job Opportunity

Another major research area involving seaweed farming is the livelihood impact on coastal communities and the income opportunities that arise. The industry is described as supporting poverty alleviation, improving quality of life in coastal communities and improving gender equality [15],[33],[34],[32], but it can be highly context-dependent [37]. It was noted in [2] that the industry has a transformative effect on rural communities and has the potential to lift them out of poverty as it is a significant source of livelihood in the context of Indonesia, provided there are supportive policies. It provides income for workers involved in various business stages of the farming process such as preparation, cultivation, harvest distribution and marketing of seaweed [13], and often uses simple technologies that are suitable for household businesses. The industry also contributes to global food security [2], [15]. While it has many benefits, there have been cases where other activities had higher income, such as fishing [27]. A dependence on seaweed farming may also leave coastal communities vulnerable to economic and environmental shocks [32], which can lead to increased vulnerability. Large exits from the industry have been noted in certain areas such as Zanzibar, most likely due to climate change [27].

The industry has been particularly highlighted for its ability to bring about large benefits for women [27]. Zanzibar is the largest producer of seaweed in East Africa, producing 103,200 t in 2018 [33] and is mainly farmed by women in the intertidal zone [27]. Farming has helped raise the economic status of rural women, with it becoming a key livelihood for them, and in turn leading to an improvement to the quality of life [33]. It has also enabled many women in patriarchal cultures to independently secure access to funds and contribute to their empowerment [32]. However as noted by both [27] and [33], these benefits have been disputed, as they report findings of negative impacts on women's health as it is a highly demanding activity. The large exit from the seaweed industry in Zanzibar has seen women moving to small-scale businesses and fisheries for higher income [34]. Initiatives such as deep water farming have been suggested to overcome challenges faced by off-bottom techniques such as low yield from temperature variation, although deep water methods are still constrained by gender norms which prevent women from learning boat handling and how to swim [34].

3 DISCUSSION OF FINDINGS

The discussion of findings reflects on potential geospatial parameters in SA, kelp farming techniques, and social impact on coastal communities. South Africa is home to three dominant kelp species, namely Laminaria pallida, Ecklonia maxima and Macrocystis Pyrifera which are brown macroalga [23]. While most of the literature focused on red algaes farmed in South and Southeast Asia, geospatial analysis techniques used, and various farming methods can still be utilised in a South African context. As a country that struggles with unemployment, the benefits to coastal communities that comes with seaweed farming would also be beneficial. Reviewing the literature that mention how to perform geospatial analyses and the different farming techniques used, the role of industrial engineering is visible in this industry. There is

a need to optimise the farming process across the supply chain for the benefit of all stakeholders, from farmer to customers and the environment.

A broad definition of Industrial and Systems Engineering (ISE) is about designing and improving integrated systems of people, materials, information, and equipment by using mathematical, scientific, and engineering tools to predict and evaluate results from such systems [39]. This paper focuses mainly on the Management Systems domain of ISE definition, as seen in Figure 4 which is relevant for the facilitation and creation of a seaweed farming industry in South Africa.

Figure 4: The major domains under the definition of ISE [39]

The following sections show the relevance of each theme and its findings to South Africa, and their ties to ISE.

3.1 Geospatial Analysis Parameters for South Africa

Various locations have already been identified that would be suitable for kelp farming operations in South Africa which were found through a geospatial analysis in [5]. The parameters used in the paper include all that are mentioned in Table 3, except for pH and current speed, and also included human settlements as another input parameter using the ESRI ArcMap 10.6.1 software. The areas identified are situated along the West Coast and coincide with designated Aquaculture Development Zones (ADZ) and naturally occurring kelp forests.

While various water quality parameters have been considered in past site identifications, a step further can be taken to consider the facility layout to account for multiple farming techniques like nearshore and offshore. As mentioned above, taking human settlements and existing infrastructure into account are another imperative step to develop a supply chain network for the selling of the kelp.

3.2 Kelp Farming Techniques for South Africa

Historically, kelp was primarily farmed by collecting washed-up kelp before drying and milling it and sending it abroad for alginate extraction in Asia, but this practice has reduced because of declining yields and higher profit from other kelp uses [23]. Abalone aquaculture has been a major use of kelp resources in South Africa since the mid-19902, whereby kelp is harvested

from boats and then brought back to land-based farms for the abalone, and this is done from wild kelp forests, not formal farms.

From the farming methods mentioned in section 2.2, some are not feasible for kelp such as off-bottom techniques. The South African Kelp Farming Project setup by the Bivalve Shellfish Association of South Africa in a recent report has showed successful trials using vertical droppers to be a viable choice of cultivating kelp [40]. This project is ongoing and shows great potential in the feasibility of an industry in South Africa, however the project and further research needs to be completed on the best methods to farm kelp.

From an industrial engineering perspective, TE as previously discussed can go further to include Inventory management and production scheduling. Production scheduling can be implemented to coordinate seeding, cultivating and harvesting to keep a steady supply in accordance with the kelp's growth cycles. Inventory management can follow on from production scheduling, as this will be important considering kelp is perishable. Possible processing options, such as drying and milling, may also be possible to increase revenue [5]. These processing techniques can require little infrastructure which makes them possible to perform in coastal communities without the need for specialised equipment.

3.3 Potential Impact for South Africa

Proximity to human settlements was an important factor in the geospatial analysis completed in [5], and towns such as Port Nolloth and Kleinzee were highlighted because they have existing aquaculture facilities. The Saldanha Bay area was another area identified, also by [23] and [40], as a good area for kelp farming, for existing aquaculture facilities relating to mussel farming but also an existing workforce.

The job opportunities that come with the kelp farming industry would be beneficial to the coastal communities in South Africa. Of the existing literature, emphasis is on farming along the West Coast only and not the South and East Coast, so further research can be done for these areas regarding the social impact of aquaculture.

While the impacts this industry can have on communities, farmers can implement tools from organisational behaviour to upskill and motivate farm workers to increase productivity and TE of the farms. While the findings can be generalised for South Africa, a more detailed assessment would need to be done to understand the economic feasibility of the industry and the labour demand of coastal communities.

3.4 Industrial engineering contextualisation

The ISE Body of Knowledge (ISEBoK) from the Institute of Industrial and Systems Engineers is a taxonomy of knowledge areas essential to ISE [41]. Figure 5 depicts these areas.

Figure 5: Taxonomy of ISE knowledge area extracted from ISSE [41]

Noted in [12], the roadblocks faced by the industry's expansion present a significant opportunity for better planning, which is where industrial engineering principles can be applied. Sustainable development and efficiency are key elements of industrial engineering. The commercial kelp industry is in its infancy, and in order the help it grow to a globally competitive level, effective planning is required.

With the ISEBoK, the areas such as 2, 3, and 4 are all useful concepts in the design and implementation of geospatial analyses. For farming methods, areas 3 and 7 are important in guiding how best to farm kelp in a South African context. For socioeconomic impact areas 3, 6, and 7 are also useful in assessing the impact that this industry could have on the South African economy and its people. This strengthens the link between ISE and the themes explored in this paper when considering the viability and design of a kelp farming industry. Within each of these areas, it is vital that sustainability remains a key focus. With pressure from global warming, the literature review showed in section 2.3.1 that seaweed has potential for carbon sequestration, which can help mitigate climate change [15], and it can bring livelihoods to coastal communities. While the literature had a focus on the seaweed itself and more qualitative components, it shows room for systems engineering to help establish farms and their operations, to maximise outputs with the least inputs.

4 CONCLUSIONS AND RECOMMENDATIONS

The systematic literature review revealed that geospatial analyses for seaweed farming commonly used GIS tools, remote sensing, and multi-criteria decision-making methods to identify optimal farming sites. Future site selection projects in South Africa should make use of these tools, but can also collaborate with marine scientists to refine the site suitability model to include data more relevant to *E. maxima* and *L. pallida*. Farming and harvesting techniques are shown to vary globally, with the use of longline systems, floating rafts and depth cycling. Each of these techniques can be recommended to be piloted to test their viability with the local kelp species and to evaluate their TE. Socioeconomic impacts include job creation and poverty alleviation, especially in coastal communities, though challenges such as gender inequality and environmental degradation persist. Inclusive training programs are recommended that can be designed to address gender barriers, such as boat handling skills for women, and rotational farming techniques could be implemented to avoid habitat stress and allow for ecosystem recovery.

The link between industrial engineering and the seaweed farming industry is clear due to the focus on optimising complex systems. ISE principles can be applied to the facility layout and site selection using geospatial data, process optimisation for farming operations and harvesting methods, supply chain design to ensure efficient distribution and minimal waste, and sustainability assessment to balance economic viability with environmental stewardship. It is recommended that systems modelling be applied to design scalable kelp farming operations and production scheduling in conjunction with inventory management to align harvesting cycles with market demand. Lastly, sustainability metrics should be integrated into operational planning to balance ecological and economic goals.

South Africa has great potential for a commercial seaweed farming industry. However, this research can continue as future work to further explore the current South African seaweed and kelp farming industry with an emphasis on empirical evidence. This includes assessing technology readiness and sustainable harvesting yields from the local kelp species with a specific focus on bio-based plastic production. Larger search horizons and more databases can be consulted to find more information relevant to a South African context.

UNIVERSITY OF PRETORIA

DEPARTMENT OF INDUSTRIAL AND SYSTEMS ENGINEERING

LEARN

Click to learn more about us

Are you ready to start your postgraduate journey?

WHY CHOOSE THE UNIVERSITY OF PRETORIA?

The University of Pretoria's Department of Industrial and Systems Engineering is an intensive research unit that works towards the integration of contributions from all engineering disciplines into a functional and cost-effective product by using systems knowledge and understanding. The Department's focus areas include:

- Supply chain management
- Enterprise engineering
- Optimisation

WHY ENROLL FOR A POSTGRADUATE QUALIFICATION?

A postgraduate qualification in Industrial and Systems Engineering can develop your ability to identify opportunities to integrate the contributions of various specialists, identify and adapt appropriate technology, and expand your global perspective. In this way, new processes and technology may be developed to solve problems and handle situations that may, at present, be unknown.

OUR POSTGRADUATE DEGREES

- BEngHons Industrial Engineering
- BScHons Applied Science
- MEng Industrial Engineering
- PhD Industrial Engineering

ABSTRACT

The problems of water supply services are experienced globally. These include difficulties in the efficient operation of systems and lack of competence in the technical skills of personnel, among others. A review of water pumping systems technologies currently used to supply potable water across South Africa shows that townships, cities, and urban and rural areas will remain under water strains because of ineffective water supply technologies. Different water pumping system technologies and water pumping system infrastructure have been reviewed. Water pumping system infrastructure consists of pipes, pumps, valves, storage tanks, reservoirs, meters, fittings, and other hydraulic appurtenances that connect treatment plants or well supplies to consumers' taps. These are main components that affect the water supply system. The strategy to ensure that potable water is supplied continuously during climate change and the increase in population is to develop frameworks to evaluate water pumping system infrastructure of potable water supply systems.

Keywords: Infrastructure, South Africa, Potable Water, Water Quality, Rural, Water Recycle System, Water Demand, Systemic Approach.

1 INTRODUCTION

The existing infrastructures in South Africa are not well maintained and managed to meet the demand of water to the consumers hence there is still shortage of water. These is because, in the process of water supply, the design, installation, operation and maintenance of the pumping systems and pumps is a challenge to the municipalities. Large amount of population (70%) access water from boreholes which are heavily contaminated due to back pit toilets used in rural areas and mine activities [1]. Other communities buy untreated water from the households with boreholes. Provision of alternative water sources such as purified groundwater and rainwater harvesting system have been investigated for rural areas in Limpopo province of South Africa, although these are not in wide use [2]. This system has not been used in rural areas of Limpopo province. The common way of accessing water is only through boreholes and rivers nearby. The Kgopaneng village area of study does not have water treatment plants and the water from individual boreholes is pumped straight to the households for consumption and domestic use which poses a high risk to the health of consumers.

A suitable household in the village of Kgopaneng is selected for development, installation and testing of the new water supply model. The purpose of this research study is to develop an empirical model of water supply system for rural areas of Limpopo province. The primary aim of this empirical model was to provide a suitable solution to the challenges of water shortages in rural communities. Given lack of funds available to municipalities to supply bulk purified water to rural communicates and the fact rural dweller do not have financial means to afford these services, there is a near absence of any bulk water supplied to the study areas of rural Limpopo province. Thus, a centralized water supply system for rural areas of these two study provinces is not suitable at this stage. An alternative system needs to be proposed and implemented for rural communicates in this province that provides water to homes at an affordable cost. In this paper, development of a model to supply water to a selected rural home of Kgopaneng village in Limpopo province is proposed as an alternative solution to water supply to rural areas of South Africa. The proposed solution, although implemented at only one home, can be easily replicated and even scaled up to supply more homes or entire villages, given resources and commitment of the municipalities of these two provinces. It is notable that demand far outweighs supply thereby leading to stressed capacity in the water sector of the provinces. This study focuses on the development of appropriate water pumping systems and capacity building tools that may result in operational and maintenance efficiencies in rural area.

2 CONCEPTUAL DESIGN

Limpopo province is largely rural areas. Subsistence farming is the core of many people's livelihoods. Frequent droughts have hampered crop production and people in the communities now keep small home gardens to try and make up for lost crops in larger fields. High temperatures, droughts and erratic rainfall contribute to crop failure and food insecurity. The bulk of household wastewater is greywater which is being produced on a daily basis. Up to 60% of household water consumption is discharged as greywater. A typical household consumes 150-200 litres of water per person per day, this can amount to 400-600 litres per day per household. Ideally it should not be discharged to the sewer where it contributes to overloading sewer systems and wastewater treatment plants and ultimately consuming more energy and resources to treat. However, in rural areas, other areas do not have electricity, so there is a need for a reliable source of water that will not only supply fresh water but also improve food security. A solar system is introduced to generate electricity to operate the entire system and provide an alternative power supply to the household.

3 SYSTEM CONSTRUCTION – GREYWATER, BOREHOLE WATER AND RAINWATER HARVEST (RWH)

The raw water for the system is abstracted from the greywater, rainwater harvesting boreholes. The water is purified until meeting quality standards according to WHO [2]. Water is defined in its Guidance for Drinking-Water Quality by the World Health Organization (WHO) as being water used for domestic purposes like consumption, bathing, and food preparation. These mean that the requirements of water to meet quality standard must be guided by World Health Organization (WHO) [2]. Water supply is evaluated on a set of different variables; the location of the water sources, how they are accessed, their quality and supply systems. The development of water infrastructure in the provinces should be done based on improving the existing infrastructures used to access water. The infrastructures are not well maintained and managed to meet the demand for water to the communities, as a result, they don't last. Figure 1 shows the detailed system construction of water purifications and greywater systems. The size of the system is limited to a single home. Figure 2 illustrates the diagrammatic representation of potable water systems and greywater systems developed for household in Kgopaneng village.

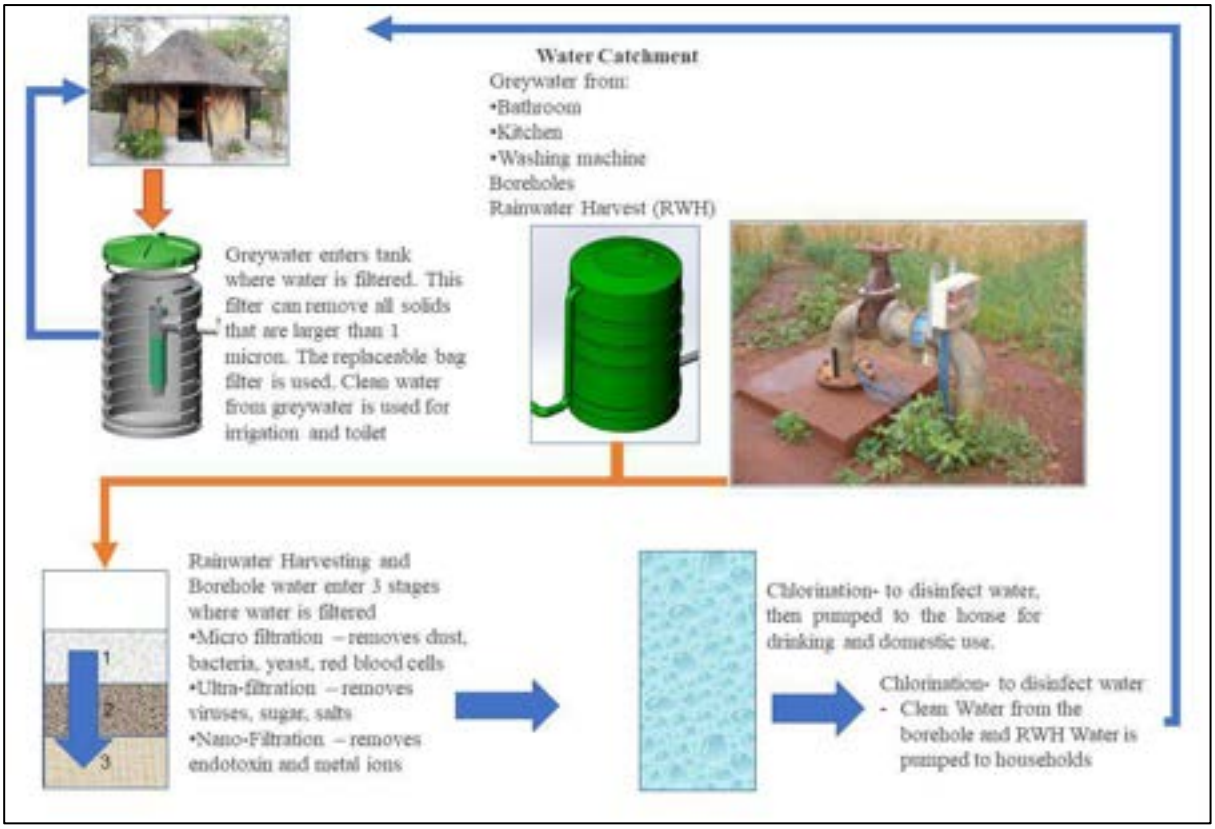

Figure 1: System Construction of Water Recycling and Purification.

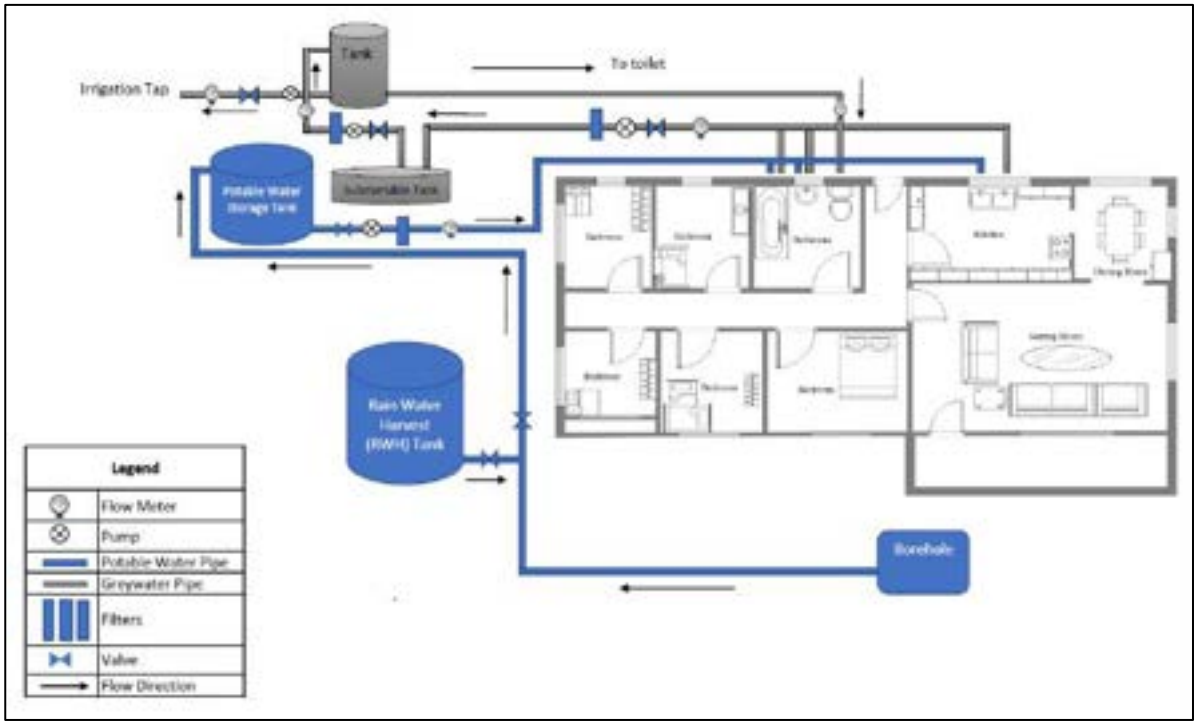

Figure 2: Diagrammatic Representation of Potable Water System and Greywater System.

4 DESIGN SPECIFICATION OF PUMPING WATER PUMPING SYSTEM

The design of water pumping system was done based on the length and diameter of the pipes to analyze the flowrate and head of water of the system and choosing the correct pump for freshwater and greywater systems. At the home where the model was installed a borehole fitted with pumps is used as the main source of drinkable water. Therefore, the same borehole system is used as a source of water instilled model water pumping system developed to supply water in the study area. Small scale was used to design a system to supply only one household for the purpose of demonstrating the new model that can be easily scaled up to supply communities. To select the pump that meet the requirement of the pumping system, the total dynamic head (TDH) was calculated using equations 1 – 3. Dynamic head means there is a change of pressures, velocities, elevations, and friction losses when the system and the pump are in operation [4, 5]. The Total Dynamic Head (TDH) is the total head of the following elements:

- The pipe friction losses (H_f),
- The static head (H_s),
- The velocity head (H_v).

The sum of these three elements of the Total Dynamic Head are as follows [4, 5]:

$$\text{Total Dynamic Head (TDH)} = H_s + H_f + H_v \quad (1)$$

whereby: H_f and H_v are given as follow:

$$H_f = \frac{f\,L\,v^2}{2gD} \quad (2)$$

$$H_v = \frac{v^2}{2g} \quad (3)$$

Parameters in equations 2 and 3 are described as follow:

- f – friction factor
- L – length of water pipe of the system
- D – diameter of water pipe of the system
- v – velocity of water inside the pipe
- g – constant gravitational acceleration of 9.8m/s^2

The pumping framework was planned based on framework determination and presumptions that the stream rate shifts from 0.011 to 0.04 m^3/s, due to the slight elevation of the landscape at the installation home. The calculations are carried out at 0.011 m^3/s and the same method is utilized to calculate the pumping framework at the stream rate of 0.04 m^3/s. The roughness of the pipe is constant depending on the pipe material used, see Table 1.

Table 1: Absolute Roughness of Pipe Material

Pipe Material	Absolute Roughness, ε	
	Mm	Microns
Drawn brass or copper		1.5
PVC Pipe	0,0025	2,5
Commercial steel	0.045	45
Wrought iron	0.045	45
Asphalted cast iron	0.122	150
Galvanized iron	0.259	150
Cast iron	0.259	260
Wood stave	0.183 – 0.914	200 – 900

4.1 Borehole System

The borehole used in this study is installed with a borehole pump. Water is pumped from the ground to the households without filtration. Water is supplied from the borehole into a water tower located 25m above the well. Required pump capacity was thus estimated at 0.0011 m^3/s. Height from the ground level to the top of the water level in the water tower tank is 15 m. Water tower is located 25 m away from the well. Static water level in the well is 20 m. Figure 3 shows water pumping system, pump curve and system curve of the borehole determined for this household.

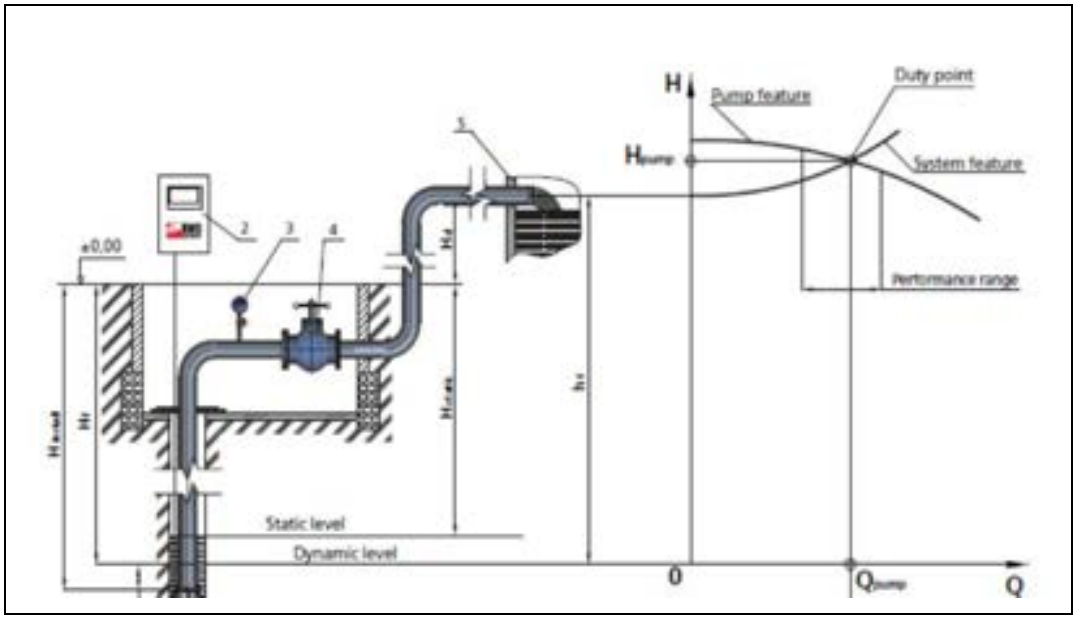

Figure 3: Water pumping system and borehole pump illustration. Duty point is determined by intersection of the system and pump curves. The intersection point is called the duty point. One of the main conditions in a pump selection is to provide the preferred operating range of 70-120% of nominal capacity [6].

4.2 Potable Water System Design and Selection of Water Pump

To design the pumping system for the potable water, the pipe material used is PVC plastic; therefore, pipe roughness is, ε = 0.0025mm, refer from Table 1. The calculations are carried out at $0.0011\ m^3/s = 66\ l/min$. The specifications are based on the diagrammatic representation of potable water system in Figure 4.

Pipe Diameter, D = 50mm = 0.05m,

Length of the pipe of the system = 45m,

The static head (H_s) = 20m,

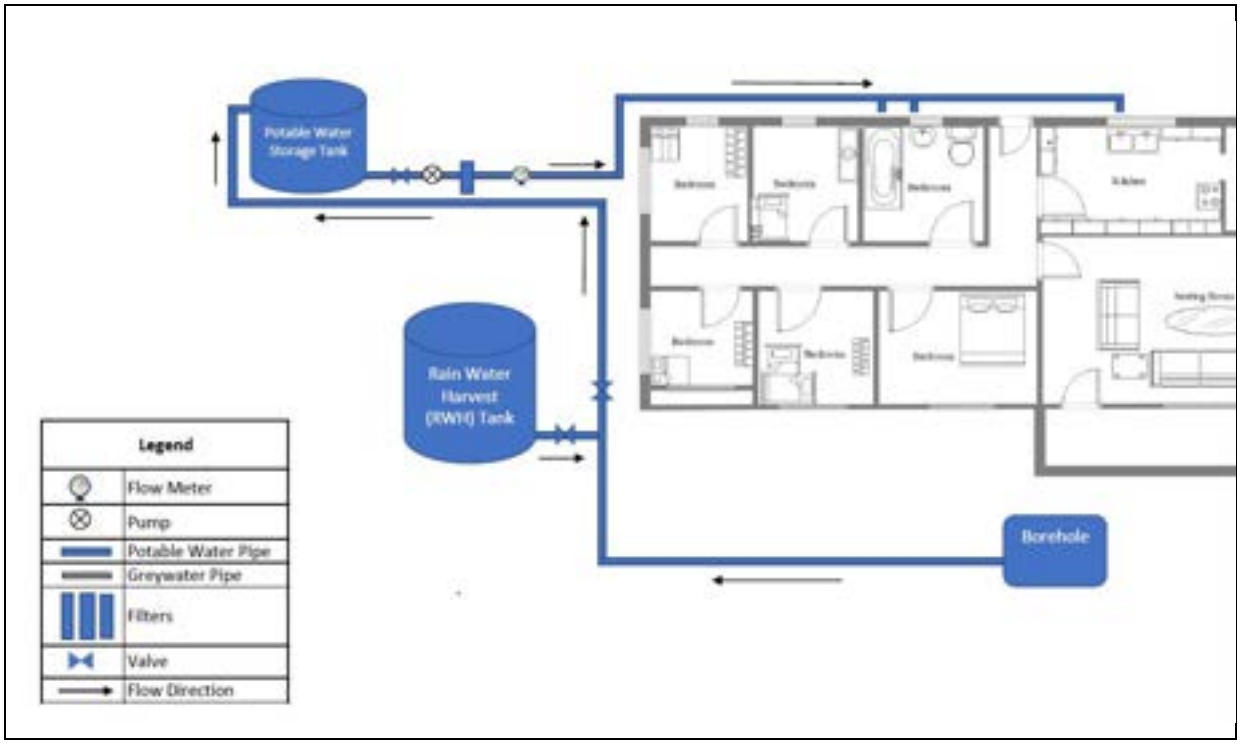

Figure 4: Diagrammatic Representation of Potable Water System.

Equations 4 –11 are used to determine the water pumping system. The friction head is the friction loss in the system that the pump must overcome. The friction occurs between the fluid and the internal surface of the pipe, valves, connections, and accessories in the suction and discharge of the pump. Equation 4 is used to calculate friction head of the pipe as follows [4, 7, 8];

$$H_f = \frac{f\,L\,v^2}{2gD} \tag{4}$$

$$Area\ of\ the\ Pipe = \frac{\pi D^2}{4} \tag{5}$$

$$= \frac{\pi \times 0.05^2}{4} = 0.00196m^2$$

$$Velocity = \frac{Flow\ Rate}{Area} \tag{6}$$

$$= \frac{0.00011}{0.00196} = 0.5612m/s$$

$$Reynold's\ Numbe = \frac{Velocity \times Diameter}{Kinematic\ Viscosity\ of\ Water} \tag{7}$$

Kinematic Viscosity of water $= 1.787 \times 10^{-6}\, m^2/s^{-2}$

$$Reynold's\ Number = \frac{0.5612 \times 0.05}{1.787 \times 10^{-6}} = 15702.294$$

To calculate the friction factor (Equation 8), Reynold's number is used [9]. Reynold's number is greater than 4000, therefore the flow is Turbulent. For Turbulent flow, the following formula for friction factor is used [10].

$$f = \frac{0.25}{\left[log\left(\frac{\varepsilon}{3.7d} + \frac{5.74}{R_e{}^{0.9}}\right)\right]^2} \tag{8}$$

$$f = \frac{0.25}{\left[log\left(\frac{0.0000025}{3.7 \times 0.05} + \frac{5.74}{(15702{,}294)^{0.9}}\right)\right]^2} = 0.02757$$

The friction losses within the system at the flow rate of 0.011 m^3/s is found to be 0.01639.

$$\mathrm{H_f} = \frac{\mathrm{f\,L\,v^2}}{\mathrm{2gD}} \tag{9}$$

$$\mathrm{H_f} = \frac{0.02757 \times\ 45 \times\ (0.5612)^2}{2 \times 9.81 \times 0.05} = 0{,}3983\ m$$

The velocity head (Hv) is given in Equation 10 as:

$$\mathrm{H_v} = \frac{\mathrm{v^2}}{\mathrm{2g}} \tag{10}$$

$$\mathrm{H_v} = \frac{0{,}5612^2}{2 \times 9.81} = 0.01605m$$

$$\mathrm{Total\ Head} = \mathrm{H_s} + \mathrm{H_f} + \mathrm{H_v} \tag{11}$$

$$= 20 + 0.3983 + 0.01605$$

$$= 20.414m.$$

Thus, the potable water system for the selected home in the study village requires a pump that can deliver total head of 20,414m and total flowrate of 66L/h. For this purpose the model was fitted with two pumps, one located before the freshwater tank, and another located after freshwater tank to boast water supplied to the households, see Figure 4. From Jojo Booster Pump, the best pump that can deliver according to this operation point is CPM158 which requires power supply of 0.78kW, refer from Figure 5. The booster pump can deliver flowrates of 40 to 80L/min and pressure heads of 19m to 28m [11]. The booster pump can reach maximum head of 32m and maximum flowrate of 100L/min.

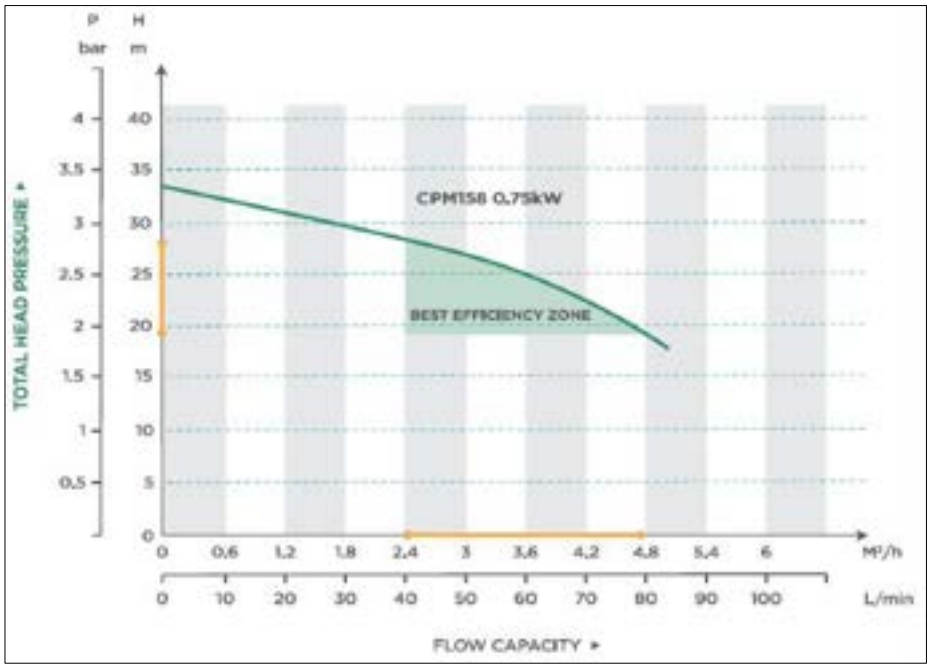

Figure 5: CPM158 0,75kW Pump Curve [11].

4.3 Greywater System Design

Greywater recycling systems have been introduced in townships, however, there is little or no progress in the rural areas like Limpopo. This system will be beneficial more in rural areas as it is where agricultural activities are mostly practised. This greywater can be very economically and easily recycled, for example treating it for reuse in toilet flushing and irrigation. The greywater from showers, bathtubs and hand washing from the selected home in the study area is pumped to a submerge storage tank and pre-filtered through the highly efficient particle filter before entering the second tank fitted with a membrane filters. Afterwards, the particle filter removes all solids that are larger than 1 micron, such as sand, hair, coal particles and pollen, see Figure 6.

This 3D filter is manufactured from synthetic polymer. Another pump provides water flow and pressure to the second tank with the membrane filtering system. The contaminants are removed in each filtration stage, the water from the bottom to the top, so that backwash can be easily done when cleaning the filters. The first filter from the bottom is called micro filter where it removes atmospheric dust, red blood cells, bacteria, yeast, and asbestos. The micro filter is also manufactured from synthetic polymer.

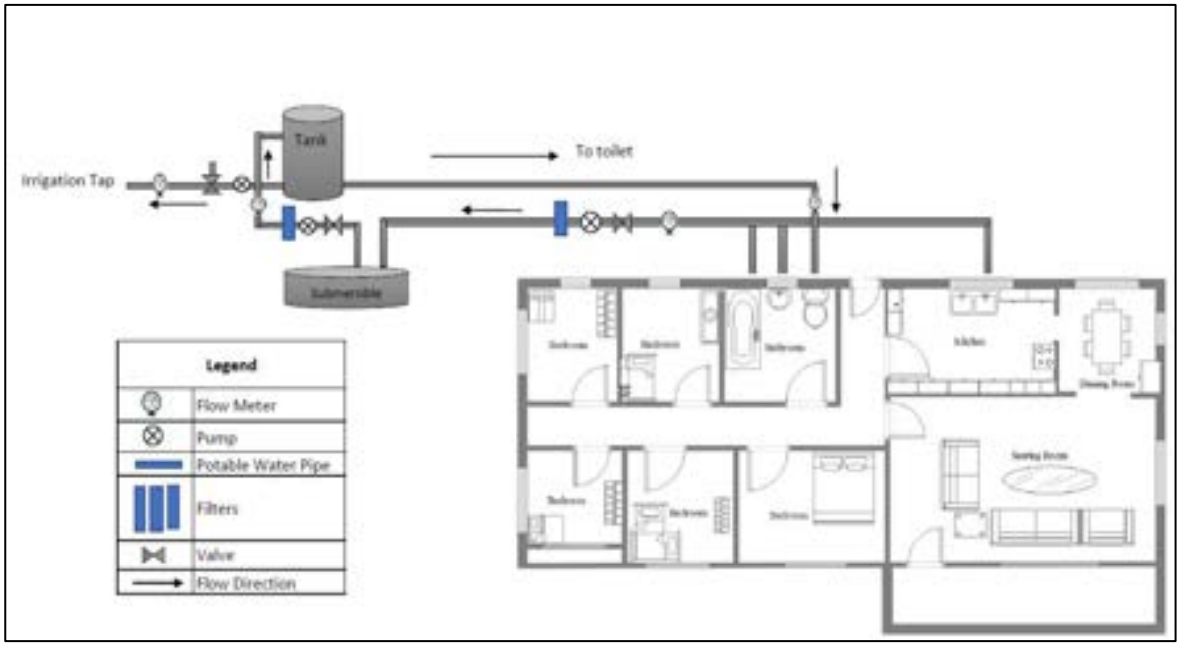

Figure 6: Diagrammatic Representation of Greywater System.

As the applied pressure on water passes through the membrane leaving pollutants trapped on the impermeable side, the water passes through the Ultra filtration process. In this stage all the contaminants that ranges from 0.1 to 0.01 micron such as pyrogen and viruses are trapped in this stage. Ultra-filtration process split up finer particles. With the assistance of pressure, the water continues to pass through the nano filtration filter. This filter is also made by the synthetic polymer. The nano-filtration process removes organic particles. It is mostly used in food processing. It has pore sizes from 1-10 nanometres, smaller than ultrafiltration and microfiltration pores but larger than Reverse Osmosis. The water is then pumped to the chlorination tank, The chlorination method is used to disinfect water. Chlorine is a highly efficient chemical liquid that destroys bacteria and is added to public water supplies to kill disease-causing pathogens, such as bacteria, viruses that commonly grow in water supply reservoirs and in storage tanks. It acts as a disinfectant. Water chlorination is the process of adding chlorine or chlorine compounds such as sodium hypochlorite to water.

Thus, the potable water system for the selected home in the study village requires a pump that can deliver a total head of 25,547m and a total flow rate of 66L/h. The system has three (3) pumps, one located after the submerged tank, 2nd supplies clean greywater into the house for toilet flushing use only. Lastly, another pump is used to pump water for irrigation, see Figure 68. From JoJo Booster Pump, the best pump that can deliver according to this operation point is CPM158 which requires a power supply of 0.78kW, refer to Figure 5. The booster pump can deliver flowrates of 40 to 80L/min and a pressure heads of 19m to 28m. The booster pump can reach a maximum head of 32m and a maximum flow rate of 100L/min.

4.4 Rainwater Harvesting

Amount of rainwater harvesting depends on the amount of rainfall. Rainwater harvesting is not always available in the system due to scarcity of rain in the study areas. As a results, rainwater is not contributing consistently to the water system hence an amount of water contributing to the system is not being specified. The base of rainwater tank is raised off the ground at about 500mm to allow the rainwater to flow to the main line by force of gravity. Using force of gravity to supply rainwater to water system reduced costs because no pump and power supply is required.

5 CONCEPT GENERATION

This study establishes that there is water available onsite at every location on the globe with the only challenge being the technological availability and technical ability to access this water, purify and supply, recycle and reuse. It is for this reason that there is a need to develop, design, install and monitor the new design of an alternative water supply strategy built on the circular economy concept and using the case of water management in Limpopo province of South Africa. Rural communities of these provinces experience water access and supply shortages due to lack of water services and difficulties associated with building stakeholder support for resource management strategies.

5.1 Water Model Concept Development

In this study, a water pumping system is designed for household use. The water pumping system is divided in two (2) sections, potable water system and grey water system. Borehole water and Rainwater Harvesting (RWH) are used for drinkable water, and they are the main sources of water in this system. The borehole pump (Figure 7) is designed to operate at the power input of 2.4kW at an efficiency of 76%. This is based on the pumping system setup of this study. One of the main conditions in a pump selection is to provide the preferred operating range of 70-120% of nominal capacity.

Figure 7: Design Model of the Borehole Pump.

Water from the borehole is pumped and mixed with the rainwater before going through filtration stage. Rainwater Harvesting (RWH) is stored in 5000liter storage tank (Figure 8) to allow unwanted particles to settle down before the water undergoes filtration process. The 5000-liter tank is also used to store potable water before is distributed into the house.

Figure 8: 5000 Liter of Storage Tank.

The filter (Figure 9) is designed to purify RWH, and borehole water to ensure that the water is drinkable and meets SANS standards. Similarly, the filter is designed to clean greywater so be reused for flushing toilets which will result in saving enough drinkable water. Different membranes of the filter are used based on the level of water contamination. Borehole water and RWH use the same filter because the water is mixed before the filtration process, whereas the greywater system uses a different filter because of the large particles inside the wastewater. The filter is designed in a way that is easy to maintain.

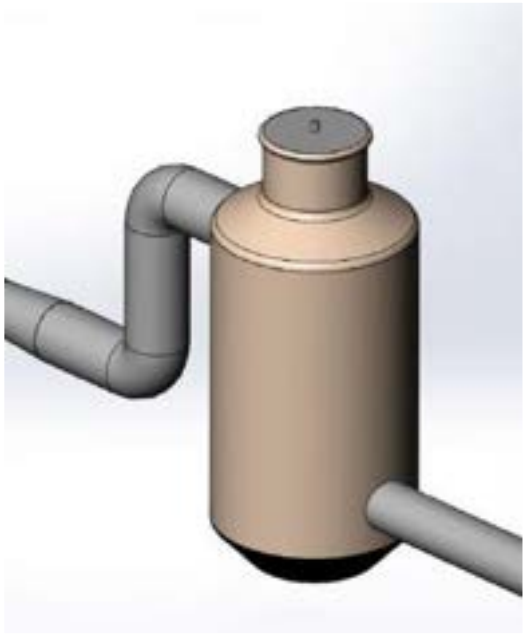

Figure 9: 3D Model of Filter.

Booster pumps (Figure 10) in the system are designed to deliver a flow rate of 40 to 80L/min and a pressure head of 19m to 28m. The booster pump can reach a maximum head of 32m and a maximum flow rate of 100L/min. The system will only need two (2) booster pumps to deliver potable water to the house. Greywater system only needs one (1) booster pump to pump water from the submerging tank (Figure 11) into the greywater storage tank through a filter. Recycled greywater is used for toilet flushing.

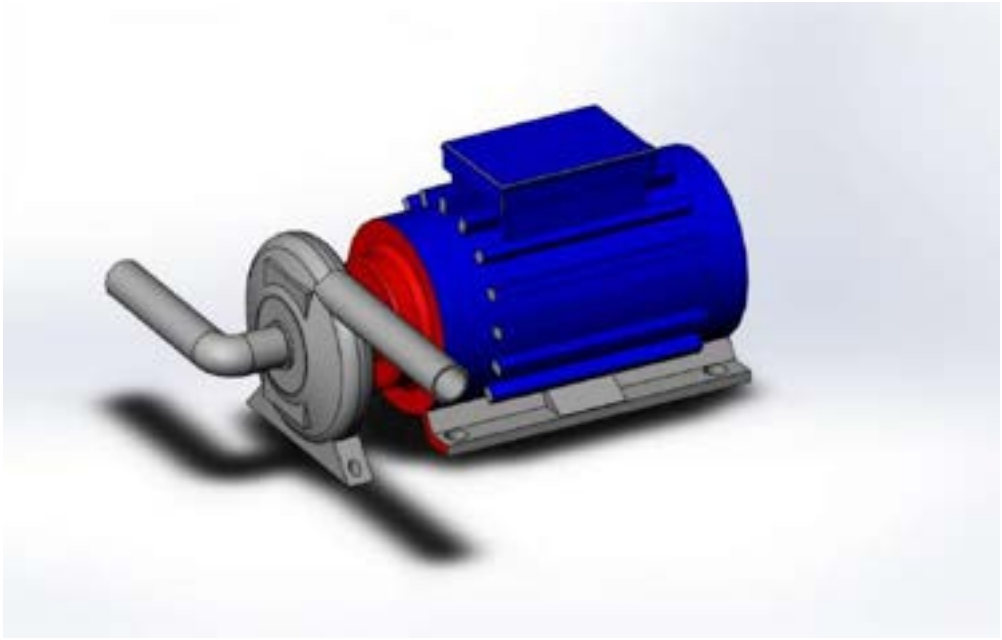

Figure 10: Boaster Pump

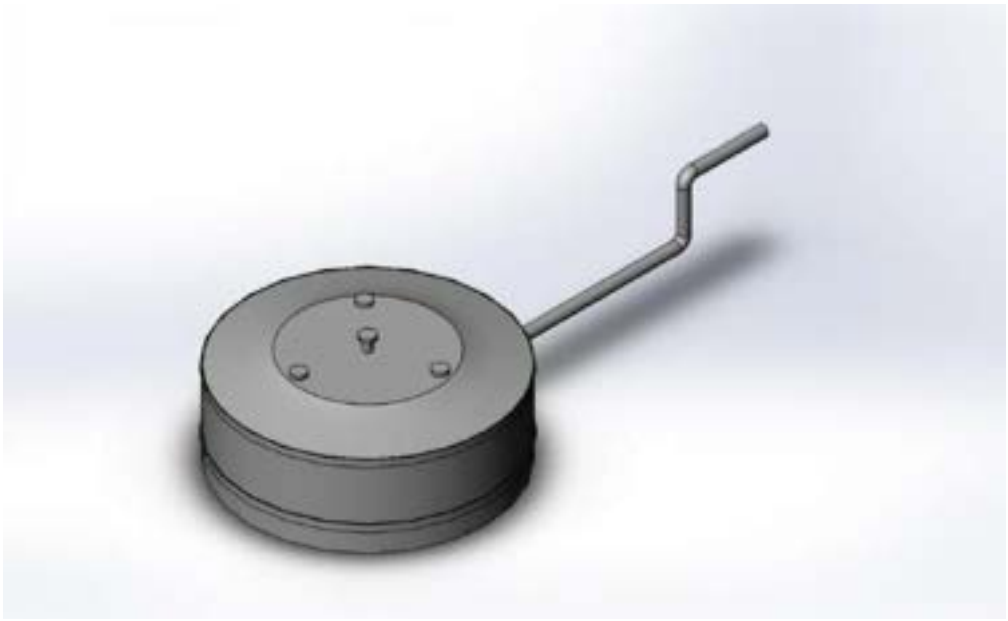

Figure 11: Submerge Tank

Figure 12 represents the completed 3D concept development of on-site water supply model for potable water and greywater systems. The model demonstrates a new concept development for a household in Kgopaneng village in Limpopo Province of South Africa and

can be suggested for wider applications. The model is developed for an area with enough water in its three forms of grey, blue and green but without technologies to make the water accessible for consumption and recycling used water. In this drawing, green represents potable water and grey color represents greywater recycling system. Figure 13 shows full details of the design and direction of water flow.

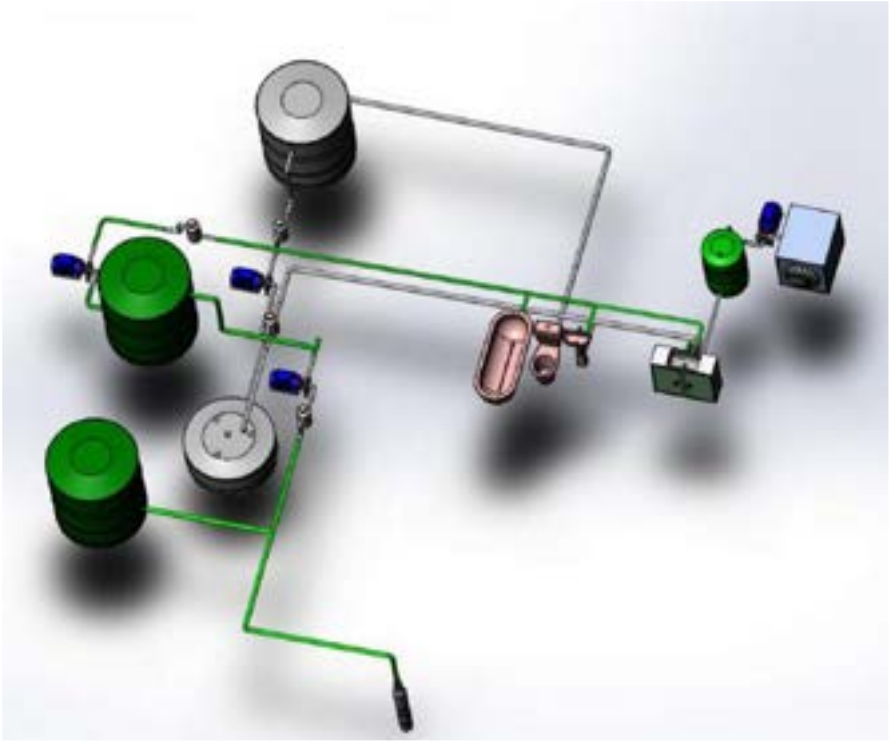

Figure 12: Empirical Design Model of Potable Water System and Greywater System for household in Kgopaneng village situated in Limpopo Province of South Africa.

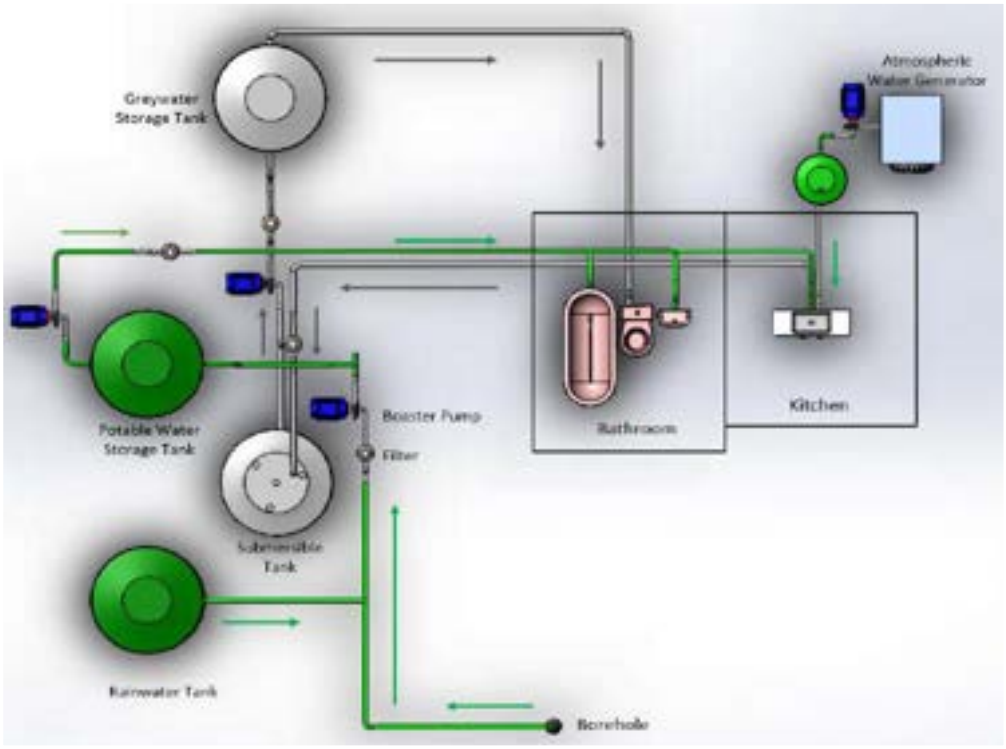

Figure 13: Detail Design Model of Potable Water System and Greywater System.

5.2 Cost Analysis

The design of a water pumping system is complex and is made in two stages. The first stage is the design and selection of different concepts based on desired technical specifications. After this stage, economic evaluation of the chosen concept from budget quotations and firm bid quotations gathered from different suppliers takes place. In this study, Life Cycle Cost (LCC) was used to develop an economic model of the water pumping system [12]. This involves its total “lifetime” cost to purchase, install, operate and maintain of the system equipment [13, 14].

The life cycle cost of a product, process or activity is the entire cost accumulated from beginning to end of life [15, 16]. The life cycle costing is a process of conducting an economic study to calculate the cost of an item over a section or entirety of its life which allows decisions to be made that will reduce the cost of the items which results in a lower ownership cost while still meeting the stakeholder requirements [15, 16]. This is done to recommend the short and long-term financial implications of the water pumping system. The life cycle costing is done to properly analyse the cost of the entire system and find ways where costs can be saved and other costs can be accounted for such as maintenance, operation, disposal and inflation. Table 2 shows all estimated costs of the water pumping system. Parts without costs were already available on-site and the house owner offered them to be used for water system.

Table 2: Estimation Cost of the Water Pumping System

Parts Description	**Dimensions**	**Unit Cost**	**Quantity**	**Total Cost**
2500 Litre Potable Water Storage Tank	2500 litres		1	R6000.00
5000 Litres RWH Storage Tank	5000 litres		1	R7500.00
Submerge Tank	250 litres	R1645.00	1	R1645.00
PVC Pipe	50mm diameter and 6m length	R275.00	6	R1650.00
Flow Meter		R379.00	9	R3411.00
Water Tank Sensors		R 663.81	6	R3982.86
Non-Returnable Valve		R 319.98	8	R2559.84
Booster Pump	0.38Kw	R 1495.00	4	R8970.00
	Sub Total			**R23023.70**
	Vat 15%			**R3453.56**
	Total Cost			**R39477.26**

6 DISCUSSION

The model equipment was delivered on site in Kgopaneng village on the 1st of May 2024. An installation at the rural home took place on the 25 May 2024. Installation of water pumping system was not complicated task because it was for one rural home. Water pump combined with electricity; the utmost care was taken to ensure that installation is done safely. Water tanks to store raw water was installed first and it depended on the availability of the space. The tank was installed on a strong, smooth and perfectly level surface that won't collapse under the weight of the water. Borehole pump was already installed and pipe network was installed from the borehole to the raw water tank. The base of the tank was lifted little beat off the ground and pump was installed slightly lower than the tank outlet to help to keep pump primed to avoid it drying and possibly breaking [3]. At the outlet of water pump, flow meter was installed to measure the amount of water used per day. Filter was also added in series to flow meter to clean the water from tank before is supplied to the house. After all installed, the system was commissioned, and 30 minutes test was conducted to check the leaks, pressure and flow rate. Water system was installed, commissioned and tested successfully.

7 CONCLUSION

Rural communities often rely on water sources that lack purification systems, making the water potentially unsafe for consumption. The current water pumping infrastructure is poorly designed, resulting in unequal access to municipal water across different areas. The study highlights that the core issue lies in the development of efficient water distribution systems. To ensure adequate access to clean water, it is essential to either design a new distribution network or expand the existing one. The research suggests that implementing small-scale household water systems could serve as prototypes for larger community-wide solutions. To date the use of purification water system for a household in the rural area of the study has not been implemented. It is therefore recommended to other researchers, engineers, or municipalities to study system models that can be used to supply potable water in remote areas across South Africa. Further improvements can be done on the water system developed for a household.

ABSTRACT

Due to South Africa's water crises and rising demand for these resources, alternate method is required to ensure that people can access power and water even during load shedding and water outages. To obtain a sustainable solution to the water problems the use of the System Dynamics model is considered. This is because it is an effective decision-support tool that helps to achieve sustainable water management in local municipalities. The model is applicable to be used in other local municipalities to manage water systems. The model was applied as a decision-support tool to assist in achieving sustainable water management. It was observed that System dynamics is a suitable approach for comprehending feedback, policy choices, and cause-and-effect interactions. It has been particularly effective in resolving water management issues. A System dynamic model was developed in the Vensim PLE 8.0.9 and prospects for enhancing water supply, management, and access are identified.

1 INTRODUCTION

The availability of potable water supply is the major challenging factor to South Africa's development. This study focuses on schools around Limpopo province of South Africa. Limpopo province is the smallest province out of the 9 provinces in South Africa. The province occupies 1,5% of the South African country's land and is the most populated province with 26% of the national population [1]. It is the most developed province with high urbanised and contains the largest city in South Africa. With all the developments, the province still experiencing the challenges of water. South Africa has been experiencing the issue of potable water supply has been ongoing, especially in schools areas [2]. This issue directly affects schools, households and businesses in their day-to-day operations, slowing the nation's economic progress [3].

The availability of clean and drinking water is another challenge faced by many in today's world [4]. Indeed, more than two billion people on the planet don't have access to clean drinking water although it was acknowledged by the United Nations General Assembly (UNGA) on July 28, 2010, that the right to clean and safe drinking water is a fundamental human right [4]. This issue is part of those addressed by the Sustainable Development Goals (SDG) but as signified in the 2022 SDG report, this goal is yet unfulfilled [4]. Hence countries like South Africa still suffer from the water issue.

South Africa is considered to be a water-stressed country [5]. This is because, according to Rand Water, each person living in the country has less than 1700m3 of water per year [5]. One of the consequences of this situation is that South African schools receive inconsistent water supplies. [6]. The South African Human Rights Commission's 2021 report on water and sanitation in schools can help highlight the effects of the water crisis [7]. It was reported by the South African Human Rights Commission in 2021 that 366 schools still do not have access to water in the country and this affects 5 429 teachers and 144 255 learners [7]. These numbers are quite big and concerning. Hence, sustainable solutions should be put in place to alleviate these problems. To the author's knowledge, the system dynamics approach has not been used to evaluate water supply systems in schools around Limpopo province of South Africa. This study aims to model the water pumping systems in Boipelo Intermediary school based in Limpopo province of South Africa. According to bench marking water usage report prepared by Water Research Commission (WRC), in 2002, the school had 787 learners and 22 educators [8]. According to the South African school net, in 2022 till 2024, the number of learners and teachers were recorded as follow, see Table 1 [9].

Table 1: Learners and Teachers information (2022-2024) [9]

	2022	2023	2024
Learners	455	699	468
Teachers	20	21	20
Total	475	720	488

System dynamics is established to determine the nature and causes of water delivery challenges in schools of Limpopo province of South Africa. System dynamics is a useful approach for comprehending feedback, policy choices, and cause-and-effect interactions. It has been particularly effective in resolving issues with water supply management.

2 METHODS

The concept of the water system was developed, and it was used to generate a System Dynamics model. The System Dynamics simulation methodology is developed based on water system theory. The model was developed using data from surveys conducted in secondary schools in Limpopo province. Schools in Limpopo were selected randomly for this study. The data on the number of students, teachers and other employees from the school was used to

develop a System Dynamics model. Characteristics of systemic approaches adopted based on the outcomes of the data collected.

The system dynamics model in this study is being built to monitor the factors that can sustain the availability of drinkable water in schools. These factors include cost, consumer, and period effects. The model was created to improve strategic management of the water supply and allocation of resources to ensure uninterrupted water supply. Water demand, water costs, water catchment, water purification process, number of learners and water demand are some crucial elements incorporated into the model. Over an accurate prediction, the water supply are simulated over 50 days, from June 2024 to September 2024 from the data obtained in Table 1. Data in Table 1 was used to develop the system dynamics model. In this research study, two techniques are used to illustrate systems dynamics models: stock and flow diagram and causal loop diagram. The causal loop diagram in Figure 1 shows the positive and negative interactions between population increase and the demand for potable water which was developed using Venism.

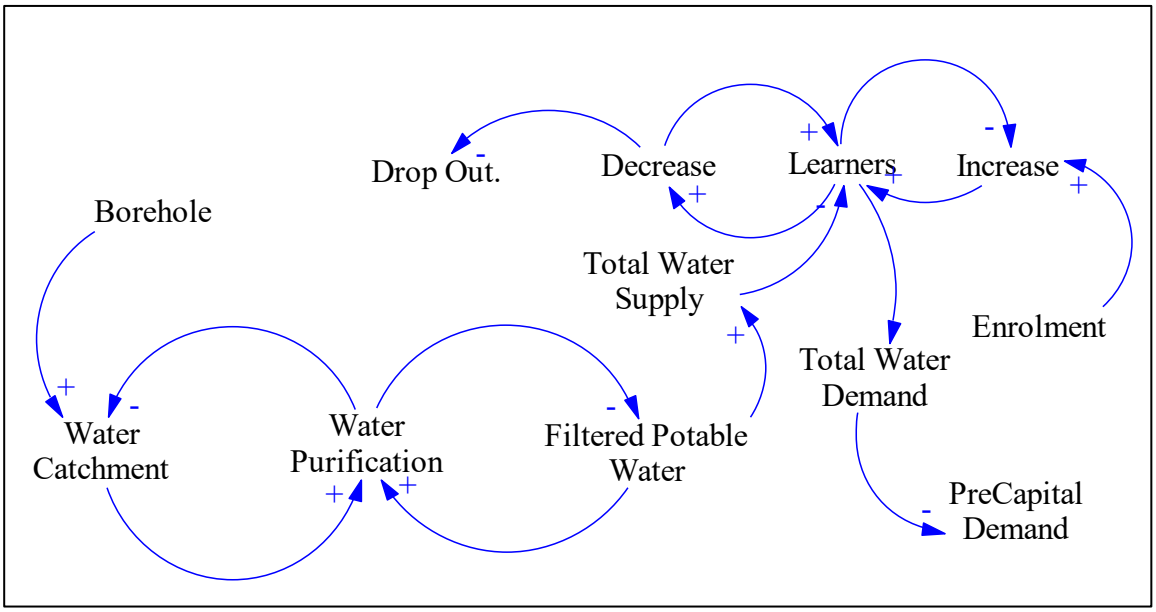

Figure 1: Causal loop diagram of water supply for Intermediary School in Limpopo province.

Causal loop diagram is used to illustrate the relationships between learners growth, the demand for potable water, and other factors influencing its supply like borehole water, filtration process and total water being supplied [10]. Casual loop diagram helps with defining the relationship between elements that contribute to water supply. It also helps with sub-models that contribute to stock and flow diagrams. Borehole, water catchment, purification and filtration systems contribute to the system dynamics model developed in this study.

- Borehole

The source of water for schools in rural communities is borehole. Borehole systems are harnessed under grey water type and supplied to the schools. The water from boreholes contribute largely to the water catchment of the system dynamics module. In this research it was assumed that 85% of water catchment is from the borehole.

- Water Catchment, Purification and Filtered Water

Water from borehole is stored in tanks already available onside before purification process takes place. Filters used were selected after the test of the water from borehole was done.

This helped to with selection of filters that will purify the water to meet WHO stands. Filtered water is then pumped to the school.

2.1. The Developed System Dynamics Model

The system dynamics model is a method that makes use of flow, internal feedback loops, table functions, and time delays to solve complex systems over an extended period. Approaches that take into consideration the dynamic relationships between water sources, water treatment facilities, water storage, potable water transportation, commercial, and potable water distribution, and end users' roles are necessary for the sustainable management of water resources [11, 12, 13]. Delivering adequate water resources to meet human requirements is a concern of the water resources management strategy hence a system dynamics model is needed. It is possible to model the population analysis in water supply using systems dynamics. Water resource management and supply complex challenges are addressed and dynamically solved through the application of system dynamics methodology. Determining the system structure between variables, feedback loops, system archetypes, and latency is the initial stage in any system dynamics modelling. Stakeholder involvement facilitates effective approaches to the problem of water management [13]. To optimize the water system's capacity, a model representing the evolution of water resources over time will be created. The model is applied to test ideas and in a complex real-world scenario. Given the complexity of the studied issues, dynamic simulation models have a long history of application in water management. In an artificial environment, the model also aids in testing real-world behaviour [14, 15].

Dynamic simulation helps to observe the performance of a modelled system and response to interventions over time. The basic elements that can be found in all systems dynamics models are arrows, auxiliary variables, rate and stock/ level Models [11].

2.1.1. System Dynamics Model

The increase in population and mismanagement of existing water systems contribute significantly to the shortage of water and power supply. Schools in Limpopo depend on the municipalities to provide access to potable water. Alternative sources of water will provide stability in the case of a shortage of water supply from the local municipality.

The systems dynamic models are developed in this study to capture the interaction between water sources and supply for Boipelo Intermediary school as shown in Figures 2. Water demand, water costs, water catchment, water purification process, number of learners and water demand are some crucial elements incorporated into the model. These are the main aspects that are affected due to the shortage of water included in the module. The model was developed using Vensim PLE 8.0.9 (Double Precision). The assumptions of water used per day were made as follows:

Boreholes = 0.85% per day

Enrolment = 0.02% per annum

PreCapital Demand = 0,35/Total Water Demand

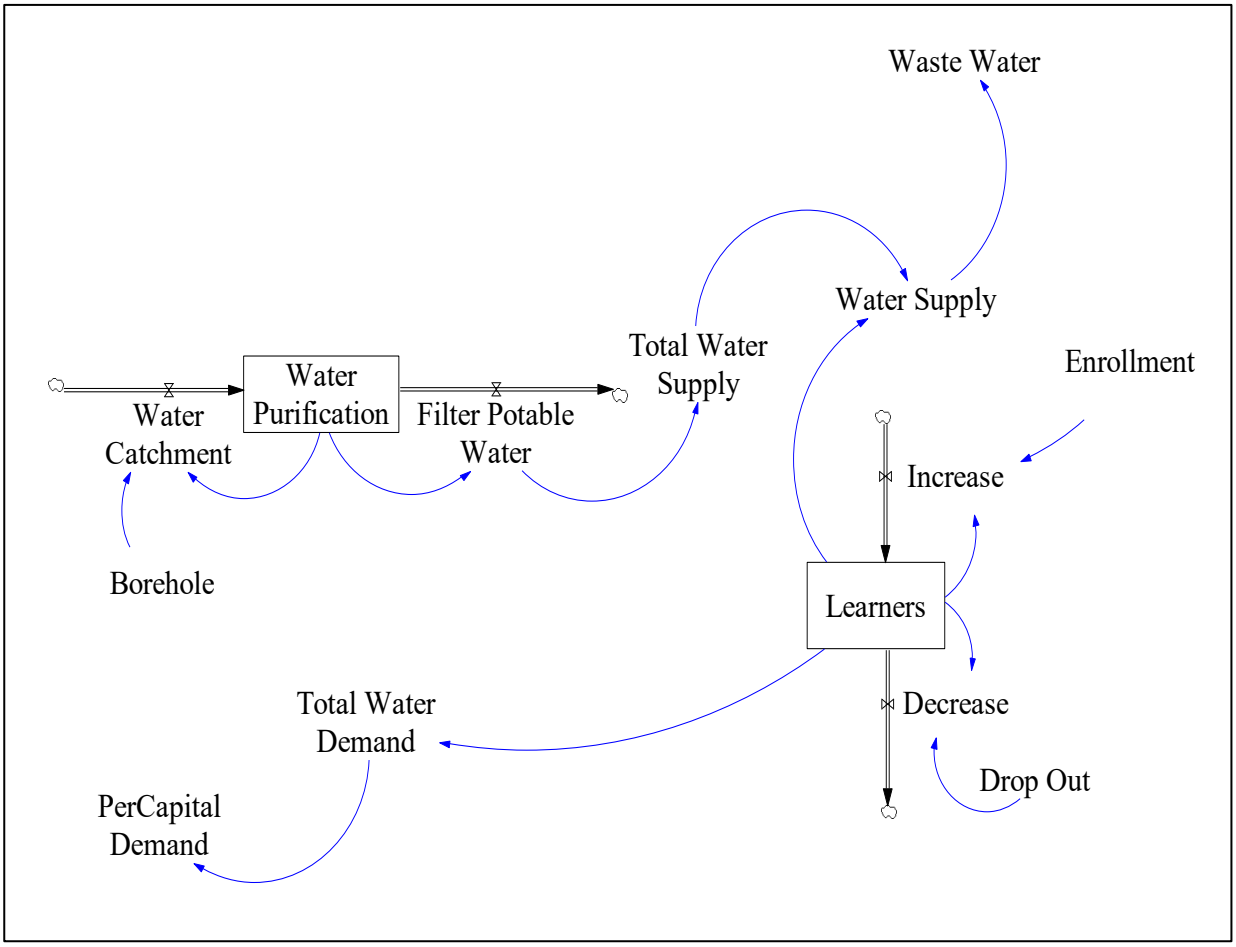

Figure 2: Stock and flow diagram of water supply for Boipelo Intermediary School.

3 RESULTS AND DISCUSSION

A technique to support long-term water management helps with ensuring that the supply of water is not interrupted, and water quality is not compromised. In this research study, the system dynamics model provides an accurate estimation to predict the positive or negative output should water supply systems not be managed as supposed. The simulation results were obtained from the stock flow diagrams in Figures 1 and 2. The models were tested through two scenarios; a comparison was made between the summer and winter seasons. In Figures 3-6, the blue trend represents the behaviour of a water system in winter while the red trend represents the behaviour of the water system in summer. The results are based on the winter and summer seasons. The number of learners enrolling and dropping (Figure 3) out also affects the performance of the system.

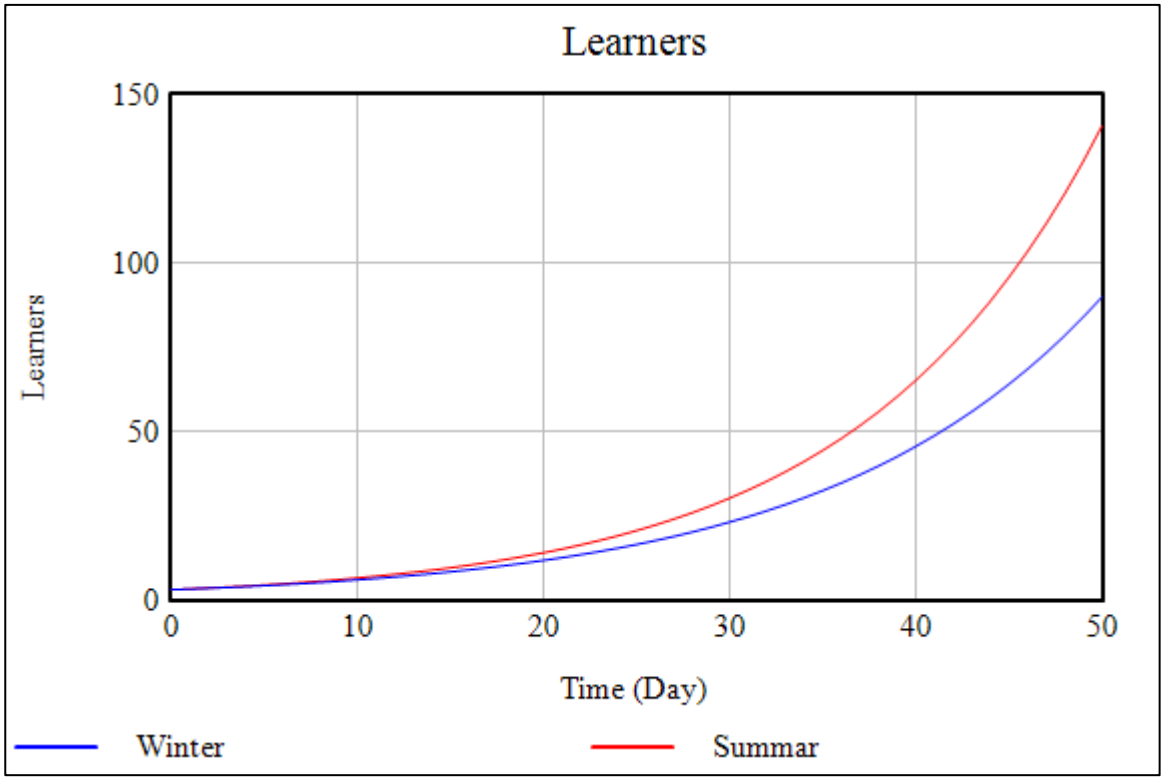

Figure 3: Simulation results of learners

Figure 4 shows the decrease in the trend of water supply which is due to the increase in the number of learners and the summer season. It was also observed that an increase in learners (including staff members) increases water consumption.

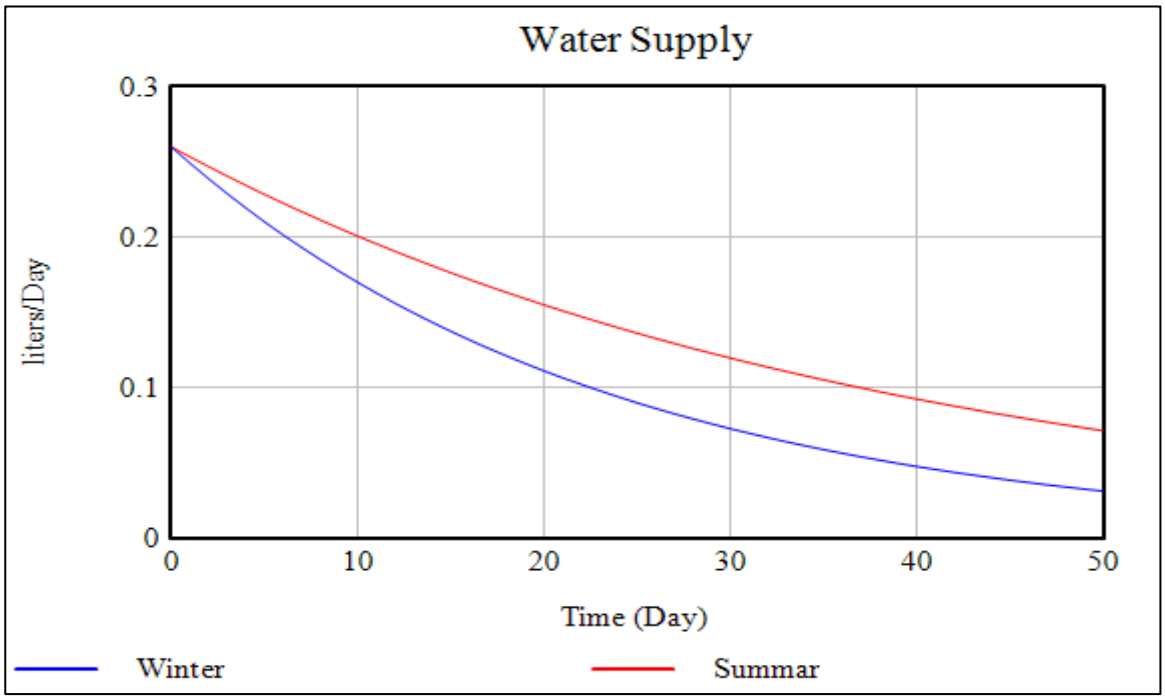

Figure 4: Simulation results showing the amount of water supply during the winter and summer seasons

The amount of water being utilized and cleansed determines the overall amount available; Figures 5 and 6 illustrate this. Furthermore, poor water management has an impact on the available water supply. Figure 5 illustrates how the new development of the alternative water supply model will increase the overall volume of water delivery. The overall amount of water supply will eventually decrease due to systemic mismanagement (Blue trend). The water supply won't be disrupted by the system's management (Red trend), according to the system dynamics research. This aids in the system's resource distribution as well, guaranteeing a steady flow of water.

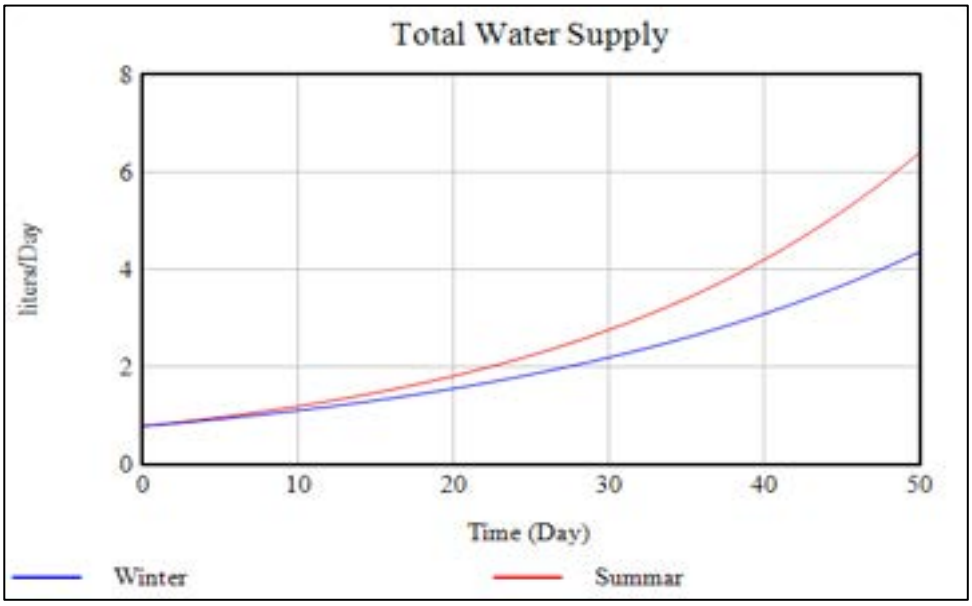

Figure 5: Simulation results showing the total amount of water during the summer and winter seasons.

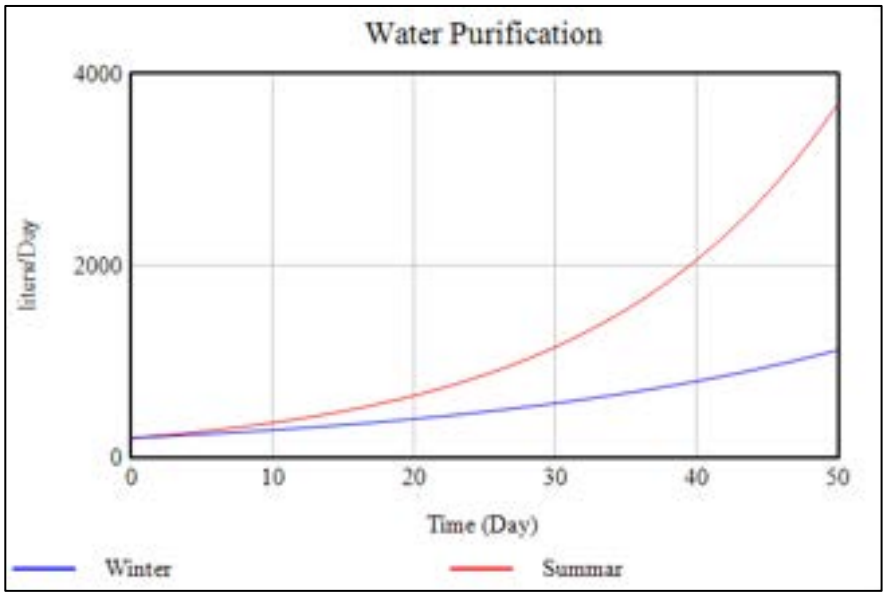

Figure 6: Simulation results showing the amount of water purification during the summer and winter seasons.

In order to forecast the long-term effects of installing different water pumping system dynamics were constructed. The findings indicate that over 50 days, the management of the water system will enhance the overall water supply. The water system's problem areas were determined using the SD model. The model's output indicates that every school must manage their water resources and systems to maintain a constant water supply. These will guarantee the schools with continuous access to water.

4 CONCLUSION

The objective of the study was to create a water supply chain simulation model and utilize it to identify the types and reasons behind problems with water delivery. Summer season increases water demand for schools, commercial, and agricultural. The study demonstrated that local school in Limpopo province can benefit from the use of system dynamics techniques to precisely estimate the amount of water needed based on the pace of demand in the schools by doing this, resource allocation will be aided, preventing interruptions in the water supply. For upcoming research, the simulation model could be a starting point for developing water system to a school.

ABSTRACT

This study evaluates the efficacy of Distributed Acoustic Sensing (DAS) using fibre optic cables to secure underground pipelines against fuel theft. Employing a mixed-methods design, the research integrates both quantitative and qualitative DAS data collected from stakeholders specialising in geophysics, geothermal energy, mining, and the oil and gas sector, including applications in high-resolution seismic and microseismic monitoring. Results indicate that the system's seismic reliability and performance are critically dependent on precise depth calibration, acoustic directivity, and optimal signal to noise ratio control. These parameters are essential for distinguishing illicit activities from background noise. Our findings underscore DAS's potential as a real time, scalable defence for safeguarding critical pipeline infrastructure worldwide.

Keywords: Depth Calibration, Directivity, Signal to Noise Ratio

1 INTRODUCTION

Fuel theft remains a global issue, with approximately R2.34 trillion (US$133 billion) worth of crude oil and refined products stolen or tampered with annually. According to [1] oil theft accounts for 5–7 % of the global market for crude oil and petroleum fuels. This illicit activity poses significant economic, environmental, and security risks particularly to long distance pipeline networks. Traditional monitoring methods often fall short in providing real time, comprehensive surveillance over extensive pipeline infrastructures, leaving them vulnerable to unauthorised access and damage.

Distributed Acoustic Sensing (DAS) technology has emerged as a promising solution to address these challenges. By utilising fibre optic cables to detect acoustic signals along the entire length of a pipeline, DAS systems can identify and locate disturbances with high precision. This capability enables continuous, real time monitoring, facilitating the early detection of potential threats such as unauthorised digging, tapping, or vehicular activity near the pipeline.

Despite its promising capabilities, the application of DAS in pipeline monitoring remains in a developmental phase, facing several technical, environmental, and operational challenges.

Notably, Distributed Acoustic Sensing (DAS) has been applied in various fields, including vertical seismic profiling [2], earthquake monitoring and traffic detection [3], hydraulic fracture geometry characterisation [4], and microseismic monitoring [5], its deployment in real world pipeline scenarios is limited.

Recent studies have begun to explore DAS for field applications, including damage state monitoring of buried pipelines and leak detection in gas pipelines. However, comprehensive research integrating both quantitative and qualitative data from diverse stakeholders is scarce, hindering the development of effective strategies for implementing DAS in pipeline security. Addressing these gaps requires interdisciplinary collaboration and extensive field trials to validate DAS technologies under varying operational conditions.

This study aims to bridge this gap by investigating the application of DAS technology in safeguarding long distance pipelines against fuel theft. Through the analysis of both quantitative and qualitative data from various stakeholders including pipeline operators, security personnel, and technology providers this research seeks to identify consistent and effective strategies for implementing DAS in pipeline security. By providing empirical evidence and practical insights, this paper contributes to the existing literature by offering a comprehensive understanding of the capabilities, challenges, and best practice associated with deploying DAS systems in real world pipeline monitoring scenarios.

2 FIBRE-OPTIC SENSOR IN DISTRIBUTED ACOUSTIC SENSING

In this section, we explore how fibre optic technology is adapted for DAS, covering the fundamental sensing principles, fibre types, deployment methods, and handling considerations. Conventional telecommunications fibres are repurposed in DAS to act as continuous acoustic sensors: light pulses injected into the fibre undergo Rayleigh backscattering, and the resulting time varying phase or intensity changes along the fibre are precisely measured to detect acoustic, seismic, or thermal disturbances.

According to [8], the optical interrogation system detects minute variations in the backscattered light and converts them into strain signals that reveal disturbances along the fibre path.

According to [9], single mode fibre with its small core (approximately 9 µm) is the preferred choice for DAS, as it supports only one propagation mode of light. This minimises modal dispersion and enhances the signal to noise ratio, in contrast to multimode fibre, whose larger core (around 50 µm) permits multiple interfering light paths that degrade measurement fidelity.

Moreover, single mode fibre exhibits lower attenuation, enabling longer sensing ranges typically up to 40–50 km depending on system design and pulse length.

Effective deployment of fibre optic cables critically influences measurement quality. In well based applications such as Vertical Seismic Profiling (VSP), embedding fibre within the cement sheath of casing provides the best coupling to the formation, yielding high quality seismic measurements. Alternative approaches such as clamping to production tubing, securing behind an inflatable liner, or using wireline tools offer ease of deployment but often suffer from poorer coupling, increased noise (e.g. tubing waves), and reduced signal to noise ratio.

In linear infrastructure scenarios such as buried pipelines, achieving adequate deformation coupling with the surrounding medium is similarly essential, with deployment proximity and mechanical constraints significantly affecting data fidelity.

Handling of fibre optic cables also demands meticulous attention: minimising sharp bends is essential to prevent light leakage and maintain sensitivity, while ensuring clean optical connections is crucial dust and oils can introduce significant losses and degrade overall system performance.

Overall, DAS repurposes standard single mode, telecommunications grade optical fibre as a continuous, distributed sensing medium using Rayleigh backscatter and coherent detection. Thanks to its high spatial and temporal resolution, long-distance coverage, and ability to operate in harsh environments, DAS is particularly well suited for real world pipeline monitoring. However, its successful deployment hinges on selecting appropriate fibre types, ensuring strong mechanical coupling, and implementing careful handling protocols.

3 INTERROGATOR UNIT AND SINGLE-MODE FIBRE OPTIC DEPLOYMENT

This section examines the pivotal role of the Interrogator Unit within Distributed Acoustic Sensing (DAS) systems, underscores the advantages of deploying single mode fibre, and emphasises the significance of depth calibration methods for dependable pipeline monitoring.

3.1 The Interrogator Unit: Core of DAS Systems

The Interrogator Unit functions as the analytical nucleus of a DAS system. It emits coherent laser pulses into single mode fibre optic cables and analyses the backscattered light using interferometric techniques. Photodetectors convert this backscattered signal into digitised electrical data, revealing phase shifts that correspond to dynamic strain events along the fibre. These shifts are crucial for detecting and locating acoustic disturbances in applications such as pipeline surveillance and seismic monitoring.

3.2 Advantages of integration of Single Mode Fibre and Interrogator Unit

Single mode fibre, with its approximately 9 µm core diameter, is preferred due to its low attenuation and excellent spatial resolution, enabling precise strain measurements over extensive distances. For instance, standard single mode fibre typically exhibits an attenuation of 0.2 dB/km at 1550 nm wavelength. To preserve signal integrity, careful handling is imperative; fibres must be protected from excessive bending, tension, and harsh environmental conditions.

4 IMPORTANCE OF DEPTH CALIBRATION IN PIPELINE MONITORING

Depth calibration is essential for accurate localisation of disturbances along the pipeline. Implementing precise calibration methods ensures that the DAS system can accurately determine the depth at which acoustic events occur, thereby enhancing the reliability of pipeline monitoring.

4.1 Depth Calibration Analysis in Distributed Acoustic Sensing Pipeline Monitoring

Depth calibration is vital to ensure that recorded channel indices accurately correspond to the physical fibre locations along the pipeline, which is essential for precise event localisation and effective operational response. One approach involves aligning DAS channel depths with known reference points tied to geospatial markers such as pipeline valves or calibration markers, as illustrated in Table 1.

At these control points, deliberate acoustic events like hammer strikes or vibroseis sweeps are generated, enabling clear mapping between the recorded data and the fibre's true position. Further refinement is achieved through regression models to correct for nonlinear paths, thermal drift, and uncertainty quantification, consistently attaining ±2 m localisation accuracy.

According to [10], this methodology aligns with established practices in DAS calibration, where depths are matched using reference features or amplitude-based correlations to well logs and geophone data

Table 1: Calibration Mapping

Description: This table presents a mapping of calibration points along the pipeline, detailing the locus index, optical path distance, and the calibration type. The data illustrates the alignment of DAS channel depths with known reference points, facilitating accurate localisation of acoustic events.

Channel Index	Distance from Reference Point (m)	Calibration Coefficient	Signal Delay (ms)	Notes
0	0	1	0	Start of fiber
100	100.5	1.002	0.5	Valve A
200	201.2	1.005	1	Borehole Geophone
300	302	1.007	1.5	Buried Calibration Marker
400	403.1	1.01	2	End of calibration zone

Table 1: Calibration Mapping

In this section, we've explored the critical role of depth calibration in DAS systems for pipeline monitoring. The Interrogator Unit's function in emitting pulses and capturing backscatter to measure strain events along single mode fibre was discussed. The preference for single mode fibre due to its high spatial fidelity and low signal loss was highlighted. Furthermore, the importance of rigorous depth calibration using geospatial markers, controlled signal injection, and modelling corrections was emphasised to ensure DAS readings are accurately mapped to physical pipeline locations. Collectively, these components support effective, high precision DAS for real world pipeline monitoring and security applications.

4.2 Depth Calibration: Channel Spacing and Gauge Length Tuning

This section elucidates how calibrating channel spacing and gauge length directly influences the spatial resolution and signal fidelity of DAS systems, particularly in underground pipeline monitoring. Refer to Table 2 for detailed calibration parameters.

According to [11], both channel spacing the physical distance between consecutive sensing channels and gauge length the length of fibre over which strain is averaged play pivotal roles in DAS performance. Channel spacing governs spatial sampling density: tighter spacing (for example, around 1 metre) enhances detection of localised events but increases data load, while broader spacing reduces processing demand at the expense of detection granularity. Likewise, gauge length involves a trade off between spatial resolution and sensitivity: shorter lengths (for instance, 5–10 metres) improve spatial resolution enabling the system to distinguish closely spaced disturbances whereas longer lengths (for example, 15–20 metres) increase sensitivity to low frequency signals and enhance signal to noise ratio (SNR), albeit at the cost of spatial precision.

To optimise these parameters, the calibration process must consider the anticipated signal characteristics such as the amplitude and frequency of intrusion events the geometry of deployment (skin depth, soil type, pipeline structure), and security coverage goals. In practice, gauge lengths ranging from 5 to 20 metres are often tested. Our study conducted calibration tests using controlled acoustic signals, such as mechanical impacts at known intervals, to evaluate how different configurations affected detection precision and SNR. A configuration with a 10 metre gauge length and 1 metre channel spacing offered a balanced compromise between signal clarity and spatial accuracy. Overlapping gauge windows helped improve detectability without significantly degrading localisation. Calibration accuracy was confirmed by matching DAS detected signal locations against geospatial control points, minimising localisation error while preserving sensitivity to low-amplitude disturbances.

Table 2: DAS Calibration Parameters: Channel Spacing vs. Gauge Length

Description: This table presents a comparative analysis of different channel spacing and gauge length configurations tested during the study. It outlines the impact of each configuration on detection precision, signal to noise ratio, and localisation accuracy, providing a comprehensive overview of the calibration process.

Gauge Length (m)	Channel Spacing (m)	Spatial Resolution	Signal-to-Noise Ratio (SNR)	Detection Accuracy	Data Volume & Processing Load	Recommended Use Cases
5	1	Very High	Moderate	Excellent	High	High-resolution intrusion detection
10	1	High	High	Excellent	High	Balanced monitoring of localized events
15	1	Moderate	Very High	Good	High	Detection of low-frequency disturbances
20	1	Moderate	Very High	Moderate	High	Broad area monitoring with enhanced SNR
10	2	Moderate	High	Good	Moderate	General-purpose monitoring
10	5	Low	High	Fair	Low	Long-range monitoring with reduced detail
10	10	Very Low	High	Poor	Very Low	Basic monitoring where high resolution is not critical

Table 2: Distributed Acoustic Sensing calibration parameters: channel spacing vs. gauge length

In summary, tuning channel spacing and gauge length is critical for optimising DAS system performance in pipeline monitoring. The deliberate balance between fine spatial resolution and robust signal quality ensures that DAS can precisely localise disturbances while maintaining sufficient detection sensitivity thus enhancing the system's effectiveness in identifying threats such as fuel theft or tampering.

5 DIRECTIVITY CALIBRATION IN DISTRIBUTED ACOUSTIC SENSING - BASED PIPELINE MONITORING

This section examines how the intrinsic directional sensitivity of DAS systems affects signal detection and how calibration for directivity can enhance event localisation, particularly in complex pipeline monitoring environments.

5.1 Directional Sensitivity and Its Implications

According to [12], DAS systems measure axial strain or vibration along the optical fibre's length. Consequently, signals aligned with the fibre (axial direction) are detected with higher sensitivity, while transverse or oblique signals may be attenuated or misinterpreted. The DAS response to incident wave orientation follows a cosine-squared dependence on the angle between the signal and the fibre axis, causing sensitivity to diminish sharply as alignment decreases. In pipeline deployments where the fibre may bend or change direction this directional bias can hinder accurate detection and localisation of events such as tampering or leaks.

5.2 Calibration for Directivity

Calibration for directivity aims to first quantify how DAS sensitivity varies with incident signal angle, then to compensate for this bias. This involves controlled acoustic events applied at known orientations relative to the fibre axis such as axial, 45°, or transverse impacts and recording the resulting responses. By analysing amplitude and signal to noise ratio variations across these orientations, one can establish a directional sensitivity profile. These profiles, in turn, guide adjustments to signal processing algorithms, thresholds, and classification models, ensuring more consistent detection across varied geometries, including curved or looped fibre segments an approach supported by signal processing frameworks that compensate for cable directivity.

Table 3: DAS Sensitivity vs. Signal Angle

Description: This table presents a comparative analysis of DAS sensitivity at various incident angles, illustrating how detection strength diminishes as the angle increases from the fibre axis.

Signal Angle Relative to Fibre Axis	Relative Sensitivity	Signal-to-Noise Ratio (SNR)	Localization Accuracy	Typical Use Cases
0° (Axial)	High	High	Excellent	Leak detection, inline vibration monitoring
45° (Oblique)	Moderate	Moderate	Good	Ground movement, nearby construction activity
90° (Transverse)	Low	Low	Fair to Poor	Lateral impacts, surface disturbances

Table 3: Distributed Acoustic Sensing sensitivity vs. signal angle

In this section, we clarified that DAS systems are inherently more sensitive along the fibre axis, potentially compromising detection of signals originating from other angles. By calibrating directivity with controlled multi angle acoustic tests, processing algorithms can be tuned to mitigate this bias, ensuring reliable and accurate detection across the fibre's deployment geometry. This calibration is essential for maintaining consistent event identification in dynamic, real world pipeline monitoring scenarios.

6 SIGNAL TO NOISE RATIO OPTIMISATION IN DISTRIBUTED ACOUSTIC SENSING PIPELINE MONITORING

This section delves into how optimising the Signal to Noise Ratio (SNR) is crucial for effective threat detection within DAS systems applied to underground pipelines.

6.1 Understanding SNR Challenges in Pipeline Monitoring

In pipeline monitoring, distinguishing meaningful acoustic signatures from environmental and electronic interference is vital. Key noise contributors include:

- External Factors: Wind, traffic, seismic microtremors, and hydrological effects.
- Systemic Noise: Detector thermal fluctuations, interrogator jitter, laser phase noise, and electromagnetic interference.

6.2 Strategies for SNR Optimisation

Effective optimisation involves a combination of field based and signal processing strategies:

- Field Assessments: Identify dominant noise sources, guiding countermeasures such as burying fibre at optimal depths or installing shielding near high noise areas.
- Signal Processing Techniques: Employ band-pass filtering (targeting intrusion-relevant frequencies, e.g., 10–200 Hz), adaptive noise reduction using reference channels, and ensemble averaging to boost detection clarity.
- System Tuning: Adjust interrogator and laser system parameters such as power output for stronger backscatter without distortion, matching coherence length to fibre characteristics, and employing backscatter enhancement techniques like phase-sensitive reflectors to maximise SNR.

Recent studies have demonstrated that simple yet effective algorithms, such as moving differential and windowed averaging, achieved SNR improvements of up to 13.1 dB, even when using cost-effective hardware configurations.

6.3 Performance Evaluation

Post-optimisation, average SNR gains ranged between 6–12 dB. Detection thresholds for acoustic events lowered by around 30%, enhancing system sensitivity to low-amplitude disturbances while significantly reducing false positive rates.

Table 4: Sources of Noise in DAS Systems

Description: This table categorises and quantifies various noise sources affecting DAS systems, providing a comprehensive overview of factors influencing SNR.

Category	Noise Source	Description
Environmental Noise	Wind-induced ground motion	Vibrations caused by wind interacting with the ground surface.
	Surface or subsurface vehicular traffic	Vibrations from vehicles moving near or above the pipeline.
	Seismic microtremors	Low-frequency ground vibrations from natural or anthropogenic sources.
	Hydrological or meteorological effects	Vibrations due to rain, flowing water, or other weather-related phenomena.
Electronic/Instrumental Noise	Detector thermal noise	Random fluctuations in the detector due to temperature variations.
	Interrogator system jitter	Timing variations in the interrogator system affecting signal consistency.
	Laser phase noise	Fluctuations in the laser's phase leading to signal instability.
	Electromagnetic interference (EMI)	External electromagnetic fields causing disturbances in the signal.

Table 4: Source of noise in the Distributed Acoustic Sensing system

Table 5: SNR Optimisation Strategies

Description: This table outlines field based and signal processing strategies employed to optimise SNR in DAS systems, detailing their implementation and effectiveness.

Strategy	Implementation	Expected SNR Improvement
Noise Source Identification and Suppression	Conduct site surveys to identify dominant noise sources. - Implement physical mitigation measures like optimized fiber burial depths and shielding near high-noise zones.	Variable, depending on site conditions
Advanced Signal Processing Techniques	Apply band-pass filtering to isolate frequencies typical of intrusion events (e.g., 10–200 Hz). - Utilize adaptive noise cancellation algorithms using real-time reference channels. - Employ ensemble averaging and stacking to enhance weak signals.	6–12 dB
Interrogator and Laser System Tuning	Optimize laser source power to increase backscattered signal intensity without inducing non-linear effects. - Match laser coherence length and stability to fiber characteristics. - Use higher-scattering fibers or apply phase-sensitive reflectors to boost SNR in low-signal regions.	Up to 20 dB

Table 5: 4.4 Signal-to-Noise Ratio optimisation strategies

Table 6: Performance Evaluation Metrics

Description: This table presents metrics assessing the effectiveness of SNR optimisation strategies, including SNR gains and changes in detection thresholds.

Metric	Pre-Optimization	Post-Optimization	Improvement
SNR Gain (dB)	Baseline	+6 to +12 dB	Enhanced signal clarity
Event Detectability Threshold	Higher amplitude required	~30% reduction in required amplitude	Improved sensitivity to low-amplitude disturbances
False Positive Rate	Higher	Significantly reduced	Increased detection accuracy

Table 6: Performance evaluation metrics

Optimising SNR in DAS pipeline monitoring demands a holistic approach that blends environmental mitigation, signal processing, and system tuning. By integrating these methods including filtering, adaptive noise suppression, hardware calibration, and smart algorithms the system's ability to detect and locate subtle threats like fuel theft or tampering significantly improves, ensuring reliable, actionable surveillance in challenging buried environments.

7 EVENT SIGNATURE LIBRARY DEVELOPMENT FOR DISTRIBUTED ACOUSTIC SENSING BASED THREAT DETECTION

This section delves into the development of an Event Signature Library, a critical advancement in enhancing the performance of Distributed Acoustic Sensing (DAS) systems used for pipeline monitoring. This library functions as a comprehensive repository of acoustic patterns corresponding to real world activities, supporting accurate detection and classification along the monitored infrastructure.

7.1 Functionality and Importance

According to [14], by cataloguing and organising signature events such as walking, vehicle motion, digging, tapping and mechanical failures the signature library empowers DAS systems, via machine-learning and pattern recognition algorithms, to enhance accuracy and reduce false alarms. Such precision is vital for timely and targeted responses. A well curated signature library thus strengthens the system's ability to distinguish between routine operational noise and genuine threats, significantly improving both reliability and effectiveness in pipeline surveillance.

7.2 Methodology for Library Construction

The methodology for constructing the Event Signature Library begins with event recording under controlled conditions. Conducting representative actions such as manual digging, repetitive tapping, pedestrian movement, or heavy machinery operation near pipeline segments provides labelled data anchored to precise GPS coordinates and timestamps. Subsequent signal processing extracts both time-domain and frequency-domain features, including:

- Duration
- Peak amplitude
- Temporal envelope
- Spectral content
- Dominant frequencies
- Statistical descriptors like RMS amplitude, kurtosis, and entropy

These features form a structured dataset that can be leveraged by rule-based approaches or learned directly through machine learning models.

7.3 Classification Models and Technique

Supervised classification models, including Support Vector Machines, Random Forests, and Convolutional Neural Networks, are trained on this labelled data to distinguish event types. Additionally, unsupervised clustering techniques, such as K-means or DBSCAN, can be deployed on unlabelled DAS data to discover natural groupings and identify anomalies.

To maintain classification accuracy over time and across varying environmental conditions, periodic ground truth calibration and validation are essential. This involves incorporating known events either manually generated or independently confirmed ensuring that classifiers remain resilient against drift due to seasonal changes or operational shifts.

7.4 Empirical Observations

Empirical observations from the library development stage are insightful:

- Digging: Produces broadband, high-amplitude signals with irregular temporal patterns.
- Walking: Yields low frequency, rhythmic patterns with moderate signal to noise ratio.
- Tapping: Creates impulsive, narrow band signatures that stand out clearly from ambient noise.
- Vehicle Motion: Signals tend to exhibit strong low frequency content and may include Doppler shifts, with variations influenced by distance, speed, and terrain.

Supervised models trained on this library have achieved classification accuracies exceeding 90% for common activity types. Furthermore, recalibrating with ground truth events has improved model stability and long-term reliability.

Table 7: Event Signature Characteristics

Description: This table presents a comparative analysis of various event types, detailing their acoustic characteristics such as frequency range, amplitude, and temporal patterns. It serves as a reference for understanding the distinctive features of each event type within the DAS system.

Event Type	Time-Domain Features	Frequency-Domain Features	Statistical Descriptors	Classification Accuracy
Manual Digging	Irregular temporal profiles with high amplitude	Broadband spectrum	High RMS amplitude, elevated kurtosis	>90%
Walking/Running	Periodic patterns with consistent spacing	Low-frequency components	Moderate RMS amplitude, low entropy	>90%
Tapping	Short-duration impulses	Narrow-band frequencies	High peak amplitude, low kurtosis	>90%
Vehicle Movement	Variable amplitude and frequency depending on speed and terrain	Strong low-frequency content with Doppler shifts	High RMS amplitude, variable entropy	>90%

Table 7: Event signature characteristics

Table 8: Machine Learning Classifier Performance

Description: This table summarises the performance metrics of different machine learning classifiers applied to the DAS dataset. It includes accuracy, precision, recall, and F1-score for each classifier, providing insights into their effectiveness in event classification tasks.

Classifier	Accuracy	Precision	Recall	F1-Score	AUC
k-Nearest Neighbors (k=1)	99.96%	99.91%	99.98%	0.99	0.99
Decision Tree	99.53%	99.38%	99.32%	0.99	0.99
Random Forest	99.95%	100%	99.86%	0.99	0.99
Multi-Layer Perceptron (MLP)	99.88%	99.87%	99.80%	0.99	0.99
Support Vector Machine (SVM)	99.79%	99.91%	99.52%	0.99	0.99

Table 8: Machine Leaning Classifier Performance

The Event Signature Library serves as the foundation for optimised DAS-based pipeline surveillance. By systematically capturing, characterising, and classifying acoustic signatures, the library empowers automated detection systems to operate adaptively and accurately in dynamic environments. This structured approach not only enhances threat detection precision but also reinforces the overall efficiency and dependability of pipeline monitoring systems.

8 TEMPERATURE AND ENVIRONMENTAL COMPENSATION IN DISTRIBUTED ACOUSTIC SENSING SYSTEMS

According to [13], this section examines how temperature fluctuations and environmental factors can substantially affect the accuracy of Distributed Acoustic Sensing (DAS) systems employed in pipeline monitoring. Temperature variations may induce fibre expansion, changes in refractive index, and phase shifts in backscattered signals, potentially causing false positives. Environmental factors such as soil moisture, wind and rainfall introduce additional noise and influence signal coupling. To mitigate these challenges, DAS systems employ several techniques: real time temperature monitoring through distributed sensing corrects thermal artefacts; baseline signal modelling differentiates normal fluctuations from genuine events; adaptive filtering dynamically compensates for phase drift; and periodic recalibration ensures consistent system response. Moreover, environmentally hardened installations such as deeper burial or the use of thermally stable substrates reduce exposure to variable conditions. Collectively, these strategies ensure that DAS systems maintain reliability and accuracy in dynamic field environments, enhancing their effectiveness in detecting genuine threats to pipeline infrastructure.

8.1 Performance Outcomes

The application of temperature and environmental compensation has led to significant improvements in DAS system performance. False positive event detections were reduced by over 40%, particularly during high thermal variability periods such as sunrise and sunset transitions. Signal drift caused by seasonal temperature shifts was normalised to less than 1% phase deviation, preserving accurate localisation over time. Enhanced fibre ground coupling

in stable environmental zones significantly improved event clarity and reduced misclassification due to noise.

Table 9: Environmental Influences on Distributed Acoustic Sensing Signal Integrity

Description: This table outlines various environmental factors such as temperature fluctuations, soil moisture, wind, and rainfall and their respective impacts on DAS signal integrity. It serves as a reference for understanding the challenges posed by environmental conditions on DAS performance.

Actor	Impact on DAS Signals	Mitigation Strategies
Ambient/Subsurface Temperature Variations	Thermal expansion/contraction alters fiber length and refractive index, leading to phase shifts misinterpreted as acoustic events.	Implement real-time temperature tracking using Distributed Temperature Sensing (DTS) to correct for temperature-induced artifacts.
Diurnal and Seasonal Temperature Cycles	Introduce slow-varying strain noise, especially in surface-laid or shallow-buried fibers.	Employ baseline signal modeling to distinguish between genuine events and temperature-induced fluctuations.
Soil Moisture and Groundwater Level Changes	Affect coupling between the fiber and surrounding medium, impacting acoustic signal transmission.	Optimize fiber burial depth and routing to maintain consistent coupling conditions.
Rainfall, Frost Heave, and Wind-Driven Vegetation Movement	Introduce non-acoustic noise, degrading Signal-to-Noise Ratio (SNR) and event localization accuracy.	Utilize adaptive filtering and calibration techniques to dynamically compensate for environmental noise.

Table 9: Environmental influences on the Distributed Acoustic Sensing signal integrity

Table 10: Compensation Techniques and Performance Outcomes

Description: This table summarises the compensation techniques employed to mitigate environmental influences on DAS systems, including real time temperature tracking, baseline signal modelling, adaptive filtering, and periodic recalibration. It also presents the performance outcomes achieved through the implementation of these techniques, highlighting improvements in false positive reduction and signal accuracy.

Technique	Description	Performance Outcome
Real-Time Temperature Tracking	Utilize DTS to measure temperature along the fiber, allowing subtraction of temperature-induced strain artifacts from acoustic signals.	Reduced false positive detections by over 40%, particularly during periods of high thermal variability.
Baseline Signal Modeling	Establish background noise profiles under varying environmental conditions to characterize "normal" fluctuations.	Improved accuracy in distinguishing genuine events from environmental noise.
Adaptive Filtering and Calibration	Apply adaptive signal processing algorithms to dynamically compensate for temperature-related phase drifts. Periodic re-calibration using known test signals.	Normalized signal drift caused by seasonal temperature shifts to less than 1% phase deviation, preserving accurate localization over time.
Environmental Hardening of Installation	Optimize fiber burial depth and routing to reduce exposure to surface temperature swings and environmental noise. Install fibers in thermally stable substrates or encase them to shield against hydrological variation.	Enhanced fiber-ground coupling in stable environmental zones significantly improved event clarity and reduced misclassification due to noise.

Table 10: Compensation techniques and performance outcomes

Environmental and thermal variations present persistent challenges in long-term DAS deployments. Implementing compensation techniques such as temperature sensing, adaptive filtering, and baseline calibration effectively mitigates these influences. Incorporating these mechanisms enhances DAS data robustness, reliability, and interpretability, ensuring accurate pipeline monitoring across diverse environmental conditions.

9 VALIDATION WITH GROUND TRUTH EVENTS IN DISTRIBUTED ACOUSTIC SENSING PIPELINE MONITORING

According to [15], this section underscores the critical importance of validating Distributed Acoustic Sensing (DAS) systems using ground truth events to ensure the accuracy and reliability of pipeline monitoring. Ground-truth events real world activities with well defined characteristics serve as benchmarks that aid in calibrating detection thresholds, enhancing localisation accuracy, and reducing false alarms, thereby strengthening pipeline safety surveillance.

9.1 Validation Methodology

The validation process commences with controlled simulations of representative events along the pipeline corridor, such as manual digging, foot traffic (walking and running), mechanical tapping on the pipeline surface, and the operation of heavy equipment like backhoes or compactors. Each event is recorded with precise geospatial coordinates, timestamps, and environmental context, including local temperature and soil type, to build a robust dataset for system tuning.

During these simulations, the DAS system continuously captures acoustic signals generated by the events. These recordings are then analysed in terms of signal amplitude, frequency content, temporal signatures, localisation accuracy relative to known positions, and signal to noise ratio. This analysis permits fine-tuning of system parameters: detection thresholds are adjusted to better discriminate genuine threats from background noise; system sensitivity is modified to accommodate different soil conditions and burial depths; and alarm criteria are refined to ensure the system remains both responsive and reliable.

9.2 Validation Outcomes

The validation results demonstrate the effectiveness of this approach. The DAS system successfully detected more than 95% of simulated events when configured with validated threshold settings, and localisation errors were typically reduced to within ±3 metres after calibration. Walking and tapping events yielded highly repeatable signal patterns, which were then incorporated into the event signature library to enhance future pattern recognition. Moreover, careful threshold tuning effectively minimised false alarms caused by benign environmental sources like animal movement or wind-induced vibrations.

Table 11: Summary of Ground-Truth Validation in Distributed Acoustic Sensing Pipeline Monitoring

Description: This table encapsulates the validation process, performance metrics, and observed results, providing a clear overview of the system's efficacy. It includes columns detailing the type of ground-truth event, the detection rate achieved, localisation accuracy, and the reduction in false alarms post-validation.

Validation Component	Details
Simulated Events	Manual digging (shovels, picks) - Foot traffic (walking, running) - Mechanical tapping on pipeline - Heavy equipment movement (e.g., backhoes, compactors)
Data Logging Parameters	Geospatial coordinates - Timestamps - Environmental conditions (e.g., temperature, soil type)
Signal Analysis Metrics	Signal amplitude - Frequency content - Time-domain signatures - Signal-to-noise ratio (SNR)
Parameter Tuning	Detection thresholds - Sensitivity levels - Alarm criteria
Detection Accuracy	Over 95% of simulated events detected post-calibration
Localization Accuracy	Localization errors reduced to within ±3 meters after alignment with ground truth
Repeatability	Events like walking and tapping produced consistent signatures, enhancing pattern recognition
False Alarm Reduction	Significant decrease in false alarms from benign sources (e.g., animal movement, wind) due to threshold tuning

Table 11: Summary of ground truth validation in Distributed Acoustic Sensing pipeline monitoring

10 CONCLUSION

In conclusion, validating DAS systems with ground truth events is an indispensable step in optimising pipeline monitoring solutions. Through systematic calibration using realistically simulated conditions and iterative tuning of detection parameters, the system achieves high detection rates, refined localisation, and improved resilience against false alarms, culminating in a more accurate and trustworthy monitoring solution.

11 KEY INSIGHTS

This study underscores the transformative potential of Distributed Acoustic Sensing (DAS) in pipeline monitoring, particularly in the context of fuel theft prevention. Key findings include:

- **Enhanced Threat Detection:** DAS systems demonstrated a high detection rate for various threats, including unauthorised digging and vehicular activity, with localisation accuracy within ±3 metres.
- **Signal Optimisation:** Strategies such as Signal-to-Noise Ratio (SNR) optimisation and temperature/environmental compensation significantly improved system sensitivity and reduced false positives.
- **Event Signature Library Development:** The creation of a comprehensive event signature library enabled precise classification of activities, enhancing the system's ability to distinguish between genuine threats and benign events.

12 RECOMMENDATIONS

Based on the study's findings, the following recommendations are proposed to enhance the efficacy of DAS systems in pipeline monitoring:

- **Integration with Complementary Technologies:** Combine DAS with other monitoring technologies, such as Distributed Temperature Sensing (DTS) and Distributed Strain Sensing (DSS), to provide a multi-faceted approach to pipeline surveillance.
- **Continuous Calibration and Maintenance:** Implement regular calibration procedures and maintenance schedules to ensure the sustained accuracy and reliability of DAS systems over time.
- **Stakeholder Training and Awareness:** Conduct training programmes for personnel to effectively interpret DAS data and respond promptly to detected anomalies.

13 LIMITATIONS

While the study provides valuable insights into the application of DAS in pipeline monitoring, several limitations should be acknowledged:

- **Environmental Variability:** Factors such as soil composition, moisture levels, and ambient temperature can affect the propagation of acoustic signals, potentially influencing detection accuracy.
- **Infrastructure Constraints:** The installation of DAS systems may be challenging in areas with limited access or where existing infrastructure is incompatible with fibre optic cables.
- **Data Interpretation Complexity:** The vast amount of data generated by DAS systems requires sophisticated data processing and analysis tools, which may necessitate specialised expertise.

In conclusion, validating DAS systems with ground-truth events is an indispensable step in optimising pipeline monitoring solutions. Through systematic calibration using realistically simulated conditions and iterative tuning of detection parameters, the system achieves high detection rates, refined localisation, and improved resilience against false alarms, culminating in a more accurate and trustworthy monitoring solution.

ABSTRACT

With its ability to produce water at the point of need and reduced resource waste, atmospheric water harvesting (AWH) is an attractive alternative source for bottled water. This study aims to understand what the main factors affecting the successful implementation of an AWH bottling concept are and to model these factors in a heuristics-based decision support tool. Using Porter's value chain and five forces, the common activities experienced by bottled water retailers are investigated, and the most important factors affecting these activities are identified. The common themes are heuristically modelled with readily accessible data. A case study application is conducted using an example from the tropical hotel industry to evaluate the tool's usefulness. By using this decision support tool, enterprises can rapidly appraise the feasibility of an AWH bottling concept, facilitating comparison and accelerating the refinement of AWH bottling concepts

Keywords: atmospheric water harvesting, decision support tool, feasibility, modelling

1 INTRODUCTION

Described by Leonardo Da Vinci as "*the driving force of all nature*" [1], water is one of the foundational elements for life. Freshwater is essential for any sustainable civilisation, enabling not only basic needs such as drinking and hygiene but also supporting commerce, travel, and agriculture throughout history [2]. Ensuring long-term water security remains a global priority, with institutions such as the United Nations and the World Bank advocating for sustained investment to secure reliable access to freshwater for future generations [3-4].

A prominent feature of the global drinking water market is bottled water, an industry projected to grow by 10% annually until 2026 [5]. The industry has been described as a great mystery of capitalism, with Queiroz [6] noting the curious practice of "*packaging and selling something already available to us for free*". Regardless of its perceived rationality, bottled water remains a dominant mode of consumption, with global sales reaching $270 billion in 2023 [7].

However, the bottled water industry faces sustained criticism for its environmental impact and questionable resource use. Hall [8] reports that bottled water producers may consume over three litres of water to produce a single litre of bottled product. The sector is further criticised for its reliance on single-use plastics, which contribute significantly to environmental pollution and waste accumulation [5]. Furthermore, concerns persist regarding water quality and sourcing, as approximately 60% of bottled water is derived from purified tap water, which may contain the same contaminants found in municipal supplies [5], [9].

In light of these challenges, atmospheric water harvesting (AWH) has emerged as a potential alternative capable of addressing several pressing issues in bottled water production [10]. AWH refers to the extraction of freshwater from atmospheric moisture using technologies such as fog harvesting, desiccant-based harvesting, and condensation-based harvesting [11]. By enabling decentralised water production at the point of consumption [12], AWH can reduce the logistical and resource demands associated with distribution. Furthermore, when integrated with renewable energy systems, AWH offers a closed-loop production cycle with minimal environmental impact [13].

A similar closed-loop approach is possible within the bottling supply chain, particularly in the hotel, restaurant, and café (HoReCa) sector [14]. By producing water on-site using AWH, HoReCa businesses can refill bottles directly, reducing the need for single-use packaging and the associated waste. The quality of atmospherically harvested water is generally high; even in regions with elevated air pollution, it can meet the standards of the United States Environmental Protection Agency and the European Union [15].

Despite these advantages, the application of AWH in bottled water production remains largely theoretical due to unresolved feasibility constraints [16]. AWH system yield, operating efficiency, and energy consumption are highly dependent on local atmospheric conditions, with warm and humid climates offering the most favourable results [17]. Moreover, the relative novelty of the technology contributes to high installation and operational costs, which negatively affect the levelized cost of water (LCOW), or the lifetime cost of producing water divided by the total volume produced [18]. These factors make it difficult to accurately quantify project feasibility, leading to uncertainty and delays in decision-making, and increasing the risk of implementation failure [15].

This study addresses a central problem: while AWH offers substantial potential for decentralised, sustainable bottled water production, its adoption is hindered by poorly quantified feasibility parameters. These uncertainties limit the effectiveness of decision-making and deter investment in AWH bottling ventures. To respond to this challenge, the research aims to develop a heuristics-based decision support tool (DST) to aid early-stage

feasibility assessment of AWH bottling projects. The DST is intended to provide a structured and rapid evaluation framework that relies on readily available data, enabling informed decisions under conditions of uncertainty.

The research is guided by the following objectives:

1. Identify and evaluate the key factors influencing the feasibility of implementing an AWH bottling concept.
2. Develop a method to heuristically model these factors using accessible data sources.
3. Design and test the DST through mathematical modelling and a structured walkthrough.

The upcoming section presents a literature review that first contextualises the use of AWH in the bottled water industry, then examines existing feasibility-focused DSTs, and finally considers tools developed specifically to assess AWH concepts. Insights from this review inform the adoption of the DMADV methodology [19] to guide the development of a heuristics-based DST. This tool is designed around three core feasibility dimensions that define the essential scope for assessing an AWH bottling concept. The paper then demonstrates the tool's practical application through a case study in the tropical hotel industry.

2 LITERATURE REVIEW

2.1 Atmospheric Water Harvesting Applied to Water Bottling

AWH applied to water bottling concepts is a relatively novel concept with the only active competitors in the space being Aqua Sky and Air Water, both operating out of South Africa [29-30], and Beyond Water based out of Dubai [22]. Beyond Water and Air Water both offer bottling as a supplementary service within their broader value proposition, whereas Aqua Sky focuses on the installation of turnkey AWH bottling plants and the production of bottled water under its own brand.

All three companies utilise condensation-based AWH machines to produce potable water [29-31] as opposed to fog harvesting or desiccant based AWH machines. The condensation-based AWH machines operate by directing moist air into the evaporator unit of a vapour compression refrigeration (VCR) system, where a circulating liquid refrigerant reduces the air's temperature below dew point. This induces condensation, which is subsequently collected, filtered, and stored for later use [23]. VCR-based AWH is an active process that requires external energy to power the compressor in the VCR system [24].

Energy is therefore a critical factor in the AWH process, and numerous barriers to broader implementation are linked to energy constraints [25]. Particularly with regard to the reliable availability of energy [26] as well as the relationship between an AWH system's energy efficiency and LCOW [27]. Gayoso *et al*. [18] conducted a techno-economic analysis of AWH systems across different climates and energy sources, finding that significant cost savings can be achieved when efficient AWH systems are paired with solar energy. The analysis further indicated that tropical climates yield the lowest LCOW.

From this, it can be deduced that climate plays a central role in determining AWH feasibility, as the volume of extractable water depends on both atmospheric moisture content and the ease of condensation. Bagheri [17] demonstrates that AWH yield increases with higher atmospheric water content and elevated dew point temperatures. Atmospheric water content is primarily a function of the relative humidity (RH) at the deployment site, while the dew point temperature is largely determined by ambient air temperature [28]. Elevation also influences atmospheric moisture availability, with Lou *et al*. [29] reporting that water vapour content increases between elevations of 600 m and 1200 m, decreases gradually between 1200

m and 1700 m, and declines sharply above 1700 m. These findings indicate that geographic and climatic conditions impose feasibility constraints on AWH deployment.

2.2 Decision Support Tools

Wong-Parodi *et al*. [30] define decision support tools (DSTs) as "computer-based tools developed to assist sound decision-making." As this research focuses on developing a DST for AWH bottling concepts, it requires knowledge of existing tools to inform design decisions. DSTs differ in both complexity and the volume of data they require [31] and as Adrienne *et al*. [32] notes; decision-makers often prefer straightforward and accessible tools. Such tools may however not be sufficient for complex problems with multiple interdependent factors influencing project success [30].

An example of a more complex DST is the Multi-Criteria Decision Analysis tool developed by Lozano *et al*. [33], which integrates geographic information systems and soft computing to evaluate optimal locations for renewable energy plants. Tools such as these provide insight into the use of climate data for decision making. Another example is the "OPTIMUS" package of DSTs, created by Doukas *et al*. [34] to assist in making cities more energy-efficient. Kumar [35] highlights that decision-makers can use feasibility studies as DSTs to evaluate technical, financial, operational, legal, and scheduling factors when assessing projects involving cutting-edge technologies.These cutting-edge technologies can also be utilised as a DST for other innovative technologies, exemplified by Liu [36] proposing the use of artificial intelligence (AI) driven DSTs to evaluate multiple project scenarios.

2.3 Atmospheric Water Harvesting Specific Tools

By understanding the general purpose of DSTs, specific tools for AWH can be investigated. Due to the large variety of AWH methods, numerous tools have been developed for different systems. For example, Zhang *et al*. [37] developed a machine-learning-based tool to predict the water-absorbing properties of various desiccant materials, while Gandhidasan *et al*. [38] employed physically based impaction and aerodynamic models to predict the yield of fog-harvesting nets in Saudi Arabia. However, as previously established, all AWH bottled water companies currently utilise VCR technology to produce potable water; therefore, only tools developed specifically for VCR-based AWH are considered relevant for this study.

Given the close relationship between VCR AWH systems and the heating, ventilation, and air conditioning (HVAC) industry, many underlying principles are shared between the two fields. This overlap has led Cattani *et al*. [24] to develop the Advanced Global Evaluation Index (AGEI), designed to assess hybrid configurations between HVAC and AWH systems.

Focusing more directly on VCR AWH-specific tools, Gido *et al*. [28] introduced the moisture humidity index (MHI), a metric ranging from 0 to 1 that evaluates the climatic suitability for AWH deployment. Complementing this, Gayoso *et al*. [39] in their techno-economic study of VCR AWH, employed several tools to assess both the technical and economic viability of different AWH concepts. Among these, a notable method involves deriving a concept's water harvesting rate using thermodynamic equations and hourly climate data.

3 RESEARCH DESIGN

The literature review establishes that while AWH offers promising opportunities for decentralised bottled water production, its adoption is constrained by climatic dependencies, energy requirements, and cost-related feasibility challenges. Existing DSTs from other sectors demonstrate potential adaptability for assessing such projects, yet few tools address the specific characteristics of condensation-based AWH systems used in the bottled water industry. This gap highlights the need for a structured, rapid-assessment tool that can evaluate feasibility using readily available data. Given the presence of unknown variables and the innovative nature of the proposed tool, the DMADV (Define, Measure, Analyse, Design, Verify)

methodology is employed for the development of the DST [19]. Figure 1 illustrates the different methods utilised in the respective phases of this research.

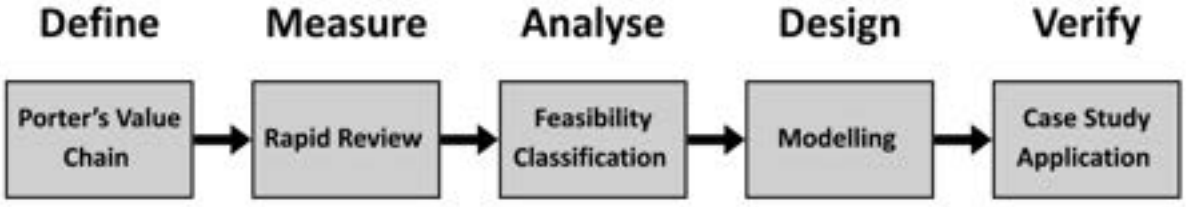

Figure 1: Research Design adapted from Mangaroo-Pillay *et al*. [40]

3.1 Define – Porter's value chain

Porter's value chain framework [41] is used to identify activities that generate value from the perspective of a bottled water retailer. Within this set, activities directly affected by the installation of an AWH bottling plant are isolated for further examination. These targeted activities form the basis for the subsequent rapid review of the literature.

3.2 Measure – Rapid Review

A rapid literature review [42] is conducted to develop a focused understanding of the selected value chain activities. The review examines these activities through the lens of Porter's Five Forces (P5F) framework [43], aligning each activity with its most relevant competitive force(s). These forces include the bargaining power of buyers and sellers, the threat of new entrants, the threat of substitutes and the intensity of industry rivalry.

3.3 Analyse – Feasibility Classification

Insights from the value chain and P5F analyses are synthesised to identify key feasibility factors that influence the viability of an AWH bottling concept within its competitive environment. Each factor is categorised into a specific feasibility dimension.

3.4 Design – Factor Modelling

Each feasibility dimension is mathematically modelled to produce a measurable score. Existing tools and methods are adapted to ensure compatibility with the DST's intended reliance on readily available, low-complexity data. The tool is implemented in quantitative modelling software to support usability and provide clear visual outputs.

3.5 Verify – Case Study Application

To validate the tool's practical applicability, it is tested using a case study from the HoReCa sector. This application demonstrates the DST's step-by-step use in real-world decision-making, including the visualisation of results and the potential for collaborative recalibration of the model.

4 APPLICATION OF DMADV

4.1 Define – Porter's Value Chain

Figure 2 illustrates the bottled water industry value chain from the perspective of a direct-to-consumer retailer, with activities selected for further analysis highlighted in green. For this study, the specific operational context of individual retailers is considered beyond the study scope to keep the tool broadly applicable. Therefore, primary activities such as *Marketing* and *Sales*, *Outbound Logistics*, and *Service*, along with secondary activities like *Firm Infrastructure* and *Human Resource Management*, are excluded from detailed examination. Concentrating on the shared value chain activities among bottled water retailers allows for a more focused analysis of key determinants of competitive advantage.

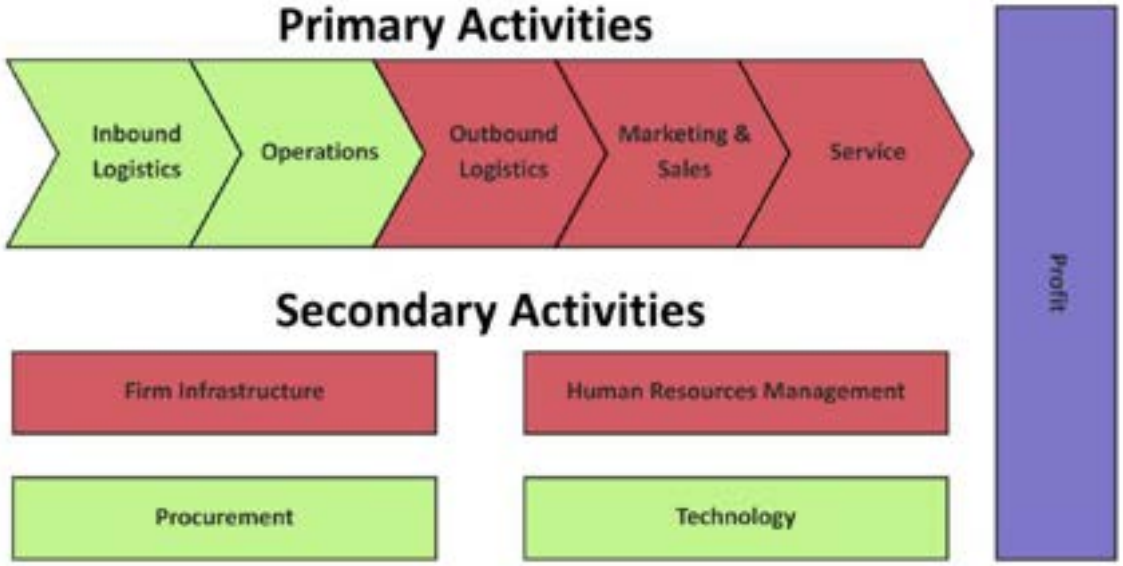

Figure 2: Porter's value chain activities included in analysis adapted from Abbasi [44]

Since bottled water retailers must source products to serve end consumers [45], *Inbound Logistics* and *Procurement* are included as primary and secondary activities in this analysis. Additionally, given the DST's purpose of evaluating an AWH technology's competitiveness, both the secondary activity of *Technology* and the primary activity of *Operations* are also deemed critical. Finally, *Profitability*, serving as a direct indicator of competitiveness within organisations [46], constitutes a vital component for evaluation by the tool.

4.2 Measure – Rapid Review of Porter's Value Chain and Five Forces applied to Bottled water Retailers

The *Inbound Logistics* process plays an important role in shaping the LCOW, and by extension the profitability of bottled water retailers, a measurement closely linked with P5Fs framework [47]. The bargaining power of suppliers is particularly evident when considering the cost implications of sourcing and transporting water from distant locations. Carlucci *et al*. [48], using a hedonic pricing model, demonstrated that bottled water prices increase significantly with the distance between the source and point of sale, highlighting the cost pressures suppliers can exert.

Additionally, upstream decisions related to packaging, such as opting for glass over plastic bottles, or premium cap designs [48] influence buyer perceptions and price sensitivity. Higher perceived quality can justify premium pricing, offering differentiation in a crowded market [49]. Therefore, optimising inbound logistics not only reduces cost but also strengthens a retailer's position against competitors, mitigating external pressures from both suppliers and substitutes.

Procurement is another pivotal activity within the bottled water supply chain that intersects with multiple dimensions of the P5F framework. Beaumais and Crastes Dit Sourd [49] note that adopting environmentally sustainable procurement practices may become a strategic necessity in response to rising consumer and regulatory pressures, which influence both the threat of substitutes and competitive rivalry.

Moreover, Niccolucci *et al*. [50] raise sustainability concerns of existing procurement practises, reporting that approximately 1.93 litres of water are required to produce just 1.5 litres of bottled water when accounting for water usage in supporting activities and materials. These inefficiencies intensify the bargaining power of suppliers in water-scarce regions,

placing further stress on already constrained resources. Furthermore, as Fhelboom and Brika [9] observe, lack of transparency regarding water sources can erode consumer trust and brand differentiation, amplifying competitive rivalry and making companies more vulnerable to substitution by brands with clearer sourcing practises.

Technology and its influence on an organisation's *Operations* constitute another area of interest. Parag *et al*. [5] identify technological innovation as a promising avenue for enhancing the sustainability of the bottled water industry, advocating targeted investments to scale existing innovative approaches. Beyond sustainability, advanced technologies can act as significant barriers to entry by requiring substantial capital investment and specialised expertise, thereby reducing the threat of new entrants. Enhanced technological capabilities can also mitigate the threat of substitutes by improving both the quality and environmental sustainability of bottled water products.

Leveraging the transformative potential of emerging technologies enables organisations to generate unique value propositions, streamline operations, and create new revenue streams [51]. These advancements not only help firms defend against substitutes by enhancing product differentiation and sustainability but also reduce the bargaining power of buyers by limiting the availability of comparable alternatives in the market.

4.3 Analyse – Feasibility Classification

Mapping the selected value chain activities to the P5F framework allows the identification of key factors influencing the feasibility of an AWH bottling concept. These include: (1) the viability of atmospheric conditions, which relates to the threat of new entrants, as optimal locations create natural barriers to entry; (2) the ability to satisfy demand, which influences the bargaining power of buyers and the threat of substitutes by fostering customer loyalty and; (3) cost competitiveness, which affects the bargaining power of suppliers and rivalry among existing firms by reducing dependency on shared supply chains and improving operational efficiency. Figure 3 illustrates the relationship between these value chain activities and feasibility factors.

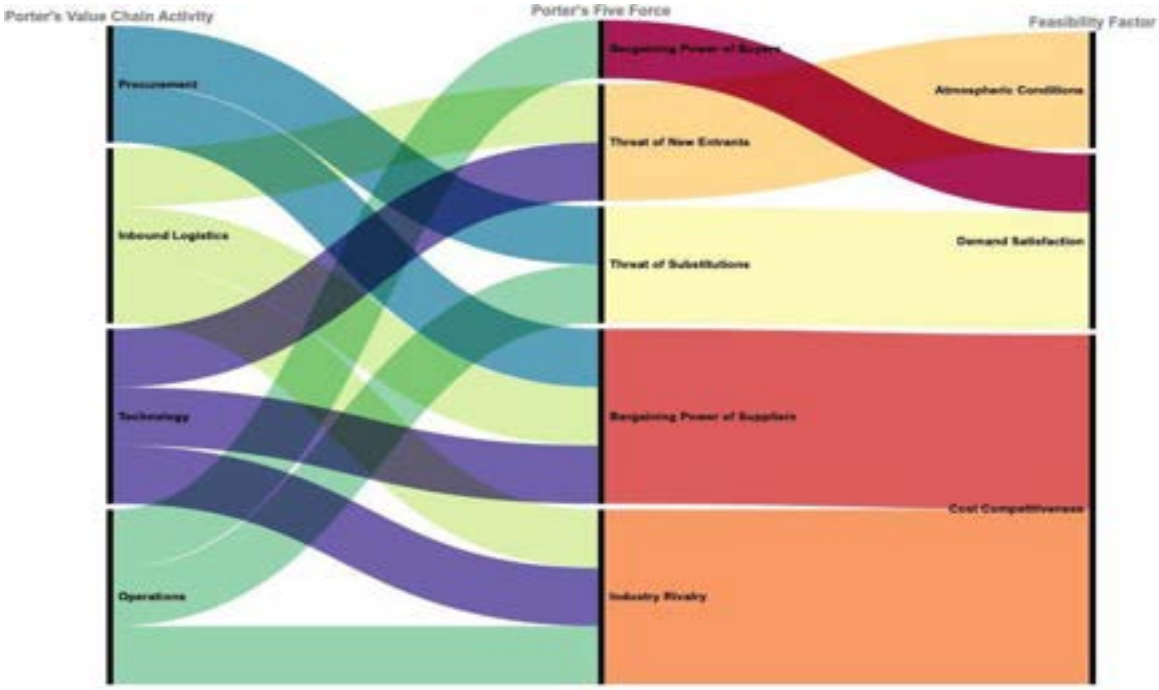

Figure 3: Relationships between Porter's Value Chain, Porter's Five Forces and Feasibility Factors

Cost competitiveness is included as it captures both the total cost of the AWH concept and its position relative to industry benchmarks, supporting market positioning and value proposition assessment [52]. It can be evaluated through methods such as cost breakdown analysis [53], value chain analysis [44], or through unit cost comparison [54]. This study compares the LCOW of the AWH concept to that of a conventional bottled water supply chain. The LCOW of a competitor is estimated while a cost breakdown analysis informs the AWH model, enabling a flexible and direct economic comparison between the two systems.

Demand satisfaction assesses the capacity of the proposed AWH bottling concept to generate sufficient fresh water to meet existing consumer needs. Meeting demand is a critical determinant of feasibility, as unmet customer needs can quickly result in loss of market share to competitors [55], justifying its inclusion as a feasibility parameter. Demand is assessed by estimating the expected water yield based on the supply capacity of the AWH system and its projected performance under the specified atmospheric conditions. This yield is then compared to existing or forecasted demand to evaluate adequacy.

The performance of an AWH system is predominantly influenced by the atmospheric conditions in which it operates, with ambient temperature and RH being key determinants [17]. Several studies have developed models to predict system yield based on these environmental parameters [33-36]. By modelling the production capacity under specific atmospheric conditions, it becomes possible to estimate the available water supply, thereby enabling the calculation of both demand satisfaction and the LCOW.

4.4 Design – Heuristic Decision Support Tool Modelling

4.4.1 Atmospheric Score Modelling

To model the atmospheric score the *MHI*, presented by Gido *et al*. [28] will be used to score the atmospheric conditions. This method is chosen due to the limited number of input variables required to form the score, aligning with the overarching goal of keeping the model dependent on readily available data, as well as its specific focus on VCR-based machines.

The *MHI* method operates as a measure of the thermodynamic efficiency of AWH via direct air cooling. In this process, ambient air is cooled below its dew point, leading to condensation. The total heat exchange (q_{tot}) includes both sensible heat, arising from temperature changes, and latent heat from vapour compression, all expressed in a per kilogram of dry air basis. Since AWH seeks to maximise heat transfer (i.e. water yield) while minimising sensible heat loss, it makes the latent to total heat ratio a relevant performance metric.

To generalise this efficiency across different conditions, the authors first assume steady-state operations. They then shift from a per-dry-air basis to a per-kilogram-of-water-produced basis, adapting q_{tot} to the total heat removed per kilogram of water condensed (q^*_{tot}). The *MHI* is then defined as the ratio of latent heat of condensation (h_{fg}) to the total heat removed, shown in Equation 1.

$$MHI = \frac{h_{fg}}{q^*_{tot}} = h_{fg}\left(\frac{h_i - h_o}{r_i - r_o}\right) \quad \textbf{(1)}$$

A constant h_{fg} value at 4°C (2492 kJ/kg) is used for simplicity, and q^*_{tot} is expanded to depend on the mixing ratio (r) and the enthalpy of moist air (h) at the inlet and outlet of the AWH machine. Thus, the *MHI* depends primarily on the ambient inlet temperature and *RH,* as well as the system's chosen condensation temperature. For simplicity the outlet mixing ratio is set to 4 grams of water per kilogram air and the outlet temperature is set to 4°C. A high *MHI* corresponds to warm, humid climates where less sensible heat is required, improving water production efficiency. Conversely, low *MHI* values reflect cooler conditions with poor harvesting potential. The authors elaborate that an *MHI* less than 0.3 is representative of unfavourable conditions for AWH, both economically and operationally.

4.4.2 Demand Satisfaction Score Modelling

To determine if supply meets demand, both must beknown or calculated as accurately as possible. This tool assumes the user already knows the water demand (in litres) over a specific period. The supply is modelled using a method adapted from Gayoso *et al*. [18] in their techno-economic analysis of AWH systems across different climates. This model is built to focus on the atmospheric conditions at the coldest month of a year in a chosen location to see if demand can be met under the worst-case scenario.

The original method requires hourly data points for *RH* and dry-bulb temperature, however the input parameters were adapted to only consist of easily accessible data points. These include the maximum daily temperature, (T_{max}) and minimum daily temperature (T_{min}), used to model the hourly temperature distribution by way of the American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE) hourly factor method [59]. This informed the modelling of the hourly *RH* distribution, where the highest *RH* value of a chosen day is taken to determine the vapour pressure. The vapour pressure can be assumed constant for a clear day [60] and the hourly *RH* distribution can thus be calculated.

The hourly temperature and RH distributions can be used to obtain the hourly dew point temperature (T_{DP}) and the machines are assumed to operate whenever the T_{DP} is larger than 0 °C. This informs the calculation of the hourly saturated water pressure (e_{sat}) through the Clausius–Clapeyron equation [61]. By rearranging the ideal gas law to solve for the hourly vapour density (ρ_{vap}), the ideal volume of water passing through the AWH machine, (V_{ideal}) can be calculated using Equation 2. V_{ideal} is also dependent on the air flow rate, (Q_{air}) and yields the mass flux of water vapour over time. This is converted to volume flow using the density of water as 1 kilogram per litre.

$$V_{ideal} = \rho_{vap} \times Q_{air} \quad \textbf{(2)}$$

The actual quantity of liquid water produced per hour is dependent on the recovery efficiency, (η) to account for system limitations [62] and V_{ideal}, shown in Equation 3. Gayoso *et al*. [18] uses a 30% recovery efficiency for climate conditions close to the benchmark climate scenario of the Association of Home Appliance Manufacturers (26.7°C/60% *RH*) and a 12% recovery efficiency for more arid climate scenarios (26.7°C/20% *RH*).

$$hourly\ water\ production = V_{ideal} \times \eta \quad \textbf{(3)}$$

Calculating the sum of water produced every hour over a given day is then compared with the daily expected demand and a demand score can be calculated using Equation 4. A demand score higher than 1 indicates the system has surplus capacity to fulfil the expected demand.

$$Demand\ Score = \frac{Daily\ Water\ Production}{Expected\ daily\ demand} \quad \textbf{(4)}$$

4.4.3 Cost Competitiveness Score Modelling

To facilitate the unit cost comparison between an AWH bottling concept and a competitor's supply chain, the LCOW must be calculated for both. The cost breakdown analysis of the AWH concept relies on input costs associated with producing a specified volume of water within a given time frame. By mapping the primary activities that directly impact the cost per unit in a typical supply chain, the most relevant cost drivers can be identified. These factors are selected to balance result accuracy with the practicality of data availability.

Since the expected hourly yield has already been calculated in Equation 3, only the cost of production must be calculated further. The total lifetime cost of the AWH concept is dependent firstly on an intended payback period (t_{pay}), as well as the capital expenditure (*CAPEX*) and operational expenditure (*OPEX*), shown in Equation 5. The *CAPEX* is estimated by multiplying the capital cost of the AWH machine(s) by a Lang factor, f, of 3 to account for

installation and transport costs [63]. The *OPEX* is calculated by estimating the total cost of electricity (*TCOE*), the total cost of maintenance (*TCOM*) and the total cost of labour (*TCOL*) and accounting for inflation (*r*). The *TCOE* is dependent on the local electricity rate, (R_e) in cost per kilowatt hour, the AWH machine's energy usage, ($E_{machine}$) in kilowatt, and the expected daily usage time (t_{use}) where T_{DP} is greater than 0°C. Equation 5 shows the calculation of the total cost over the intended payback period.

$$Cost_{total} = CAPEX + \left(1 + \frac{r}{12}\right)^{t_{pay}} (OPEX) = f \times Cost_{machine} + \left(1 + \frac{r}{12}\right)^{t_{pay}} (TCOE + TCOM + TCOL) \quad \textbf{(5)}$$

Equation 6 shows the calculation to obtain the LCOW for the AWH bottling concept ($LCOW_{AWH}$), where the total costs incurred over the payback period needs to be divided by the total quantity of water produced over the intended time frame, informed by Equation 3.

$$LCOW_{AWH} = \frac{Cost_{total}}{Water\ Produced\ over\ time\ t_{pay}} \quad \textbf{(6)}$$

The LCOW from a retailer's perspective can be estimated by removing the retailer margin from the price of a bottle of water—estimated at 2.33 for soft drinks [64]—and then calculating the LCOW of a competing supply chain ($LCOW_{CSC}$). Equation 7 now shows the Cost competitiveness score by comparing the $LCOW_{AWH}$ and the $LCOW_{CSC}$. A value lower than 1 indicate a cost competitive AWH bottling venture.

$$Cost\ Comeptitivenss\ Score = \frac{LCOW_{AWH}}{LCOW_{CSC}} \quad \textbf{(7)}$$

4.4.4 DST System Design

The DST is built in an R *Shiny* model, where *Shiny* was selected due to its seamless integration with R, which supports advanced computation through extensive package libraries. Its interactive dashboard capabilities make it well-suited for scenario analysis and sensitivity testing. Additionally, as a web-based platform, it enables easy dissemination of the decision support tool via a shareable URL.

Owing to the dimensionless nature of the scores, radar plots serve as an effective visualisation tool for representing and comparing the performance of different AWH bottling concepts. The radar plot within the Shiny application is generated using the R package *fmsb* [65], while all psychrometric calculations are conducted using the *psychrolib* R package [66], which has been unit-tested against reference tables from ASHRAE.

5 MODEL VALIDATION THROUGH CASE STUDY APPLICATION

5.1 Case study description

Many hotels continue to opt for bottled water as the primary source of drinking water for guests due to a variety of factors, including convenience, perceived health and safety, brand recognition, cost considerations, and consumer preferences [67]. The inbound logistics of bottled water supply to hotels can generally be categorised into three main approaches. First, a hotel may choose to produce bottled water on-site, within its own facilities [68]. Secondly, hotels may procure bottled water from local suppliers or, thirdly rely on international brands such as Fiji Water.

To demonstrate the practical utility of the tool, it will be applied to a case study from the tropical hospitality sector, specifically focused on a beachfront hotel located on the south-eastern coast of Mauritius. The study is conducted in July, the coldest month of the year, to evaluate the feasibility of implementing an AWH bottling initiative under the least favourable climatic conditions.

5.2 Atmospheric score modelling

According to the World Bank Group's Climate Change Knowledge Portal, the mean surface air temperature in Mauritius during the month of July is approximately 21.9°C, with an average *RH* of 75.23% [69]. Given the proximity of the hotel facilities to the shoreline, it is reasonable to assume that the AWH system would be installed at or near sea level. For the purposes of this analysis, an elevation of 20 meters above sea level is assumed for engineering practicality. Based on these climatic parameters and the assumptions outlined in the derivation of the MHI, the *MHI* is calculated to be 0.499.

5.3 Demand satisfaction score modelling

According to the World Bank Group's Climate Change Knowledge Portal, the mean maximum and minimum surface air temperatures for Mauritius during the month of July are 23.32°C and 20.41°C, respectively [69]. The maximum daily *RH* is estimated at 95%, based on data provided by the Mauritius Meteorological Services [70]. The AWH system selected for this analysis is the Cumulus C5000, manufactured by GENAQ [71], which features an inlet fan with a nominal airflow rate of 22,000 m^3/h. The hotel's daily potable water requirement is 2,000 litres. Under the given climatic conditions, the system is projected to generate approximately 2,812.67 litres of water per day, resulting in a demand satisfaction score of 1.41.

5.4 Cost competitiveness score modelling

Taking the contextual information of an intended payback period of 3 years, yearly inflation of 5% and an electricity rate of 3 R/kWh into account, the total cost incurred over the payback period can be estimated as R19,643,937.79. This amount is informed by assuming the Cumulus C5000 operates according to the nominal values listed in its specification sheet, as well as a maintenance cost of R400, incurred every two months. The minimum wage in Mauritius is around R45 per hour and a single worker, working an 8-hour shift is assumed.

Using weather data from the Mauritius Meteorological Services [70] and the airflow of the Cumulus C5000 machine, the estimated total water yield over the payback period is 2,948,779.34 litres. By applying Equation 6, a $LCOW_{AWH}$ of R6.66 per litre is found. Comparing this with a R50 cost for a 1 litre bottle at the hotel, the $LCOW_{CSC}$ is calculated as R21.36 per litre. Utilising Equation 7 the cost competitiveness score is calculated as 0,31, indicating that the water produced by AWH is substantially more affordable than that of competitors.

5.5 DST Case Study Application Results

The case study yielded a *MHI* of 0.499, indicating that local conditions are suitable for AWH [28], and a demand satisfaction score of 1.41, translating to a daily production surplus of 812.67 litres. The cost competitiveness score is calculated to be 0.31, indicating water production through AWH is significantly cheaper than through traditional supply channels. Figure 4 shows a radar plot to visualise the respective scores.

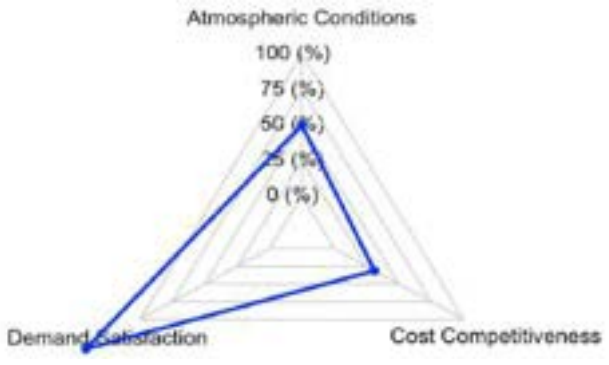

Figure 4: Decision Support Tool Results Visualisation

6 CONCLUSIONS AND RECOMMENDATIONS

A heuristics-based DST was developed by synthesising techniques from existing literature to support the early scoping of AWH bottling projects. The tool provides a novel approach for evaluating early-stage ventures in contexts where data availability is limited. Although useful for preliminary assessments, the DST is subject to several generic assumptions that limits its use for precise decision-making.

Future research should focus on integrating empirically validated methods for estimating critical parameters, such as competitor cost structures and the water recovery efficiencies of different AWH technologies. Incorporating advanced approaches, such as AI-driven DSTs integrated with Industry 4.0 data collection techniques, may further enhance predictive accuracy and decision-making utility.

Key feasibility dimensions, including environmental impact, system reliability, and scalability were excluded due to their complexity and data intensity. Expanding the model to address these factors would increase its comprehensiveness and real-world applicability. In addition, future efforts should consider improved validation methods, including sensitivity analysis, systems dynamics modelling, a comparison with observed project data, and expert evaluation to strengthen the tool's credibility.

The development of similar DSTs for other emerging technologies deployed in novel contexts is also recommended. Such tools can offer valuable guidance to public agencies, policymakers, investors, and other stakeholders during early-stage decision-making when reliable data is scarce.

This research serves as a stepping stone towards more reliable and decentralised potable water solutions. By developing a heuristics-based decision support tool tailored to AWH's unique challenges, this work initiates a ripple effect—creating waves of innovation in how freshwater resources are assessed, produced, and delivered. In doing so, it lays the groundwork for future advancements that merge sustainability, technology, and strategic decision-making to address growing global water challenges.

ABSTRACT

Cricket embodies a bat-and-ball game, characterised as a multi-billion-dollar enterprise. The success of cricket predominantly stems from global league competitions concerning a high volume of Twenty20 matches played across a short period of time. These league competitions place significant strain on players, management, and organisers alike owing to the extensive travel distances involved. Ample literature exists on the scheduling of cricket players, teams, and matches using numeric methods. However, minimal research has been completed on the scheduling of cricket commentators for global league competitions. Therefore, this paper proposes an integer linear programming model for optimising the scheduling of cricket commentators using the SA20 league as case study. The formulated mathematical model minimises the difference in travel distance between the commentators subject to various tournament constraints. Consequently, this study contributes to academia and industry by offering an objective approach towards scheduling cricket commentators while identifying prospective research opportunities.

Keywords: commentators, cricket, integer linear programming, optimisation, SA20

* Corresponding Author

1 INTRODUCTION

Cricket is characterised as a field sport played between two opposing teams [1]. Each player in a cricket team assumes a specialist role, with performance governed by numerous internal and external factors [2]. The sport of cricket has a documented history dating back to the 16th century [3], [4]. Ryan [5] mentioned that cricket was the most recognised sport of the British Empire. However, cricket has transitioned from traditional origins into a multi-billion-dollar enterprise [6]. The multinational success of cricket is primarily attributed to the popularity of Twenty20 (T20) league competitions. T20 league competitions ultimately transformed cricket into a commercially lucrative and globally accessible sport.

The T20 format was first introduced in 2003 by the England and Wales Cricket Board (ECB) as a creative approach to combat the continuous decline in interest in the sport [7], [8]. The T20 format transformed cricket [7] by presenting a faster and more exciting playing structure. The substantial initial popularity of the format eventually led to the first T20 World Cup in 2007, where India emerged as the winner [7]. Following the success of India in the first T20 World Cup, the Board of Control for Cricket in India (BCCI) founded the Indian Premier League (IPL) [7]. The IPL is recognised as the most viewed T20 league competition globally [9]. Alternative countries pursued the same initiative, resulting in several high-profile T20 league competitions globally. Among the numerous T20 league competitions, the SA20 is one of the most recent, with the inaugural season taking place in 2023.

The SA20 represents the foremost T20 league competition in South Africa. Global T20 league competitions, such as the SA20, involve a high volume of games played over a short period. To promote spectator engagement, games are frequently conducted across various host cities, resulting in extensive travelling throughout the contest. The demanding schedule underpinning the extensive travelling required in a T20 league competition places tremendous strain on players, management, and organisers alike. Substantial research has been performed on match scheduling for T20 league competitions using various numerical methods.

However, minimal research has been conducted on the scheduling of cricket commentators within a T20 league competition. Therefore, this study proposes a contemporary integer linear programming model for optimising the scheduling of commentators using the SA20 league as the chosen case study. The proposed solution aims to balance the assignment of commentators by minimising the difference in total travel distances. This study presents an objective approach to fairly scheduling commentators, ensuring equal exposure and division of responsibilities. The proposed mathematical model fosters fairness by ensuring that all commentators comment on the same number of games. The mathematical model accommodates viewing experience by ensuring that no single commentator predominantly commentates on a specific team or venue. The relationships between the commentators are considered to further guarantee that no two commentators predominantly work together.

This study contributes towards the existing work by pursuing research yet to be extensively investigated. The mathematical model presented in this study extends beyond academia, with numerous practical applications supported by the use of contemporary data. Moreover, the solution proposed in this study is not limited to cricket but also proves appropriate for other sporting events, requiring the suitable scheduling of commentators. Subsequently, this study contributes to both industry and research by introducing a numerical approach for objectively scheduling commentators in T20 league competitions, using the SA20 as the chosen case study.

The study comprises five sections, each of which complements the other. Section 1 introduces the study by providing the necessary background. Section 2 offers a literature review covering cricket and mathematical optimisation. Section 3 specifies the considerations, notation, and formulation of the mathematical model. Section 4 verifies and validates the mathematical

model, illustrating the model's correctness and effectiveness, respectively. Finally, Section 5 concludes the study, providing recommendations for prospective research.

2 LITERATURE REVIEW

Section 2 provides a brief review of cricket and mathematical optimisation, characterising the foundation of the study.

2.1 Review of cricket

Section 2.1 describes cricket, the global enterprise, and the SA20 league competition.

2.1.1 Introduction to cricket

Cricket is often characterised by the complexity of the gameplay and laws [10]. Malcolm [10] discussed that cricket embodies honour and fairness, with few sports as widely recognised for equality. Fundamentally, cricket is described as a bat-and-ball game involving two opposing teams having 11 players each [11]. The objective of the game is to accumulate more runs than the competing team, subject to the limitations imposed by the applicable playing format [12]. Cricket is unique in that it accommodates various spectator audiences through distinct playing formats [10]. Internationally, the sport is divided into three playing formats, distinguished by the number of overs, with limited and unlimited overs [13]. Unlimited overs cricket refers to test cricket, where no limit exists for the number of overs played per innings [14]. Conversely, limited overs cricket refers to One Day Internationals (ODIs) and Twenty20s (T20s), where a prearranged number of overs per innings exists [15]. The main difference between ODIs and T20s lies in the number of overs permitted per innings [15]. ODIs embody the longest limited overs cricket format, where each team is bound to an innings of a maximum of 50 overs [16]. Inversely, T20s represent the shortest limited overs cricket format, restricting each team to an innings of a maximum of 20 overs [17].

2.1.2 Enterprise of cricket

The inception of different formats has led to cricket evolving into a multifaceted and multi-billion-dollar international enterprise [18]. The sport of cricket is frequently recognised as a once-premodern pastime that prioritised the spirit of the game above commercial needs [19]. However, while century-old traditions previously dominated the game, profitability now drives cricketing conventions, regulations, strategies, and scheduling [19]. McMillan [19] noted that despite the exalted cultural claims of cricket, the modern form of the game was shaped by industrial capitalism. This transformation is primarily attributed to the inception of global T20 league competitions, which, alas, take precedence over international assignments for most players [19]. The apparent influence of capitalism in cricket is depicted in the Indian Premier League (IPL) [19]. The IPL represents the foremost T20 league competition [20] and is often described as the most successful product of the cricketing industry [19]. The Economic Times currently values the IPL at an estimated $12.00 billion [21], internationally regarded as one of the foremost viewed sporting events [22]. The IPL offered the foundation for other global T20 league competitions, including the SA20.

2.1.3 SA20 league competition

The SA20 is the leading T20 league competition in South Africa [23]. The contest is among the most recent global league competitions, with the inaugural season being 2023. The SA20 marks the third attempt at promoting a T20 league competition in South Africa [24]. The T20 Global League was scheduled to commence in 2017 before Cricket South Africa (CSA) unsuccessfully launched the contest [24]. In 2018, the T20 Global League was replaced by the Mzansi Super League, which featured six locally owned teams [25]. The Mzansi Super League completed two seasons before the COVID-19 pandemic led to the discontinuation of the contest [26]. Unlike these predecessors, the SA20 has demonstrated considerable promise since inception. In 2024,

the SA20 experienced a 21% increase in global viewership, followed by a 37% increase for its most recent edition in 2025 [23].

The SA20 is a month-long affair, annually contested between January and February [23]. The contest involves 34 games, played between six teams across various regions of South Africa [23]. Each team characterises a popular city in South Africa and is owned by a franchise representing a privately held corporation. Table 1 defines the various franchises, along with the associated abbreviations, first participation seasons, and home stadiums [23].

Table 1: SA20 franchises [23]

Number	Franchise	Abbreviation	First season	Stadium
1	MI Cape Town	MICT	2023	Newlands
2	Durban's Super Giants	DSG	2023	Kingsmead
3	Joburg Super Kings	JSK	2023	Wanderers
4	Paarl Royals	PR	2023	Boland Park
5	Sunrisers Eastern Cape	SEC	2023	St George's Park
6	Pretoria Capitals	PC	2023	SuperSport Park

The playing structure of the SA20 follows a double round-robin approach, where each franchise competes against each other franchise twice in the pool stage of the tournament [23]. During these two games, each of the participating franchises receives an opportunity to play a match at the home stadium [23]. As such, each franchise plays a total of five home games and five away matches in the pool stage of the tournament. After all franchises have competed against each other twice, the top four qualify for the playoffs, involving one eliminator, two qualifiers, and a final [23]. The winner of Qualifier 1 progresses to the final, while the loser plays against the winner of Eliminator 1 in Qualifier 2 [23]. The losers concerning Eliminator 1 and Qualifier 2 are eliminated from the tournament, whereas the winner of the latter proceeds to the final [23]. Appendix A specifies the complete schedule of the 2025 SA20 [23], while Figure 1 depicts the approximate locations of the six cities corresponding to the stadiums specified in Table 1.

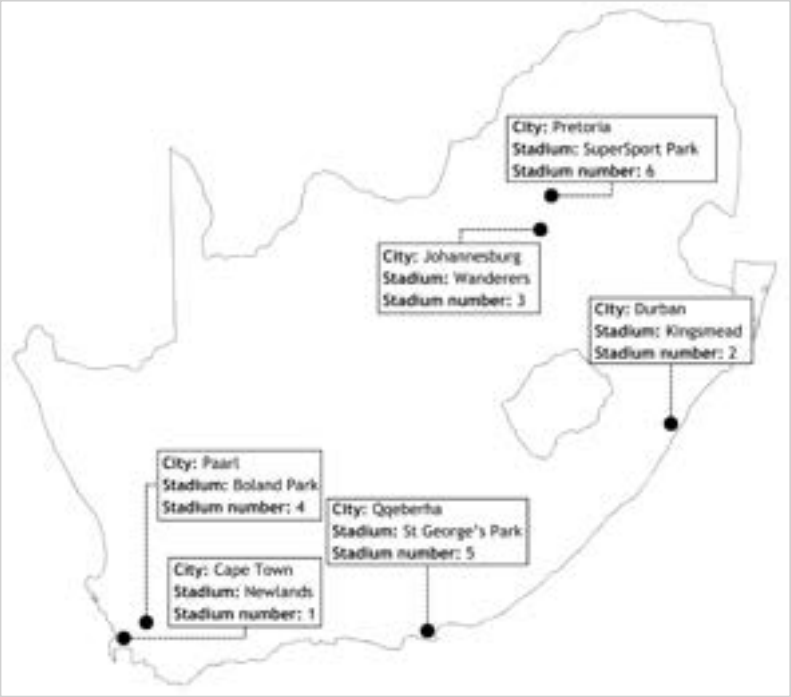

Figure 1: SA20 playing locations [23]

Table 2 provides a matrix defining the rounded travel distances between each of the stadiums based on the labelling assignment specified in Figure 1.

The travel distances, between the venues are determined using the Haversine equation, where (ϕ_j, λ_j) specifies the coordinates of the jth stadium. Noteworthy, the radius r of the Earth was assumed to be 6371 kilometres. Equation (1) gives the expression of the Haversine equation.

$$d = 2r\, arcsin\left(\sqrt{sin^2\left(\frac{\phi_1 - \phi_2}{2}\right) + cos(\phi_1)\, cos(\phi_2)\, sin^2\left(\frac{\lambda_1 - \lambda_2}{2}\right)}\right) \quad \textbf{(1)}$$

Finally, the scale of the distances denotes kilometres, with the decimal values of the locations of the venues omitted for simplicity.

Table 2: Travel distances (km) between stadiums, represented by η_{jg}

Stadium	1	2	3	4	5	6
1	0	1270	1268	55	658	1300
2	1270	0	506	1215	686	524
3	1268	506	0	1215	902	33
4	55	1215	1215	0	611	1246
5	658	686	902	611	0	935
6	1300	524	33	1246	935	0

Table 2 exhibits the substantial travel distances involved in the SA20. Although the necessary infrastructure remains fixed for each game, selected officials and personnel travel across the country during the contest to guarantee the successful facilitation of each game. Among these personnel are the commentators responsible for reporting the events occurring at each match. Commentators promote the overall experience of audiences [28] by adding excitement and context to games [29]. Furthermore, commentators provide real-time analyses of occurrences [29] by explaining the different tactical incentives employed by competing teams. During the most recent edition of the SA20, a minimum of one game was played each day during the pool stage of the tournament [23], resulting in significant travel obligations for commentators. The 2025 SA20 utilised a total of 17 commentators for English commentary. The schedule governing the allocation of these commentators is determined internally. Therefore, the schedule for commentators in the SA20 is not publicly known, further underpinning the significance of the mathematical model presented in this study.

2.2 Review of mathematical optimisation

Section 2.2 defines mathematical optimisation, focusing on linear and integer programming.

2.2.1 Introduction to mathematical optimisation

Mathematical optimisation concerns finding the best solution in a feasible set of alternatives subject to a collection of available resources [30]. Padamwar and Pandey [30] mentioned that mathematical optimisation pillars the field of operations research by enabling decision-makers to derive optimal solutions to intricate problems. Operations research draws on analytical and mathematical techniques to improve processes underpinning complicated systems [30]. As a subset of operations research, Sinha [31] specified mathematical optimisation as a method for achieving some objective through the satisfactory use of resources. Figure 2 shows the general procedure characterising mathematical optimisation, adapted from Andréasson *et al*. [32].

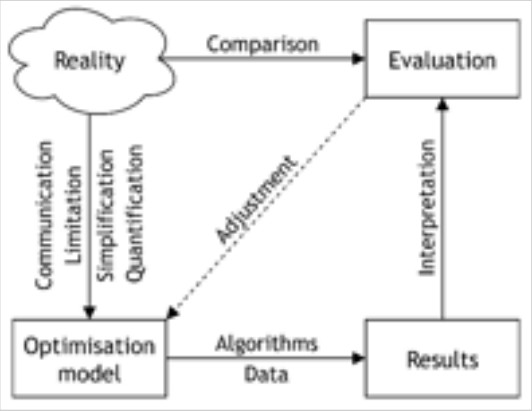

Figure 2: Mathematical optimisation procedure [32]

From Figure 2, Andréasson *et al.* [32] discussed that the problem faced in reality is converted into a mathematical equivalent, expressed as an optimisation model. This conversion involves communicating with all applicable entities, limiting and simplifying the problem to ensure the model's traceability, and quantifying all qualitative statements [32]. The optimisation model describing the practical problem is then solved using applicable algorithms supplied with data [32]. The results are evaluated using interpretation, with necessary adjustments made to the optimisation model [32]. The conclusions obtained from the evaluation are assessed based on practical applicability, with the selected solution finally translated back into reality [32].

2.2.2 Linear programming

Linear programming denotes a mathematical optimisation technique [33], proposed by Dantzig in 1947 [34]. Linear programming optimises a linear function subject to a combination of linear equalities and inequalities described as constraints [35]. Adedipupo *et al.* [35] noted that the simplex method is the most widely applied technique for solving linear programming problems. Equations (2), (3), and (4) provide the standard formulation for a linear programming problem of type minimisation.

$$\text{Minimise} \quad Z = \sum_{j=1}^{n} c_j x_j \tag{2}$$

$$\text{Subject to} \quad \sum_{j=1}^{n} a_{ij} x_j \geq b_i, \quad \forall i = 1, 2, \dots, m \tag{3}$$

$$x_j \in \mathbb{R}_+, \quad \forall j = 1, 2, \dots, n \tag{4}$$

From the standard formulation in Equations (2), (3), and (4), c_j is the cost coefficient assigned to the non-negative decision variable x_j, with a_{ij} presenting the related constraint coefficient and b_i the constraint requirement, for $i = 1, 2, \dots, m$ and $j = 1, 2, \dots, n$.

2.2.3 Integer linear programming

Integer linear programming represents an expansion of linear programming that restricts some or all of the decision variables to discrete values [36]. Integer linear programming originated from the cutting plane method founded by Gomory in 1958 [37]. Bingfeng *et al.* [38] mentioned that the branch-and-bound method represents the most popular technique for solving integer linear programming problems. Hossain and Hasan [39] characterise integer linear programming problems as either pure, mixed, or binary. Pure integer linear programming problems denote those for which all decision variables are integer [37]. Equations (5), (6), and (7) showcase the standard formulation for a pure integer linear programming problem of type minimisation.

$$\text{Minimise} \quad Z = \sum_{j=1}^{n} c_j x_j \tag{5}$$

$$\text{Subject to} \quad \sum_{j=1}^{n} a_{ij} x_j \geq b_i, \quad \forall i = 1, 2, \dots, m \tag{6}$$

$$x_j \in \mathbb{Z}_+, \quad \forall j = 1, 2, \dots, n \tag{7}$$

As previously, considering the standard formulation in Equations (5), (6), and (7), c_j is the cost coefficient involving the integer-valued decision variable x_j, with a_{ij} the affiliated constraint coefficient and b_i the constraint requirement, for $i = 1, 2, \dots, m$ and $j = 1, 2, \dots, n$.

3 MATHEMATICAL MODEL

Section 3 presents the considerations, notation and affiliated formulation of the mathematical model developed for scheduling cricket commentators in the SA20.

3.1 Mathematical model considerations

The mathematical model facilitates fairness in travelling among the commentators while also ensuring equal distribution of the games commented on. Since limited prior research exists on the scheduling of commentators in T20 league competitions, this study implements numerous considerations dictating performance. The mathematical model ensures that commentators are not scheduled to comment on games occurring on the same day. Moreover, commentators may not commentate on consecutive games to ensure sufficient time for travel and recovery. The 2025 SA20 schedule encompasses 34 games, as outlined in Appendix A. Six commentators are required per game, resulting in a total of 12 games per commentator as a collection of 17 commentators were used in the tournament. This leads to each commentator working with five other at each match, therefore Equation (8) presents the total pairing combinations among the different commentators.

$$12 \times 5 = 60 \tag{8}$$

Considering Equation (8), and each commentator commentates on 12 games accompanied by five other commentators. Dividing the 60 commentating pairs among the remaining 16 commentators yields the number of times each commentator should commentate with another for an equal distribution of commentators amongst each other, provided in Equation (9).

$$\frac{60}{17-1} = 3.75 \tag{9}$$

From Equation (9), for an equivalent allocation of commentators across the tournament, each commentator should commentate 3.75 times with another. Accordingly, a limitation of at most four times is assumed. Balancing the commentators evenly between the different participating teams proves challenging. Therefore, an upper limit of six is proposed as the maximum number of times a commentator may commentate on a specific team.

3.2 Mathematical model notation

The notation describes the various sets, set functions, variables, and constants used to develop the mathematical model. Table 3 explains the unique sets applied in the mathematical model.

Table 3: Sets relating to the mathematical model

Set	Indexing	Explanation
I	$i \in I$	Set describing the commentators applicable to the tournament.
J	$j \in J$	Set describing the stadiums applicable to the tournament.
K	$k \in K$	Set describing the games applicable to the tournament.

Set functions describe a collection of subsets relating to a given set under consideration. Table 4 explains the various set functions used in the mathematical model.

Table 4: Set functions relating to the mathematical model

Function	Indexing	Explanation
$\alpha(k)$	$k \in K$	Set function describing the teams played in the game.
$\zeta(k)$	$k \in K$	Set function describing all the previous games per match, $\{f = \zeta(k):\ f\ < k, \forall k \in\ K, f \in K\}$.

Variables characterise the adjustable parameters for minimising or maximising the objective function. Table 5 explains the different variables utilised in the mathematical model.

Table 5: Variables relating to the mathematical model

Variable	Index sets	Domain	Explanation
d_{ih}	$i \in I,\ h \in I$	$\{0,1\}$	Variable for determining which commentator travel further.
q_{ikg}	$i \in I,\ k \in K, g \in J$	$\{0,1\}$	Variable for the commentator per team selection of each game.
t_{ihk}	$i \in I,\ h \in I,\ k \in K$	$\{0,1\}$	Variable for collective commentator selection per game.
x_{ijk}	$i \in I,\ j \in J,\ k \in K$	$\{0,1\}$	Variable for commentator selection per game.
y_{ijk}	$i \in I,\ j \in J,\ k \in K$	$\{0,1\}$	Variable for commentator position per game.
z_{ijgk}	$i \in I, j \in J, g \in J, k \in K$	$\{0,1\}$	Variable for travel selection of commentators per game.
r_{ig}	$i \in I, g \in J$	$\mathbb{N}_0$	Variable for the commentator per team similarity score.
s_{ih}	$i \in I,\ h \in I$	$\mathbb{N}_0$	Variable for individual commentator similarity score.
v_{ih}	$i \in I,\ h \in I$	$\mathbb{N}_0$	Variable for the difference in total travel distance of commentators.
w_i	$i \in I$	$\mathbb{N}_0$	Variable for the total distance between stadiums of each commentator.

Constants denote the numeric values that remain fixed during the optimisation process. Table 6 explains the various constants used in the mathematical model.

Table 6: Constants relating to the mathematical model

Constant	Index sets	Explanation
χ	$k \in K, f \in K$	Binary matrix restricting selection of a commentator to games occurring on the same days.
ϵ_g	$g \in J$	Constant for the number of commentators involving each team.
η_{jg}	$j \in J, g \in J$	Constant for travel distances between stadiums.
μ	-	Constant for the number of games required per commentator.
ω	-	Constant for the number of commentators required per game.
σ_{jk}	$j \in J, k \in K$	Constant for venue selection per game.
M	-	Constant for conditional equality constraints.

3.3 Mathematical model formulation

The objective function in Equation (10) minimises the summation of the differences in travel distances between the different commentators.

$$\text{Minimise} \quad \sum_{i \in I} \sum_{h \in I} v_{ih} \qquad \textbf{(10)}$$

From Equation (10), the variable v_{ih} characterises the positive unit of difference between the commentators. Accordingly, if commentator i travels more than commentator h, the variable v_{ih} captures the corresponding difference, leading to v_{hi} assuming a value of zero. Equations (11) to (13) implement the aforementioned logic.

$$v_{ih} \leq w_i - w_h + M[1 - d_{ih}],\ \forall i \in I, h \in I \qquad \textbf{(11)}$$

$$v_{ih} \geq w_i - w_h + M[d_{ih} - 1],\ \forall i \in I, h \in I \quad \textbf{(12)}$$

$$v_{ih} \leq M d_{ih},\ \forall i \in I, h \in I \quad \textbf{(13)}$$

Equations (11) and (12) serve as conditional equality constraints limiting v_{ih} to the difference between the total travel distance of the commentators. Equation (13) guarantees that v_{ih} is forced to zero in the case where Equations (11) and (12) fail to limit its value to the difference in total travel distances. Subsequently, Equations (14) to (18) define the constraints dictating the behavioural characteristics of the commentators.

$$w_i \leq w_h + M d_{ih},\ \forall i \in I, h \in I \quad \textbf{(14)}$$

$$w_i \geq w_h - M d_{ih},\ \forall i \in I, h \in I \quad \textbf{(15)}$$

$$d_{ih} + d_{hi} \leq 1,\ \forall i \in I, h \in I \quad \textbf{(16)}$$

$$d_{ii} = 0,\ \forall i \in I \quad \textbf{(17)}$$

$$w_i = \sum_{k \in K} \sum_{j \in J} \sum_{g \in J} \eta_{jg} z_{ijgk},\ \forall i \in I \quad \textbf{(18)}$$

Equations (14) and (15) ensure d_{ih} assumes a value of one in the instance where commentator i travelled further than commentator h. Equation (16) ensures that the preceding constraints hold for all commentators. Equation (17) prevents the occurrence of commentators travelling further than themselves. Equation (18) associates the variable w_i with the sum of the travelled distances between the games involving each commentator for the duration of the tournament. Equations (19) to (22) define the travelling constraints for the commentators.

$$z_{ijgk} + 1 \geq y_{ij(k-1)} + y_{igk},\ \forall i \in I, j \in J, g \in J, k \in K \setminus \{1\} \quad \textbf{(19)}$$

$$\sum_{j \in J} \sum_{g \in J} z_{ijgk} = 1,\ \forall i \in I, k \in K \quad \textbf{(20)}$$

$$z_{ijj1} \geq y_{ij1},\ \forall i \in I, j \in J \quad \textbf{(21)}$$

$$\sum_{j \in J} y_{ijk} = 1,\ \forall i \in I, k \in K \quad \textbf{(22)}$$

Equation (19) links the travel variable z_{ijgk} to the location variable y_{ijk} so as to measure the movement of commentators between venues. The movement of each commentator is limited to one per game per Equation (20). Subsequently, Equation (21) ensures that the initial move for each commentator is from and to the venue pertaining to the first game. Constraint (22) ensures that all commentators are restricted to one venue per game. Next, Equations (23) to (27) focus on accurately capturing the positioning of the commentators for the games.

$$y_{ijk} \geq x_{ijk},\ \forall i \in I, j \in J, k \in K \quad \textbf{(23)}$$

$$u_{ik} + 1 \geq y_{ijk} + y_{ig(k-1)},\ \forall i \in I, j \in J, g \in J \setminus \{j\}, k \in K \setminus \{1\} \quad \textbf{(24)}$$

$$c_{ik} \geq u_{if},\ \forall i \in I, k \in K \setminus \{1\}, f \in \zeta(k) \quad \textbf{(25)}$$

$$c_{ik} \leq \sum_{f \in \zeta(k)} u_{if},\ \forall i \in I, k \in K \setminus \{1\} \quad \textbf{(26)}$$

$$y_{ijk} + y_{igf} \leq 1 + c_{ik},\ \forall i \in I, j \in J, g \in J \setminus \{j\}, k \in K \setminus \{1\}, f \in \zeta(k) \quad \textbf{(27)}$$

Equation (23) ensures that each commentator is situated at the respective venue according to the predetermined schedule in Appendix A. Equation (24) constrains the movement of the commentators between various venues to the scheduled games. Equations (25) to (27) ensure that each commentator may not travel between different venues after the completion of the first game. Accordingly, Equations (28) to (31) govern the selection of the commentators.

$$\sum_{k \in K} u_{ik} = \mu,\ \forall i \in I \quad \textbf{(28)}$$

$$u_{ik} = \sum_{j \in J} x_{ijk},\ \forall i \in I, k \in K \quad \textbf{(29)}$$

$$\sum_{i\in I} x_{ijk} = \omega\sigma_{jk},\ \forall k \in K, j \in J \quad \textbf{(30)}$$

$$\sum_{i\in I} u_{ik} = \omega,\ \forall k \in K \quad \textbf{(31)}$$

Equation (28) enforces equal selection of all commentators in the schedule. Equation (29) links the selection variable per venue x_{ijk} to the commentator selection variable μ_{ik}. Subsequently, Equations (30) and (31) collectively guarantee that the required number of commentators is selected per game for the related venue. Next, Equations (32) and (33) regulate the workload of the commentators by managing the selection for specific games.

$$u_{ik} + u_{i(k-1)} \leq 1,\ \forall i \in I, k \in K \setminus \{1\} \quad \textbf{(32)}$$

$$u_{ik} + u_{if} \leq 2 - \chi_{kf},\ \forall i \in I, k \in K, f \in K \setminus \{k\} \quad \textbf{(33)}$$

Equation (32) ensures that commentators cannot commentate on two consecutive games. Also, Equation (33) prevents the selection of a commentator for games occurring on the same day. Noteworthy, the vector constant χ_{kf} consists of a binary matrix capturing games occurring on the same day. Equations (34) to (38) regulate the relationship between the commentators.

$$u_{ik} + u_{hk} \leq 1 + t_{ihk}, \forall i \in I, h \in I \setminus \{i\}, k \in K \quad \textbf{(34)}$$

$$u_{ik} + u_{hk} \geq 2t_{ihk}, \forall i \in I, h \in I \setminus \{i\}, k \in K \quad \textbf{(35)}$$

$$t_{iik} = 0, \forall i \in I, k \in K \quad \textbf{(36)}$$

$$s_{ih} = \sum_{k\in K} t_{ihk}, \forall i \in I, h \in I \quad \textbf{(37)}$$

$$s_{ih} \leq 6, \forall i \in I, h \in I \quad \textbf{(38)}$$

Equations (34) and (35) capture the number of times commentators work together across the different games. Equation (36) guarantees that the number of times commentators work with themselves is set to zero. Equation (37) derives the number of times a commentator worked with another across the entire tournament. Accordingly, Equation (38) defines the upper limit for the number of times commentators may work together throughout the tournament. Finally, Equations (39) to (42) govern the relationship between the commentators and teams.

$$u_{ik} = q_{ikg}, \forall i \in I, k \in K, g \in \alpha(k) \quad \textbf{(39)}$$

$$r_{ig} = \sum_{k\in K} q_{ikg}, \forall i \in I, g \in J \quad \textbf{(40)}$$

$$\sum_{i\in I} r_{ig} = \epsilon_g, \forall g \in J \quad \textbf{(41)}$$

$$r_{ig} \leq 6, \forall i \in I, g \in J \quad \textbf{(42)}$$

Equation (39) relates the commentator selection variable μ_{ik} to the variable q_{ikg} defining the specific teams playing, $g \in \alpha(k)$, during the game. Equation (40) derives the number of times a commentator commentated on a game played by a specific team. Accordingly, Equation (41) prevents the mathematical model from selecting more similarities between commentators and teams. In conclusion, Equation (42) limits the number of times a commentator may comment on a game in which a given team plays.

4 VERIFICATION AND VALIDATION

Section 4 demonstrates the verification and validation of the mathematical model, showcasing the model's correctness and effectiveness, respectively. The results were computed using a licenced CPLEX optimisation solver.

4.1 Mathematical model verification

The verification of the mathematical model involves systematically adding the constraints to investigate the influence on the objective function value. As a baseline for comparison, the

investigation is initiated by evaluating the objective function in Equation (10). Considering Equation (10), the unbounded mathematical model is restricted by the domain of the variable v_{ih}. Consequently, the resulting objective function value equals zero. Equations (11) to (18) are added to the mathematical model for further inspection.From Equations (11) to (18), the variable z_{ijgk} remains constrained by the variable y_{ijk}, which specifies the positioning of each commentator per game. Therefore, the variable v_{ih} is linked to the prevalent difference in total distances travelled by the commentators. The objective function again results in a value of zero. Equations (19) to (31) are applied to the mathematical model.

Incorporating Equations (19) to (31) in the mathematical model yielded the objective function value of 278 648 km. The mathematical model assigned each commentator to 12 games in the schedule, with each match comprising a maximum of six commentators. Noteworthy, for the purpose of brevity, only the findings involving the first four commentators and first five games are subsequently discussed. Table 7 specifies the jth venue relating to the kth game to which the ith commentator is assigned.

Table 7: Verification of stadium selection per commentator

	$i = 1$	$i = 2$	$i = 3$	$i = 4$
$k = 1$	-	-	$j = 5$	-
$k = 2$	$j = 2$	$j = 2$	-	-
$k = 3$	-	-	-	$j = 4$
$k = 4$	$j = 3$	-	-	-
$k = 5$	-	-	-	$j = 6$

Table 8 specifies the starting position for each commentator across the five games. Evidently, Table 8 confirms that the initial positions of said commentators represent the first assigned venue. Further, Table 8 sustains the considerations of the mathematical model and the desired outcome of the preceding constraints.

Table 8: Location of the commentators

	$i = 1$	$i = 2$	$i = 3$	$i = 4$
$k = 1$	$j = 2$	$j = 2$	$j = 5$	$j = 4$
$k = 2$	$j = 2$	$j = 2$	$j = 5$	$j = 4$
$k = 3$	$j = 2$	$j = 2$	$j = 5$	$j = 4$
$k = 4$	$j = 3$	$j = 2$	$j = 5$	$j = 4$
$k = 5$	$j = 3$	$j = 2$	$j = 5$	$j = 6$

Table 9 defines the values used in the computation of the positive difference in total distance travelled between the commentators. The values calculated in Table 9 result from the sum of the related Haversine distances obtained using the expression in Equation (9)

Table 9: Distances travelled by the commentators

Variable	Total distance travelled (km)
w_1	7 657
w_2	9 486
w_3	8 719
w_4	5 316

Applying the values in Table 9, the difference in total travel distances between the different commentators is expressed in Table 10. The difference between the travel distances is only computed in the case where the first commentator has a higher total travel distance.

Table 10: Difference in travel distances of the commentators

	$h = 1$	$h = 2$	$h = 3$	$h = 4$
$i = 1$	0	0	0	2 341
$i = 2$	1 829	0	767	4 170
$i = 3$	1 062	0	0	3 403
$i = 4$	0	0	0	0

Considering Table 10, all entries involving the column of the second commentator and row of the fourth commentator are zeros since they travelled the furthest and shortest, respectively. Finally, Equations (32) to (42) are applied to the mathematical model. Incorporating Equations (32) to (42) in the mathematical model decreased the objective function value to 192 146 km. As previously mentioned, the mathematical model assigned each commentator to 12 games, with each match comprising six commentators. Table 11 presents the venues of the games to which the commentators were assigned.

Table 11: Verification of stadium selection per commentator

	$i = 1$	$i = 2$	$i = 3$	$i = 4$
$k = 1$	-	-	$j = 5$	$j = 5$
$k = 2$	-	$j = 2$	-	-
$k = 3$	-	-	$j = 4$	$j = 4$
$k = 4$	$j = 3$	$j = 3$	-	-
$k = 5$	-	-	-	$j = 6$

Table 11 indicates that the first commentator commented only on one game, while the fourth commentator commented on three. Table 12 specifies the number of times each commentator worked with another.

Table 12: Similarity scores among commentators

	$h = 1$	$h = 2$	$h = 3$	$h = 4$
$i = 1$	0	1	0	0
$i = 2$	1	0	0	0
$i = 3$	0	0	0	2
$i = 4$	0	0	2	0

The results in Table 12 correspond with the selection of commentators exhibited in Table 11. Similar to Table 12, Table 13 expresses the number of times each commentator commented on the different teams.

Table 13: Similarity scores among the commentators and teams

	$i = 1$	$i = 2$	$i = 3$	$i = 4$
$g = 1$	1	1	1	2
$g = 2$	0	1	0	0
$g = 3$	1	1	0	0
$g = 4$	0	0	1	2
$g = 5$	0	0	2	2
$g = 6$	0	1	0	0

The findings in Table 13 correspond with the selection of commentators provided in Table 11. In conclusion, the suitable functioning of all constraints is confirmed, ultimately verifying the model's correctness in coding and formulation.

4.2 Mathematical model validation

The validation concerns investigating the model's effectiveness in scheduling commentators accurately. Two schedules were created based on the round-robin approach of the tournament that randomly assigns commentators to games. These two schedules are based on two distinct validation datasets, where the first presents an unbalanced selection of commentators, and the second provides a balanced selection. Both schedules were investigated to ensure that no commentator commentated on games occurring on the same day.

Equations (28), (32), (38), and (42) are excluded from the mathematical model for generating the first validation schedule. Further, Equation (43) is included to link the predefined schedule to the commentator selection of the mathematical model.

$$u_{ik} = \phi_{ik}, \forall i \in I, k \in K \quad \textbf{(43)}$$

From Equation (43), ϕ_{ik} represents a binary matrix, where 1 defines the assignment of the ith commentator to the kth game, and 0 otherwise. Employing the mathematical model for the validation calculations ensures that the same travel computations and measures of difference in travel distances are used. Subsequently, the number of times a commentator was selected in the first validation schedule varied between 8 and 17, leading to an objective function value of 411 854 km. Accordingly, the first validation schedule provided an unbalanced selection of commentators, with each individual assigned to a distinct number of games.

The second validation schedule satisfies the requirements associated with Equation (28) of the mathematical model. Consequently, each commentator was equally allocated to 12 games, resulting in an objective function value of 327 830 km. Appendix B defines the number of times each commentator was selected during the two validation schedules, with the corresponding travel distances. The first validation schedule demonstrated a clear imbalance between the commentators who were scheduled eight times and the one who was scheduled 17 times. Also, the maximum difference in travel distance for the first validation schedule is 12 427 km. Only a single commentator contains a travel distance further than the maximum difference in total distance for the first validation schedule. The second validation schedule comprises a smaller maximum difference in travel distance, being 7 251 km. For the second validation schedule, 14 commentators travelled further than the maximum difference in total distance. Evidently, the balanced selection of the second validation schedule presents a significant improvement over the unbalanced selection of the first validation schedule, resulting in a 41.65% reduction in the maximum difference and an 11.80% reduction in the objective function value.

Applying the complete mathematical model formulated in Equations (10) to (42) produced an objective function value of 183 250 km. Accordingly, the summation of the difference in travel distances between the commentators for the schedule yielded by the complete mathematical model is significantly lower than those of the validation schedules. Appendix C demonstrates the schedule of the commentators obtained using the complete mathematical model.

Appendix C includes the venues of the 12 games each commentator attended, and the distance travelled between each according to the travel sequence. Further, Appendix C shows the total travel distance of each commentator between the 12 games. Figure 3 compares the schedule obtained using the complete mathematical model to the second validation schedule in which a balanced allocation of commentators transpired. Noteworthy, the average travel distances for both schedules are included in Figure 3 as a reference for analysing the performance.

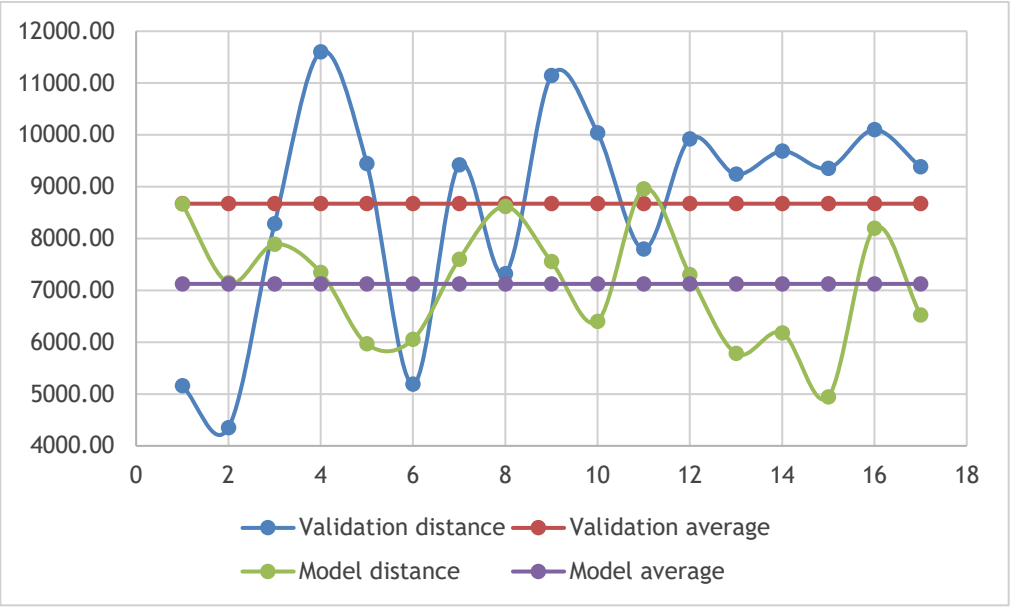

Figure 3: Comparison of individual and average distances

Considering Figure 3, the schedule obtained from the complete mathematical model contains a standard deviation of 1 146 km, whereas the second validation schedule contains a standard deviation of 2 085 km. As such, the schedule obtained from the complete mathematical model notably outperforms the second validation schedule. The second validation schedule consists of only three commentators who travelled a total distance less than the average distance of the mathematical model. Contrary hereto, the schedule for the complete mathematical model consists of just one commentator exceeding the validation average distance.

Figure 4 shows the standard deviation for each commentator, describing the relationship with the teams. The average standard deviation for the schedule of the complete mathematical model is lower than that of the second validation schedule, being 1.39 and 1.49, respectively. Figure 4 illustrates that the standard deviation for the schedule of the complete mathematical model varies between the minimum and maximum standard deviations relating to the second validation schedule. This occurrence results from the addition of Equation (42), which restricts the similarity scores defining the number of times a commentator may comment on a specific team to a maximum of six. The ideal combination would be to assign each commentator to a total of four games based on the underlying logic of Equation (8). However, such an assignment is not feasible as some teams participated in more games, resulting in higher similarity scores.

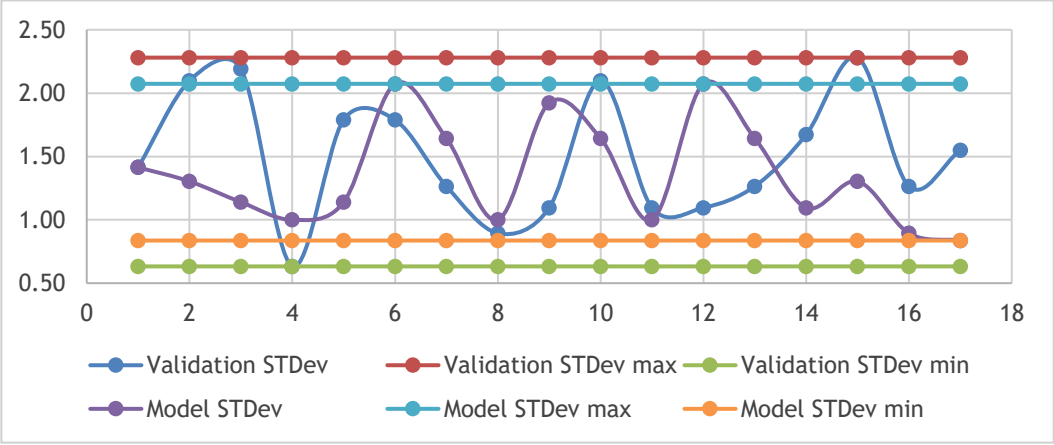

Figure 4: Standard deviation of commentators for teams

In conclusion, the practicality of the mathematical model is confirmed, thereby validating the model's effectiveness in scheduling commentators appropriately.

5 CONCLUSION AND RECOMMENDATIONS

The objective of this study concerned minimising the difference in total distance travelled by commentators subject to a predefined playing schedule of the 2025 SA20. The combination of commentators and games gained by the mathematical model promotes a balanced distribution of work among commentators. The computational complexity of balancing the scheduling of commentators caused difficulties in solving the mathematical model in a feasible time. Hence, the selected limits for Equations (38) and (42) ensure a suitable trade-off between balancing commentator assignment and computational time. The mathematical model proposed in this study helps to bridge the gap in research involving the equivalent distribution of commentators among themselves, the participating teams, and the playing venues. Thus, the mathematical model introduces a framework for managing different T20 league competitions that mitigates the travel strain placed on commentators. The mathematical model provides at least one rest day for each commentator between distinct games for ease of travel arrangements during the demanding schedule of the contest. Therefore, the proposed solution addresses a multifaceted balancing problem, which serves as a potential basis for parallel research. The mathematical model assists organisers in executing data-driven decisions regarding a balanced allocation of fixed resources (commentators), ensuring a streamlined process (tournament). Therefore, the mathematical model exhibits the importance of industrial engineers in scientifically enhancing procedural operations across various industries.

Future research can consider exploring the application of team scheduling in the mathematical model to provide a collectively balanced schedule for players and commentators. The current approach can be redefined to address the length of travel while developing a schedule that minimises the distance covered by teams and commentators. Future work could also consider extending the mathematical model to alternative T20 league competitions to investigate the suitability for related environments. Finally, prospective research can extend the solution to alternative sporting events that require extensive travelling for commentators.

NATURE-INSPIRED RESILIENCE: A SYSTEMATIC LITERATURE REVIEW FOR FINTECH START-UPS

N. Dlamini[1*] and M. Roopa[2]

[1,2]Department of Industrial Engineering
Stellenbosch University, South Africa
[1]19198663@sun.ac.za, [2]meelanroopa@sun.ac.za

ABSTRACT

FinTech start-ups operate in turbulent markets, facing continual waves of regulatory pressure, funding constraints, and customer uncertainty. Building resilience is vital to stay afloat and thrive amid these shifting tides. This systematic literature review explored whether nature-inspired principles from biomimicry could help FinTech start-ups navigate such volatility. Reviewing literature across FinTech challenges, biomimicry, and business resilience, the study revealed a clear gap since no existing research fully integrating all three domains. However, biological concepts such as decentralised coordination, feedback loops, and redundancy offer new strategies for withstanding disruption and adapting under pressure. These insights suggest that biomimicry may provide more than a metaphor since it can offer practical guidance for resilience. The review sets the stage for future interdisciplinary research to define how such principles could be embedded into FinTech systems, enabling start-ups not only to withstand disruption, but to harness it like a wave that propels growth.

Keywords: Resilience, Start-ups, FinTech, Biomimicry, Systematic Literature Review

1 INTRODUCTION

1.1 Background

The South African banking sector, much like its global counterparts, is undergoing a profound digital transformation driven by the strategic integration of digital technologies into traditional banking operations [1]. This transformation is fundamentally reshaping how banks function, interact with customers, and deliver services, thus leading to new operational models and heightened customer expectations. Digital transformation initiatives are enabling banks to enhance client engagement, reduce operational costs, and streamline internal processes, thereby improving overall efficiency and competitiveness [2].

A major catalyst for this transformation has been the rapid rise of FinTech start-ups. These innovative, technology-driven enterprises have revolutionised the financial services landscape by offering cost-effective, personalised, and accessible financial products and services [3]. FinTech start-ups leverage cutting-edge technologies to deliver financial solutions that are not only more efficient and convenient but also more affordable than those provided by traditional financial institutions. Their disruptive influence has compelled incumbent banks to re-evaluate and adapt their business models in order to remain relevant in an increasingly digital marketplace [4].

Recent academic research defines FinTech companies as those that utilise technology to offer new financial services or to enhance the efficiency of existing financial systems [5-7]. By improving both the accessibility and delivery of financial services, FinTech start-ups are playing a pivotal role in the ongoing evolution of the banking industry.

There are five commonly referred to stages of a generic start-up as elucidated by Dorf [8]:

1. Pre-Seed Stage: Brainstorming the concept and building a prototype
2. Seed Stage: Seeking initial funding for product development, market validation and resourcing
3. Early Stage: Product development, developing a customer base and refining the business model
4. Growth Stage: Scaling the business by expanding operations, increasing market share, and enhancing revenue streams while optimising internal processes and infrastructure to support increased demand
5. Maturity and Exit Stage: The business reaches a stable and established position in the market, and may explore exit options

Research shows that startup failure rates tend to decrease with each successive funding round, indicating that early-stage startups are particularly vulnerable. For example, about 60% of pre-seed startups fail to reach seed funding, and roughly 35% of startups at the Series A stage do not advance further [4]. Overall, approximately 30% of venture-backed startups fail, and failure rates can be as high as 90% among all startups. These figures highlight the critical challenges faced by startups in their earliest phases of growth and scaling [9].

FinTech startups operate in a particularly complex and fast-moving environment defined by rapid technological change and strict, evolving regulatory frameworks. In developing economies, these challenges are even more pronounced due to infrastructural deficits, regulatory uncertainty, and limited access to capital and skilled human resources [10]. Additionally, FinTech startups are highly vulnerable to cybersecurity threats because they often lack sophisticated security infrastructures [11]. This makes them prime targets for increasingly advanced cyberattacks, including ransomware and phishing schemes. Resource constraints further challenge resilience, with limited financial capital, talent, and technological infrastructure restricting long-term strategic development[12]. Moreover, intense market uncertainties driven by technological disruption, changing consumer

behaviour, and economic volatility make sustained competitiveness and adaptability difficult to achieve [13].

Understanding these key challenges and risks, early-stage vulnerability, regulatory complexity, infrastructural and resource constraints, and escalating cybersecurity threats provides the foundation for exploring novel approaches, such as biomimicry, to enhance resilience and sustainability in FinTech startups. By framing the discourse around these documented issues, the research aims to investigate how nature-inspired strategies could offer innovative solutions to bolster the adaptive capacity and long-term viability of FinTech ventures.

In an era where disruption is the norm rather than the exception, FinTech start-ups find themselves at the frontline of volatility as they grapple with regulatory uncertainty, relentless cybersecurity threats, rapid technological evolution, and chronic resource constraints. Traditional risk management and business strategies often fall short in addressing the scale and complexity of these challenges [14]. Approaches that are bold, innovative, and inherently adaptable may hold potential for helping organisations navigate disruption and thrive amid uncertainty. Against this backdrop, Biomimicry offers a compelling and unconventional strategy—drawing inspiration from nature's 3.8 billion years of evolutionary resilience to inform the design of systems that are agile, sustainable, and resilient by nature. Nature's systems have evolved adaptive solutions to survive in changing, resource-scarce environments. For example, decentralised structures in coral reefs can inspire flexible organisational models, while immune system defences offer analogies for layered cybersecurity [15, 16]. By applying these nature-inspired strategies, FinTech start-ups can better navigate risk, adapt to uncertainty, and enhance their long-term sustainability-especially within the unique challenges of the South African market.

This study presents a systematic literature review (SLR) aimed at investigating whether nature-inspired strategies, specifically those drawn from Biomimicry, have been explored in addressing resilience challenges within South African FinTech start-ups. In a landscape where FinTechs must continually navigate waves of disruption and uncertainty, this review examines whether lessons from nature can help these ventures build the resilience needed to ride, rather than resist, the tides of change.

1.2 Research opportunity and scope

Biomimicry, the practice of emulating strategies from natural systems to solve human problems, provides a theoretical lens for examining potential resilience strategies [17]. A study published in the *Journal of Business Venturing Insights* questioned conventional entrepreneurship models by suggesting that nature's principles could redefine innovation and sustainability practices [17]. While this perspective was framed around general entrepreneurship, it offers conceptual relevance to FinTech start-ups, which—like biological systems—must adapt to volatility, resource scarcity, and high failure rates. This review seeks to determine whether such thinking has been applied specifically within the FinTech resilience literature. The purpose of this review is not to develop new resilience frameworks, but rather to assess the extent to which Biomimicry has already been considered as a strategic approach in the FinTech start-up context. In particular, it explores whether natural systems—known for their resilience, adaptability, and regenerative capacity—have been studied as sources of inspiration for tackling the resilience challenges unique to early-stage FinTech ventures. Although Biomimicry has found applications in fields such as engineering and design, its presence in FinTech literature remains uncertain and appears underexplored [18]. By mapping current research, this review will help identify conceptual gaps and, if relevant, offer suggestions for future studies that could bridge the disciplines of Biomimicry and FinTech resilience [15].

FinTech start-ups face considerable obstacles to building resilience, including regulatory burdens, cybersecurity threats, limited funding, and market volatility. Despite their capacity for innovation, many fail to survive due to inadequate strategies for navigating such challenges [19]. While existing literature addresses general resilience strategies, there is limited clarity on whether these approaches are suited to the complexities of FinTech ecosystems. Moreover, the potential of Biomimicry to inform such strategies has not been clearly established.

1.3 Research Aim and Objectives

This paper aims to systematically identify challenges faced by FinTech start-ups and explore potential Biomimicry-based solutions that could address these challenges.

The objectives of this study are to (1) conduct a systematic literature review to identify and synthesise the key challenges faced by FinTech start-ups, and (2) explore nature-inspired approaches that could inform practical and theoretical solutions.

1.4 Novelty

This research explores and conceptualises potential solutions to FinTech startup challenges through the lens of Biomimicry, drawing on nature-inspired strategies to enhance resilience, adaptability, and sustainability within the FinTech ecosystem. Natures time tested mechanisms for dealing with change and complexity may provide valuable models for start-ups struggling with conceptually similar challenges. By investigating these possibilities, this research seeks to conceptualize new strategies that FinTech startups might adopt to improve their resilience and long-term viability. The application of biomimicry could foster more integrated and holistic solutions, helping startups to navigate complexity not just through technology, but through systemic innovation inspired by the natural world.

2 METHODOLOGY: SYSTEMATIC LITERATURE REVIEW

A Systematic Literature Review (SLR) of academic sources and was used to identify the key challenges and risks FinTech start-ups face as well as possible strategies in nature that can inspire resilience.

The research was based on a SLR aimed at identifying key challenges and risks encountered by FinTech start-ups, particularly those related to resilience and long-term sustainability. Sources included peer-reviewed journal articles and conference papers obtained from databases such as ScienceDirect, Scopus, Emerald and Journal Storage (JSTOR).

The applied literature review will also include an exploration of biological systems that exhibit resilience, adaptability, and sustainability. The selection of sources will follow clearly defined inclusion and exclusion criteria to ensure quality and relevance. Table 1 below details the Search Protocol applied for the SLR.

Table 1: Search Protocol for the Systematic Literature Review

Component	Description
Review Objective	To compile and synthesise literature on the challenges faced by FinTech start-ups and the application of nature-inspired (Biomimicry-based) strategies.
Research Questions	1. What are the key challenges faced by FinTech start-ups and what themes emerge from existing literature on FinTech challenges in these stages?
	2. What systems in nature experience similar challenges and how has nature resolved these problems.
Search Strategy	Systematic search of academic databases and relevant literature sources using predefined keywords.
Databases Searched	Science Direct, Scopus, Emerald, JSTOR

Component	Description
Search String	"FinTech" AND (" nature-inspired " OR " Biomimicry ") AND (" resilience " OR " adapt- " OR "sustainabl-")
Inclusion Criteria	Studies published in English.
	Peer-reviewed journal articles, conference papers, and other credible literature.
	Studies focused on FinTech start-ups resilience and using nature-inspired solutions in business.
Search time frame	2014 - 2024
Exclusion Criteria	Studies unrelated to drawing inspiration from nature or Biomimicry or articles unrelated to FinTech challenges
Screening Process	Titles and abstracts will be screened first, followed by a full-text review for relevance and eligibility.
Data Extraction	Key information such as study focus, methodology, geographic scope, identified challenges, nature-inspired solutions and conclusions will be extracted and analysed.
Synthesis Method	Thematic analysis to identify common challenges and gaps in the literature.

3 LITERATURE OVERVIEW

3.1 Fintech startups

FinTech start-ups, characterised by their integration of advanced technologies such as AI, blockchain, and digital payments into financial services, are fundamentally reshaping traditional financial systems [20]. Recent systematic literature reviews (SLRs) have mapped the evolution of FinTech research, identifying key themes and gaps [19, 21]. These studies collectively show that FinTech start-ups face multifaceted challenges that span regulatory compliance, risk management, funding, market uncertainty, and resource challenges [19].

3.1.1 Regulatory Challenges

Regulation emerges as the most extensively discussed challenge in the literature. FinTech start-ups operate within a complex and rapidly evolving regulatory landscape that differs widely across jurisdictions [5, 19]. Unlike general start-ups, FinTech companies must comply with sector-specific regulations concerning anti-money laundering (AML), know-your-customer (KYC) protocols, and data privacy laws, which require specialised compliance systems and legal expertise [19, 20]. Kashika Khanna et al. [19] also re-iterate the burden this fragmented regulatory environment places on FinTechs, which must balance the pursuit of innovation with the need to adhere to strict legal frameworks.

3.1.2 Licensing Challenges

Licensing requirements represent an interconnected but distinct challenge. These are often stringent and inconsistently applied, with some regions enforcing partial licenses or varying rules across sub-national jurisdictions, which complicates both market entry and cross-border scaling efforts [22]. The approval processes involved can be costly and time-consuming, creating significant barriers for new entrants. Delays in obtaining necessary licenses, coupled with the high administrative burden, further exacerbate operational uncertainty for start-ups in this space [7, 21].

3.1.3 Data Security

Data security is a critical concern for FinTech start-ups due to their handling of sensitive financial and personal information. Cybersecurity threats, vulnerabilities in digital infrastructure, and insufficient investment in secure systems can expose companies to data

breaches with serious legal and reputational consequences [19]. Suryono, et al. [6] emphasize that such breaches are among the most significant barriers to FinTech adoption, necessitating ongoing investment in robust, secure technology infrastructure to safeguard against evolving threats [6]. Compared to other start-ups, the consequences of a data breach in FinTech are often more immediate and severe, potentially resulting in regulatory penalties and loss of market credibility.

3.1.4 Customer Trust

Closely tied to data security is the issue of customer trust, which is essential for user adoption and retention in the FinTech space. Consumers are particularly cautious when it comes to financial platforms, and any perceived weaknesses in data protection or user interface design can quickly undermine confidence. Trust deficits are amplified by broader concerns over digital fraud and privacy, making it imperative for FinTech start-ups to build transparent, user-friendly systems that reassure users about the safety of their data [19]. As trust is a foundational element in financial services, its erosion can be particularly damaging, stalling growth and limiting the ability to scale.

3.1.5 Technological and Human Capital Challenges

Maintaining technological control and attracting skilled human capital are significant challenges. Constant innovation is necessary, but so is maintaining secure, reliable, and scalable systems [6]. Finding people with the right mix of financial and technical skills is especially difficult, as this combination is relatively rare [19]. Without access to such specialised expertise, scaling operations and remaining competitive become much more difficult in a fast-changing industry. This scarcity creates bottlenecks in recruitment and limits a start-up's ability to scale operations or pivot rapidly in response to external pressures. The socio-technical nature of FinTech systems means that deficiencies in either domain—technological capability or human expertise—can critically undermine resilience, innovation capacity, and competitive positioning in a rapidly evolving industry.

3.2 Resilience

Resilience in the business context is broadly understood as an organisation's ability to anticipate, absorb, adapt to, and recover from adverse events while maintaining or regaining its core value proposition [23, 24]. A bibliometric analysis of over 700 articles indexed in SCOPUS reveals that business resilience research has surged, particularly following global crises such as the COVID-19 pandemic [23]. The literature suggests that business resilience is not static but evolves as organisations and their environments change, with resilience-forming features continuously developing over time [23-25].

Conz [25] proposes a dynamic perspective, emphasizing the temporal dimension of resilience and the need for organisations to adapt their strategies and structures over time. The framework categorizes resilience capabilities into proactive (anticipation and preparation), reactive (response and recovery), and adaptive (learning and transformation) dimensions, underscoring that resilience is both a process and an outcome [25].

3.3 Biomimicry applications

A 2025 review published in the *International Journal of Arts, Humanities and Social Sciences* highlights how Biomimicry is driving sustainable business practices across a wide range of industries, including transportation, packaging, and beyond [16]. In the transportation sector, Biomimicry has inspired the development of aerodynamic designs modelled after bird flight, particularly that of birds like kingfishers and falcons. For instance, the nose design of Japan's Shinkansen bullet train was influenced by the beak of the kingfisher, enabling it to travel faster while reducing noise pollution and energy consumption. Such

adaptations not only improve performance but also contribute to sustainability by lowering fuel use and emissions [16].

In the packaging industry, Biomimicry has led to innovations that reduce material waste and improve functionality. One notable example includes the development of self-cleaning surfaces inspired by lotus leaves, which naturally repel water and dirt due to their micro- and nano-structured surfaces. This principle has been adopted in packaging materials and coatings that require less cleaning or processing, thereby conserving water and reducing chemical use [16]. These nature-inspired solutions not only enhance technical performance but also promote circular economy principles by reducing reliance on non-renewable resources and supporting regenerative design.

Research published in *ScienceDirect* underscores the integration of Biomimicry and creative problem-solving in management education, demonstrating that teaching these principles to future business leaders fosters a mindset oriented toward sustainable innovation. By studying natural systems' adaptability and resource efficiency, practitioners, students and organisations learn to devise solutions that balance economic growth with ecological responsibility [26]. Academic literature demonstrates that Biomimicry offers a rich, interdisciplinary approach for businesses seeking to solve complex challenges and transition toward sustainability. By emulating nature's time-tested strategies, companies can innovate in ways that are both economically viable and ecologically responsible, paving the way for a new era of sustainable business [16, 17, 26].

Biomimicry research offers valuable insights from nature's adaptive systems, such as decentralisation and redundancy, that can inspire innovative resilience strategies. While business resilience literature emphasizes flexibility and proactive risk management, there is a clear gap in applying biomimetic principles specifically to FinTech resilience. This gap presents a promising opportunity for future research to develop nature-inspired models that enhance the adaptability and sustainability of FinTech start-ups amid rapid change and uncertainty.

4 SYSTEMATIC LITERATURE REVIEW

The SLR findings serve as a foundation for nature-inspired strategies are explored as potential solutions to strengthen the adaptability and longevity of FinTech start-ups.

4.1 Selected research papers

Figure 1 illustrates the PRISMA 2020 flow diagram used to guide the systematic literature review process in this study. It outlines the identification, screening, eligibility, and inclusion stages through which relevant studies were selected, ensuring transparency and rigor in the selection of literature related to FinTech start-up challenges and Biomimicry-based solutions.

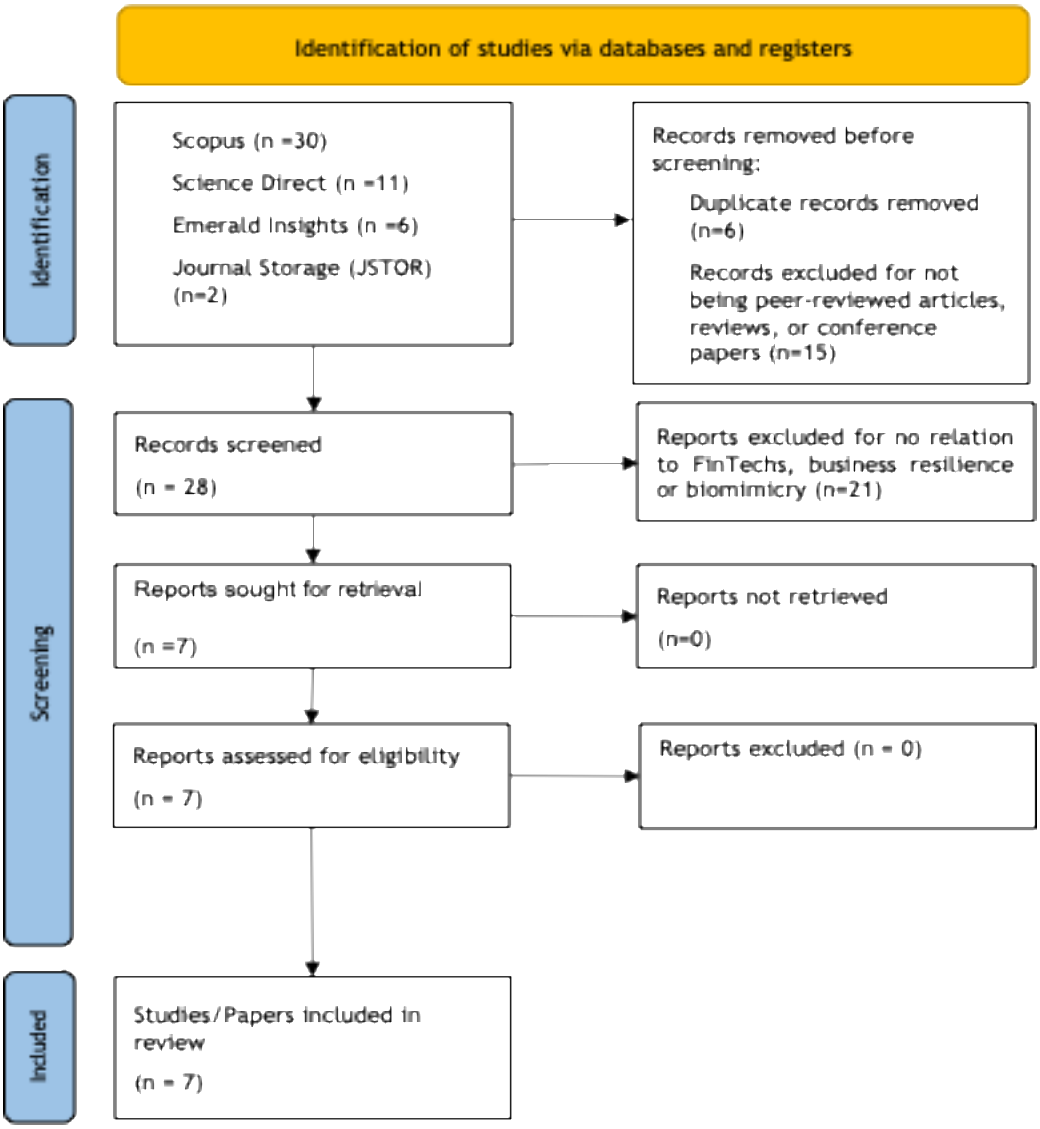

Figure 1: Prisma Flow Diagram

4.2 Findings and results

A structured literature search was conducted using the PRISMA 2020 framework across four academic databases—Scopus, Web of Science, ScienceDirect, and IEEE Xplore. This process initially identified 49 records. After the removal of duplicates and books or book sections were removed 28 articles remained. Subsequently the titles and abstracts of these articles were screened for relevance. 21 articles were removed as they were not directly related to any of the three research categories of challenges of fintech start-ups, Biomimicry in business, business resilience. Ultimately only seven studies were thoroughly assessed for eligibility and included for review. The primary reasons for exclusion were:

- Lack of interdisciplinary integration - The majority of studies focused solely on either FinTech start-up challenges or Biomimicry in business, but did not combine both perspectives.
- Absence of FinTech context in resilience framing - Some Biomimicry-focused studies explored resilience principles but were not related to FinTech or FinTech start-ups. Table 2 below provides a summary of the key takeaways of the articles included in the

review as well as their relation to the topics of challenges of FinTech start-ups and nature-inspired solutions.

Table 2: Summary of SLR papers included

Paper No.	Year	Authors	Title of Study	Key Takeaways	Identifies key challenges of FinTech start-ups	Identifies possible solutions in nature	Business resilience
1	2023	Alzubaidi, et al. [27]	Towards Risk-Free Trustworthy Artificial Intelligence: Significance and Requirements	Methods for increasing data privacy i.e. deidentification, federated learning techniques, and data agreements	ü	û	û
2	2025	Borrero and Yousafzai [28],	Spinning the circle: unravelling the "why?" behind social motivations in circular economy entrepreneurship	Presents the concept of circular necessity entrepreneurship and introduces circular business model (CBM) strategies for resource constrained, smaller companies	û	ü	ü
3	2025	Mo and Zeng [29]	Analysis of technology innovation efficiency and its impact factors based on DEA-fsQCA method: Evidence from listed seed companies in China	Proposes five main ways seed companies can get better at innovating: Focusing on employees, improving talent and management, encouraging a mix of skills and company sizes, working closely with the government, combining different types of talent and ideas	ü	û	ü
4	2024	Valarmathi and Dhanalakshmi [30]	Persistent Fish School-Inspired Deep Belief Network for Object Detection in Varied Weather Traffic Surveillance	Introduces a new algorithm called PFSS-DBN, inspired by the way fish swim in schools and adapt to their environment. It uses deep learning to adjust itself to different weather conditions, improving how	û	ü	û

Paper No.	Year	Authors	Title of Study	Key Takeaways	Identifies key challenges of FinTech start-ups	Identifies possible solutions in nature	Business resilience
				well it detects objects on the road.			
5	2022	Jiang, et al. [31]	DSGWO: An improved grey wolf optimizer with diversity enhanced strategy based on group-stage competition and balance mechanisms	The DSGWO algorithm, inspired by grey wolf hunting behaviour, improves how optimisation problems are solved by enhancing diversity and balancing exploration with focus—key traits found in nature.	û	ü	û
6	2023	Jiang, et al. [32]	ATSA: An Adaptive Tree Seed Algorithm based on double-layer framework with tree migration and seed intelligent generation	An optimisation method inspired by how trees and their seeds spread and adapt in an ecosystem	û	ü	û
7	2025	Jiang, et al. [33]	KATSA: KNN Ameliorated Tree Seed Algorithm for complex optimization problems	Research that further expands on the paper above and combines it with K-Nearest Neighbour (KNN) logic — a machine learning method that mimics how organisms might make decisions based on their local environment (or "neighbours"	û	ü	û

The final selection of studies reflects the limited but emerging dialogue between these distinct fields, underscoring the need for greater interdisciplinary exploration. The next section discusses the implications of these findings for theory, practice, and future research.

4.3 Implications of the Review

4.3.1 Identified Research Gap

The small number of qualifying studies highlights a clear research gap at the intersection of FinTech start-up challenges, Biomimicry in business, and business resilience. This gap is underscored by the limited cross-disciplinary engagement, while Biomimicry has proven valuable in areas like architecture and systems engineering, its potential in financial technologies remains underexplored. Furthermore, resilience strategies in FinTech tend to be

siloed within regulatory or technological domains, missing opportunities to leverage nature's adaptive, decentralized problem-solving approaches. Figure 2 illustrates this gap and the lack of integrated research connecting these three domains. The numbers in the diagram represent the research domain of the paper IDs referenced in the previous table.

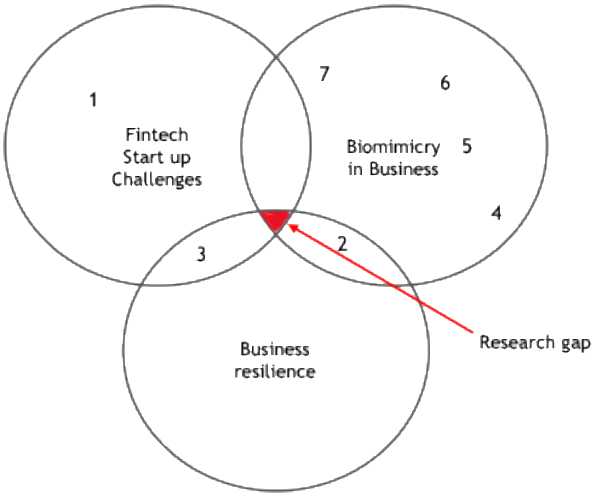

Figure 2: Venn diagram of Research Gap

A key focus of this review is to explore how existing literature addresses the convergence of FinTech start-up challenges, nature-inspired (Biomimicry-based) approaches, and strategies that support business resilience. While this intersection remains underexplored, insights drawn from a diverse range of fields—such as algorithmic development, entrepreneurship, and financial technology—offer promising avenues for future investigation.

Only one study (Alzubaidi, et al. [27]) directly identified challenges specific to FinTech start-ups, focusing on data privacy and trust in artificial intelligence. The authors propose technical methods like federated learning and data de-identification to mitigate risk, but the study does not incorporate nature-based analogies or resilience-building frameworks. By contrast, several other papers introduce biologically inspired strategies such as the fish school-inspired PFSS-DBN (Valarmathi and Dhanalakshmi [30]) and grey wolf-based DSGWO (Jiang, et al. [31]) that, while developed in non-FinTech domains like traffic surveillance and general optimisation, present valuable metaphors for adaptability and decision-making under uncertainty. These nature-based algorithms simulate biological behaviours such as schooling, hunting, and seed dispersion, offering abstract models that could potentially be adapted for FinTech applications, especially in contexts requiring agility, robustness, and decentralised control.

Borrero and Yousafzai [28] also contribute meaningfully to this discussion by introducing circular business models (CBMs) in resource-constrained settings, which overlap conceptually with FinTech environments. These models, grounded in circular economy principles, promote sustainability and business resilience by reusing resources and fostering social entrepreneurship, these are traits that can be mapped onto FinTech start-ups navigating regulatory and resource constraints. The work of Mo and Zeng [29], although not biomimetic, adds a resilience lens by outlining strategic innovation practices such as talent diversity, adaptive management, and collaboration with government. These findings parallel biological strategies like redundancy, diversity, and symbiosis, reinforcing the relevance of Biomimicry as a framework for resilient innovation in FinTech.

Overall, while direct connections between FinTech, Biomimicry, and resilience are sparse in the literature, several studies implicitly align with biomimetic principles. The reviewed papers suggest that integrating nature-inspired strategies such as decentralised adaptation,

intelligent learning, and resource circulation, could offer novel pathways to enhance the resilience and adaptability of FinTech start-ups.

4.3.2 Theoretical Contributions and Practical Opportunities

This review offers a novel theoretical contribution by bridging FinTech innovation, Biomimicry, and business resilience fields often examined in isolation. By integrating these perspectives, it introduces a new lens for understanding how FinTech start-ups can adapt and thrive under uncertainty, complexity, and resource constraints. Biomimicry, in particular, provides a foundation for reimagining resilience not just as risk mitigation, but as a dynamic capacity for adaptation and growth.

The studies reviewed highlight that nature-inspired principles such as decentralisation (fish schooling), adaptability (tree seed dispersal), and self-organisation (grey wolf hunting) can inform both technical innovations and organisational strategies in FinTech. These analogies support solutions for regulatory complexity, market volatility, and limited resources, while also guiding models for fraud detection, compliance, and customer engagement.

Moreover, the research points to the potential of antifragile design systems that strengthen through stress—as a strategic advantage. Adaptive approaches identified in works by Jiang, et al. [31] and Mo and Zeng [29] show how FinTechs can leverage intelligent, modular models to enhance innovation and resilience. Insights from Borrero and Yousafzai [28] further show how circular thinking and talent diversity contribute to organisational resilience, echoing ecological principles such as redundancy and feedback loops.

Building on these insights, the review underscores that Biomimicry offers a multi-level framework through which resilience can be embedded into FinTech systems. The natural principles identified (i.e. decentralisation, adaptability, and self-organisation) can be applied not only to isolated functions but also scaled to broader organisational and industry contexts. For instance, decentralisation observed in fish schooling supports distributed decision-making in FinTech networks, while adaptability drawn from tree seed dispersal aligns with scalable growth strategies. Grey wolf hunting behaviour, reflecting self-organisation, informs how FinTechs might dynamically reconfigure teams or operations in response to environmental shifts. These nature-inspired strategies do not operate in isolation but interact as layered systems, offering functional models that transcend specific industry boundaries and instead respond to core systemic needs.

4.4 Enablers to address the research gap

To address the research gap between FinTech start-up challenges and business resilience, key enablers include developing interdisciplinary research frameworks that align technological risk, regulatory complexity, and organisational adaptability. Academic-industry partnerships can support real-time data collection from FinTech start-ups, enabling empirical studies on how resilience traits present themselves in high-uncertainty environments.

Bridging the gap between Biomimicry and FinTech start-up challenges requires greater methodological integration. Enablers include cross-disciplinary collaboration between FinTech experts and Biomimicry scientists to translate natural systems (e.g., swarm intelligence, decentralised coordination) into practical FinTech models. Development of simulation environments or digital sandboxes could help test biomimetic principles against real-world FinTech constraints such as scalability, data privacy, and user trust.

To close the gap between Biomimicry and business resilience, enablers include advancing conceptual models that map ecological principles such as self-organisation, modularity, and regenerative capacity onto core business functions. Importantly, the application of Biomimicry can transcend industry boundaries by aligning with specific industry needs. For example, modularity may support scalability in financial technology, while regenerative capacity may

enhance sustainability in agriculture or energy sectors. Research institutions and think tanks can catalyse this integration through systems thinking workshops, curated case study repositories, and scenario-based testing. These tools can facilitate the design of adaptive business models inspired by nature's problem-solving strategies and tailored to the resilience needs of different industries.

4.5 Limitations

The SLR reveals a key limitation in the lack of studies integrating FinTech start-up challenges, business resilience, and Biomimicry within a single research framework. Most articles addressed these themes in isolation, limiting the ability to generate holistic insights. Additionally, while Biomimicry appeared in several studies, it was largely applied to optimisation rather than to organisational or strategic resilience—restricting its practical application for FinTech start-ups facing issues like regulation or customer trust.

5 CONCLUSIONS AND RECOMMENDATIONS

This study set out to explore how Biomimicry principles can be integrated into strategies that enhance the resilience of FinTech start-ups. Guided by the PRISMA 2020 framework, the systematic review examined literature across three domains: FinTech start-up challenges, Biomimicry, and business resilience. Although several papers addressed explored nature-inspired optimisation and adaptive behaviours and others FinTech issues, such as market uncertainty and limited resources, no study explicitly bridged all three domains in an integrated framework.

This lack of convergence presents a critical research gap but also an untapped opportunity. Concepts from nature such as redundancy, decentralised coordination (as seen in grey wolf and fish school-inspired algorithms), and circular models of resilience offer novel perspectives for addressing persistent FinTech challenges like market volatility, customer trust, and resource constraints. These biological principles have the potential to reframe resilience—not just as resistance to disruption, but as a dynamic, adaptive capacity for growth under pressure.

Ultimately, this review lays the groundwork for interdisciplinary exploration by proposing a new theoretical lens through which FinTech resilience can be understood and strengthened. Like a wave that adapts its shape to navigate ever-changing currents, future research should focus on identifying the functional requirements for embedding biomimetic strategies into FinTech architecture, governance, and operations. Doing so could lead to more robust, adaptable, and sustainable FinTech systems capable of thriving in complex and evolving environments. In this way, just as waves continually reshape the coastline through their persistent and dynamic energy, biomimicry-informed innovation could enable FinTech to reshape its boundaries and remain resilient amidst ongoing disruption.

UNDERSTANDING THE IMPACT OF THE DUAL USE REGULATION FOR UNIVERSITIES

W.W. Francis[1*], C. Malherbe[2] and C.S.L Schutte[3]

[1,2,3]Department of Industrial Engineering
Stellenbosch University, South Africa
[1]21708126@sun.ac.za, [2]cvdm2@sun.ac.za, [3]corne@sun.ac.za

ABSTRACT

Dual-use items, including software and technology, are designed for civilian use, but the unintended use can lead to human rights violations and terrorist attacks (such as using it as nuclear or biological weapons). The EU Regulation (EU 2021/821) aims to regulate export control of dual use items and allow universities to navigate global competitiveness and manage controls to prevent weapon proliferation. Universities and research institutions are challenged by navigating complex dual use regulatory frameworks, which hampers universities' ability to comply, to ensure that ethical practices, collaboration and academic freedom are adhered to. Without a compliance strategy in place, universities are unable to comply with EU Regulations. This study aims to explore university perspectives gathered from interviews and literature emphasising that compliance is crucial for regulations to achieve its intended outcome. Applying a systems engineering approach to analyse different solutions and propose pragmatic solutions leads to enhanced compliance strategies.

Keywords: Dual-Use Items, EU Regulation, Universities, Research Institutions, Systems Engineering Approach

[1] The author is enrolled for an M Eng (Engineering Management) degree in the Department of Industrial Engineering, University of Stellenbosch.

1 INTRODUCTION

The impact of international export regulation on dual-use items in universities is a topic of increasing importance, particularly in the context of research and development (R&D) and technology transfer (TT). Regulating dual use items presents a multitude of complex challenges, where research and technology intersect with stringent national and international export regulations. Understanding and adhering to dual-use compliance regulation is crucial for universities engaged in cutting-edge research. Navigating the complex regulatory landscape poses significant challenges. The League of Research Universities (LERU) reported several compliance challenges with the European Union (EU) Dual Use Regulation and related export regulations (henceforth collectively called the "Regulations") and highlighted aspects such as fragmented regulations leading to inconsistent interpretation, lack of compliance guidance and tools leading to increasing compliance risks, resource constraints within universities and government, increased barriers to international collaboration, infringement of academic freedom, the overreach of EU competencies, and research integrity and ethical dilemmas [1]. Without a comprehensive compliance strategy, universities lack the required preparedness and ability to respond to the Regulations.

The EU Regulation, specifically, the Regulation (EU) 2021/821, aims to regulate export control and control of dual use items with the main purpose of preventing the violation of human rights. The EU specifies which items are subject to export control through the **EU dual-use export control list in Annex I** updated (2024) [2].

The European Parliament defines **dual-use goods** as [3]:

"Dual-use products are goods designed for civilian use that in the wrong hands could be used to supress human rights or launch terrorist attacks. They can be anything from drones to chemicals. Although these goods can improve people's lives, they can be misused. Authoritarian regimes might use them to keep the population under control, while terrorist groups could use them to stage attacks."

It further states that Dual Use Regulation is required *"to prevent dual-use goods being repurposed in ways that violate human rights, the EU wants to make sure strict export rules prevent them being sold to people or organisations wanting to misuse them [3]."*

Export Control is defined as *"… restrictions on international trade in certain sensitive goods, software and technology"* [4]. Export control incorporates aspects of licensing requirements and prohibitions across the border and regulates tangible and intangible monitored items. The consequences of not having the correct exporting license include **revocation** of the current license, **seizure of goods**, and as this is equivalent to a **criminal offence**, the possibility of imprisonment [5].

Although this study focuses on the EU's Regulations, it should be noted that there are several other international regulations and treaties [6] governing dual use, such as the United States of America [7], United Nations [8], and South Africa [9]. There is also an increased awareness from research funders to ensure that universities understand the potential negative implications that their scientific outcomes might hold and this lead to several funders providing frameworks and require responsibile research practices from the recipients of their funding (such as the World Health Organisation (WHO), and the Stockholm International Peace Research Institute (SIPRI)) [10][11][12].

This study brings perspectives from universities obtained during interviews and reported concerns in literature on the implications of the Regulations. Compliance regulations will ultimately only achieve what they intend if those affected by them are indeed able to comply.

The **problem statement** for this study is that *in the absence of a framework for Compliance Strategies, universities subject to the EU Regulation 2021/821 are significantly exposed to non-compliance consequences, which could otherwise have been systematically identified, assessed, and mitigated.*

The discipline of Industrial Engineering (IE) is well-positioned to address the problem statement to develop a **Compliance Strategy Framework (CSF) for Dual-Use** due to IE's inherent focus on **systematic integration, process optimisation, and risk management**. We believe Industrial Engineers are uniquely positioned to design, implement, and sustain robust compliance mechanisms that account for the complexity of modern university research environments.

This relevance is particularly critical in the context of:

- **Increasing regulatory pressure** on universities to manage the risks of misue of reearch outputs.
- The growing prevalence of **interdisciplinary research**, where technologies developed for civilian use may have unintended military applications.
- The need for **process-driven, stakeholder-informed frameworks** that align operational practices with national and international export obligations.

For this study, the Key Objective is identified and is supported by the accompanying Sub-Objectives:

Key Objective:

Developing a framework for innovative compliance strategies for universities to improve compliance with dual-use regulations: *Developing a systematic strategy to handle the difficulties and needs of managing research and technology with both civilian and military uses is necessary to increase compliance with dual-use laws.*

Sub-Objectives:

1. Investigate the current scope of the EU export control regulations affecting universities.
2. Determine what universities should implement to comply with export control regulations, including the process for identifying and classifying sensitive dual use items.
3. Explore the existing frameworks or strategies aiming to address how EU universities manage security concerns related to the proliferation of weapons of mass destruction, which are utilised by universities to identify reoccurring themes and areas for improvement.
4. Identify gaps and challenges faced by universities to comply with the regulations.
5. Develop a CSF for Dual-Use outlining guidelines for effective implementation tailored to the needs of universities. Additionally, the effectiveness and feasibility of the proposed framework is evaluated within diverse university settings.
6. Device a validation strategy for the comprehensive framework.

At the time of this paper, Sub-Objectives 1-4 are completed, and Sub-Objective 5 has been initiated through a participatory process with stakeholders.

2 METHODOLOGY

The 7-Step Soft Systems Methodology (SSM), a systems engineering process (Figure 1), provides a pragmatic and structured approach to obtaining a solution to business, management or real-world problems [13]. The research methodology is briefly described:

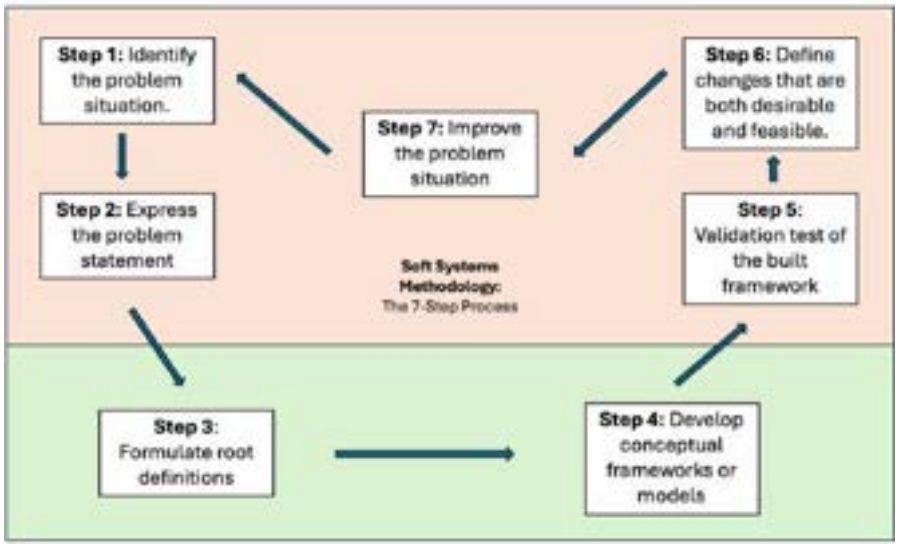

Figure 1: Soft Systems Methodology [13].

2.1 Step One: Identify the problem situation

This step comprises undertaking some preliminary research to find out more about the important prospective participants and identify any initial problems [13]. If university R&D outputs pose a security risk, or could be utilised maliciously, or involve research collaboration outside the EU region, then certain actions are subject to the Regulations. The rationale, however, is that universities are advised to use the regulatory framework as a measure of safety when exporting these dual-use items [14][15].

Through a literature review on EU Dual Use Regulation and the challenges experienced by universities, a narrative understanding of the problem was identified. From this, a comprehensive set of interview questions was developed, and two pilot interviews were conducted with dual use experts to ensure that the interview questions are fit for purpose. The required ethics clearance was obtained, and several universities were approached to participate in this study through interviews.

2.2 Step Two: Expressing the problem situation

This step comprises understanding the identified problem situation and expressing this in a problem statement which further incorporates multiple views and perspectives from various stakeholders to provide potential solutions. Universities are bound by Regulations that are ill-defined – citing the need to clarify the nuances of the Regulations' restrictions and ambiguous definitions [13].

Interviews were conducted with eight universities which follow or are subjected to the Regulations (Norway (1); United Kingdom (UK) (2); Belgium (2) and Netherlands (3)). Combining the interview results and the challenges identified from literature, the problem situation was identified and expressed.

2.3 Step Three: Formulate root definitions

This step comprises a problem statement that summarises the problem situation in a clearly defined, fundamental definition [13]. The root definition logically deduces tasks that adhere to the definition, which is supported through two systems engineering models, namely the Conceptual Model (creating fundamental definitions and establishing the foundation in a logical manner) and the CATWOE Model (an acronym that verifies the quality of knowledge within the root definition and deems it acceptable) [13]. Applying the CATWOE Model yields the following results, captured in Table 1 below.

Table 1: CATWOE Model [13]

	Definition	***Description***	***Application for this study.***
C	Customer	The end user of purposeful activities[4]	End users are academics, research compliance teams and the university as a legal entity.
A	Actors	Systems that enable transformation to occur.	Actors are ethic committees, compliance officers, legal advisors and research managers responsible for, or supporting the customer.
T	Transformation	Process of the purposeful activity.	Shifting the narrative from a reactive compliance approach towards a proactive and innovation-driven approach. A further narrative shift from bureaucratic process to that of preventing human rights violations is critical for the success of the compliance framework.
W	Weltanschauung	Considers the bigger picture and the influences thereof.	Balancing compliance with Regulations and academic freedom and collaborative innovation.
O	Owner	Catalysts or barriers within the system	Funding bodies, EU export control authorities who authorise licenses, and compliance teams within universities.
E	Environmental Constraints	Elements that exist within the environment.	The different interpretations per member state, uncertainty regarding responsibilities to ensure adherence and monitoring compliance as well as the lack of uniformed strategies for compliance.

As part of Steps Two and Three, further brainstorming sessions were held with six universities (UK (1); Belgium (2) and Netherlands (3)). The purpose of these sessions was to firstly, obtain input on potential conceptual models and secondly, address the GAP analysis to determine which areas of compliance are the most pressing for universities and researchers. This process aims to highlight areas of alignment in terms of existing compliance strategies and risk management approaches for dual-use items, which are currently available in the public domain.

2.4 Step Four & Five: Build and Compare conceptual models with the real world

These steps collectively, through validation and verification processes, evaluate whether the intended model framework, contrasts the perceptions of the real world. Discrepancies between what occurs, and the logical model raise the issues that will ultimately enforce change [13]. Through this phase, the process of developing the framework for Innovative Compliance Strategies commences. At the time of this paper, the conceptual models have not yet been fully developed. This paper report on the process leading to the potential conceptual model.

[4] Not to be confused with the definition of end-user in the EU dual use regulations.

2.5 Step Six: Define changes that are both desirable and feasible

This step comprises pragmatic techniques which require recommendations that are put into action. World views typically present themselves in such a way that improvements are made to problematic solutions. Views are required on what is considered to be the most desirable and feasible and offers a chance to reconsider various aspects of real-world activities [13].

2.6 Step Seven: Take action to improve the problem situation

During this step, an allocation of resources is made to determine the desired and feasible solutions. The broader, newer systems will be impacted; however, this poses opportunities for more development and possible improvement [13].

3 UNDERSTANNDING THE EU DUAL USE REGULATION

The Regulation 2021/821 incorporates provisions for technological adaptations to address the ever-evolving technological climate to safeguard against the possible risk without stifling innovation [16]. The core classification process within this regulation falls within its technical characteristics, as this enables the overall system to be robust but also challenging based on the objectives and specifications of the Regulations. This becomes especially important when managing emerging and/or abstract technologies and knowledge [17]. While this approach may prevent subjective approaches in the classification of dual-use items, it unfortunately places the responsibility of dual-use identification, classification and compliance in the hands of academics, universities and exporters who may have limited understanding of export control and compliance [18].

3.1 Regulatory Framework

The Regulations aimed to incorporate the evolution of emerging technology and technology governance and expanded their scope to consider not only the physical goods, but the intangible assets that have recently taken precedence in an R&D context [19]. Additionally, the Regulations consider the coordination of export controls, how licensing for the items displayed in Annex I are required as well as provisions for technical assistance [20].

The tiered approach to licensing has been cited by literature as the defining feature. Exporters and regulators are provided a coordinated approach in exporting certain items, particularly those dual use items not regulated by the regulatory framework, but items that are subjected to the ‘catch-all clauses’ based on risk assessments [21]. At most, these Regulations aim to address and mitigate the geopolitical aspect by lessening the disparities that may have otherwise been taken advantage of. Although member states have their discretion over the regulation applicable on a national level, these Regulations aim to collectively strengthen the sanctions, security and legislation placed towards potential threats such as the proliferation of weapons of mass destruction and cyber warfare [22].

Divided into ten categories, dual use items have been categorised according to a classification metric ranging from Category 0 (nuclear materials) to Category 9 (aerospace and propulsion), whereas items such as systems, software, and technology are categorised into detailed sub-categories. Each item is assigned a custom alphanumeric identifier that aligns with international export control regime (Wassenaar Arrangement). This metric, although standard, increases in complexity when considering intangible elements that can be classed under multiple categories - a system academics struggle to navigate [22]. Universities are providers of data, knowledge or expertise and other intangible items. As a result, a level of difficulty arises when deciphering whether activities or items are controlled, particularly when items are not clearly defined in the Annex I [14].

Risk response methods are the key drivers of the expansion of the Regulations. The export control regime (Wassenaar Arrangement) includes these intangible items in the definition and lists of dual use items. However, the absence of well-defined processes for identifying or managing such transfers makes the enforcement a challenge [23].

3.2 Research and Development Challenges

The integration of dual-use compliance remains an underdeveloped concept in academic research. Academics and universities historically operated under the assumption that research, more specifically, basic research, is exempt. Challenges in academia stem from the lack of awareness and perception of these Regulations on intangible items [24]. Concerns reported regarding limited awareness relate to [20][24]:

- Researchers remain unaware that their research (collaborations, publications, data transfers or technical assistance) may require an export license.
- Researchers remain unaware that their research involved controlled items.
- Researchers often view compliance as a violation to academic freedom.
- Researchers remain unaware that the regulation includes and is applicable to universities as well.

3.2.1 Internal Compliance Programs

I Internal compliance programs are essential for dealing with dual-use items, as well as shifting the narrative from passive compliance to proactive enforcement. It is mandated that organisations incorporate a risk-based system that includes compulsory training, protocols for classification, auditing procedures and reporting (documenting strategies) [2].

The EU identified seven core elements to an effective internal compliance guideline, namely [2]:

- Top Level Management Commitment to Consequences
- Organisational Structures, Responsibilities and Resources
- Training and Awareness Raising
- Transaction Screening Process and Procedures
- Performance Reviews and Reporting
- Record-keeping and Documenting
- Physical and Information Security

These elements provide a structured framework and approach to lowering potential non-compliance and add a layer to internalising the legal obligations. Despite the importance of adoption within institutions, universities underutilise these guidelines [2]. The main reason for this originates from many universities only recently incorporating the prospect of dual use compliance within their governance structures.

3.2.2 Technology Readiness Index and its Impact on Research

In R&D, different TRLs relate to the research and how this corresponds to export licensing. Lower TRLs (TRLs 1-2), are ideally considered basic research and not subjected to export controls, however, for TRLs higher than 3 (applied research), export licensing is required before potential publication and/or collaboration. This is particularly relevant for expected research outcomes where the border between civilian and military applications become progressively blurred and there is security relevance [24][25].

Universities are subjected to further limitations because of this regulatory rationale. A prime example of this is a drone imaging prototype or artificial intelligence (AI) surveillance. Although the original intended use remained scientific, due to certain technical thresholds and export, authorisation was required [25]. This reinforces the ideology that researchers, research offices, TT-teams and ethics committees are required to be aware when a project or activity oversteps the regulatory technical thresholds [24]. Initiatives funded by the EU have provided training and awareness; however, the reception and commitment thereof have become inconsistent. As such, many institutions lack the common guidelines for utilising the index to assess dual use items - an outlet for possible non-compliance in regulation [24].

4 TOWARDS AN INNOVATIVE COMPLIANCE STRATEGY

To ultimately achieve the key objective of developing a framework for innovative compliance strategies (ICS) for universities to improve compliance with the Regulations, it is crucial to identify and understand the problematic situation (addressing Step 1 of the SSM and addressing Sub-Objective 3). From the literature and interviews conducted, several concerns were raised, which serve as requirements for designing an ICS.

4.1 Problematic Areas and Concerns Raised through the Literature

The following areas were reported as the most pressing concerns:

4.1.1 Fragmented or Misinterpreted Regulatory Framework for Dual Use Items

The legal uncertainty and inconsistent interpretation of these Regulations across Member States were classified as a significant challenge faced by universities [15][26]. The lack of unity created a fragmented compliance landscape, where institutions were left uncertain on how to carefully view and implement obligations under the export control law. Many researchers, as a result, have a growing fear of research paralysis - driven by the inability to correctly understand the Regulations [24]. This, accompanied by the ambiguous nature of definitions, increased the risk of inadvertent noncompliance [26]. Examples highlighted in literature include technical assistance and physical export of knowledge. Despite revision, the definition of what constitutes dual-use items remains vague and incomplete, leaving room for interpretive inconsistencies. LERU identified the following points of concern:

- Dual use listing in Annex I is technically dense and not easily interpreted [26].
- The catch-all clause considerations is a residual mechanism to allow authorities to exert control over items which are not specifically listed in Annex I [15].

4.1.2 Compliance Risks and Lack of Internal Compliance Guidance and Tools

LERU highlights many challenges in the current Dual Use Regulatory framework that pose a risk to academic freedom [24]. Firstly, the most notable risk is the unclear roadmap to guide researchers in assessing compliance needs. This gap is compounded by insufficient training and supporting tools, despite the need for a ‘train-the-trainer’ approach. Secondly, increased requirements pose a threat to open access publishing [26]. National authorities often lack the resources or capacity to handle matters timeously. Lastly, universities face an increased due diligence obligation, particularly with growing geopolitical tensions and legal risks [26].

4.1.3 Issues related to European Union competences

Concerns were raised that the framework may infringe upon national sovereignty in education and research sectors where EU competences remain supporting or shared rather than exclusive [15]. These sensitivities are reflected by the UK’s decision against incorporation of the recast’s technical changes in the Regulations post Brexit - asserting regulatory independence in research governance [19].

4.1.4 Barriers to International Collaboration

The high demand for security practices in R&D reshapes the culture of academic freedom. Additional security measures are required to restrict information from being exchanged within research groups [26]. As a result, researchers hesitate to engage in international collaboration or findings that might later be deemed sensitive - especially in areas of study in AI, Quantum Physics and Computing, and Biotechnology [15].

4.1.5 Impact on Research Integrity and Academic Freedom

Inherent tensions between the goals of open science and security-based export control regulations are reported [15]. The inclusion of dual-use technology research within military applications raises the potential criticisms from non-government agencies [24].

4.2 Problematic Areas and Concerns Raised through the Interviews with Universities:

The following areas were reported as the most pressing concerns through the interviews conducted:

4.2.1 Lack of Awareness and Understanding in Academic Community

A widespread concern is the lack of awareness that persists amongst academic staff regarding the Regulations. Many academics assume these Regulations apply exclusively to military or high-risk technologies. Furthermore, these researchers also mistakenly believe that openly published knowledge is exempt from export controls, failing to recognise that intangible knowledge sharing (collaboration) can be regulated as technical assistance, which causes major compliance risks.

4.2.2 Complexity and Ambiguity of Regulations

The regulatory complexity is often difficult to navigate, even for staff well-trained in compliance. Researchers frequently struggle to identify whether their work classifies or falls within the scope of the control lists, as the definitions and descriptions used are vague and written with technical language that some universities are not familiar with. This challenge becomes further complex and ambiguous due to the evolving nature of the regulations. This creates a persistent fear of unintentional non-compliance.

4.2.3 Difficulty identifying dual-use items

For interdisciplinary fields such as AI, engineering, physics and life sciences, the growing concern is the difficulty in determining whether research outputs are subject to export control. The characteristics of dual use embedded within complex research topics make it harder to distinguish which elements are controlled or not. While some employ a compliance officer to assess these risks, the expectation that the individual should possess deep technical expertise across all disciplines is unfeasible. This challenge is particularly noticeable in the context of emerging technologies.

4.2.4 Limited institutional resources and expertise

The lack of resources with specialised expertise in export control (technical dimensions required for accurate assessments) is most noticeable across many universities. In institutions that have designated such roles, the responsibilities are often shared across research contracts, legal services, technology transfer officers, or ethics offices, limiting the capacity for focused export control compliance. Institutional investment in needed systems and tools for risk management and documentation remains insufficient, leaving many underprepared to manage obligations effectively.

4.2.5 Dispersed responsibility and gaps in accountability

There is significant ambiguity with regards to who holds responsibility for identifying and reporting controlled research. In practice, some universities rely heavily on researchers to flag potential dual-use concerns as compliance teams frequently lack the technical expertise to assist complex projects. Without clearly defined processes, critical export control steps are easily ignored.

4.2.6 Insufficient training and supporting mechanisms

Training within universities is often ad hoc and limited to brief sessions with minimal guidance. Online tools provided by government agencies have a core focus on industry use only, typically catering to companies with smaller technology scopes, making them unfeasible for use in an interdisciplinary context in academic research. Universities frequently lack accessible case studies or practical examples that could enable researchers to be more familiar with the complex Regulations and apply them to their own projects.

4.2.7 Challenges in international collaboration

International collaborative research especially in high-risk countries, has the greatest risk of non-compliance when considering intangible transfers and deemed exports classified under technical assistance. Universities often struggle to navigate and monitor the access that international collaborators have to sensitive data (cloud-based platforms, remote teaching or virtual connections). Many universities do not have formal processes in place to orderly vet international collaborators or students for export control risks.

4.2.8 Rise in Emerging Technologies

The pace at which technological innovation moves often outpaces the ability to update regulatory frameworks, especially in multidisciplinary fields such as AI, computing and biotechnology. There is a concern that Regulations lag innovation significantly, which results in a rather reactive policy approach than a proactive policy. Without a deep understanding of the technologies, regulators may impose overly broad controls that could potentially stifle innovation, particularly in fundamental research stages. As highlighted by a UK university, " *technological advancements cannot happen in a policy vacuum and policy without an understanding of that technology, will always overregulate. There, consequently, is a very high risk of stifling innovation or putting an end to that emerging technology completely. It thus becomes vitally important that policymakers are actively engaged with our academic community and industry as well, to fully understand how they enable innovation without stifling it and how does innovation and emerging technology develop."*

In conclusion, sections 4.1 and 4.2 above provide an understanding of the problematic situation and identify areas for improvement which would assist with the formulations of root definitions in Step Three.

5 DATA COLLECTION RESULTS

To effectively collect data to substantiate the premise of this study, Steps Four and Five of the SSM will be applied. As this a qualitative research study, the most applicable metric or tools to obtain data, is the interview process. Prior to obtaining ethical clearance, the interview questions have been formulated and tested through pilot interviews with experts in the field, to gauge the thoughts and views of the prospective participants. The objective behind performing this interview process, is derived by the adherence academic institutions have when complying to the Regulations.

5.1 Interview Questions

The interview questions aim to identify deficiencies and challenges faced whilst complying with the Regulations. Furthermore, it aims to provide a thorough understanding of the impact of these Regulations on operational practices at the institution. The interviews were thematically analysed and assisted in achieving a better understanding of the impact of these Regulations on universities.

5.2 Thematic Analysis

From the interviews, the following themes were identified and reported:

5.2.1 Challenges regarding Identification and Classification

Several challenges are faced by universities that relate to the identification and export control of dual-use items. The core issues are defined by the ambiguity of the Regulations, as dual use is not clearly defined. Intangible items, such as knowledge or software, direct the struggles institutions face when navigating the Regulations or determining whether a project falls within them. It is further complicated by the complex, yet vague use of technical language, leading to interpretation difficulties. The classification aspect is another cause for concern. The definition and what constitutes technical assistance have left many universities in an uncertain state, particularly those universities that are regarded as non-technical, as these institutions lack familiarity with the technical language needed to understand the Regulations.

Universities overall face numerous challenges in identifying and classifying dual-use items. As literature reports, there is a notable lack of clarity on acceptable regulatory practices and how to decipher limitations accordingly. This uncertainty is exacerbated due to the following two reasons:

- Insufficient education on the EU Regulations, which, upon evaluation, is accompanied by limited number of dual-use cases that are reported. This hinders opportunities for learning and development of best practices and internal expertise.
- Limited comprehension of the concept of Trusted Research, as referred to by the UK universities, and Knowledge Security by EU Member States.

The underlying fear of loss of funding due to non-compliance or reputational risk underpins the need for clearly defined regulations, alignment with the jurisdictional context as well as accessible educational resources. In an effort to manage and mitigate these challenges, some have developed internal policy documents (that are informed by national laws and frameworks) to offer support and guidance towards their research groups. Some Dutch universities have agreed to collaboratively work together to identify shared views and build towards a more consistent approach to compliance. These measures, however, are still fragmented, calling for a more unified and practical interpretation of the legislation.

Lastly, another challenge that causes significant inconsistencies is from the principles of open science, and the maturity levels of technology (in fundamental research). While transparent knowledge sharing methods are implemented, the increased concern for possible conflicts with the nature of the regulation exists. Some development has been made whereby universities have sought to online tools (designed to assist with the identification and classification process) to navigate compliance. National authorities are simultaneously operating as a supportive measure; however, the complexity of classification remains intact.

5.2.2 Safety by Design Approach

Universities are grappling with a crucial issue of awareness about Trusted Research (the commitment to uphold principles of integrity and transparency) and Knowledge Security (safeguarding research outputs), and the boundary between what gets regulated in

fundamental or applied research. Although fundamental research is technically exempt (case-by-case process), the research and technology may transition, although not intentionally, into applied research, being subjected to export control laws. The shift usually occurs unbeknownst to academics or researchers; however, institutions have reported that the Knowledge Security team proactively tries to offer support to streamline compliance more effectively for researchers. While legal limitations are not viewed as an initial barrier or boundary, the evident lack of awareness and forward-thinking risk assessments remains a cause for concern.

Most limitations are perceived as procedural hurdles (obtaining export authorisation). The ambiguous language used causes confusion and misinterpretation, especially involving the publication of research. Universities have reported that there is a clear lack of consistent reporting mechanisms, as participants are not included or a part of export control teams. Institutions recognise this flaw and aid towards the legal obligations of compliance with these Regulations despite the broadness of the Regulations. Evidently, there is a growing need for more precise guidance and support to navigate and manage the regulatory framework.

5.2.3 Associated Risks

Academic freedom is an important principle in universities. This, however, also comes with its inherent risks, such as the potential misuse of technology and research - a prime example includes the spread of misinformation from AI systems towards harmful purposes. Institutions, particularly those from the Norwegian region, suggest shifting the narrative from the compliance risks to the exporting risks. Institutions from Belgium, Netherlands and UK shift the narrative towards prohibiting human rights violations. Geopolitical tensions are the key drivers for this shift as international cooperation may be limited. Legal conditions do not largely hinder researchers; however, a significant concern is placed on the possibility of legal and reputational risk becoming more and more prominent. Collectively, universities share the consensus that academic freedom must be cautioned with academic responsibility but only when clearer information and guidance are provided to manage these issues effectively.

5.2.4 Enhancing Awareness

The importance of collaborative networks is emphasised by universities in our current climate. The European Association of Export Control (ECARO) is an organisation that aims to facilitate meaningful exchanges with other institutions to enable a better understanding of diverse institutional practices and challenges in navigating dual use compliance - an organisation that most universities have reported to be a part of. ECARO also encourages open communication with government agencies (although many have reported that the response from these agencies varies from quick responses to months). Many of the institutions believe that a one-size-fits-all policy approach is ineffective. Rather, universities aim for autonomy to tailor their compliance practices whilst receiving pragmatic guidance and rules.

As a consensus across universities that were involved in this study, the need for better clarity and communication, institutional and government support as well as awareness raising remains the greatest needs for universities at this stage.

6 CONCLUSION

Different member states have different views on challenges and principles, but there are also definitive areas where the general challenges are agreed upon. From these findings, we might identify learnings for Southern African universities as part of potential future work. At the time of this article, Steps One and Two of the SSM are concluded, as a problem definition is identified and formally composed. By leveraging industrial engineering principles such as systems thinking, control systems design, and continuous improvement, the proposed framework not only supports legal compliance but also fosters a culture of responsible innovation. It ensures that compliance is not reactive or fragmented but becomes a strategic

capability embedded within the university's research ecosystem. Ultimately, the intersection of dual-use compliance and operations within the university underpins the need for Industrial Engineering principles that not only enhances efficiency but also integrates legal, ethical, and strategic considerations, traits vital for designing systems that are both innovative and compliant.

7 ACKNOWLEDGEMENTS

This work is based on the research supported in part by the National Research Foundation of South Africa (Ref: TTK240320210060). We extend our sincere gratitude to the universities that participated in the interviews and generously shared their knowledge and expertise.

ABSTRACT

To predict future opportunities and risks, knowledge management necessitates the continual strengthening of organisational frameworks. Manufacturing performance metrics monitor and control operational efficacy, display the status of manufacturing operations, inspire improvement initiatives, and assess the efficacy of manufacturing decisions. This systematic literature review, conducted in accordance with PRISMA guidelines, aims to investigate how knowledge management and operations management are integrated in the manufacturing sector. The review focuses on how knowledge management enhances processes, affects operational effectiveness, productivity, and quality, and supports the establishment of key performance indicators for the manufacturing process. Combining knowledge management and operations management can transform manufacturing processes, supporting short-term operational targets and long-term strategic objectives in a market that is becoming more competitive and dynamic. There is limited consolidated research on how knowledge management and operations management are integrated to achieve manufacturing excellence across diverse contexts; therefore, future studies should concentrate on empirical studies to study their dynamic interaction.

Keywords: Knowledge management, Operations management, Process improvement, Manufacturing performance, Operational efficiency

* Corresponding Author

1 INTRODUCTION

Knowledge management (KM) is a set of practices that enables organisations to produce, preserve, share, and use knowledge [1]. It is the method by which businesses produce and apply their institutional or organisational expertise. KM uses several iterative procedures, some of which may be integrated and executed simultaneously [1]. It requires the ongoing and continuous reinforcement of organisational frameworks to forecast future possibilities and threats [2]. Businesses with strong KM practices and transfer capabilities are more innovative, productive, better at decision making, and attest to noticing increased productivity [3]. Figure 1 illustrates the KM process.

Figure 1: Knowledge Management Process [2]

Lyons et al. [4] found that creating KM ideas, plans, and procedures implemented across their organisation transformed the organisational perspective on knowledge. Figure 2 illustrates a methodical way for gathering, modifying, sharing, and repurposing knowledge, expertise, and awareness to improve company performance significantly and provide advantages to clients, staff, and the business.

Figure 2: Organisational view of knowledge by Lyons et.al., [4]

An organisation's ultimate purpose is to provide value to its clients, but what truly makes a corporation successful is developing, producing, evaluating, and eventually providing a product or service [5]. Senaji [5] further expressed that these labour processes work together

to create the organisation's operations, which is the ultimate purpose. Using and leveraging knowledge as a crucial competitive resource requires actions that support implementing the basic KM processes (acquisition, conversion, application, and preservation) [5]. Berawi and Woodhead [6] suggested a method that integrates KM, process evaluation, vision and mission planning, and production process management (managerial and technical elements) to meet production system performance goals.

Compared to non-manufacturing firms, manufacturing organisations typically find it easier to distinguish between operational and strategic knowledge [7]. Manufacturing performance indicators are widely used to track and manage operational effectiveness, show the state of manufacturing activities, motivate improvement projects, and evaluate the effectiveness of manufacturing choices [1]. Typical production key performance indicators (KPIs) include quality, delivery, time, cost, adaptability, and customer satisfaction [1].

There are several steps in a manufacturing process, all of which are necessary to produce a particular product [8]. This systematic literature review aims to investigate the integration of KM and operations management in the manufacturing industry. The focus is on how KM helps enhance manufacturing processes, affects operational effectiveness, productivity, and quality, and how it may be applied to establish key performance indicators for manufacturing. This study is significant in understanding the manufacturing sector as it requires a methodical approach to increase productivity and enhance production procedures.

The study aims to address the following research questions.

1. How does KM contribute to process improvement in the manufacturing industry?
2. What KM practices influence operational efficiency, productivity, and quality?
3. What KM tools are used to identify and develop key performance indicators related to manufacturing processes?

2 METHODOLOGY

A rigorous methodology was used to ensure transparency, replicability, and thoroughness in identifying, selecting, and synthesising relevant publications. The review defined strategies for searching publications, which included specifying the databases, keywords, and the inclusion and exclusion criteria to limit the publication to those relevant to the study [9].

2.1 Search strategy and keywords

The search strategy was developed by identifying keywords that sought to answer the research questions, and the keywords were then used to formulate search phrases. The phrases were constructed to produce a wide yet manageable set of publications that are related to the research topic [10]. The identified keywords were *Knowledge Management, Knowledge Management Practice, Knowledge Management Tools, Operations Management, Process Improvement, Manufacturing, Manufacturing Industry, Manufacturing Performance, Quality, Operational Efficiency, Productivity, and Manufacturing Key Performance Indicators.*

The search phrases were used in the Web of Science and Scopus databases. These databases were chosen due to their comprehensiveness, as they encompass a wide variety of indexed sources, disciplines, document types, and citations, which makes them suitable for this literature review [11]. To enhance the precision of the search results, proximity operators were used. The search query described below was used in Web of Science.

Knowledge Management NEAR Operations management *(Topic) or* ***Knowledge Management NEAR process improvement*** *(Topic) or* ***Knowledge Management NEAR Manufacturing*** *(Topic) or* ***Knowledge management practice NEAR operation efficiency*** *(Topic) or* ***Knowledge management practice NEAR productivity*** *(Topic) or* ***Knowledge management practice NEAR quality*** *(Topic) or* ***Knowledge Management tool NEAR key performance indicator***

(Topic) or ***Knowledge Management tool NEAR key performance indicator*** *(Topic) or* ***Manufacturing NEAR key performance indicator*** *(Topic)*

The following inclusion and exclusion criteria were used to refine the search further and assess the retrieved publications for relevance.

Inclusion criteria:

- Articles and review articles.
- Publications published between 2014 and 2024.
- Studies focusing on knowledge management practices, tools, and their impact on manufacturing processes.
- Studies that discuss the integration of knowledge management and operations management in the manufacturing industry.

Exclusion Criteria

- Publications that were not written in English.
- Publications that were not accessible.
- Publications that did not address the concepts of this study in their title, abstract, and full text.

2.2 Screening and selection

The review follows the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) guidelines. The PRISM 2020 flow diagram, shown in Figure 3**,** was used. The flow diagram includes identification, screening, and inclusion of studies via databases and registers [12]. After retrieving publications from the initial search, the inclusion and exclusion criteria were incorporated into the PRISMA diagram to screen and select eligible publications.

2.3 Methods of synthesis and analysis

To synthesise and analyse the data collected from each publication, a concept matrix was used to systematically scrutinise the data, allowing for a structured representation of the interrelationships between key themes and concepts. The publications were first categorised according to the themes, such as the influence of KM on manufacturing performance, the influence of KM on manufacturing process improvements, and the development and use of key performance indicators in manufacturing. Concepts were then created to align with the research questions and themes. A concept matrix analysing the coverage of the concepts described by each publication was developed as shown in Table 1.

3 LITERATURE REVIEW RESULTS

The literature search approach and review results are presented below. The results outline the database searches using PRISMA guidelines, the descriptive statistics of the selected articles, and insights on KM's influence on manufacturing process improvement and performance and on the development and use of key performance indicators.

3.1 Database and literature search

The initial search yielded a total of 1,250 articles. After applying the inclusion and exclusion criteria, the literature population was refined to a manageable set of 95 publications. After a full text screening, 32 publications were included for the review study. Figure 3 shows the screening and selection steps and results.

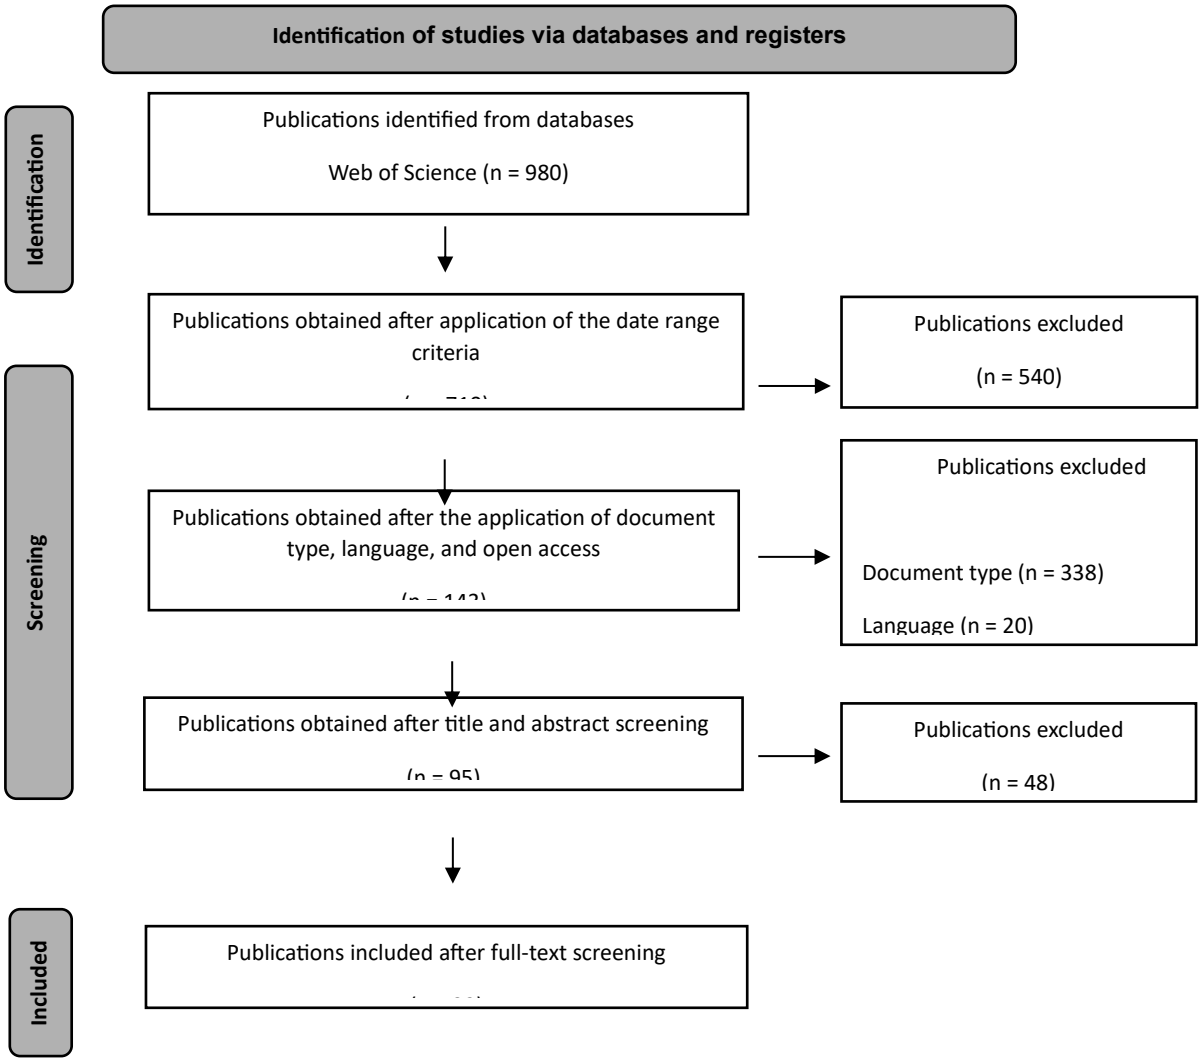

Figure 3: Screening and selection process and results

3.2 Descriptive statistics

Descriptive statistics were used to summarise key study characteristics to provide a clear overview of the results. An analysis was done to determine the distribution of selected articles based on the year of publication. Figure 4 shows the distribution of the year of publication of the selected publications. The distribution indicates yearly publications on KM in the manufacturing industry between 2014 and 2024, with peaks in 2017 and 2022. The growing momentum in adopting Industry 4.0 and increased focus on digital manufacturing may have contributed to the peak seen in 2017. The 2022 peak may be attributed to the post-pandemic acceleration of digital transformation, which further drove organisations to focus on knowledge-driven operational excellence. The field of study analysis for the reviewed publications was done as shown in Figure 5. It was seen that 75% of the reviewed articles are in the Engineering, Manufacturing, and Industrial Engineering fields, which are directly related to OM and manufacturing processes. The geographic focus of the studies shown in Figure 6 shows that most of the studies were published in the United States of America and England, with four publications each. It can also be seen that countries in the Asian continent have a cumulative high occurrence.

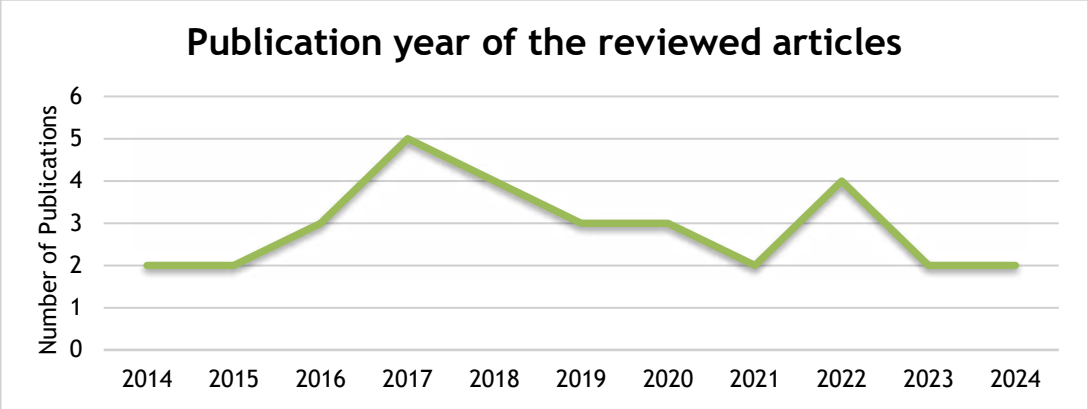

Figure 4:Year of publication of reviewed articles

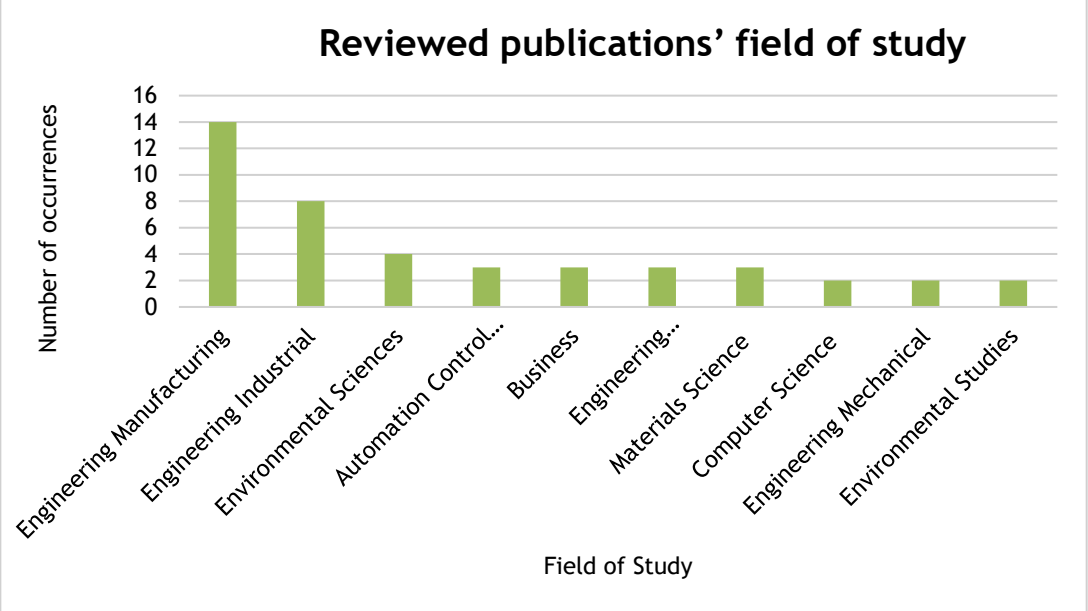

Figure 5: Reviewed publications' field of study

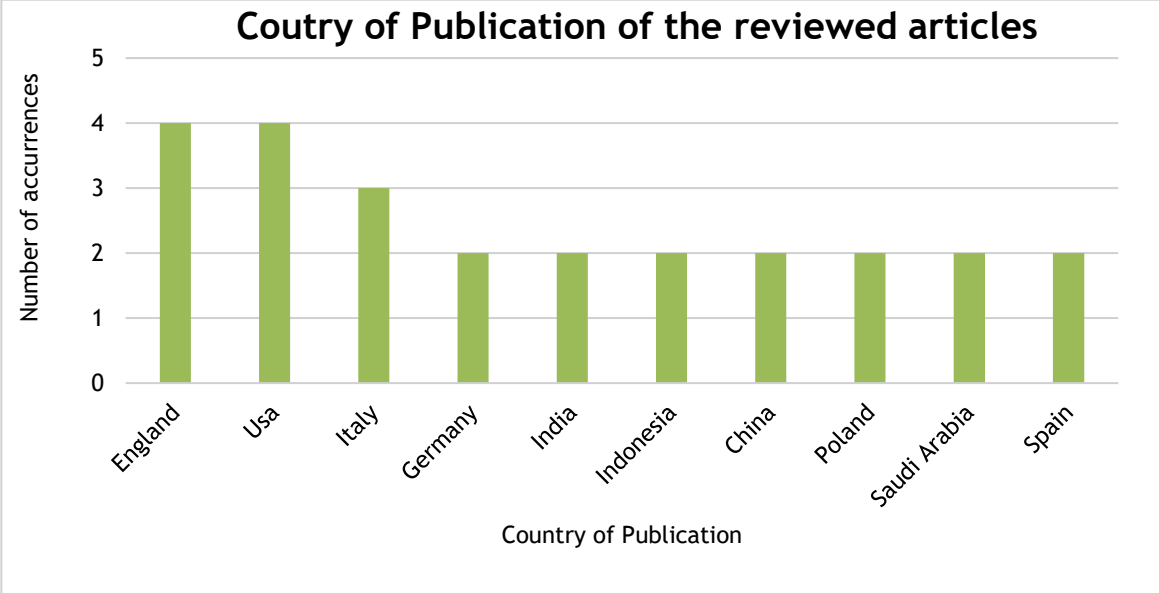

Figure 6: Geographic focus of reviewed articles

3.3 Influence of knowledge management on manufacturing process improvement

The concept matrix reveals that the successful implementation of KM initiatives often correlates with applying specific quality management tools and techniques. These tools and techniques can be directly linked to process improvement. This is supported by some of the findings shown in the author matrix presented in **Error! Reference source not found.**.

3.4 Influence of knowledge management on manufacturing performance

The concept matrix in Table 1 shows that most articles address manufacturing performance in one way or another. There is a link between manufacturing performance and productivity, operational efficiency, and quality. This is supported by how some publications use productivity, operational efficiency, and quality as performance metrics. These concepts fit into the main topic of operations management. Manufacturing performance is realised because of operations management. The author matrix in Table 2 reinforces how KM significantly impacts process improvement by showcasing recurring themes and findings across various studies, illustrating the correlation between KM practices and enhanced operational performance in manufacturing.

3.5 The development and use of key performance indicators in manufacturing

The reviewed literature indicates a strong link between specific KM practices and enhanced operational efficiency. Istrate and Herghiligiu [29] emphasise the role of key performance indicators in measuring and improving manufacturing operations. Establishing a multi-level key performance indicator structure allows organisations to identify meaningful relationships between key performance indicators, facilitating targeted interventions for operational enhancement. The comprehensive framework proposed by Istrate and Herghiligiu [29] provides a valuable tool for manufacturing managers seeking to evaluate KM performance systematically. By integrating KM with operational metrics, organisations can better understand their performance and identify areas for improvement.

Table 2: Author matrix of the reviewed articles

Author(s)	Research approach	Main Objective	Main Findings	Limitations and recommendations
[13]	Case study	Develop a KM framework specifically for manufacturing SMEs	A KM framework that emphasises low resource use, cost-effectiveness, and usability, suitable for similar regulated environments	Broader applicability to larger organisations or less regulated sectors is not discussed
[14]	Quantitative study	Investigate the link between Green Technology Implementation (GTI) and KM in reducing manufacturing risk	Validated that GTI positively correlates with KM processes, which together contribute to minimising manufacturing risks	Capture a more comprehensive view of the GTI-KM relationship in different manufacturing contexts
[15]	Structural equation modelling technique	Examine the effects of primary TQM factors (OM, measurement, analysis, and KM) and strategy on the relationship between supportive TQM factors and organisational results	Found that supportive TQM factors enhance primary factors; strategy and primary factors collectively mediate the relationship between supportive factors	Future research could further investigate the role of each primary TQM factor individually
[16]	Analytical Hierarchy Process	Propose a set of KPIs to evaluate sustainable manufacturing performance in the cement industry	KPIs aimed at guiding the cement industry toward sustainable manufacturing, enhancing performance	Recommended KPIs are tailored to cement manufacturing and may need adaptation for other industries
[17]	Quantitative analysis	Investigate how KM practices predict process innovation in FMCG companies	KM practices positively influence process innovation	Study limited to FMCG companies in specific cities
[18]	Quantitative research	Examine the combined effect of KM and marketing innovation on the performance of manufacturing companies	KM directly and positively impacts manufacturing performance	Suggests focusing more on KM strategies to enhance firm performance
[19]	Case study	Explore the challenges SMEs face in adopting Industry 4.0, focusing on MES's role in data capture and process management	KPI framework that supports operational efficiency and enhanced operator engagement	Recommends transitioning from big data to smart data
[20]	Survey	Provide insights and recommendations for evolving KPIs to align with Industry 4.0, focusing on cyber-physical systems and the human role	Need for redefined KPIs to integrate human and intelligent automation; emphasises human-centred manufacturing	Suggests revision of KPI definitions to reflect collaboration between humans and intelligent systems better
[21]	Graph-based visual representations	Explore the analytic relationships between KPIs in manufacturing processes to improve performance strategies	Highlights the importance of understanding KPI interdependencies	Recommends developing interactive tools for visualising KPI relationships
[22]	Qualitative study	Facilitate knowledge capture and reuse in manufacturing by integrating CBR and PLM	Continuous Improvement Process approach to enhance KM on the shop floor, enabling better	Limited to specific KM techniques and technologies

Author(s)	Research approach	Main Objective	Main Findings	Limitations and recommendations
		technologies to support technicians in problem resolution	problem-solving during production	
[23]	Qualitative study	To bridge the gap between knowledge sources (government, academic, etc.) and manufacturing Micro, Small and Medium Enterprises (MSMEs) in India	Highlights the lack of awareness among MSMEs regarding key knowledge sources and emphasises mutual enrichment through knowledge exchange	Suggests further research to improve awareness and collaboration between MSMEs and knowledge-providing organisations
[24]	Empirical investigation	Designing a collaborative basis for KM that improves the integration of manufacturing data between design and engineering teams, including suppliers	Integrating internal and supplier-generated manufacturing data enhances design processes and improves quality through defect reduction	Discusses the need for more extensive empirical research in similar high-value, low-volume industries to validate the proposed framework
[25]	Case study	To provide a methodology for integrating, sharing, and updating domain-specific knowledge in smart manufacturing contexts	Lack of mechanisms for integrating data and knowledge as a primary barrier in manufacturing; proposes a structured methodology to improve knowledge management	Further exploration of specific mechanisms that can facilitate better integration of knowledge in various manufacturing applications
[26]	Literature review	To provide an overview of knowledge sharing in the product development process and review key concepts in manufacturing knowledge management	KM influences product development, emphasising future challenges and research directions in sharing manufacturing knowledge	The review may benefit from a more comprehensive analysis of case studies to illustrate the discussed concepts and approaches
[27]	Quantitative study	To explore the twin impacts of organisational innovation and organisational learning on the relationship between knowledge management and organisational performance	Organisational innovation and learning mediate the relationship between KM and organisational performance, with firm characteristics acting as moderators	Suggests further research to refine the framework and explore additional variables that could influence the observed relationships
[28]	Questionnaire	Investigate drivers and the role of knowledge management on manufacturing energy management maturity	Knowledge management practices are positively associated with environmental management maturity	Limited by the specific context of U.S. manufacturing, which potentially affects generalizability to other regions or industries
[29]	Bibliographical research	Improve the evaluation process of Knowledge Management Performance (KMP) in manufacturing organisations	KMP is vital in assessing goals, improvements, and competitive advantages	May require validation through empirical studies to ensure the framework's effectiveness across different manufacturing contexts
[30]	Analytical Hierarchy Process	Introduce a multi-level structure for the identification and analysis of KPIs and their	Defined and layered KPIs into basic KPIs, comprehensive KPIs, and supporting metrics; identified relationships	The complexity of manufacturing systems may limit the ability to capture all interdependencies among

Author(s)	Research approach	Main Objective	Main Findings	Limitations and recommendations
		intrinsic relationships in production systems	and dependencies between KPIs for continuous improvement	KPIs in practical applications fully
[31]	Discrete-event simulation model	Quantify the impact on productivity, quality, and material supply from implementing inspection processes in multistage production lines	The simulation model can evaluate productivity and quality in two manufacturing scenarios, and provides a method for cost-effectiveness analysis	The complexity of accurately modelling all inspection strategies and production variability may limit the model's applicability in diverse scenarios
[32]	Literature review	Propose a methodology for the integration between KM and World Class Manufacturing (WCM)	Identified a lack of theoretical interaction between KM and WCM; most literature focuses on broad conceptual aspects and basic tools without current context	Limited by the focus on theoretical and conceptual aspects, potentially lacking practical applications or empirical validation
[33]	Survey questionnaire	To identify patterns of company activities in KM and their relationship with manufacturing processes in the metal industry	Revealing a significant difference between large and medium-sized enterprises regarding the perception of KM's importance for sustainable development	Limited to the Polish metal industry, which may not reflect practices in other sectors or regions; potential biases in self-reported data
[34]	Case study	To translate five generic KPIs into a continuous real-time cost function in a batch order-based manufacturing environment	Created a dynamic financial cost model integrating operations management data with performance metrics, facilitating collective decision-making across departments	Focused on specific industries, which may limit applicability; the complexity of integrating diverse data sources can pose challenges for implementation
[35]	Modelling	To provide an overview of quality techniques and methods within the manufacturing process to enhance productivity, quality, and cost efficiency	Proposes deployment methods for standard quality techniques to improve KPIs.	The application of quality techniques may vary across different manufacturing contexts, which could affect generalizability
[36]	Survey-based methodology using Structural Equation Modelling	To explore the relationship between KM, product/process innovation, and operational performance in sports manufacturing firms in Thailand	Significant positive influence of KM on both product and process innovation; process innovation positively impacts operational efficiency, while product innovation does not significantly influence it	The focus on sports manufacturing firms in Thailand may limit the applicability of findings to other sectors or geographical contexts, and there may be potential biases in survey responses
[37]	Case study	To improve customer satisfaction by developing and testing a method to study quality management systems through key performance indicators of the balanced scorecard	Results revealed a new understanding of quality management systems, aiding in systemic and strategic decisions to enhance long-term company performance	Limited to one leading manufacturing company; findings may not be generalisable across different organisations or sectors

Author(s)	Research approach	Main Objective	Main Findings	Limitations and recommendations
[38]	Four-step	To provide guidelines for manufacturing companies to identify energy waste and improve energy productivity	The proposed approach allows companies to increase energy productivity without negatively affecting existing manufacturing structures	The study may not account for variations in manufacturing processes across different industries, which could affect the generalizability of the findings
[39]	Literature and report review	To explore cognitive technology applications in smart manufacturing and their potential benefits for manufacturers	Cognitive manufacturing merges sensor-based information and analytics to enhance KM and improve key business metrics such as productivity, reliability, quality, safety, and yield while reducing downtime and costs	The study primarily relies on existing literature and reports, which may not capture all nuances of technology adoption in diverse manufacturing settings
[40]	Four-step approach	To propose a method for implementing KPIs to assess manufacturing process effectiveness and improve productivity	Identify causes for not reaching targeted KPI values, and recommendations are made to enhance manufacturing productivity based on these insights	The focus on specific KPIs may overlook other relevant factors affecting manufacturing process effectiveness, limiting a comprehensive evaluation
[41]	Questionnaire	To understand and evaluate the knowledge sharing culture at Polman Astra to improve the product prototyping process	A culture of knowledge sharing is essential for effective KM and preventing knowledge loss in product prototyping projects	The sample size is relatively small (44 out of 80), which may affect the reliability of the findings and limit the generalizability of the results
[42]	Qualitative research	To explore KM insights specific to Indian manufacturing SMEs and provide managerial implications	Key driving factors for effective KM include market orientation, learning from consultants, attending conferences/workshops, extensive internet use, and frequent employee interactions	The study's focus on Indian SMEs may limit the applicability of findings to larger organisations or different cultural contexts
[43]	Literature review	To introduce enabling indicators that can be analysed or assessed during the early phases of product and manufacturing system development, emphasising the importance of KPIs throughout the life cycle of the manufacturing system	KPIs are critical in manufacturing operations and product development phases. It highlights the alignment of KPIs (Quality, Delivery, etc.)	Further exploration into the practical applications of these enabling indicators across different industries and their impact on operational efficiency could be beneficial
[44].	Survey	To highlight the specific operational performance evaluation needs of the process industry and	Existing KPIs may require modifications to better suit the operational	Further research into the practical implementation of the proposed KPI modifications across

Author(s)	Research approach	Main Objective	Main Findings	Limitations and recommendations
		propose modifications to the KPIs defined in ISO 22400	context of the process industry	various process industries to validate their effectiveness in enhancing performance evaluation

4 DISCUSSIONS

The integration of knowledge management and operations management has gathered significant attention in literature studies, particularly regarding its potential to enhance process improvement, operational efficiency, and overall manufacturing performance. The following discussion explores this integration in detail, focusing on how knowledge management contributes to process improvement, how it influences operational efficiency and quality and how it supports the identification of key performance indicators.

4.1 How does Knowledge Management contribute to process improvement in the manufacturing industry?

Based on the insights gathered from the studies reviewed, some knowledge management practices were identified as directly impacting process improvement in the manufacturing industry. These practices include the systematic gathering and sharing of knowledge. Camarillo et al. [22] demonstrated how knowledge management practices, such as case-based reasoning and product life cycle management, can be used to fast-track problem solving in day-to-day manufacturing processes on the shop floor. These insights show manufacturing organisations can improve decision-making and streamline operations by leveraging historical knowledge.

Integrating knowledge management in manufacturing processes is essential, as it significantly contributes to reducing defects and improving quality by fostering a culture of shared learning and innovation. Prusak et al. [33] discuss the collaborative nature of knowledge management in the aerospace manufacturing sector. They emphasise the need for continuous knowledge capturing between the design and operations teams, which also ensures process improvement by sharing operations knowledge with the design teams, enhancing innovation, and sharing design knowledge with the operations team, which improves operational performance. This is supported by Souri et al. [24], who highlighted the complexity of integrating manufacturing data within workflows, necessitating a structured knowledge management framework to enable effective team collaboration.

Feng et. al. [25] and Saengchai et al. [35] discussed various quality methods that enhance knowledge management practices in the manufacturing process. These articles suggest that the proactive use of quality techniques can significantly reduce operational inefficiencies and defects, thereby contributing to overall process improvement. Based on the insights gathered from the articles and the concept matrix, it can be said that the successful implementation of knowledge management practice, tools, and techniques often goes hand in hand with applying specific quality management tools and techniques.

4.2 What knowledge management practices influence operational efficiency, productivity, and quality?

From the general insight across most of the publications, it was found that operational efficiency, productivity, and quality are often identified as factors that influence process improvement. Alanazi [15] highlights the importance of organisational learning and innovation as mediators in the relationship between knowledge management and organisational performance. The findings from these studies indicate that companies that prioritise

knowledge management practices, such as knowledge sharing and continuous learning, often exhibit higher levels of productivity and quality. This suggests that organisations should adopt a holistic approach to knowledge management, integrating it into their strategic objectives and operational processes. Psarommatis et al. [34] highlighted that translating key performance indicators into a real-time cost function enables organisations to make informed decisions that enhance efficiency and quality.

4.3 What knowledge management tools are used to identify and develop key performance indicators related to manufacturing processes?

The reviewed literature showed a range of knowledge management tools and frameworks used to develop and monitor key performance indicators in manufacturing processes. Martinez and Ahmad [31] introduce discrete-event simulation models as a tool for quantifying the impact of inspection processes on productivity and quality. This model exemplifies how simulation can serve as a KM tool that facilitates the identification of KPIs and helps organisations visualise and analyse the interdependencies among various operational metrics.

Mendes and de Mattos [32] highlight the necessity for an integrated methodology that combines knowledge management and World Class Manufacturing (WCM) principles. This approach emphasises the importance of using knowledge management tools, such as Total Quality Management (TQM) and Just-in-Time (JIT) practices, to establish effective key performance indicators that align with manufacturing objectives. The findings suggest that organisations must proactively adopt knowledge management tools that foster real-time monitoring and feedback mechanisms for continuous improvement.

5 CONCLUSION AND LIMITATIONS

This systematic review explored the integration of KM with operations management in the manufacturing industry, focusing on how KM practices contribute to process improvement, efficiency, productivity, and quality. The findings highlight that KM is a pivotal driver for manufacturing excellence, allowing organisations to harness collective knowledge, optimise production processes, and enhance competitive advantages through continuous improvement and innovation.

By synthesising research across diverse manufacturing contexts, this study affirms that effective KM practices, particularly those enabling knowledge sharing, real-time monitoring, and structured data management, positively influence operational performance. The review also identified critical tools and methodologies, such as key performance indicators (quality, delivery, time, cost, adaptability, and customer satisfaction) and collaborative knowledge-sharing platforms, essential for translating KM initiatives into tangible operational outcomes. Further, it underscores the strategic role of KM in supporting sustainable practices and quality management, aligning well with modern demands for environmental responsibility and resource optimisation.

It is concluded from the review that KM, when strategically integrated with operations management, can significantly enhance manufacturing performance, fostering a culture of learning, collaboration, and innovation. For managers, this insight emphasises the need to align KM initiatives with specific operational targets and adapt them to the unique context of their organisation. Future research should continue to explore KM's evolving role within emerging manufacturing paradigms, focusing on scalability, cross-industry applicability, and digital integration. By addressing these areas, KM can be further refined as a tool for operational excellence and sustainable and adaptive manufacturing in an increasingly competitive global landscape.

While the review process was methodologically robust, some limitations were inherent to the chosen design and approach. First, excluding non-English articles may have inadvertently

omitted relevant research from non-English-speaking regions where KM and operations management practices might differ, potentially limiting the global applicability of the findings. Additionally, while comprehensive, the review's reliance on digital databases may have missed relevant studies outside of indexed journals, such as industry reports or white papers, that could provide valuable insights into practical KM applications in operations management settings. Another limitation stems from the variability in study designs and outcome measures, which posed challenges in synthesising findings consistently.

COULD INDUSTRIAL ENGINEERING BE SOUTH AFRICA'S KNIGHT IN SHINING ARMOUR?

S. Grobbelaar[1*]

[1]Department of Engineering and Technology Management,
University of Pretoria, South Africa
schalk.grobbelaar@up.ac.za

ABSTRACT

South Africa's economic competitiveness per capita has been decreasing in recent decades. The National Development Plan (NDP) 2030 aims to eliminate poverty and reduce inequality. On both these fronts, South Africa has not experienced improvements. The NDP recognised the potential of South Africa but acknowledged that it was a damsel in distress. Industrial Engineering aims to improve integrated socio-technical systems using engineering and social science knowledge. The theory of constraints (TOC) forms part of the knowledge domains of Industrial Engineering. A key feature of the TOC is that it simplifies the process of continuous improvement by arguing for a clear goal, necessary conditions and relevant measurements. The TOC has been extensively applied to companies, but is it possible to apply it to a country? This study used document analysis and descriptive statistics to evaluate whether Industrial Engineering could be South Africa's hero to kickstart a wave of change.

Keywords: Economic Freedom, Theory of Constraints, Competitiveness, Prosperity

1 INTRODUCTION

Michael Porter [1] argued that national prosperity is created and sustained by offering the most productive environment for businesses to succeed and that countries compete to develop and maintain such environments. He further explained that competitive advantage is created, not inherited. It is not achieved through access to natural resources, abundant cheap labour, plentiful land, favourable interest rates, or currency values, but rather through sustained innovation and firms' ability to continuously improve and upgrade. To enable this, a nation requires skilled labour, sophisticated and demanding local customers, internationally competitive related and supporting industries, and strong local rivalry among similar firms.

Acemoglu and Robinson [2] provide an extension of the Endogenous [3], [4] and Schumpeterian [5], [6] Growth Theories and argue that innovation, education, and entrepreneurship translate into national prosperity when embedded within inclusive economic and political institutions. These institutions uphold the rule of law, ensure secure property rights, provide a level playing field, encourage competition, and offer broad access to economic opportunities. Thus creating incentives for investment, innovation, and sustained economic growth. They explicitly reject the notion that geography, culture, or ignorance (i.e., not knowing how to make nations prosper) are the primary reasons for poverty. In this respect, they align with Porter [1] in arguing that prosperity is not determined by inherited or static factors but rather by the institutional and systemic environment that shapes how economies function. Acemoglu and Robinson also emphasise that poverty often leads to national discontent when extractive institutions concentrate power and limit access to opportunity for the majority.

The South African National Development Plan (NDP) 2030 [7] provided a promise of active participation by citizens, a capable and developmental state, and collaborative leadership across society to enable inclusive economic growth, job creation and improved living standards where opportunity is determined by ability, education and hard work. The NDP is aligned with the Constitution of the Republic of South Africa [8] and specifically the objective included in the preamble: "*Improve the quality of life of all citizens and free the potential of each person*". However, it has been argued that South Africa fails to uphold the rule of law [9], and economic hardship and inequality promote discontent, identity-based polarisation and weakened institutions [10]. South Africa continues to grapple with systemic challenges, including ineffective service delivery, entrenched corruption, the legacy of state capture, administrative inefficiencies, and persistently high unemployment, poverty, and inequality [11]. These effects are typical of extractive institutions instead of inclusive institutions [2].

Jung [12] postulated that all humans share a collective unconscious, a deep psychological layer that contains archetypes (universal, inherited patterns of thought and behaviour). These archetypes often manifest in myths and fairy tales, enabling individuals to understand themselves, navigate moral development, and interpret complex societal realities.

A typical narrative structure features a character representing latent potential or value (the damsel in distress), a chaotic threat (the dragon), and a heroic figure (the knight in shining armour) who voluntarily confronts this chaos to restore order and meaning [13]. This paper explores whether this symbolic framework can be meaningfully applied to South Africa and whether Industrial Engineering can be conceptualised as an archetypal "hero" (a discipline capable of imposing order on disorder through systems thinking, optimisation, and innovation).

To pursue this inquiry, the study addresses three guiding research questions:

1. Can South Africa be interpreted as a symbolic "damsel" (a nation with untapped potential and latent value)?
2. Is the country facing a "dragon" (persistent social and economic chaos or dysfunction)?

3. Can Industrial Engineering be a modern "heroic" discipline capable of addressing systemic complexity and restoring order?

In the following section, the methodology for the study is briefly explained, after which each question is evaluated. Finally, the results are synthesised into conclusions and recommendations.

2 METHODOLOGY

The paper used two methods to evaluate the research questions:

1. Document analysis
2. Descriptive statistics

Including document analysis (qualitative) and descriptive statistics (empirical) improves the study's methodological validity. Document analysis offers contextual insights from reputable texts, while descriptive statistics provide measurable trends and international benchmarks. Together, they allow for an understanding of South Africa's socio-economic position.

2.1 Document analysis

Document analysis systematically reviews, interprets, and synthesises existing written materials to extract meaningful insights and evidence. This study used document analysis to extract, interpret, and integrate content from a wide range of authoritative global reports and indices.

These sources were interpreted to construct arguments about South Africa's latent value, systemic dysfunctions, and potential avenues for systemic improvement through Industrial Engineering. The metaphorical framing of South Africa as a "damsel" and its dysfunctions as a "dragon" is rooted in this interpretive synthesis.

Document analysis [14] can be a time- and cost-efficient research method, offering access to readily available data, especially from public records. It often provides precise details and broad historical coverage. However, typical limitations include a lack of depth, potential access issues, and biased selectivity, as some documents are not necessarily created for research purposes. Despite these drawbacks, the method remains valuable for qualitative studies, particularly when primary data collection is impractical.

2.2 Descriptive statistics

Descriptive statistics involve summarising and presenting quantitative data meaningfully to identify patterns, trends, and comparisons. This work used descriptive statistics to present, compare, and benchmark quantitative data across countries and periods. The objectives were to quantify South Africa's performance across a range of development, competitiveness, and well-being indicators, providing a clear and measurable understanding of the country's status in these domains. Additionally, descriptive statistics helped to illustrate important trends over time, such as the decline in GDP per capita, offering insight into the direction and pace of socio-economic change. They also facilitated benchmarking South Africa's performance against other countries, enabling comparisons that highlight relative strengths and weaknesses within a global context.

Descriptive statistics simplifies complex data, revealing patterns and trends and enabling benchmarking [15]. In this study, South Africa's development, competitiveness, and well-being indicators were used for contextual evaluation. However, these methods also have limitations. Descriptive statistics cannot establish causality, may oversimplify complex socio-economic realities, and depend on data quality and availability [16]. They often fail to capture underlying contextual factors influencing observed outcomes [17]. Despite these constraints,

descriptive statistics remain valuable for summarising large-scale data and supporting comparative analyses.

3 DISCUSSION

3.1 A nation with untapped potential and latent value

This section explores whether South Africa can be viewed as a symbolic "damsel" (a nation rich in untapped potential). Drawing on international indices and resource assessments, it examines how natural capital, nonrenewable wealth, and demographic strength position South Africa for transformative development if its latent assets are strategically mobilised within a scarcity-aware framework.

A paradigm of scarcity assumes that resources are finite and that their availability places practical limits on growth and development. Within this framework, the value of a nation is often evaluated based on its existing natural endowments (such as minerals, arable land, forests, and water) and its demographic profile, particularly the size and structure of its population. Rather than being inherently limiting, this view can be a pragmatic tool for identifying and quantifying a country's latent value and untapped potential [18].

From this perspective, a country's developmental opportunities are evaluated based on what is presently accessible and exploitable. For example, a country with vast underutilised forests, a young workforce, or unexploited mineral reserves may be seen as possessing significant strategic potential. Meadows et al. [19] argue that this type of analysis is essential to understanding how resource constraints shape future planning scenarios. In doing so, the scarcity paradigm helps policymakers and planners identify where investments or innovations are needed to unlock undeveloped capacity.

This approach objectively assesses national assets, mapping potential routes for resource management, infrastructure development, and population engagement decisions. Although grounded in the recognition of limits, the scarcity perspective can thus be applied not only to caution against overuse but also to spotlight areas where careful mobilisation of resources can yield transformative results.

The Natural Capital Index by SolAbility [20] assesses a country's environmental foundation for sustainable development. It measures the availability and condition of key natural assets (water, biodiversity, land, and climate) across 38 indicators in six clusters. High scores indicate strong potential for long-term self-sufficiency, even in countries with limited social or institutional capacity. By considering resource availability and degradation, the index highlights nations with unexploited ecological value, particularly those in tropical regions or with low population density, offering a lens to evaluate future competitiveness based on natural endowments. The report scored 191 countries, and South Africa was ranked 139th (Natural capital: 156th, Resource Intensity: 112th, Social capital: 186th, Intellectual capital: 76th, Economic Sustainability: 160th, and Governance: 93rd).

In the Changing Wealth of Nations 2024 report [21], the World Bank defines renewable natural capital as natural resources that can regenerate over time if managed sustainably. This category includes agricultural land (such as cropland and pasture), forests (valued for both timber and ecosystem services), mangroves, marine fisheries, and renewable energy sources like hydropower. These assets are distinct in their ability to replenish naturally and are valued based on a projected 100-year lifespan. The 2020 data included 151 countries and South Africa, on a per capita basis ranked 75th in total (Agricultural Land: 69th, Agricultural Land – Cropland: 65th, Agricultural Land – Pastureland: 78th, Fisheries 85th, Forest Recreation, Hunting and Fishing Services: 97th, Forest Water Ecosystem Services: 43rd, Hydropower Energy: 99th, Mangroves: 36th, Nonwood Forest Protection Ecosystem Services: 99th, and Timber: 30th.

The Changing Wealth of Nations 2024 [21] also defines nonrenewable natural capital as finite resources like fossil fuels and minerals that cannot regenerate within human timeframes. While valuable, these assets are exhaustible and subject to price and extraction risks. The report stresses that countries must reinvest extraction revenues into other forms of capital, such as infrastructure or education, to sustain wealth. Without such reinvestment, reliance on nonrenewables can lead to long-term declines in national wealth despite short-term economic gains. This highlights the importance of managing nonrenewable resources responsibly to ensure intergenerational sustainability. The 2020 data included 151 countries, and South Africa, on a per capita basis, ranked 22nd in total (Coal: 3rd, Copper: 36th, Gold: 16th, Iron Ore: 16th, Lead: 22nd, Nickel: 11th, Phosphate: 6th, Silver: 37th; Zinc: 17th; Metals and Mineralssub-Indextotal: 22nd). Apart from this, South Africa possesses a significant portion of the world's mineral reserves [22], including approximately 91% of global platinum-group metals (PGMs), 40% of manganese, and 35% of chromite. It also accounts for 16% of vanadium reserves, 13% of fluorspar, 10% of zirconium, and around 5% each of ilmenite and gold. In addition, the country holds notable reserves of andalusite, antimony, coal, iron ore, nickel, phosphate rock, uranium, and vermiculite.

The 2024 edition of the World Population Prospects represents the 28th official release of population estimates and forecasts produced by the United Nations Department of Economic and Social Affairs, Population Division [23]. According to the data from a sample of 237 countries, South Africa is the 24th most populous country, its average age is the 90th lowest, and when considering the core working age of 25 to 54, the country has the 21st most people in this age group.

Interpreting South Africa as a symbolic "damsel" is both apt and analytically grounded. Within the scarcity paradigm, the country's inherent value becomes visible through its considerable, albeit underutilised, reserves of natural capital (both renewable and nonrenewable). As highlighted by international indices, South Africa holds a wealth of ecological and mineral resources that remain only partially mobilised for sustainable development. Its position among the global leaders in mineral wealth and pockets of high-value renewable assets like timber and cropland suggests immense strategic potential.

Demographically, South Africa also holds latent value: with one of the largest core working-age populations globally and a relatively young median age, it stands at a demographic advantage. However, rankings on indices such as the Natural Capital Index suggest that institutional, environmental, or socio-economic factors constrain the full development of these assets.

The metaphor of the "damsel" thus captures South Africa's current posture, a nation rich in promise with unclaimed abundance waiting to be converted into sustainable national wealth.

3.2 Persistent social and economic chaos or dysfunction

One must assess multiple dimensions of national well-being and economic performance to determine whether South Africa faces a "dragon" (persistent social and economic chaos or dysfunction). This section draws on four authoritative global indices: the World Happiness Report, the Index of Economic Freedom, the IMD World Competitiveness Ranking, and GDP per capita data. These sources provide a multi-faceted view of South Africa's socio-economic health, institutional stability, and long-term competitiveness, enabling a holistic evaluation of systemic challenges and persistent dysfunctions.

The World Happiness Report [24] is a global study that ranks countries by how happy their citizens feel based on data from over 140 nations. Published annually by Oxford's Well-being Research Centre with global partners, it uses science to promote well-being. Launched in 2012 following Bhutan's UN initiative, the report aims to guide governments and individuals in

creating happier, healthier societies by making happiness a key measure of development. According to the report, South Africa ranked 95th overall (Social Support: 80th, GDP per capita: 79th, Freedom: 96th, Generosity: 121st, Perceptions of Corruption: 106th, Positive Emotions: 46th, Negative Emotions: 56th, Donated: 121st, Helped a stranger: 74th, Volunteered: 76th, and Inequality: 127th).

The Index of Economic Freedom [25] is an annual ranking by The Heritage Foundation that measures economic liberty in 184 countries. It evaluates 12 freedoms, including property rights and trade freedom, to assess how policies support prosperity. The Index promotes an understanding of how Economic Freedom fosters growth, individual empowerment, and opportunity, offering insight into the relationship between free markets and human prosperity globally. According to the report, South Africa ranked 103rd overall (Property Rights: 113th, Government Integrity: 75th, Judicial Effectiveness: 69th, Tax Burden: 151st, Government Spending 104th, Fiscal Health: 130th, Business Freedom 99th, Labour Freedom 10th, Monetary Freedom: 51st, Trade Freedom: 109th, Investment Freedom: 133rd, and Financial Freedom: 102nd).

The IMD World Competitiveness Ranking is an annual assessment that evaluates how well countries create conditions for long-term economic value and prosperity. Launched in 1989, it goes beyond GDP (Gross Domestic Product) by analysing political, social, and institutional factors that impact businesses. Using data and surveys, it benchmarks 67 global economies, helping governments and organisations understand and improve their competitive standing in a complex global landscape. According to the report, South Africa ranked 60th overall (Economic Performance: 61st, Government Efficiency: 61st, Business Efficiency: 48th, and Infrastructure: 60th).

GDP per capita (current US$) measures a country's average economic output or income per person by dividing total GDP by population [26]. It is expressed in current U.S. dollars and reflects the value of goods and services produced without adjusting for inflation. Used widely by policymakers and investors, it helps assess economic performance, compare countries, and guide policy decisions. Though it doesn't capture inequality, it remains a key indicator of economic well-being and national productivity. When evaluating the GDP per capita for South Africa from 1995 to 2023 (see Figure 1), one will notice that South Africa's GDP per capita has declined from a high in 2011 ($8 646 per capita) to 2023 ($6 023 per capita) and is currently sitting at a value similar to that of 2006 ($6 077 per capita). However, if one looks at South Africa's ranking (out of a sample of 214 countries), it has declined from 1995, 74th, to 2023, 112th. Thus, South Africa has not only seen a decline in GDP since 2011 but also lost competitiveness since 1995.

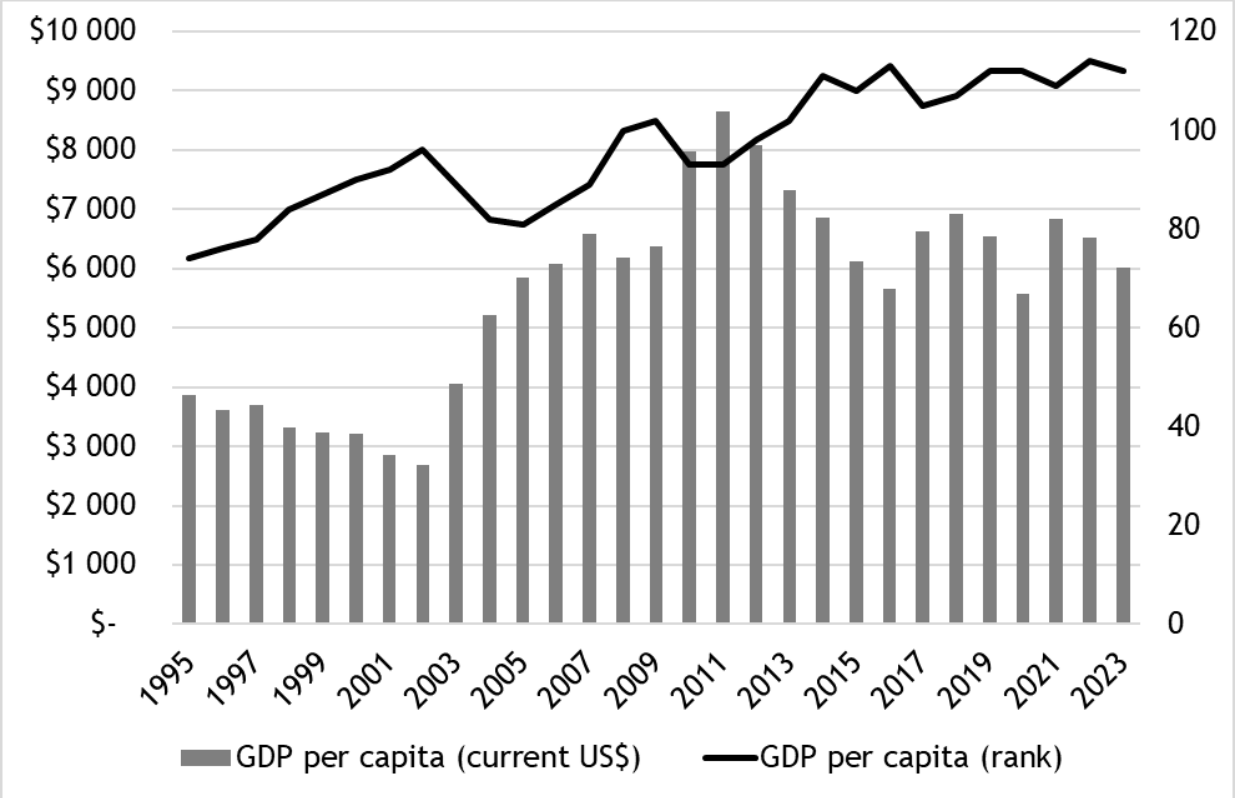

Figure 1: GDP per capita (current US$)

The data present a concerning picture of South Africa's socio-economic trajectory (declining GDP per capita, weakening competitiveness, middling Economic Freedom, and low rankings in happiness and social indicators), which points to underlying systemic issues. While the country maintains pockets of institutional and economic resilience, the cumulative evidence suggests it grapples with persistent dysfunctions marked by inequality, poor governance, and economic stagnation. These conditions align with the characteristics of a "dragon," signalling the need for structural reforms to restore long-term stability and prosperity.

3.3 Addressing systemic complexity and restoring order

This section explores how Industrial Engineering can confront systemic complexity and contribute to restoring order in socio-technical systems. Drawing on the Industrial and Systems Engineering Body of Knowledge (ISEBoK), the discipline integrates analytical, economic, operational, and design tools to manage complexity effectively. Applying principles such as the Theory of Constraints enables organisations to identify and overcome limiting factors in performance. Evidence from high-growth countries illustrates how systemic interventions, institutional reforms, and digital innovation can lead to significant national growth. These examples offer insight into how a modern, structured engineering discipline can address complex, real-world challenges at scale.

The Institute of Industrial and Systems Engineers (IISE) is a global nonprofit advancing industrial and systems engineering and has developed an Industrial and Systems Engineering Body of Knowledge (ISEBoK) [27]. Since 1948, it has supported professionals designing and improving complex systems and offers resources, training, and a professional network to help members solve critical problems with a systems-based approach. The industrial and systems engineering field combines engineering principles with knowledge from the sciences to optimise integrated systems of people, materials, and technology. The body of knowledge includes fourteen (14) knowledge areas:

1. Work Design & Measurement
2. Operations Research & Analysis
3. Engineering Economic Analysis
4. Facilities Engineering & Energy Management
5. Quality & Reliability Engineering
6. Ergonomics & Human Factors
7. Operations Engineering & Management
8. Supply Chain Management
9. Engineering Management
10. Safety
11. Information Engineering
12. Design and Manufacturing Engineering
13. Product Design & Development
14. System Design & Engineering

Knowledge areas of specific note to the context of this paper are:

- **Operations Research**, as defined by the IISE, applies mathematical and computational models to improve system efficiency and support decision-making. It spans areas like linear and nonlinear programming, dynamic programming, network optimisation, simulation, queuing theory, and decision analysis under risk and uncertainty. It equips engineers to solve complex problems across various industries with analytical and data-driven approaches.
- **Engineering Economic Analysis** helps industrial engineers assess the financial viability of engineering solutions. It covers value and utility, cost types, interest and cash flow analysis, decision-making under risk and uncertainty, public project evaluation, depreciation, taxes, and replacement analysis. The goal is to support sound economic decisions across engineering alternatives and complex operations.
- **Operations Engineering and Management** focuses on designing and analysing production and service systems to optimise efficiency and resource use. It encompasses planning, forecasting, scheduling, inventory control, capacity and maintenance management, and project execution. Ensuring operations meet customer needs effectively while tracking key performance metrics such as cost, quality, delivery, and productivity.
- **Supply Chain Management** involves coordinating materials, products, and services from origin to consumption. It includes strategic planning, logistics, supplier and customer relationships, risk management, reverse logistics, and network design. Ensuring efficiency, agility, and alignment with strategic goals to enhance value, reduce complexity, and improve overall supply chain performance.
- **Engineering Management** applies engineering principles to business operations, focusing on leadership, strategy, systems, and performance. Key areas include customer focus, teamwork, process improvement, human resources, ethics, project and strategic management. It supports innovation, organisational development, and performance monitoring across technical and business functions to enhance productivity, quality, and customer satisfaction.
- **Systems Design and Engineering** integrates diverse disciplines to develop effective, cohesive systems. It spans mission definition, requirements analysis, system architecture, verification, modelling, and lifecycle cost management. Delivering robust, user-focused systems through structured, repeatable processes and ongoing refinement.

Industrial Engineering is often associated with the Theory of Constraints (TOC) by Goldratt [28]. The central argument is that the primary objective of any business is to make money,

and all efforts should align with this goal. The story follows Alex Rogo, a plant manager, as he turns around an underperforming factory by focusing on improving throughput rather than efficiency. TOC asserts that every system has at least one constraint limiting its performance. To achieve the goal, organisations must identify and manage these constraints effectively.

The process begins by defining three key performance measures: throughput (sales revenue), inventory (tied-up capital), and operational expense (costs to generate throughput). The constraint (the bottleneck) can be identified by finding the slowest or most overloaded part of the system that limits output.

Goldratt outlines five focusing steps:

1. Identify the system's constraint,
2. Exploit the constraint by maximising its use,
3. Subordinate all other processes to support the constraint,
4. Elevate the constraint by investing in improvements, and
5. If the constraint shifts, repeat the process.

Ultimately, thinking is shifted from local efficiencies to holistic system optimisation, encouraging continuous improvement focused on what truly drives performance.

To evaluate whether other countries have been able to improve their competitiveness from 1995 to 2025, a benchmarking analysis was performed on countries that had a similar GDP per capita to South Africa in 1995. Four countries (Estonia, Latvia, Lithuania, and Romania) were used for this purpose. The results are indicated in Table 1, which illustrates that all four countries significantly improved their GDP per capita in absolute and relative terms. It is also worth noting that the four countries scored much better than South Africa in the 2025 Index of Economic Freedom.

Table 1: GDP per capita (current US$)

Country	GDP per capita 1995	GDP per capita 2010	GDP per capita 2023	Rank 1995	Rank 2010	Rank 2023	Index of Economic Freedom 2025
Estonia	$3 134	$14 664	$30 133	82	66	47	8
Lithuania	$2 183	$11 829	$27 786	99	74	49	16
Latvia	$2 257	$11 188	$22 503	97	77	56	24
Romania	$1 650	$8 400	$18 404	107	88	66	51
South Africa	$3 856	$7 973	$6 023	74	93	112	103

Estonia, Latvia, and Lithuania were part of the Soviet Union until its collapse in 1990, and they joined the European Union (EU) in 2004. Romania was not part of the Soviet Union and joined the European Union in 2007. The success of these countries against the failure of South Africa is stark, but the reasons for the difference are likely multi-faceted and complex and fall outside the scope of this study. However, the following is worth noting:

- To join the European Union, the countries were required to adopt values and norms typical of the EU states. For example, they had to manage and reduce corruption actively [29].
- Estonia's e-government strategy uses digital tools to streamline public services, cut bureaucracy, and boost competitiveness. Citizens can access nearly all services online via e-ID, saving time and public funds. E-residency and startup visas attract global

entrepreneurs. Estonia aims to deliver world-class digital services to most of its population to support a resilient and efficient society [30]. Similar initiatives in the private sector have enabled Estonia to become a digital leader [31].

- A study examining the EU's Structural, Cohesion, and Pre-accession Funds across 27 EU countries and the UK (1989–2020) shows that their impact on growth depends on institutional quality. Funds boost growth only where governance is strong (low corruption, strong rule of law, effective governments, and strong regulatory quality) [32].

The evidence suggests that South Africa's "throughput" is constrained by its relatively low level of Economic Freedom. This directly affects businesses' ability to operate, innovate, and expand, influencing job creation and productivity. From a TOC perspective, "inventory" represents latent economic capacity (capital, skills, and resources) that remain underutilised because policy and regulatory conditions inhibit deployment. Excessive regulatory requirements, inefficiencies in governance, and corruption raise the "operating expense" of doing business, reducing the net return on productive activity. By applying TOC's five focusing steps, the following overarching roadmap could likely increase South Africa's throughput:

1. Identify the system's constraint

Low Economic Freedom (weak property rights, excessive regulation, corruption, and restricted trade/investment policies).

2. Exploit the constraint by maximising its use

Maximise existing institutional capacity by streamlining current administrative processes, reducing unnecessary regulations, and enhancing transparency without large-scale reform (quick wins).

3. Subordinate all other processes to support the constraint

Align all national economic strategies, industrial policies, and public sector reforms to support improvements in Economic Freedom, ensuring that other development efforts don't bypass or ignore this constraint.

4. Elevate the constraint by investing in improvements

Strengthen judicial independence.

Ensure relentless accountability for corruption.

Affirm property rights.

Reduce barriers to trade and investment.

Simplify the tax regulations.

Digitise and automate administrative governance.

5. If the constraint shifts, repeat the process

Once Economic Freedom improves, new constraints will emerge (e.g., infrastructure, skills gaps). Reassess and address the following constraint to maintain momentum.

Through its systems-based and constraint-focused approach, Industrial Engineering offers powerful tools to address complexity and restore order. The success of countries like Estonia, Lithuania, Latvia, and Romania demonstrates how structured reforms, digital innovation, and institutional strengthening, aligned with Industrial Engineering principles, can drive national transformation. By focusing on constraints, enabling systemic

optimisation, and fostering continuous improvement, Industrial Engineering proves itself a modern, “heroic” discipline capable of tackling real-world challenges and enabling sustained progress.

4 CONCLUSION

This paper evaluated whether South Africa can be seen as a symbolic damsel (a nation of latent potential or value) facing a dragon (entrenched dysfunctions and persistent socio-economic chaos) and whether Industrial Engineering might be a modern hero capable of confronting systemic complexity and restoring order.

Through the appraisal of global indices, benchmarking data, and comparative case studies, the evidence suggests that South Africa possesses untapped value but is constrained by structural inefficiencies and institutional weaknesses that lead to economic decline. These indicators confirm the presence of a dragon that threatens the nation’s prosperity and resilience. However, the study also illustrates how Industrial Engineering, especially through systems thinking, constraint-based logic, and operations research, can offer powerful tools to foster an environment that promotes prosperity. In this symbolic narrative, the discipline emerges as a viable hero capable of restoring coherence, performance, and long-term value.

Limitations include the narrow country comparison group and the largely conceptual application of Industrial Engineering at a national scale. Further empirical work is needed to operationalise these methods in policy and governance contexts.

Future research should focus on developing actionable frameworks that adapt Industrial Engineering principles to public sector complexity. Such frameworks could establish a clear theoretical contribution by formalising the mechanisms through which Industrial Engineering can function as a national-level change agent. This could provide both a scholarly foundation for advancing Industrial Engineering theory in socio-technical macro-systems and practical guidance for policymakers seeking structured approaches to systemic reform. Future research may also deepen the statistical analysis by applying structured thematic or coding methods, complemented with comparative and visual analytics, to uncover cause–and–effect relationships and provide stronger evidence for observed trends. Case-based learning from reforming economies and interdisciplinary collaboration can also help create effective strategies for South Africa’s renewal and bring its “damsel” potential to life.

5 ACKNOWLEDGEMENT

The author acknowledges the use of OpenAI’s ChatGPT as a supportive tool during the development of this paper. ChatGPT was used to gather background information, brainstorm ideas, draft and refine sentences, and summarise content. The author critically reviewed, verified and integrated all outputs to ensure academic integrity and originality.

ABSTRACT

Blockchain technology has emerged as a transformative technique in supply chain operations, offering significant benefits for small and medium enterprises (SMEs). However, selecting and implementing blockchain solutions remains challenging. This article critically reviews existing literature to analyse blockchain's role in enhancing SME supply chains, focusing on its impact on efficiency, trust, and transparency, while addressing adoption barriers. Blockchain enables transparency, traceability, and fraud reduction, positioning SMEs for greater competitiveness in international trade. Despite these advantages, adoption is hindered by inter-organisational challenges, including cost constraints, limited technical expertise, and regulatory hurdles. This study provides actionable insights and strategies for researchers and industry stakeholders to overcome these barriers, ensuring SMEs can effectively harness the potential of blockchain technology.

Keywords: Blockchain Technology, Supply Chain, Transparency, Traceability, Adoption Barriers

* Corresponding Author

1 INTRODUCTION

In recent years, Blockchain Technology (BCT) research has gained significant global attention, particularly in domains such as banking and finance, supply chain and logistics, healthcare, the government sector, energy, and operations [1]. Initially conceptualised by Satoshi Nakamoto in 2008 and implemented in 2009, blockchain was introduced as the core technology underpinning Bitcoin [2]. Since then, it has evolved into a disruptive innovation with potential applications across various industries. Despite considerable attention in finance and large-scale enterprise supply chains [3], its adoption within Small and Medium-sized Enterprises (SMEs) remains comparatively limited [4]. Blockchain operates as a decentralised and immutable digital ledger that records transactions between parties securely, transparently, and tamper-proof [5]. It offers transformative advantages such as enhanced transparency, traceability, and accountability in supply chain operations [6], making it a compelling solution to address inefficiencies, fraud, and data integrity issues that frequently hinder traditional supply chains [7], [8]. While smart contracts, a self-executing agreement with terms written into code, enable automation and trust across distributed systems [9], SMEs often encounter substantial barriers to adoption. These include limited technical expertise, high implementation costs, regulatory concerns, and scalability challenges [10], [11], [12]. Consequently, a significant gap remains in understanding how SMEs, particularly in mining, agriculture, and manufacturing sectors, can integrate BCT into their operations. To address these gaps, this study aims to examine the application of BCT in SME supply chains, with particular emphasis on the mining sector. The research is guided by the following research questions (RQ):

RQ1: What are the benefits of adopting blockchain technology in SME supply chains, especially within the mining sector?

RQ2: What challenges hinder the adoption of blockchain technology in SME supply chains?

RQ3: How can SMEs implement blockchain technology to enhance their supply chain operations effectively?

By answering these questions, the study seeks to contribute to the growing discourse on digital transformation in SMEs and propose a structured framework for adopting blockchain technology in complex, resource-constrained environments. Current literature affirms blockchain's potential in enhancing cooperation transparency [13], optimising logistics through integration with the Internet of Things (IoT) [14] and improving export performance by streamlining processes and reducing intermediaries [15], [16]. Notable frameworks, such as Blockchain-Enabled and Event-Driven Tracking (BET), have been proposed for manufacturing environments [13]; however, their application to broader SME contexts remains limited. Moreover, sectors such as food, dairy, and specialised high-value industries such as jewellery and semiconductors remain underrepresented in implementation-focused studies [17], [18]. Although recent studies suggest that BCT adoption could significantly enhance SME competitiveness within global supply chains, there is still a lack of practical guidance on strategies to overcome the associated technological and organisational barriers [19], [20]. This highlights the need for a targeted approach involving stakeholder collaboration, phased implementation, and alignment with existing digital infrastructures [21], [22].

2 REVIEW METHOD

This study employed a systematic literature review (SLR) to investigate the application of BCT in SME supply chain operations. The review process focused primarily on indexed and peer-reviewed publications relevant to the RQs, to ensure quality and reliability [25]. A structured search strategy was adopted using combinations of keywords such as *"Blockchain Technology"*, *"SME Supply Chain"*, *"Small and Medium Enterprises"*, *"Blockchain in Logistics"*, and

"Blockchain in Operations". Searches were conducted within Scopus-indexed databases such as IEEE Xplore and ScienceDirect, as well as Web of Science for indexed sources, while Google Scholar and relevant conference proceedings served as sources for non-indexed materials. The search was limited to articles published between 2017 and 2025, reflecting the period in which blockchain adoption in supply chain contexts gained notable scholarly attention. Filters were applied to titles, abstracts, and keywords to ensure alignment with the RQs. The review followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines to ensure a transparent and replicable selection process [38] [40].

A rigorous selection process was employed to capture a broad range of perspectives on integrating blockchain technology within supply chain systems. In total, 70 publications were retrieved, 59 from indexed journals and 11 from non-indexed sources. Duplicate entries (n = 2) were removed, leaving 68 papers for initial screening. Screening was conducted based on relevance to the main theme, focus on blockchain in SME supply chain operations, and adherence to the search criteria. Ten papers were excluded, the reasons for the exclusion include: Not focusing on the main theme (n = 3); Not addressing blockchain in SME supply chain contexts (n = 3); Not meeting search criteria (n = 4). A total of 58 papers (53 indexed, 5 non-indexed) met the inclusion criteria and were critically analysed for content, methodological approaches, and key findings. The synthesis process involved thematic coding to identify trends, challenges, and research gaps within the literature. Particular attention was given to works that explicitly examined the interplay between blockchain and supply chain operations. The complete PRISMA flow in table format is presented in Table 1. The screening and selection process for the review is presented in Figure 1.

Table 1. PRISMA Summary of the Literature Selection Process

	Stage	Description	Count (n)
1	Identification	Time frame covered: 2017-2025	-
2	Identification	Records from Indexed Journals	59
3	Identification	Other Sources (Non-Indexed Journals)	11
4	Identification	Duplicates removed	2
5	Screening	Screened Journals	68
6	Screening	Excluded – Not focusing on main theme	3
7	Screening	Excluded - Not focusing on Blockchain in SMEs supply chain	3
8	Screening	Excluded – Not related to search criteria	4
9	Eligibility	Journals assessed for review (Indexed)	53
10	Eligibility	Journals assessed for review (Non-Indexed)	5
11	Included	Total Journals included	58

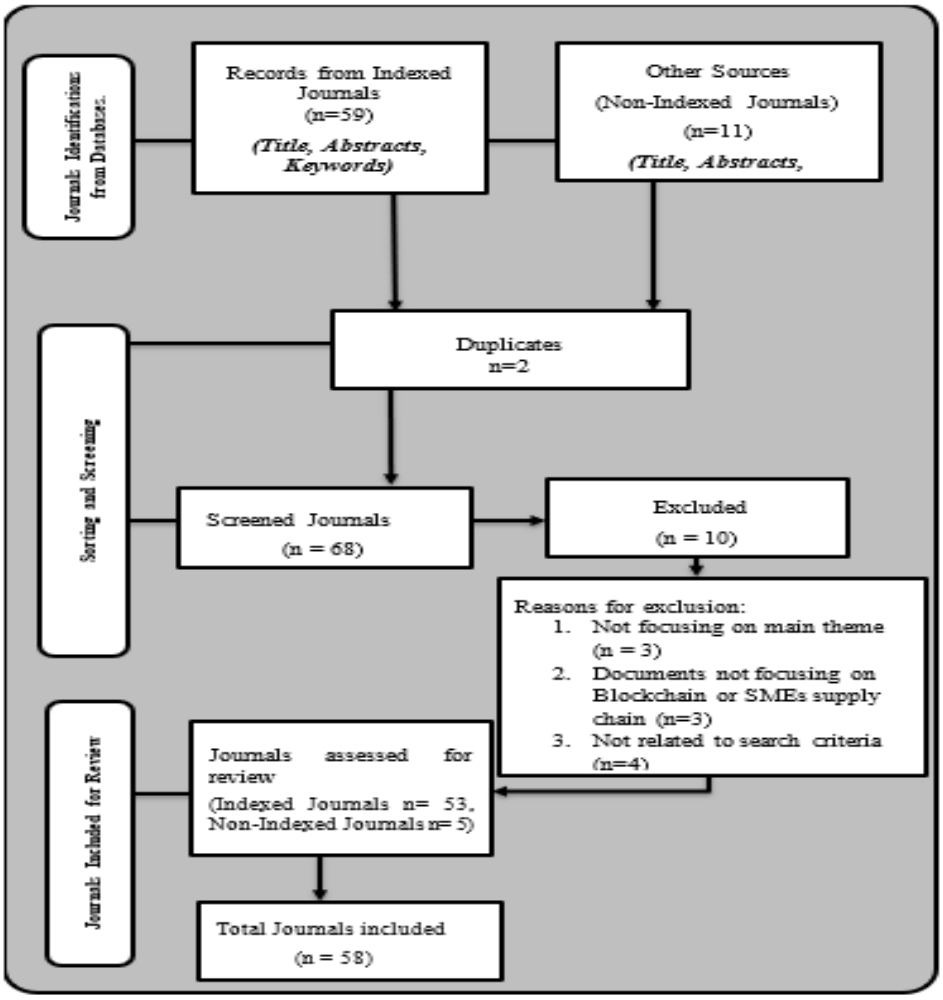

Figure 1: Screening and Selection Process for Literature Review (Authors Compilation)

To ensure the relevance and currency of the literature review, specific inclusion criteria were applied, focusing on studies published between 2017 and 2025. Figure 2 presents the distribution of the selected studies by year of publication.

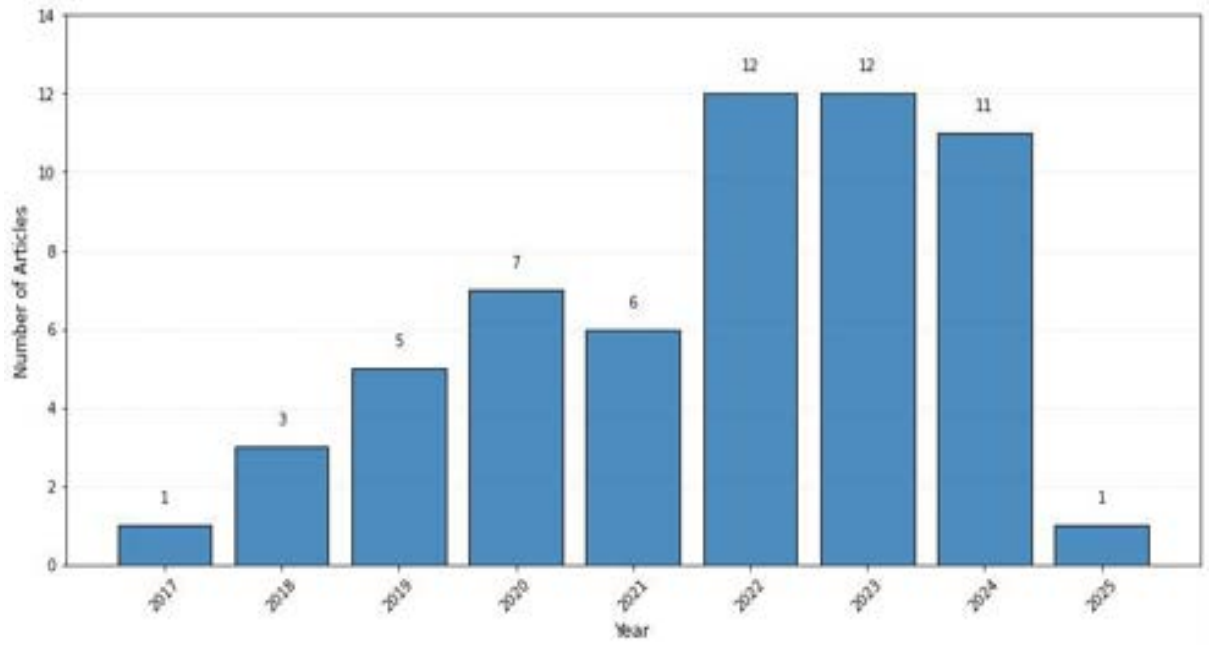

Figure 2: Number of articles and the concurrent years published

Another consideration in the journal selection process was aligning the research questions and the corresponding keywords. Table 2 presents a matrix that illustrates these relationships. RQ1 shows a broad association with multiple keywords, reflecting its comprehensive scope. RQ2 is linked to a more focused subset of keywords relevant to adoption challenges. RQ3 is aligned explicitly with keywords that target implementation strategies, addressing the core objectives of this study.

Table 2: Conceptual Matrix of Linking Keywords to Journals in BCT SMEs Supply Chain

#RQ	SMEs Supply Chain	BCT	Traceability	Transparency	Adoption Barrier & Challenges	Implementation
RQ1	X	X	X	X	x	X
RQ2	X	X	X	X	x	
RQ3	X	X			x	X
Ref.	[3], [6], [9], [10] [20]	[6], [7], [10] [11] [15], [27], [29], [31] [41]	[1], [9], [42] [43], [44], [45], [46], [47]	[3], [6], [19], [11], [21], [29], [30] [48]	[2], [14], [32], [36], [49], [50] [51], [52]	[4], [8], [19], [30], [33], [43], [53], [54]

3 RESULTS AND DISCUSSION

The SLR highlights a persistent gap in the practical implementation of BCT within SMEs. Although scholarly interest in BCT has grown, particularly within the supply chain context, real-world adoption remains limited across most industries. Transparency and traceability consistently emerge as the most promising attributes of BCT for enhancing supply chain operations. These features are widely recognised for their potential to optimise integration and improve accountability among supply chain stakeholders. However, a comprehensive and widely adopted framework for implementing BCT in SME supply chains is still absent. Notable contributions, such as those by [46] and [54], have proposed experimental frameworks, but their application in industrial practice remains constrained. Several barriers to adoption have

been identified in the literature, including high setup costs, high energy use for validating transactions, and limited technical skills in SMEs.

In addition, unclear regulations, poor system compatibility, and challenges in scaling up also limit wider use. Table 3 presents the research methods used in the reviewed studies, showing the growing academic interest in applying BCT in supply chains. A closer look at specific sectors reveals that while industries like mining have started exploring BCT, others, such as textiles, food, healthcare, automotive, and electronics, still show low levels of adoption. Although BCT is widely recognised for its potential to improve transparency and efficiency, its use remains uneven. This is mainly due to the lack of standard adoption frameworks and ongoing global and organisational challenges [14], [55].

3.1 Block Chain Integration in SMEs Supply chain

BCT is gaining increasing attention as a transformative solution for supply chain operations, particularly within SMEs [1]. [1] and [16] highlight its decentralised and tamper-proof nature, which enhances transparency and trust across supply chain networks. Furthermore, BCT supports secure collaboration among supply chain partners, which is especially valuable for resource-constrained SMEs [5]. In specific sectors such as mining, BCT plays a critical role in ensuring ethical sourcing by verifying the origin of minerals [42]. It also enables real-time tracking, fraud detection, and helps meet regulatory requirements, contributing to improved supply chain integrity [43]. Smart contracts, a self-executing agreement coded on the blockchain, further streamline operations by automating payment and order fulfilment processes, reducing errors and delays [44]. In addition, BCT improves visibility, traceability, and operational efficiency, while also helping to minimise counterfeiting and administrative burdens [45]. Despite these clear benefits, adoption among SMEs remains limited [58]. However, growing scholarly interest reflects recognition of BCT's potential to optimise supply

chain performance [59]. As shown in Table 4, blockchain-related technologies exhibit diverse capabilities that can accelerate transactions and support their application in SME supply chain operations.

Table 4: Related BCT application to SMEs Supply chain

Related Technologies in Blockchain	Key Aspect	Appli*+5cability in SMEs Supply Chain	Reference
Permissioned Blockchain	Restricted access with authorized participants; shared ledger for trusted data sharing	Enables traceability and compliance in /multi-party networks (e.g., vendor onboarding, product sourcing)	[2], [4], [33], [23]
Public Permissionless Blockchain	Open participation; decentralized validation via consensus mechanisms	Suitable for public verification of product authenticity (e.g., ethical sourcing claims).	[2], [4] , [33], [41]
Hybrid (Consortium) Blockchain	Partial decentralizati on with pre-approved nodes; balances control and trust	Facilitates collaborative platforms for SMEs in shared industries (e.g., logistics partnerships)	[33], [37] , [41]
Mining Algorithm	Secures transactions via computational work (e.g., Proof of Work)	Limited direct applicability; energy-efficient variants reduce operational costs for blockchain adoption	[15], [33], [41], [54]
Smart Contract	Self-executing code that automates workflows upon predefined conditions	Streamlines payments, compliance checks, and dispute resolution (e.g., automated invoice processing)	[16],[33], [56]
Zero-Knowledge Proof (ZKP)	Validates data authenticity without exposing sensitive details	Verifies certifications (e.g., organic/fair-trade labels) while protecting proprietary supplier data-85	[44]
Merkle Tree	Cryptographic data structure for efficient transaction verification.	Enhances auditability by enabling quick verification of supply chain records (e.g., batch integrity checks).	[44]

3.2 Blockchain Connectivity and Implementation Strategies in SME Supply Chains

Blockchain helps SMEs make better decisions by providing accurate, real-time information on inventory, shipments, demand forecasting, and transactions [32]. Partnering with technology providers or joining consortia can give SMEs access to shared systems and technical support [37]. However, for blockchain to be used effectively, it must be carefully planned and matched to specific business needs, such as improving traceability or reducing transaction costs [45].

Since blockchain improves connectivity by allowing real-time data sharing between supply chain partners [58], having a clear plan with defined steps and proper resource management is essential for successful adoption [59]. Consortium blockchain models are especially useful, as they allow multiple organisations to work together while keeping control of their own data [60].

Despite these benefits, blockchain adoption in SMEs remains limited, mainly due to high implementation costs and technical complexity. Table 5 outlines the main benefits, challenges, and strategies for successful blockchain use in SME supply chains.

Table 5: Benefits. Challenges and Implementation Strategies of BCT in SMEs' Supply Chain

Benefits of Blockchain in SMEs' Supply Chain	Challenges	Implementation Strategies
Enhanced transparency	High implementation costs	Strategic planning
Improved operational efficiency	Lack of technical expertise	Partnership development
Cost savings	Regulatory uncertainty	Employee training
Competitive advantage	Organizational resistance	Change management

3.3 Barriers and Drivers to Blockchain Adoption in SME Supply Chains

Adopting blockchain technology can yield substantial cost savings for SMEs by eliminating intermediaries and making operations more efficient. By reducing the need for third-party verification, blockchain lowers the expenses linked to traditional centralised systems [49], while real-time tracking helps reduce losses from theft or fraud, improving cost-effectiveness [5]. However, SMEs face several technological challenges in blockchain adoption. Connecting blockchain with current systems often needs advanced technical skills that many SMEs do not have [19]. Also, high implementation costs, limited technical expertise, and problems with scaling up are major obstacles [30]. Interoperability remains a major challenge, as different blockchain platforms often cannot work together smoothly. This limits data sharing and reduces the overall effectiveness of the technology [35]. Then, the high computing power and energy required by blockchain can be especially difficult for SMEs with limited resources [42]. Regulatory uncertainty also makes adoption more difficult, as differing standards across regions create compliance risks for businesses using blockchain. Resistance within organisations can also slow progress. Employees may be reluctant to accept new technologies because they fear job losses or do not understand the benefits of blockchain. To overcome this, managers should clearly explain the advantages of blockchain and involve staff in training programmes. Open communication and involving employees in the process can help build a culture of innovation and make the transition smoother.

Table 6 presents the key drivers and barriers influencing blockchain adoption in SMEs. Adoption is shaped by both internal and external drivers, while barriers can be categorised as intra-organisational, inter-organisational, and system-related challenges [32]. One major advantage of blockchain is its ability to enhance transparency, which fosters trust and customer loyalty, critical for SMEs operating in competitive markets. In sectors such as pharmaceuticals and food safety, blockchain ensures product authenticity and quality assurance across the supply chain [32], [34].

Table 6: BCT Drivers and Adoption Barriers to SMEs' Supply Chain.

DRIVERS FOR ADOPTION	ADOPTION BARRIERS	REFERENCE
Internal Drivers	**Intra-Organization Barriers**	
• Enhancement of SMEs Supply chain • Traceability • Transparency • Efficiency • Combat SMEs Fraud	• High Implementation Cost • Lack of Knowledge and expertise in BCT. • Transparency and Piracy confusion • Suitability Issues of the Technology	[17], [25], [28], [33], [41], [44]

• Reduction in Transactional & Operational cost		
External Drivers	**Intra-Organization Barriers**	
• Pressure from consumers • Pressure from buyers/suppliers and competitors • Pressure from regulators • Internet of Things.	• Lack of readiness on SMEs supply chain • Data input challenges • Lack of standards • Regulatory issues • Global adoption Issues	[3], [5], [8], [9], [34]
Systems Related Issues		
	• Scalability Issues • Enforcement, traceability and trust of smart contracts. • High cost of investment • High energy consumption • Breach in algorithm	[15], [34], [45]

3.4. Roadmap to Blockchain Implementation for Small and Medium Enterprises

As mentioned earlier, there is an increasing move towards consortium blockchains, where multiple organisations collaborate to share resources and lower costs. Drawing from the findings, a structured roadmap has been proposed to support SMEs in integrating blockchain technology into their supply chain operations. This roadmap, illustrated in Figure 3, outlines five critical stages: Assessment, Planning, Partnership and Integration, Training, and Monitoring. Successful implementation across these stages can enhance efficiency, transparency, and overall supply chain performance in SMEs.

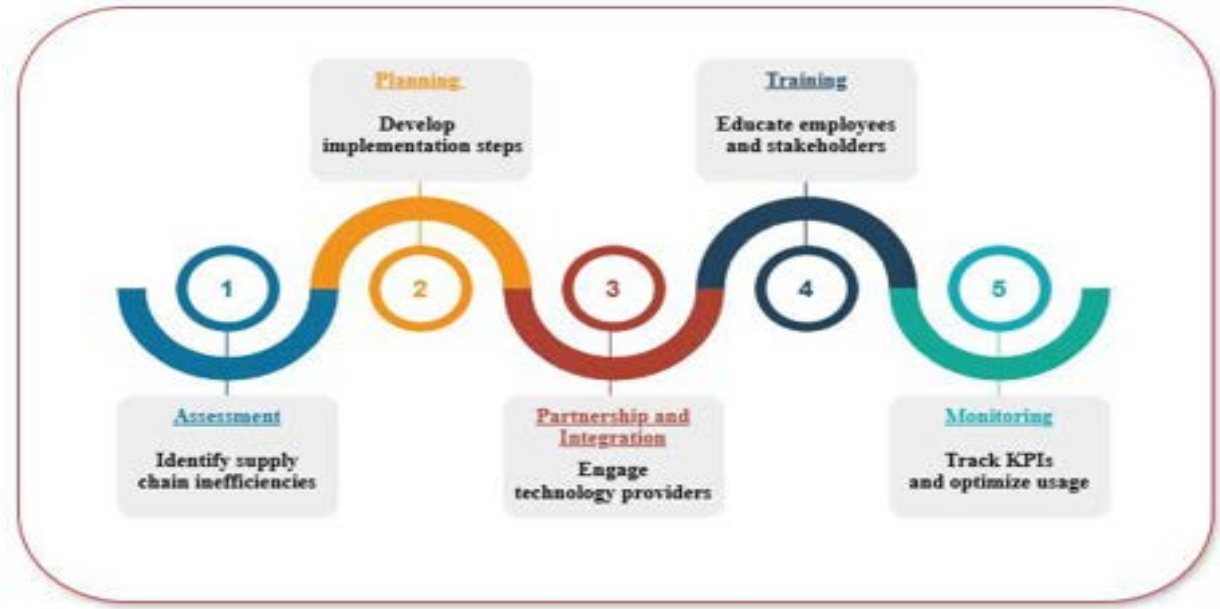

Figure 3: Recommended Roadmap for Blockchain Adoption by SMEs supply chain (Authors Compilation)

3.5 Summary of the Blockchain Integration Roadmap

The integration roadmap begins with an Assessment phase, where SMEs evaluate their current supply chain operations to identify inefficiencies and determine areas where BCT could add value. This includes analysing data flows, bottlenecks, and potential blockchain impact. Next is the Planning stage, which involves defining the project scope, identifying resource needs, and establishing a clear implementation timeline. A structured plan helps minimise disruptions during integration. The third stage, Partnership and Integration, focuses on collaborating with technology providers to ensure system compatibility, data integration, and tailored blockchain

solutions aligned with SME needs. Following integration, the Training stage equips employees and stakeholders with the skills required to operate the new system, covering technology fundamentals, system usage, and data management. Finally, the Monitoring stage involves tracking key performance indicators (KPIs), system updates, and ongoing optimisation. Continuous evaluation ensures the blockchain system remains effective and evolves with supply chain needs. Together, these five stages support a smooth and effective BCT adoption, enhancing SME supply chain transparency, efficiency, and long-term success.

4 CONCLUSION

This SLR examined the application of BCT within SME supply chain operations, synthesising findings from 58 peer-reviewed and indexed journal articles published between 2017 and 2025. Guided by structured inclusion criteria and the PRISMA framework, the study offers comprehensive insights addressing three core research questions. In RQ1, the study found that BCT is applicable to SMEs primarily through enhancing transparency, traceability, and operational efficiency. These benefits support improved decision-making and supply chain optimisation, although adoption remains limited. Addressing RQ2, the review identified key barriers to BCT adoption in SMEs, including high implementation costs, limited technical capacity, regulatory uncertainty, and interoperability issues. Nonetheless, it also highlighted critical enablers such as stakeholder collaboration, decentralised data sharing, and smart contracts as drivers of adoption. For RQ3, a five-stage implementation roadmap was proposed, covering assessment, planning, partnership and integration, training, and monitoring. This roadmap provides a structured approach for SMEs to adopt blockchain in a phased, strategic manner, minimising disruptions and maximising impact. Blockchain holds transformative potential for SMEs, offering fraud reduction, enhanced transparency, and increased competitiveness. Realising these benefits requires overcoming systemic and organisational barriers. Strategic planning, investment in capability development, and inclusive change management are essential to drive adoption. In conclusion, BCT represents a robust tool for SMEs aiming to enhance global supply chain performance. Stakeholders must act decisively to harness its benefits, fostering innovation, trust, and sustainable growth in an increasingly digital and interconnected business environment.

5 FUTURE RESEARCH RECOMMENDATIONS

To complement the findings of this study, future studies should incorporate empirical validation through surveys, interviews, and case studies of SME supply chain managers across industries and regions. Such approaches would provide grounded insights into how blockchain's opportunities and barriers manifest in practice, while also testing the effectiveness of proposed implementation roadmaps. Comparative studies between developed and emerging economies would further reveal contextual adoption dynamics. By combining systematic reviews with empirical investigations, future research efforts can generate actionable frameworks that enable SMEs to overcome barriers and fully harness blockchain for supply chain resilience, competitiveness, and sustainable growth.

ABSTRACT

This study introduces a fuzzy logic-based decision-making framework to evaluate digitalisation readiness among small and medium-sized enterprises (SMEs) in South Africa's mining sector. Using input from thirty (30) industry experts, the framework was implemented using MATLAB R2024a, to evaluate five key dimensions: Technological Infrastructure (TI), Human Skills and Training (HST), Operational Efficiency (OE), Organisational Culture (OC), and Financial Resources (FR). Converting qualitative survey data into quantitative readiness scores, the model provides a comprehensive view of digital maturity. Findings highlight Organisational Culture and Human Skills as key enablers of digital transformation, while moderate scores in technology, operations, and finance point to capacity and funding limitations. The framework offers strategic guidance for SMEs, policymakers, and industry leaders to drive effective and inclusive digital transformation in constrained environments.

Keywords: Digital Technology, Fuzzy Logic, Mining SMEs, MATLAB R2024a

1 INTRODUCTION

The global shift toward digitalisation is transforming the operational environment of industries, offering pathways to increased efficiency, competitiveness, and sustainability. While sectors such as manufacturing and logistics have made notable strides in digital adoption, the mining industry, particularly its small and medium-sized enterprises (SMEs), continues to lag. Mining SMEs often face unique challenges, including limited financial capacity, outdated infrastructure, low digital literacy, and a workforce unaccustomed to technology-driven change [1]. These constraints hinder their ability to embrace digital transformation, despite its potential to optimise production processes, reduce operational risks, and improve environmental compliance. South Africa, endowed with rich mineral resources and a well-established mining sector, is no exception to this trend. While large mining corporations have begun integrating advanced technologies such as automation, remote sensing, and data analytics, smaller players remain constrained by structural, economic, and organisational barriers [1]. For mining SMEs to remain competitive and resilient in the face of increasing market pressures and technological disruptions, a clear, computational technique for assessing and advancing digital readiness is crucial [2]. Classical models for evaluating digital transformation tend to rely on rigid, quantitative indicators that often fail to capture the sophisticated, qualitative aspects of organisational readiness.

The primary aim of this study is to design a decision-support framework to evaluate and improve the digitalisation readiness of small and medium-sized enterprises (SMEs) operating within South Africa's mining industry. The specific objectives include to Identify and define key factors influencing digitalisation readiness in mining SMEs; design and implement a fuzzy logic framework using MATLAB R2024a that can effectively evaluate the digital readiness of mining SMEs under conditions of uncertainty and qualitative input; Apply the framework to real-life SME case studies in the mining sector to assess varying levels of digital readiness and identify strengths and weaknesses; Analyse the impact of human skills, financial resources, and organisational culture on the digital transformation process, highlighting common challenges and best practices. Provide insights and recommendations for SMEs, policymakers, and industry stakeholders to support strategic planning, capacity building, and investment in digital technologies.

2 REVIEW OF LITERATURE

2.1 Digital Transformation in Industries

Digital transformation is vital for improving competitiveness, efficiency, and sustainability, yet SMEs face obstacles such as limited funding, lack of technical expertise, and resistance to change [2]. These challenges are particularly pronounced in the mining sector, where operations are complex and labour-intensive. Recent research highlights the necessity for well-structured frameworks that evaluate digital readiness in ways that are sensitive to the specific demands of each sector [3]. Conventional assessment approaches frequently fall short in addressing the uncertainty and subjectivity involved in determining organisational preparedness; this challenge is evident in SMEs with varying degrees of digital maturity.

Studies have demonstrated that digitalisation significantly influences financial performance [4], business revitalization [5], and broader economic outcomes [6]. For instance, Indriastuti and Kartika [7] surveyed Micro, Small, and Medium Enterprises (MSMEs) within a region to assess the effects of digital adoption on their financial performance. It was observed in their study that digitalisation leads to notable improvements. Similarly, Gunawan and Somantri [4] explored the relationship between digital technology and financial inclusion among MSMEs, identifying technology adoption as a mediating factor. Their findings indicate that both the digital economy and the adoption of technology significantly enhance financial inclusion.

These results suggest that digitalisation is a key driver of future economic growth and development, as evidenced by the rapid evolution of business transactions.

Several recent studies have emphasised the critical role of digital transformation in revitalising and sustaining SMEs, which has direct implications for advancing digitalisation frameworks. Putri and Asyari [5] investigated the effects of digital transformation on selected MSMEs within a particular cluster, revealing a significantly positive impact on business revitalisation. Their findings signify the importance of strengthening digital capabilities and highlight the need to improve digital literacy as a foundational step toward successful transformation, an insight highly relevant for mining SMEs navigating complex technological transitions.

In another study, Nata et al. [6] explored how digitalisation contributes to economic growth through the development of adaptive business models tailored to the evolving market system. The study suggests that digitization empowers MSMEs to overcome structural limitations by embracing tools like digital marketing, which enhances market access and revenue potential. This adaptive behaviour is key for mining SMEs seeking to stay competitive in dynamic environments. In addressing the broader challenges of the recent industrial revolution, Fajria [8] advocated for the integration of MSME 4.0 principles, encouraging businesses to adopt digital technologies that align with a fast-changing ecosystem. Such digital strategies support not only operational efficiency but also market expansion, enabling SMEs, including those in the mining sector, to extend their reach beyond local boundaries.

2.2 Traditional Method of Analysis vs Computational Techniques

Classical methods of analysis often treat these factors in isolation or rely on rigid deterministic models that fail to properly represent the inherent ambiguity in real-world decision-making [9]. In a recent study conducted by Shao et al. [10], a robust contribution was significantly made to the discourse by proposing a classical hybrid Grey-DANP model to analyse the multi-dimensional factors influencing digital transformation in Chinese SMEs. The model reflects the complex interplay of resources, competencies, and institutional frameworks that drive transformation [10]. Key determinants identified include digital infrastructure, internal organisational change, employee work style, talent team development, and business model innovation. Dynamic Capabilities Theory is a notable theoretical anchor in the literature, which underscores the need for reconfiguring capabilities in stochastic environments [11].

Other traditional multi-criteria decision-making techniques, such as TOPSIS and AHP, have also been criticised for their inability to handle ambiguity and causal feedback loops simultaneously [12,13]. Furthermore, [10] pointed out the fact that successful digital transformation strategies must align with external realities where fuzzy systems can model more adaptively than rigid numerical methods. For instance, the influence of leadership mindset [14], employee adaptability [15], and socio-cultural inertia [16] may be better captured through fuzzy inference rules than binary classifications. Another advantage of Fuzzy model is the ability to accommodate feedback and reinforcement among variables [10]. For instance, economic development, government support, and technological infrastructure were found to have mutual causal relationships, a complexity well-handled by fuzzy cognitive maps. While [10] successfully integrates various factors influencing SMEs' digital transformation using Grey-DANP, the transition to fuzzy logic analysis can enhance high-level accuracy of models, particularly when applied to mining SMEs where data uncertainty and regulatory complexity are more pronounced. In summary, recent studies have shown that problems in this space rely more on classical or traditional methods for analysis with limited emphasis on advanced computational approaches. This study fills this gap by highlighting the significance of intelligent decision-making frameworks, like fuzzy logic, in navigating the challenges of digital transformation within mining SMEs.

2.3 Fuzzy Logic for Advancing Digital Transformation in Mining SMEs.

Fuzzy logic, widely regarded as a robust decision-support system, offers a sophisticated approach for assessing digitalisation readiness, particularly in environments characterised by imprecise, uncertain, or qualitative data [17]. Its inherent capacity to handle vagueness and ambiguity makes it an ideal tool for tackling complex, real-world scenarios where traditional methods fall short. Studies by Nguyen et al. [18] underscore the implementation of fuzzy logic in modelling intricate systems and relationships. By leveraging linguistic variables and fuzzy if–then rules, fuzzy logic provides a robust stochastic decision-making process that is difficult to quantify with conventional quantitative techniques [19]. The underutilisation underscores a critical gap in the existing literature and practice, highlighting the need for a specialised fuzzy logic-based framework tailored to the unique challenges of mining SMEs.

3 METHODOLOGY

The methodological steps followed in this study are detailed in this section, covering the research design, readiness factors, fuzzy logic implementation, data collection, and justification of input factors using the TOE (Technology–Organization–Environment) framework, as well as fuzzy model notation and formulation. The Fuzzy Logic Implementation Flowchart provides a structured overview of the sequential phases undertaken to operationalize the framework.

The process begins with problem identification and data collection, where primary data were obtained through a structured survey distributed via Qualtrics and analysed using MATLAB R2024a. Five critical readiness dimensions—Technological Infrastructure (TI), Human Skills and Training (HST), Organisational Culture (OC), Operational Efficiency (OE), and Financial Resources (FR), were identified and justified within the TOE framework as essential determinants of digitalisation readiness in SMEs.

Following this, the fuzzy inference system (FIS) was designed in MATLAB to model the decision-making process. The first phase of the FIS involves fuzzification, where input data are converted into fuzzy sets using membership functions to account for uncertainty and qualitative judgment. A rule-based system is then constructed, embedding expert knowledge in the form of “if–then” rules to define relationships between input variables and their influence on digital readiness. The inference mechanism, based on the Mamdani model, is employed to aggregate rules and derive intermediate fuzzy outputs. These outputs are then processed through defuzzification, where the centroid method is applied to generate crisp digital readiness scores that can be readily interpreted.

The next stage involves validation and optimisation, where the model is tested against the dataset and fine-tuned to improve accuracy, consistency, and interpretability. Membership functions and fuzzy rules are iteratively adjusted to ensure alignment with expert knowledge and empirical observations. The methodology culminates in the analysis and implementation strategy, where final readiness scores are interpreted, ranked, and translated into practical recommendations for SMEs, policymakers, and industry stakeholders.

3.1 Research Design

The study employed a quantitative, decision-support approach based on fuzzy logic to evaluate digital readiness among mining SMEs in South Africa. Fuzzy logic was chosen because of its effectiveness in handling uncertainty and qualitative assessments, which are commonly encountered in organisational evaluations.

3.2 Identification of Key Readiness Factors

Key digital readiness dimensions were identified through an extensive literature review and expert consultations within the mining industry, focusing on five critical factors such as

Technological Infrastructure (TI): Availability and integration of digital tools, hardware, and connectivity; Human Skills and Training (HST): Workforce competency in digital technologies and access to training programs; Operational Efficiency (OE): Adoption of automation, data utilization, and process optimization; Organisational Culture (OC): Leadership commitment, openness to change, and innovation orientation and Financial Resources (FR): Accessibility of financial support for digital technology investment (See Table 1). Each of these dimensions were expressed using linguistic variables (very low, low, medium, high and very high) suitable for processing through fuzzy inference systems. The flowchart developed specifically for this study is presented in Figure 1.

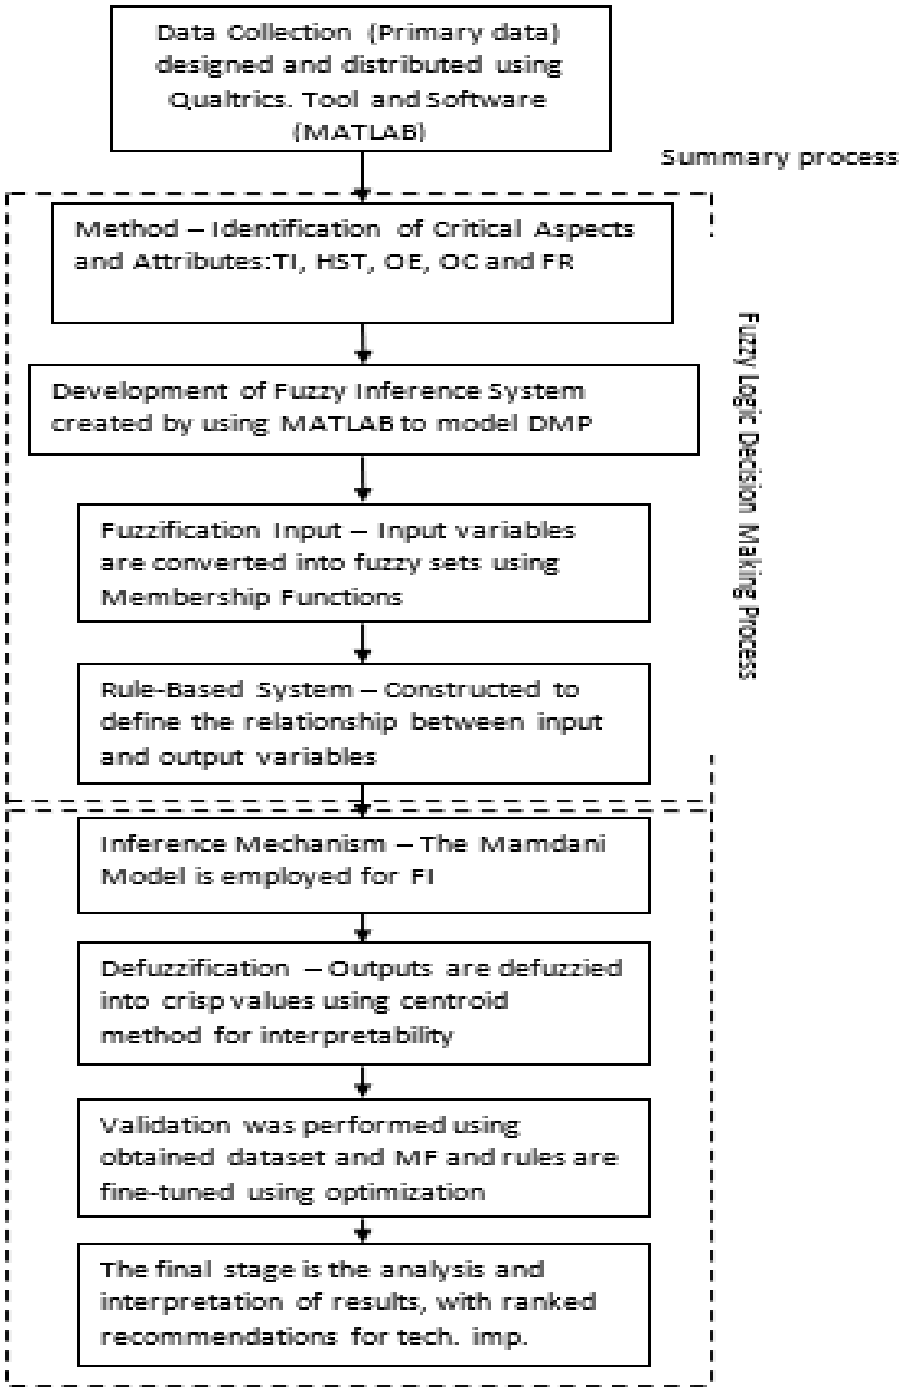

Figure 1: Fuzzy Logic Implementation Flowchart

3.3 Data Collection

Primary data was collected from selected mining SMEs using a structured survey questionnaire developed and distributed using Qualtrics. A total of thirty 30 participants from the Mining SME sector responded, including strategists and operational experts. Responses were given on a scale of 0–100 and subsequently classified into five readiness levels as presented in Table 1. The five dimensions and their associated criteria were identified to capture SMEs' readiness for digital transformation. To strengthen the conceptual basis of these dimensions, they are further mapped onto the Technology–Organisation–Environment (TOE) framework.

Table 1: SMEs Readiness for digital transformation across five critical aspects in Mining

Dimensions	Criteria
Technological Infrastructure (TI)	Availability of digital tools and systems
	Integration of advanced technologies
	Network connectivity and infrastructure
Human Skills and Training (HST)	Employee technical competency
	Training and development programs
	Management knowledge and leadership in digital transformation
Operational Efficiency (OE)	Process automation and optimization
	Data-driven decision-making
	Flexibility and adaptability of processes
Organisational Culture (OC)	Openness to innovation and change
	Collaboration and communication
	Alignment of organisational vision with digital technologies goals
Financial Resources (FR)	Strategic financial commitment to digitalisation
	Flexibility of financial resources
	Return on digital investment (ROI)

3.4 Justification of Input Factor Using the TOE Framework

The selection of the five input factors which include Technological Infrastructure (TI), Human Skills and Training (HST), Operational Efficiency (OE), Organisational Culture (OC), and Financial Resources (FR), followed a structured and rigorous process. First, the review of existing literature on digital transformation in SMEs and mining-related industries was conducted, which highlighted recurring themes such as technology availability, workforce competence, cultural orientation, and financial capacity. Second, consultations with thirty (30) mining industry experts provided practical validation, ensuring that the factors captured the real challenges and opportunities faced by SMEs in the South African mining context. Third, clustering overlapping elements, such as combining employee skills, training, and leadership into the Human Skills and Training (HST) dimension, and merging system availability, integration, and connectivity under Technological Infrastructure (TI). Fourth, these consolidated factors were aligned with established theoretical models, particularly the Technology–Organisation–Environment (TOE) framework, to reinforce conceptual validity. Finally, the dimensions were iteratively refined through expert validation to ensure contextual relevance.

Within the TOE framework, these five factors map logically onto its three core domains. Technological Infrastructure (TI) and Operational Efficiency (OE) align with the *technological context*, reflecting a firm's capacity to adopt, integrate, and optimise digital tools. Organisational Culture (OC) and Human Skills and Training (HST) align with the *organisational context*, capturing leadership, workforce competence, and cultural openness to change. Financial Resources (FR) corresponds to the *environmental context*, as it reflects external resource availability, investment access, and financial flexibility that shape digital adoption.

Thus, the five chosen dimensions are well grounded in practice, supported by evidence, and fit established theory, making them suitable for assessing digital readiness in mining SMEs.

To facilitate the fuzzification process in this study, a linguistic scale was developed to translate qualitative expert judgments into quantifiable fuzzy scores. Table 2 presents the linguistic terms adopted, their corresponding percentage ranges, and assigned scores. The scale ranges from *Very Low (VL)* to *Very High (VH)*, enabling consistent interpretation of subjective assessments. This structured mapping ensures that qualitative perceptions, such as the degree of technological readiness or organisational capacity, can be represented numerically within the fuzzy inference system. The linguistic scale thus serves as a critical foundation for the subsequent analysis, where input variables are systematically evaluated to model the digitalisation readiness of South African mining SMEs.

Table 2: Linguistic Scale with Percentage Ranges and Scores for Fuzzy Analysis

S/N	Fuzzy Linguistic Term	Range (%)	Score
1	Very Low (VL)	0-25	1
2	Low (L)	26-50	2
3	Moderate (M)	51-70	3
4	High (H)	71-85	4
5	Very High (VH)	86-100	5

3.5 Fuzzy Model Notation and Formulation

To formally represent the fuzzy logic-based model, the following notations and linguistic conventions are defined. These provide a structured basis for formulating the fuzzy rules and deriving the digital readiness score (DR) for mining SMEs.

x_1= Technological Infrastructure (TI)

x_2= Human Skills and Training (HST)

x_3= Operational Efficiency (OE)

x_4= Organisational Culture (OC)

x_5= Financial Resources (FR)

L = linguistic term representing low

M = linguistic term representing medium

H = linguistic term representing high

x_i= input variables

R_j= Fuzzy rules

DR = Digital readiness score

A_{ij}= Fuzzy set applied to input x_i in rule j

B_j= Fuzzy set representing the output

y*= Defuzzified output

y: Output universe of discourse (e.g., readiness scale from 0 to 100)

DR: Digital readiness score

f = The fuzzy logic model combining fuzzification, rule inference, and defuzzification

$\mu R_j(y)$ = is the output fuzzy set for rule j and **max** operator is used for aggregation (standard in Mamdani inference)

Each x_1 is obtained from expert survey data and is typically scaled.

Each variable x_i is rated on a qualitative scale and fuzzified into linguistic terms already defined. Each term is also defined using triangular membership functions. Each input x_i is converted to a fuzzy value using its membership function as presented in system of equation 1.

$$\mu L(x), \mu M(x), \mu H(x) \in [0,1] \quad (1)$$

The degree of membership of input x in fuzzy set A is presented in equations (2) to (4).

$\mu_L x_i$: Degree to which input x_i is low (2)

$\mu_M x_i$: Degree to which input $x_i$is medium (3)

$\mu_H x_i$: Degree to which input $x_i$is high (4)

Rule Base (If-Then Rules): Based on expert defined rules:

IF TI is High AND HST is High AND OC is High THEN Digital Readiness is High; IF TI is Medium AND HST is Low THEN Digital Readiness is Low; IF FR is Low OR OE is Low THEN Digital Readiness is Medium, with Rj representing the jth rule then the system of equation 5 is established.

Rj: IF x_1 is A_{1j} AND x_2 is A_{2j}…..THEN y is B_j (5)

Using Mamdani fuzzy inference to evaluate the rules. The fuzzy output for each rule is presented:

$$\mu Rj(y) = \min [\mu A1j(x1), \mu A2j(x2), \ldots..] \quad (6)$$

The aggregated to form a combined fuzzy output is:

$$\mu Y(y) = \frac{max}{j} [\mu Rj(y)] \quad (7)$$

This score represents the overall digital readiness of an SME.

The fuzzy output is converted into a crisp digital readiness score using the centroid method:

$$y^* = \frac{\int y.\mu Y(y)dy}{\int \mu Y(y)dy} \quad (8)$$

The digital readiness score is thus presented:

$$DR = f(x1, x2, x3, x4, x5) \quad (9)$$

$$DR = Defuzzify\ [\cup_{j=1}^{n} Fuzzify(xi)\ \rightarrow Apply\ (Rj)] \quad (10)$$

3.6 Fuzzy Logic Framework Development

The fuzzy logic-based framework was developed and implemented using MATLAB R2024a. The development process include fuzzification which has to do with converting linguistic data into fuzzy values via predefined membership functions (MF); Rule Base Construction where a series of fuzzy "if-then" rules derived from expert opinions are well harmonized; Inference Engine which involve the application of Mamdani inference mechanism to process the rules and generate fuzzy outputs and Defuzzification which involves translating the fuzzy outputs into numerical scores. Figure 2 illustrates the membership function plot, while Figure 2 depicts the fuzzy structure of the input-output variables.

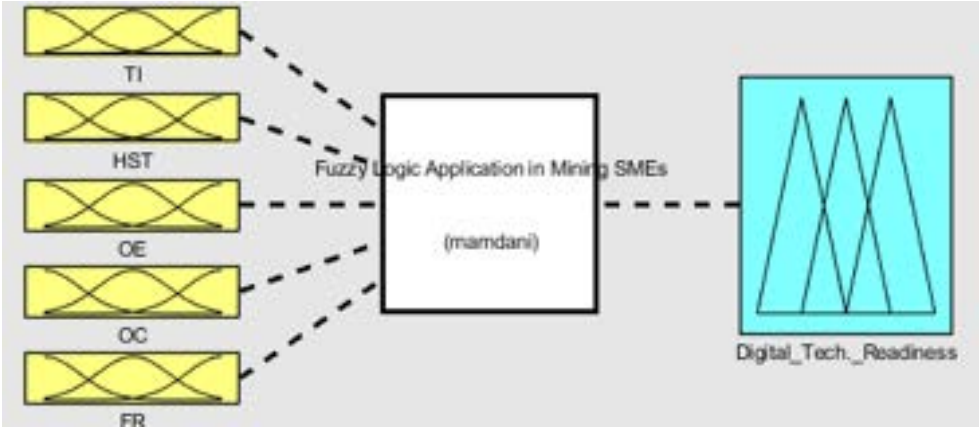

Figure 2: Structure for the Input-Output Variables

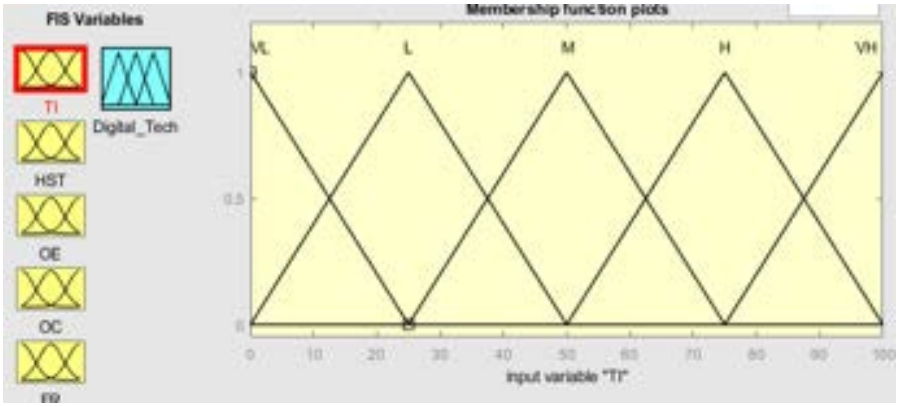
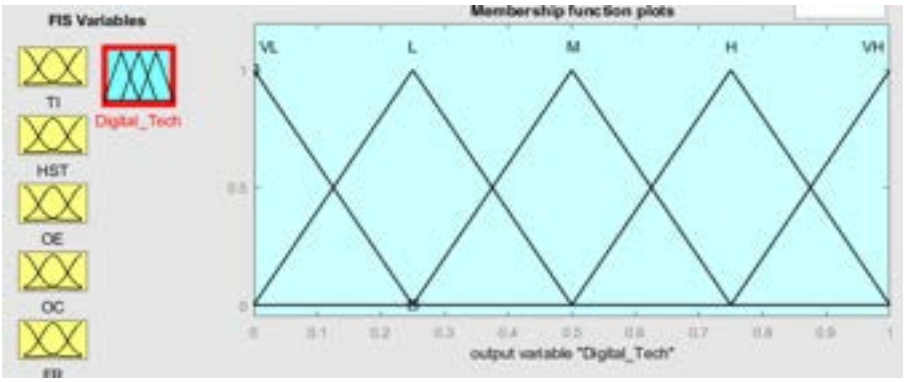
3.7 Evaluation

The data utilised in this study was sourced from the system via the Qualtrics platform, which facilitated the collection of responses. This data was subsequently entered into a fuzzy logic mechanism in order to calculate individual digital readiness scores. The qualitative responses provided by participants were converted into corresponding fuzzy numerical values through the application of predefined membership intervals as depicted in Figure 3. These intervals served as a framework for interpreting subjective inputs in a structured, quantitative manner.



(a)



(b)

Figure 3: Membership Function Plot for the System

(a) Input Variable (b) Output Variable

Following the translation of qualitative responses into fuzzy data, the information underwent further processing and analysis. This analytical stage aimed to identify organisational strengths, areas of deficiency, and key focus points essential for the advancement of digital transformation initiatives. During the evaluation process, the alpha-cut method highlighted in yellow within the documentation was applied to refine the analysis. As a result, the system autonomously produced the optimal output values, which are illustrated in blue in Figure 4. This output facilitated a clearer understanding of the digital readiness which is presented on the fuzzy rule viewer for strategic recommendations.

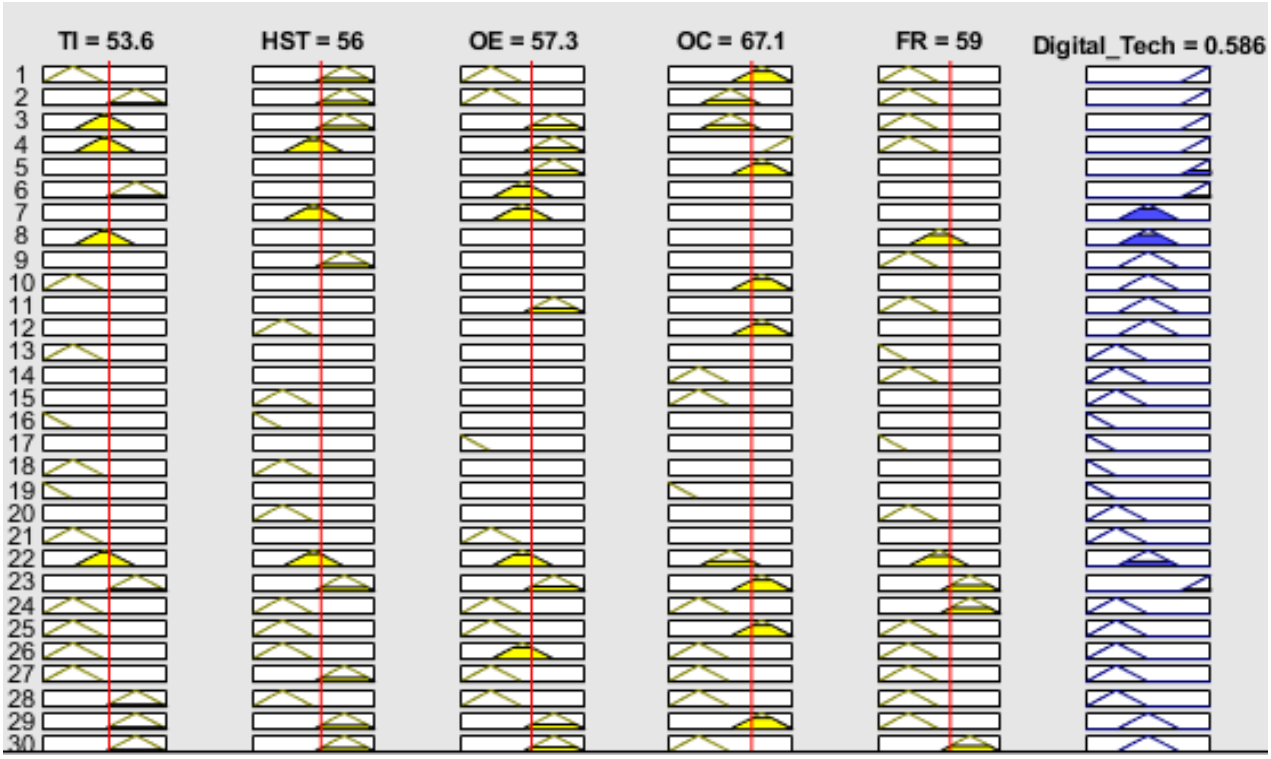


Figure 4: Fuzzy Solution Rule Viewer

The rule structure of the fuzzy model was derived through an iterative process and visualised using the rule viewer to support effective decision-making. The output values are generated by varying input values, as illustrated in Figure 4. Each rule is represented by a row of plots, while each column corresponds to an input variable. The system generates output values in real time, displayed in blue colour in the last column of Figure 4.

Red lines indicate the 5 input variables utilized in the current study. Alpha cuts applied to the linguistic terms, along with the assigned values for each variable, facilitate the prediction of optimal output results. Subsequently, average scores for each dimension were computed per participant. These individual results were then aggregated to derive sector-level averages for comparative analysis (refer to Table 3).

3.8 Three-Dimensional (3D) Surface Plot

The surface plot illustrates how the output of the Fuzzy Inference System (FIS) evolves following the alpha-cut procedure. The 3D surface plots in Figure 5 illustrate the fuzzy logic-based interactions between the five digitalisation readiness dimensions Technological Infrastructure (TI), Human Skills and Training (HST), Operational Efficiency (OE), Organisational Culture (OC), and Financial Resources (FR), and their combined impact on overall *Digital Tech Readiness*. Each surface shows how two independent variables jointly influence readiness, highlighting both synergies and constraints. For instance, the OC–TI plot

(top left) shows that while organisational culture provides a relatively stable foundation, low technological infrastructure suppresses readiness, reflecting the gap between cultural openness and practical implementation. Similarly, the HST–TI surface (top right) demonstrates that even strong skills and training cannot fully elevate readiness without adequate technological infrastructure, reinforcing the finding that people-driven initiatives require complementary technical support. The TI–OE interaction (bottom left) depicts that outdated systems and limited efficiency strongly depress readiness, even where other dimensions are favourable. In contrast, the OE–OC surface (bottom right) peaks sharply, confirming that when a strong culture aligns with operational efficiency, readiness scores improve significantly—indicating that culture acts as a catalyst but only reaches its potential when paired with process improvements. Together, these plots visually capture the study's conclusion: cultural and human factors are enablers, but without corresponding investment in technology, operations, and finance, digital transformation in mining SMEs remains constrained.

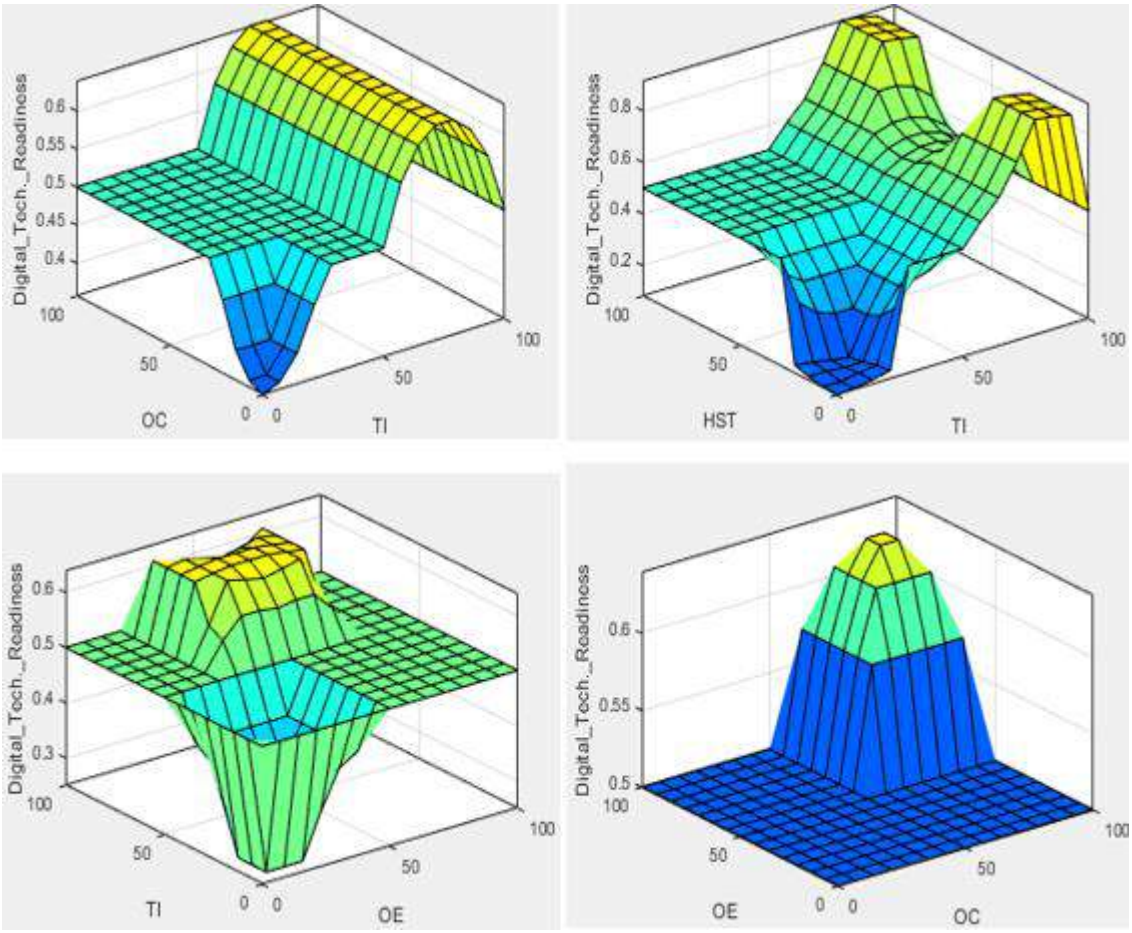

Figure 5: Three-Dimensional Surface Plot

Table 3: Fuzzy Logic-Based Analysis and Interpretation

Dimension	Avg. Fuzzy Score	Readiness Level	Key Interpretation
Technological Infrastructure (TI)	53.62	Moderate	Many SMEs have digital tools like computers, spreadsheets, or software for managing workers or equipment. But advanced tech (e.g., AI, IoT, Blockchain) is underutilized.
Human Skills and Training (HST)	55.98	Moderate	Employee technical competency and training efforts are present but not widespread.
Operational Efficiency (OE)	57.29	Moderate	Some automation exists, but integration of data-driven processes is limited.
Organisational Culture (OC)	67.12	Moderate-High	Strongest area: leadership and openness to innovation are relatively high.
Financial Resources (FR)	59.00	Moderate	Budget constraints remain a barrier, though some investment in digital is evident.

4 DISCUSSION OF KEY FINDINGS AND IMPLICATIONS

(i) Organisational Culture is a Strength - The analysis identified Organisational Culture (OC) as the highest-scoring dimension, with an average score of 67.12. This reflects a strong cultural foundation and a notable openness among mining SMEs toward digital transformation. Qualitative responses and expert-derived weightings within the fuzzy logic model further support the presence of a pro-change mindset and a degree of transformational leadership across these firms. Such cultural alignment represents a significant enabler for digitalisation, suggesting that with the right technical infrastructure and financial support, progress could be accelerated. However, the findings also reveal a critical gap: while the mindset and leadership orientation appear ready, practical implementation remains constrained by external factors. This indicates substantial untapped potential that could be unlocked by removing these barriers.

Implication: Policymakers and support institutions should capitalise on this cultural readiness by offering targeted financial and technical assistance. By doing so, they can amplify the efforts of internal change agents and drive more effective digital transformation within the SME sector.

(ii) Human Capital is Pivotal - The fuzzy logic model highlighted *Human Skills and Training (HS)* as a pivotal factor influencing digital readiness. SMEs with active training programs, ongoing upskilling efforts, and digitally proficient leadership consistently demonstrated higher readiness scores. This finding reinforces the widely held perspective that successful digital transformation is driven by people as much as by technology. Organisations that foster a culture of continuous learning and possess leadership capable of navigating digital tools tend to exhibit greater agility and a higher propensity to adopt emerging technologies.

Implication: Investing in workforce development emerges as a non-negotiable for sustainable digital transformation. Public-private partnerships focused on vocational training and leadership development could significantly elevate digital maturity levels across the SME mining sector.

(iii) Technology and Operational Efficiency Lag Behind Culture

Despite strong cultural readiness, *Technology Infrastructure (TI)* and *Operational Efficiency (OE)* recorded only moderate scores, highlighting a clear gap between digital ambition and actual implementation. Many SMEs continue to rely on outdated legacy systems with minimal digital integration. The adoption of process automation and data analytics remains limited, constraining operational efficiency, scalability, and adaptability in an increasingly dynamic market environment.

Implication: To bridge this digitalisation gap, support like government funding could help SMEs upgrade their technology faster. Simple, practical digital solutions made for small businesses can also bring quick results and encourage further progress.

(iv) Financial Constraints Undermine Readiness

The Financial Resources (FR) dimension yielded a moderate average score, indicating that budgetary limitations are a major bottleneck. Many SMEs struggle to access affordable financing options, grants, or investment capital necessary for adopting and maintaining advanced digital technologies. As a result of limited funds, small businesses often plan only for the short term, and by using digital tools in a stochastic manner, they also lack a clear, consistent strategy for going digital.

Implication: Introducing more flexible financing instruments, such as digital innovation vouchers, tax incentives, or microcredit for technology investments, could be pivotal in empowering SMEs to plan and execute digital initiatives more sustainably and effectively.

(v) Differences in Digital Readiness Among SMEs

The study showed that SMEs are at very different stages when it comes to using digital technology. Some are clearly digital frontrunners with modern systems, agile processes, and well-trained staff, especially in areas like organisational culture and employee skills and training. Others are just starting out and scored low in most areas of digital readiness. These differences may be due to factors like company size, location, type of ownership, or whether the business focuses on exploration or processing.

(vi) Implication

A one-size-fits-all intervention is unlikely to be effective, that is, giving all SMEs the same kind of digital support or resources, even though some are advanced and others are not. This can be ineffective because not all businesses require the same kind of assistance. Instead, support should be customised based on each company's specific needs and stage of development. Using a maturity model to group businesses by their digital progress could help target the right training and resources to where they are most needed.

5 CONCLUSIONS, POLICY RECOMMENDATIONS AND LIMITATIONS

This study presents a fuzzy logic-based framework to assess how ready mining SMEs are for digital change. It offers a practical and flexible tool to help them manage digital transformation, especially where resources are limited. The results reveal a varied readiness profile across five key areas, with strong cultural readiness but notable gaps in technology, operations, and finance. Human capital emerges as a key driver, emphasising the importance of continuous skills development and leadership. Given the wide variation in readiness levels, tailored support strategies are essential as generic solutions will not work. The framework supports informed decision-making for SMEs, policymakers, technology providers, and researchers. Aligning support with actual readiness levels can promote more inclusive and sustainable digital transformation. Ultimately, digital progress in SMEs requires not just technology but strategic alignment, targeted investment, and collaboration across the ecosystem.

This study offers specific recommendations for key stakeholders, including government, SMEs, technology providers, and academic institutions. Government and regional support programmes should design tailored digitalisation strategies that reflect the actual readiness levels of SMEs. These strategies should combine training, targeted funding mechanisms, and advisory services to help address gaps in technology, operations, and finance. SMEs, can equally apply the fuzzy logic model as a diagnostic tool to evaluate their current state and prioritise areas requiring improvement. Technology providers are encouraged to align their

solutions with the evolving needs of SMEs, particularly by supporting strengths in organisational culture and skills development. Academic institutions can employ the model as a framework for further research, extending its application to other sectors and refining its methodological approach. Through coordinated action across these stakeholders, the mining SME sector can enhance its digital capabilities, increase competitiveness, and build greater long-term resilience.

The findings of this study are derived from survey data collected from a relatively small sample of thirty industry experts, which may limit the generalisability of the results. Future research should therefore consider expanding the sample size to ensure broader representativeness and more robust validation. Disaggregating results by factors such as SME size, geographic location, or mining subsector would also provide much more robust insights into variations in digital readiness. In addition, conducting longitudinal assessments of digital readiness could help monitor progress over time and refine both policy interventions and organisational strategies. Such studies would contribute to building a more dynamic understanding of digital transformation in the mining SME context.

LIFE CYCLE ASSESSMENT (LCA) AS A TOOL FOR MARITIME DECARBONISATION: OPPORTUNITIES AND CHALLENGES IN SOUTH AFRICA

A.E. Ramulifho[1] and G.A. Thopil[2]

[1,2]Department of Engineering and Technology Management
University of Pretoria, South Africa
[1]elijah.ramulifho@gmail.com, [2]george.alexthopil@up.ac.za

ABSTRACT

The maritime sector plays a significant role in global trade and economic growth, yet it also significantly contributes to greenhouse gas (GHG) emissions. For South Africa, decarbonising this sector is particularly important due to its unique challenges and opportunities linked to its strategic location and dependence on maritime trade. This paper investigates how Life Cycle Assessment (LCA) can be used to evaluate and guide the South African maritime sector's decarbonisation efforts, while assessing environmental impacts of maritime activities from production to disposal. The investigation within compiles insights on LCA's applicability to identify emission hotspots, assesses alternative fuels and technologies, and aids in policymaking for sustainable maritime practices. In conclusion, the paper highlights the significance of LCA as a decision support tool for fostering a sustainable and low-carbon maritime future in South Africa, aligning with both global climate objectives and local economic needs.

Keywords: Life Cycle Assessment (LCA), maritime decarbonisation, greenhouse gas emissions, alternative fuels, sustainable shipping.

1 INTRODUCTION

1.1 LCA and its relevance to the maritime industry

The maritime sector is a cornerstone of global trade, responsible for transporting approximately 90% of the world's goods by volume [1], [2], and 70% by value [3]. However, it contributes significantly to environmental impacts such as greenhouse gas (GHG) emissions and other marine pollution. It accounts for nearly 3% of the global anthropogenic CO_2 emission and is projected to increase [1]. As international efforts to mitigate climate change intensify, decarbonisation of maritime transport has emerged as a priority. The International Maritime Organisation (IMO) has set ambitious targets to reduce GHG emissions from shipping by at least 50% by 2050, compared to the 2008 levels [4], [5].

In response to increasing regulatory and societal demands for sustainability, the maritime industry has turned to scientific tools, such as Life Cycle Assessment (LCA), to quantify and mitigate its environmental footprint [6]. LCA offers a comprehensive framework for evaluating the environmental impacts of products, processes, or services throughout their entire life cycle, from raw material extraction to end-of-life disposal [7]. Its application in maritime is particularly pertinent given the complexity and global reach of shipping operations. Applying LCA can help the maritime industry identify emission hotspots, assess the environmental performance of various maritime activities, promote sustainability, and achieve emission-reduction targets.

Despite the growing recognition of LCA significance in the sector, systematic literature synthesis by geographic region, particularly in developing economies such as South Africa, remains relatively underexplored. Previous reviews have often focused on technological advancements, methodological developments, or specific environmental impacts, but few have adopted a continental lens or addressed the contextual factors influencing LCA uptake in the Global South [8], [9], [10] [11] [12]. This gap is significant because regional disparities in regulatory frameworks, technological infrastructure, and data availability can profoundly affect the feasibility and effectiveness of LCA in maritime operations.

This paper provides answers to the following research questions, 1) what is the global landscape of LCA research in maritime contexts? 2) how does LCA literature vary by continent, revealing regional trends and disparities? and 3) what are the challenges and opportunities for applying LCA in South Africa's maritime sector? In answering these questions, the paper seeks to advance and contribute to the industry's needs by recommending and leveraging for LCA utilisation to address environmental impacts and resource constraints in South Africa's maritime sector, while supporting sustainable maritime practices that align with global decarbonisation goals. It employs the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) method to ensure methodological rigor and transparency [13].

1.2 The growing importance of maritime decarbonisation

Increasing global industrialisation and over-exploitation of fossil fuels have led to an increase in GHG emissions [14], [15]. Shipping industry has a substantial environmental impact owing to the unprecedented growth of the global seaborne trade [16]. The urgent need to address these impacts has led to a growing focus on decarbonisation and the need to transition towards cleaner and more sustainable practices [17].

The global commitment to address climate change, as reflected in the Paris Agreement and other international protocols, has also created a strong impetus for the shipping industry to decarbonise [18]. However, the transition towards zero-emission shipping requires adoption of innovative technologies, alternative fuels, and operational practices that minimise GHG emissions [19]. This pathway involves not only reducing emissions from ships but also

addressing the broader life cycle impacts of the industry, including the production and transportation of fuels and the construction and decommissioning of vessels [20].

South Africa presents unique challenges and opportunities for maritime decarbonisation. Its role in facilitating international trade stems from its geographical location, developed port infrastructure, and economic influence [17]. However, South Africa's maritime sector faces unique challenges in its transition to low-carbon operations due to limited access to alternative fuels, and infrastructural constraints [21]. Given these unique considerations, there is a pressing need for decarbonisation studies tailored to South African ports. These tailored assessments provide valuable performance insights within port environments (Table 1) and inform the development of effective sustainability strategies.

Table 1: South African commercial ports and their operational variability.

Port	Main Cargo Types	Key Emissions Sources	LCA Boundary Challenges
Durban	Containers, vehicles	Cranes, trucks, ships	Multi-modal, high hinterland emissions
Port	Main Cargo Types	Key Emissions Sources	LCA Boundary Challenges
Durban	Containers, vehicles	Cranes, trucks, ships	Multi-modal, high hinterland emissions
Cape Town	Fruit, containers	Refrigeration, ships	Seasonal variability, cold storage impacts
Saldanha Bay	Bulk minerals	Rail, bulk loaders	Long-distance rail, specialised equipment
Cape Town	Fruit, containers	Refrigeration, ships	Seasonal variability, cold storage impacts
Saldanha Bay	Bulk minerals	Rail, bulk loaders	Long-distance rail, specialised equipment
Richards Bay	Coal, bulk minerals	Rail transport, bulk handling equipment	Energy-intensive operations, specialised equipment impacts

2 LITERATURE REVIEW

Life Cycle Assessment (LCA) is a vital tool for evaluating the environmental impact of products and processes in various industries [22]. Its application in the maritime sector is gaining traction [8], [9], [23]. It offers a systematic approach for assessing environmental burden associated with a product, process, or service at all stages of its life cycle from raw material extraction to end-of-life management [24], [25]. As outlined in ISO 14040, LCA comprises four key phases: goal and scope definition, life-cycle inventory analysis, life-cycle impact assessment, and interpretation [7], [26]. Among these, inventory analysis is the most labour-intensive, requiring detailed data collection protocols to identify environmental impacts and emission hotspots [8].

In recent years, LCA has gained prominence in the maritime sector, driven by growing awareness of climate change and the need for sustainable practices [27]. It enables systematic quantification of environmental burdens and supports efforts to decarbonise maritime operations. LCA can analyse, predict, and minimise short- and long-term environmental effects [28]. Furthermore, LCA has been widely applied to evaluate the economic and environmental impacts through lifecycle cost analysis [29]. It is also instrumental in identifying opportunities to reduce environmental impacts and improve resource efficiency [25], [30], [31].

Annually, the sector consumes approximately 300 million tons of fossil fuels, predominantly heavy fuel oil (HFO), contributing substantially to GHG emissions [32], [33], [34], [35]. From 2012 to 2018, GHG emissions from shipping increased from 977 to 1076 million tons, with CO_2 increasing from 962 to 1056 million tons [4], [17], [36]. Maritime transportation now accounts for nearly 3% of the total global CO_2 emissions, comparable to the sixth largest CO_2 emitting country. Table 2 lists the CO_2 estimations from the ships [36]. Projections suggest that without mitigation strategies, CO_2 emissions from the sector could escalate by 50–250% by 2050 [32], [35], [36], [37].

Table 2: Global CO_2 emissions from ships

Year	Global CO2 Emissions (Mt)	Shipping CO2 Emissions (Mt)	Shipping as a Percentage of Global (%)	Voyage-based Shipping CO2 Emissions (Mt)	Voyage-based as a Percentage of Global (%)	Vessel-based Shipping CO2 Emissions (Mt)	Vessel-based as a Percentage of Global (%)
2012	34,793	962	2.76	701	2.01	848	2.44
2013	34,959	957	2.74	684	1.96	837	2.39
2014	35,225	964	2.74	681	1.93	846	2.37

As regulatory and environmental pressures intensify, LCA offers an essential data-driven approach to guide the maritime sector toward more sustainable practices. In response, the IMO established targets to reduce GHG emissions from ships by 50% by 2050, compared to 2008 levels [35], [36], [38]. Achieving these requires technological innovations, operational changes, and regulatory reforms, including the transition to alternative fuels like LNG, hydrogen, ammonia, and biofuels [15], [39], [40], [2], [41], [42], [43].

Historically, LCA application in maritime began in the mid-1990s where studies highlighted environmental challenges in shipbuilding and called for improved design and LCA research [8], [10]. LCA provides science-based insights for decision-making on sustainable practices and technologies, thereby supporting the development of effective policies and legislation aimed at decarbonisation [4], [17]. IMO acknowledges LCA's essential role in its efforts to decarbonise the sector [20]. This is apparent through the development of GHG strategies and subsequent LCA guidelines to provide a standardised framework, particularly for Well-to-Wake (WtW) emission analysis of marine fuels [44].

The application of LCA in the maritime industry has evolved and is seeing growing interest, reflecting the global trend towards sustainability. Before 2000, Turnock [45] recognised the environmental challenges in shipbuilding and emphasised the need for better design and quantitative research to minimise environmental damage across the lifecycle. In the early 2000s, LCA focused on emission trade-offs between traditional fuels like Heavy Fuel Oil (HFO) and Marine Gas Oil (MGO) [46]. Shama, [47] further highlighted the importance of energy consumption and material rationalisation across construction, operation, and scrapping phases. By 2010, comparative assessments of conventional and alternative fuels such as LNG and biofuels gained prominence [48], [48], [49]. These was driven by emerging regulatory pressures and technologies like scrubbers and hybrid fuel blending [50]. Studies also explored links between LCA and international conventions on ship scrapping and recycling [51]. Recent studies in the 2020s have focused on lifecycle emissions of emerging fuels, such as ammonia and hydrogen, particularly in the context of global decarbonisation efforts [34], [42], [52], [53]. Recent work integrates LCA with economic analysis, policy compliance, circular economy principles, and digital tools to address data challenges, marking a shift toward holistic, future oriented maritime sustainability [8], [9], [10], [17], [36], [54],[57], [58].

The distribution of these studies reflects strategic importance of maritime transport in various national and regional economies [17]. Countries with major shipping lanes tend to have higher publication counts. This geographical proximity to key shipping corridors stimulates both academic and applied LCA research, as demonstrated by the concentration of publications in countries adjacent to these routes [8]. However, Africa is often constrained by limited access to high-quality data and regionally relevant LCA tools [12]. These disparities affect the volume and depth of research and policy relevance.

Furthermore, the IMO's guidelines provide a standardised framework for calculating Well-to-Wake (WtW) emissions for marine fuels. These guidelines propose various fuel pathways for WtT and Tank-to-Wake (TtW) emissions, expressing the results as carbon intensity (gCO2eq per MJ) [4]. The WtW, WtT, and TtW GHG emission factors (gCO2eq=MJ fuel or electricity) can be calculated using the following equations [34]:

$$(\text{WtW}): GHG_{WtW}\ [gCO_{2eq}/MJ] = GHG_{WtT} + GHG_{TtW} \quad (1)$$

Table 3: Well-to-Wake terms.

Term	Units	Explanation
GHG_{WtW}	gCO2eq/MJ	Total well-to-wake GHG emissions per energy unit from the use of the fuel or electricity in a consumer on board the ship
GHG_{WtT}	gCO2eq/MJ	Total well-to-tank GHG upstream emissions per energy unit of the fuel provided to the ship
GHG_{TtW}	gCO2eq/MJ	Total tank-to-wake GHG downstream emissions per energy unit from the use of the fuel or electricity in a consumer ship

$$(\text{WtT}): GHG_{WtT}\ [gCO_{2eq}/MJ] = e_{ec} + e_{l} + e_{p} + e_{td} - e_{c} - e_{sca} - e_{ccs} - e_{ccu} \quad (2)$$

Table 4: Well-to-Tank terms

Term	Units	Explanation
e_{ec}	gCO2eq/MJ	Emissions from the extraction or from the cultivation of raw materials
e_{l}	gCO2eq/MJ	Annualised emissions from carbon stock changes caused by land-use change (over 20 years)
e_{p}	gCO2eq/MJ	Emissions from processing, including electricity generation
e_{td}	gCO2eq/MJ	Emissions from transport and distribution
e_{c}	gCO2eq/MJ	Emissions credits generated by biomass growth
e_{sca}	gCO2eq/MJ	Emission savings from soil carbon accumulation via improved agricultural management
e_{ccs}	gCO2eq/MJ	Emission savings from CO2 capture and geological storage
e_{ccu}	gCO2eq/MJ	Emission savings from CO2 capture and utilisation

(TtW): $GHG_{TtW} = [(1 - C_{slip}) \times (S_F \times C_{fCO2} + C_{fCH4} \times GW_{PCH4} + C_{fNO2} \times GW_{PNO2}) + (C_{slip} \times GW_{PCH4}) - e_{occs}] / LCV$ (3)

Table 5: Tank-to-Wake terms

Term	Units	Explanation
S_F	0 or 1	Carbon source fuel
C_{slip}	% of fuel mass	Coefficient accounting for fuel (methane) slip (share of the total fuel in use)
C_{fCO2}	$gCO_2/_g fuel$	CO_2 emission conversion factor (g CO_2/g fuel)
C_{fCH4}	$gCH_4/_g fuel$	CH_4 emission conversion factor (g CH_4/g fuel)
C_{fNO2}	$gN_2O/_g fuel$	N_2O emission conversion factor (g N_2O/ g fuel)
GW_{PCH4}	$gCO_{2eq}/_g CH_4$	Global Warming Potential of methane over 100 set at 29.8 for fossil and at 27.5 for non-fossil methane (IPPC AR 6)
GW_{PNO2}	$gCO_{2eq}/_g N_2O$	gN_2O Global Warming Potential of N_2O over 100 set at 273 (IPCC AR 6)
e_{occs}	gCO_{2eq}/MJ	Emission savings from on-board CO_2 capture and geological storage
LCV	MJ/g_{fuel}	fuel Lower Calorific Value of the fuel (MJ/g fuel)

3 METHODOLOGY

This review employs the systematic literature review (SLR) method. The SLR is essential for synthesising a rapidly expanding and heterogeneous body of literature. The maritime sector has witnessed a significant increase in LCA-related studies, especially over the past two decades, as environmental concerns and regulatory pressures have intensified. This proliferation of research has led to a diverse array of methodologies, functional units, system boundaries, and impact assessment approaches, making it challenging to draw coherent conclusions without structured synthesis [8], [10]. The rationale for employing this method lies in its ability to provide a transparent, reproducible, and comprehensive synthesis of existing evidence.

A structured search strategy was used across multiple databases and sources like Scopus, Web of Science, ScienceDirect, and Google Scholar. Search terms included "Life Cycle Assessment," "LCA," "Maritime Industry," "Shipping," "Ports," "Shipbuilding," “Decarbonisation,” and "African Maritime." These terms were combined using Boolean operators (AND, OR, and NOT) to refine search results. Studies within data range between 2005 and 2025 were included if they used LCA to assess environmental impacts of maritime activities. Using the PRISMA framework, over 1200 records were identified using the search terms above, with pre-screening assessment resulting in approximately 500 records being removed because of duplications and ineligibility to be downloaded. Screening (588 articles) further led to those not relevant to maritime-related LCA and in languages other than English being excluded. Of the remaining 103 articles, 58 were eligible for review.

4 RESULTS

A systematic review of 58 articles on LCA and maritime decarbonisation provided a comprehensive overview of research trends, methodologies, and regional contributions in the maritime sector between 2005 and 2025. The key results are summarised below.

The temporal distribution of articles shows a marked increase in publications over time, particularly from 2019 to 2025 (Figure 2), reflecting growing academic interest in maritime decarbonisation and LCA. The main results revealed that alternative marine fuels and decarbonisation were the most researched focus areas, accounting for 48.3% (28 articles) of the research studies conducted. In second place are studies focusing on LCA methodologies and frameworks contributing 25.9% (15 articles), followed by shipbuilding and recycling with 8.6% (5 articles) (Table 6). Regional LCA perspectives, such as those specific to Africa, were less represented in only 5.2% or 3 articles. Other topics accounted for 12.1% of the total, indicating a broader but less focused scope in some studies [12], [57].

Table 6: Articles by focus area.

Focus Area	Number of Articles (%)
Alternative Marine Fuels and Decarbonisation	28 (48.3%)
LCA Methodologies and Frameworks	15 (25.9%)
Shipbuilding and Recycling	5 (8.6%)
Regional LCA Perspectives	3 (5.2%)
Other (e.g., port operations)	7 (12.1%)

Continentally, results further revealed that Europe and Asia are frontrunners, each contributing 50.0% (29 articles) and 24.1% (14 articles) respectively (Table 7). **Error! Reference source not found.**Africa and North America accounted for 6.8% of the articles, highlighting a regional disparity in research activities.

Table 7: Articles distribution by continent

Continent	Number of Articles (%)
Europe	29 (50.0%)
Asia	14 (24.1%)
Africa	2 (3.4%)
North America	2 (3.4%)
Unknown	11 (19.0%)

At a country level, Italy and China ranked higher (Table 8), each with five articles, followed by South Korea and Denmark, with four articles each. The results also depicted a strong alternative fuel concentration in Europe, LCA methodology concentration in Asia, and limited or variable concentrations in other regions.

Table 8: Articles distribution by county.

Country	Articles	Rank
Italy	5	1
China	5	1
South Korea	4	3
Denmark	4	3
UK	3	5
Spain	2	6
Sweden	2	6
USA	2	6
South Africa	2	6
Turkey	2	6
Japan	2	6
Others	25	12

The results further depicted variability in focus areas per region (Figure 1). A significant amount of research in Europe and Asia aligns with their strong maritime industries and policy support for decarbonisation [2], [58]. This is supported by the concentration, depth, and intensity of the studies conducted in these regions. Europe's studies are concentrated on alternative fuels and decarbonisation, while Asia concentrates on LCA methodologies. Africa, as an emerging LCA research market with limited resources, has a blended focus on regional LCA, shipbuilding, and recycling.

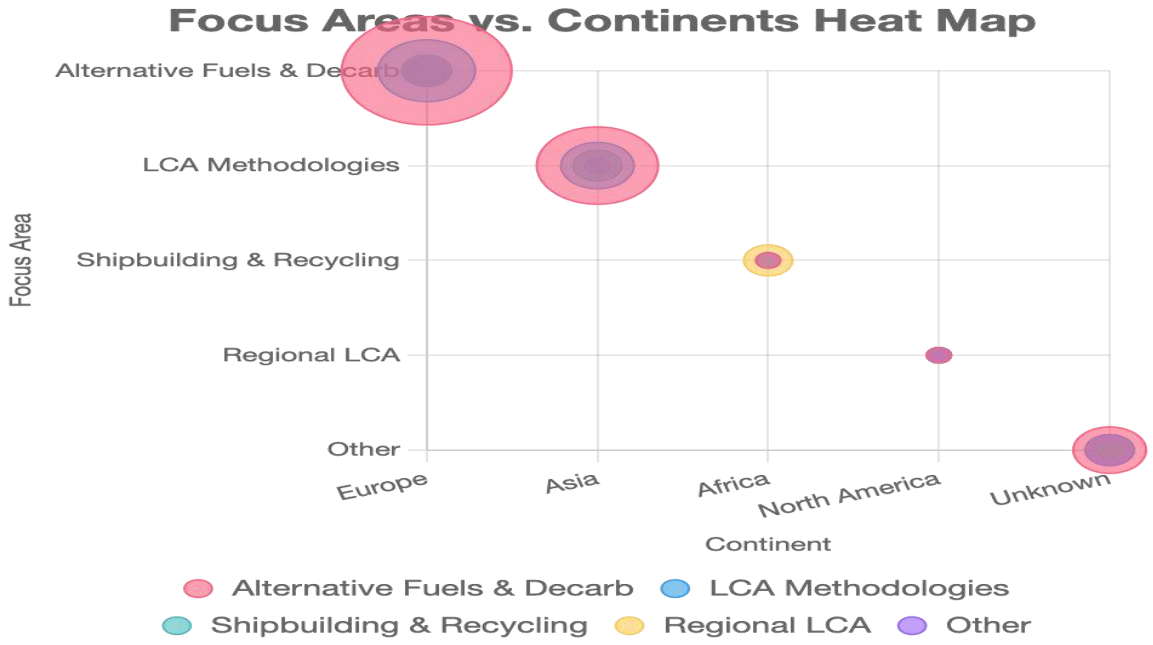

Figure 1: Focus area heatmap by continent.

The analysed studies employed diverse methodologies (Figure 2). Case studies, narrative reviews, and systematic reviews led the pack with 18 (31.0%), 15 (25.9%), and 8 (13.8%) articles, respectively, followed by comparative LCA in seven (12.1) articles. This distribution underscores the reliance on LCA-based case studies to evaluate environmental impacts in the maritime sector, particularly for alternative fuels and shipbuilding [5], [59].

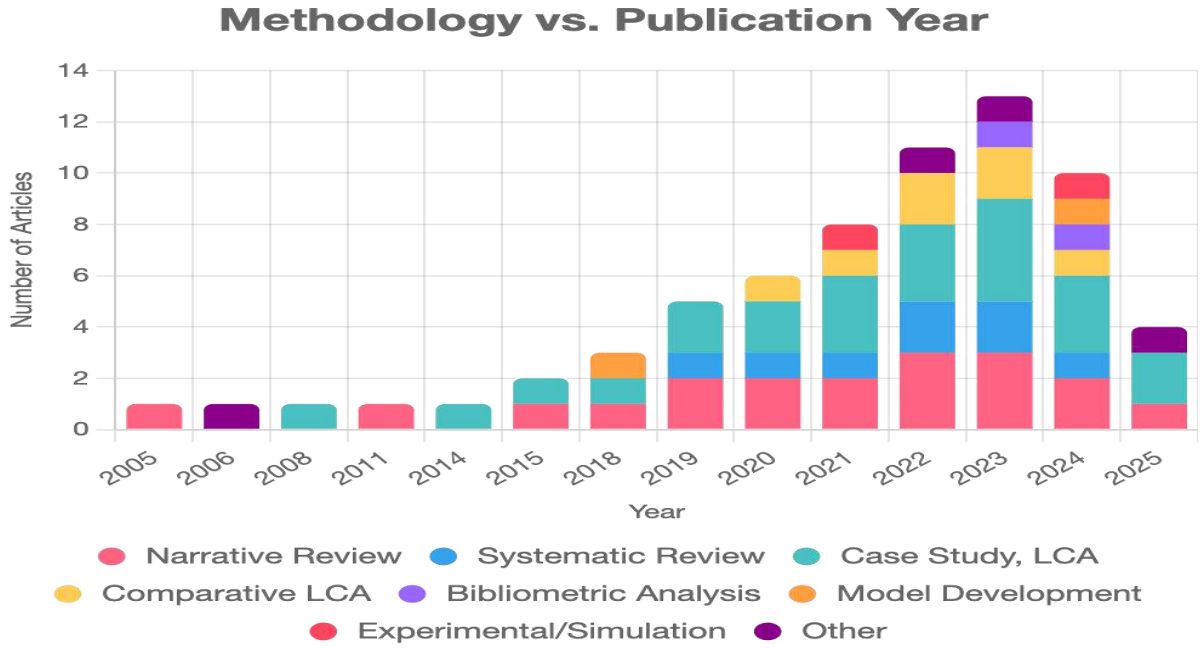

Figure 2: Articles distribution by methodology between 2005 and 2025.

5 FINDINGS

5.1 Key findings and research gaps

The findings reveal a robust academic focus on maritime decarbonisation driven by global imperatives to reduce GHG emissions, in line with the IMO 2020 and 2023 strategies [4], [34]. Interestingly, there is a dominance of alternative marine fuel research, reflecting the sector's transition toward low-carbon and zero-carbon solutions, such as hydrogen and ammonia, which offer significant emission reduction potential but face challenges in terms of infrastructure and cost [32], [52]. However, other approaches, ranging from case studies to comparative analyses, suggest the need for methodological standardisation to enhance the comparability and reliability of the findings [60].

Geographically, a significant amount of research in Europe and Asia aligns with their strong maritime industries and policy support for decarbonisation [2], [58]. This suggests strong resource investment and research infrastructure availability on these continents. On the other hand, Africa and South America depict lower outputs and focus, reflecting resource constraints or differing research priorities compared to North America, where a balanced contribution signals a broader undefined research interest.

Despite these valuable insights, several gaps in the literature have been identified, especially in African and South African maritime contexts.

1) **Limited Focus on Maritime Activities:** Most LCA studies in South Africa have focused on other sectors, such as water, energy, agriculture, and cement production, with limited attention given to maritime activities such as shipping, port operations, and shipbuilding.
2) **Lack of Comprehensive Assessments:** There is lack of comprehensive LCA studies covering the entire life cycle of maritime products and services, from raw material extraction to end-of-life disposal or recycling.

3) **Insufficient Consideration of Social Impacts:** Many LCA studies in South Africa have primarily focused on environmental aspects, with insufficient consideration given to the social impacts on local communities and stakeholders.
4) **Limited Integration with Economic Analysis:** There is need for greater integration of LCA with economic analysis to assess the cost-effectiveness of sustainable maritime practices and policies.

In addition, over-reliance on case studies and reviews suggests that, while the field is advancing, there is a gap between experimental and simulation-based research. This can provide deeper insights into the practical implementation of decarbonisation technologies [2]. Furthermore, the focus on shipbuilding and recycling underscores the importance of circular economy principles in maritime sustainability; however, this area remains underexplored compared with fuel-related studies [61], [62]. Data transparency and sharing by all key players remain vital. Uncertainties related to data inputs, such as fuel quality, system boundaries, and inherent complexity of maritime supply chains (Table 9), remain a challenge.

Table 9: Sources of uncertainty in maritime LCA applications.

Source	Example	Impact on Results
Data variability	Fuel sulfur content, vessel age	Wide GHG emission range
Methodological choice	Allocation of port emissions	Different impact distribution
System boundary	Inclusion/exclusion of hinterland	Under/overestimation of impacts

5.2 Challenges and opportunities for LCA implementation

5.2.1 Challenges

The implementation of an LCA in the South African maritime industry presents several challenges. One major obstacle is the lack of reliable and standardised data on material flows, energy use, and emissions, partly because of confidentiality concerns and insufficient data collection systems. Methodological issues such as defining system boundaries, selecting functional units, and choosing impact assessment methods complicate LCA studies, particularly for complex maritime systems. Small and medium-sized enterprises (SMEs) struggle because of the high costs, limited expertise, and lack of regulatory or market incentives to adopt LCA in South Africa [21], [11].

To overcome these barriers, a multi-stakeholder approach (

Table 10)**Error! Reference source not found.** is required. Government interventions such as subsidies, mandatory reporting, and green certification could encourage LCA adoption in the sector. Private business and industry collaboration can also improve data sharing and standardisation. Academic partnerships may also assist in developing localised LCA databases and training programs to address the shortage of skilled professionals. Furthermore, adopting international best practices and proxy data can help supplement the gaps in regional data. By addressing these challenges, South Africa can enhance sustainable maritime practices and align itself with global environmental and decarbonisation standards.

Table 10: Key institutional stakeholders and potential LCA roles.

Identified Stakeholders	LCA Role/Responsibility	Coordination Challenge
Transnet National Ports Authority (TNPA)	Port operations data, infrastructure	Limited data sharing with shipping lines
Department of Transport	Policy oversight	Competing priorities with environmental goals

Shipping Companies	Vessel operation data	Varied LCA adoption, proprietary concerns
Department of Forestry, Fisheries & Environment	Emissions reporting, standards	Regulatory overlap with Transport
Logistics Providers	Supply chain emissions data	Fragmented data, lack of standardisation
SAMSA	Maritime safety, LCA promotion	Training gaps and limited technical expertise
Transnet Port Terminals (TPT)	Terminal emissions data, operations	Coordination with port authorities and logistics providers
Freight Forwarders	Cargo movement emissions data	Disparate systems, lack of comprehensive data sharing

5.2.2 Opportunities

The adoption of LCA in the South African maritime industry presents significant opportunities to enhance sustainability and competitiveness. Companies can identify environmental hotspots across their value chains, from ship design to fuel selection, port operations, and waste management. LCA enables companies to reduce emissions, improve resource efficiency, and adopt cleaner technology. For instance, comparing fuel options (e.g., heavy fuel oil vs. LNG) or optimising shipyard water use can lead to cost savings and regulatory compliance, while fostering green innovation in propulsion systems and materials. LCA further supports policy development, helping regulators incentivise sustainable practices within the sector [11], [21].

Beyond its operational benefits, LCA strengthens market positioning in the global economy, which is increasingly driven by environmental accountability. Companies leveraging LCA can differentiate themselves, meet international standards (e.g., IMO 2020 sulfur caps), and attract eco-conscious investors and customers [8]. For South Africa's maritime sector, this translates into improved competitiveness, access to green supply chains, and alignment with global sustainability trends. By integrating LCA into decision-making systems, the industry can balance economic growth with ecological stewardship, thereby ensuring long-term resilience and sustainability.

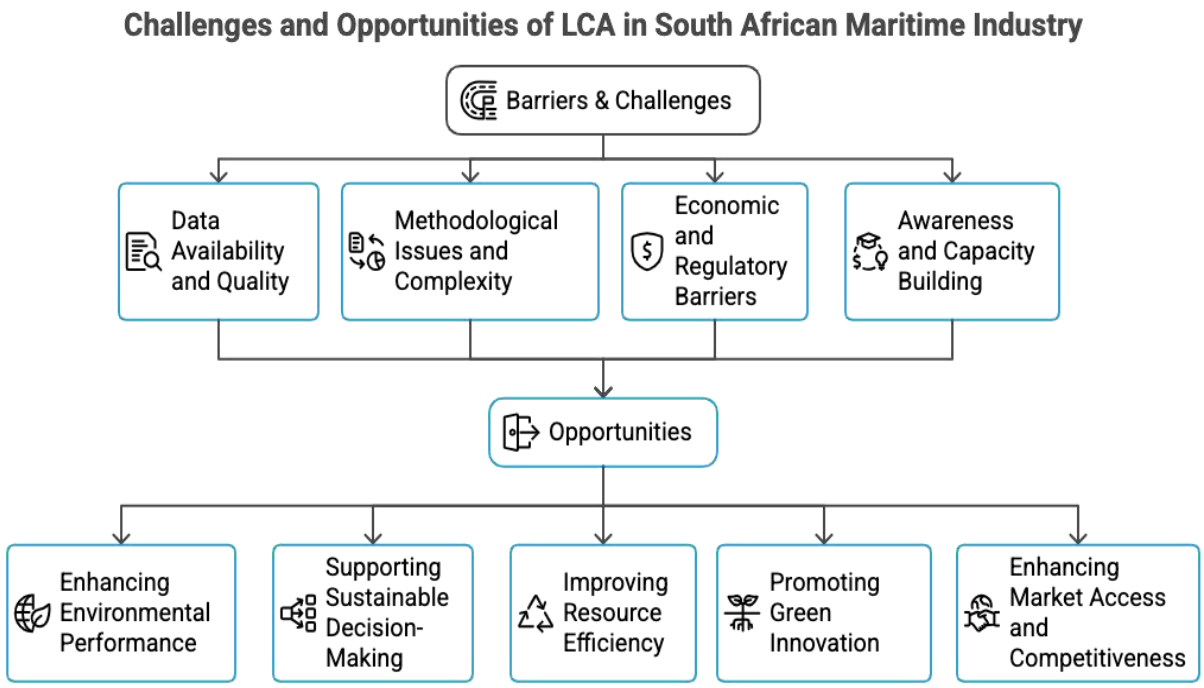

Figure 3: Key challenges and opportunities for LCA adoption in the South African maritime sector.

5.2.3 Implications and future direction

The findings of this study have several implications for maritime decarbonisation. First, the emphasis on alternative fuels calls for increased investment in infrastructure, such as port facilities for hydrogen and ammonia, to support their adoption [68]. Second, the prominence of LCA highlights its utility as a decision-making tool; however, future research should address methodological inconsistencies to improve its robustness. Third, regional disparities suggest a need for capacity building in underrepresented regions, such as Africa, to ensure globally inclusive decarbonisation strategies [12].

Future research should prioritise experimental studies to validate LCA findings and explore emerging technologies such as digitalisation for emission monitoring and sector coupling for energy efficiency [2]. Integrating cost analyses with environmental assessments could provide a more holistic understanding of decarbonisation pathways for future strategies and policy directions [69], [70].

6 DISCUSSIONS AND RECOMMENDATIONS

This study significantly advances and contributes to the industry by leveraging LCA to address environmental impacts and resource constraints in South Africa's maritime sector. By systematically exploring the global landscape of LCA research, the paper reveals how LCA quantifies environmental impacts from maritime activities, enabling optimised resource allocation and sustainable decision-making. In the South African context, LCA identifies emission hotspots in aging vessel fleets and port operations, addressing challenges like data scarcity and limited alternative fuel infrastructure. Furthermore, LCA provides a structured methodology to enhance operational efficiency under resource constraints, particularly for SMEs, by evaluating trade-offs between environmental performance and economic feasibility. This supports sustainable maritime practices, aligning with global decarbonisation goals while enhancing South Africa's competitiveness through resource-efficient strategies and green innovation.

South Africa faces unique challenges and opportunities for the adoption and application of lifecycle assessment within its maritime and shipping industries. These are shaped by both technological and regional factors. As part of the global industry, South Africa endures a unique economic structure that impacts data availability and competing policy priorities. A significant challenge in South Africa is the historical lack of localised LCI datasets, which are essential for accurate LCA [11]. By contrast, Europe and Asia have long benefited from established national LCA databases, which facilitate more granular and comparative analyses across many facets of the shipping industry and maritime operational scenarios [9].

The maritime sector's reliance on fossil fuels remains a global challenge, with shipping being responsible for a growing share of CO_2 emissions. This challenge is universal but is compounded in regions where access to alternative fuels and clean energy infrastructure is limited. In South Africa, the transition to renewable energy and alternative marine fuels is further complicated by economic and policy barriers as well as the need for sector coupling to integrate sustainable energy sources into maritime operations [2]. Opportunities for innovation have emerged from the exploration of green hydrogen and alternative fuels. Green hydrogen and other alternative fuels have the potential to be game changers in the quest to decarbonise the sector [71], [40], [52], [53], [72]. The integration of such technologies presents a significant opportunity for South Africa to leapfrog traditional pathways and adopt cleaner propulsion systems, thereby providing the necessary infrastructure and policy support.

Collaboration and knowledge transfer are essential drivers for advancing LCA applications in the maritime and shipping industries. Analysis of organisational collaboration networks reveals that, on a global scale, there is a notable deficiency in close partnerships among key maritime research institutions. This lack of intimate collaboration restricts the sharing of expertise, research experience, and ultimately, the dissemination and practical utilisation of research outcomes. Asia, particularly China, tops the volume of scholarly output related to sustainable maritime transport, followed by the United States and United Kingdom. This dominance is not only a function of research investment but also of the ability to attract talent and prioritise maritime-related research agendas [17]. Unsurprisingly, however; the overall number of research articles and collaborative initiatives remains limited in Africa compared with the more established networks in Asia, Europe, and North America. The limited collaboration in the South African context can be attributed to the scarcity of LCA studies focusing on maritime and shipping [73].

In charting the way forward, key recommendations are made to promote LCA applications in the maritime sector. These include:

1. **Green Finance Eligibility**: LCA-based GHG reduction metrics as a prerequisite for access to green bonds, concessional loans, and climate finance for maritime projects.
2. **Risk Assessment**: LCA is used to quantify transition and physical climate risks associated with maritime assets, informing insurance, lending, and investment decisions.
3. **Performance-Based Incentives**: Structure public subsidies, tax incentives, and port fee reductions around verified life-cycle emission reductions, as opposed to solely operational emissions.

Additionally, the government should establish a comprehensive national LCA database center with standardised data collection protocols to ensure reliable and updated information for decision-making. Tailored LCA training and capacity-building programs must be implemented in collaboration with universities and industry stakeholders, equipping participants with skills to conduct, interpret, and apply LCA studies. Economic incentives, such as tax breaks or grants, along with regulatory measures that mandate LCA adoption, reporting, and sustainable

practices, should be put in place as essential tools for motivating industry stakeholders and leveling the playing field.

Furthermore, promoting collaboration and knowledge sharing is vital for accelerating LCA adoption. Establishing industry-specific working groups can facilitate the exchange of best practices, tools and resources. Integrating LCA into the policy and planning processes is equally important. This includes requiring LCA studies for major infrastructure projects, using LCA results to shape environmental regulations, incorporating LCA indicators into national sustainability metrics, and prioritising sustainable products in public procurement. By implementing these measures, South Africa can position its maritime industry as a leader in sustainability and alignment with the global environmental goals.

7 CONCLUSION

This review contributes to the body of knowledge regarding LCA in the maritime sector, particularly in South Africa. It further provides insights into the current state of LCA application in the South African maritime industry, barriers to its adoption, and opportunities for implementation. The study not only confirms the lack of LCA application in the maritime sector in South Africa but also advances the conversation by demonstrating the significant opportunities and potential benefits of adopting and applying LCA in the maritime sector. These benefits can manifest as enhanced environmental performance, sustainable decision making, improved resource efficiency, green innovation growth, enhanced market access, and improved competitiveness. To realise this potential, it is essential that the South African government, in collaboration with industry stakeholders, take proactive steps to address the challenges and barriers to LCA implementation. These include developing a national LCA database, establishing LCA training and capacity building programs, providing economic incentives and regulatory support, fragmented institutional responsibilities, data gaps, technological and digitalisation barriers, integrating LCA into policies and planning, and balancing socioeconomic priorities with environmental objectives.

Furthermore, this review paper highlights the global state of LCA utilisation in the maritime sector using the PRISMA methodology. Europe and North America led in terms of methodological sophistication and practical application, whereas Asia emerged as a player with targeted contributions. South Africa, remains underrepresented, but possesses considerable growth potential particularly with its unique position as a maritime leader in Africa. The findings of this review not only illuminate global and regional disparities in LCA applications but also chart a forward-looking agenda for maritime and shipping stakeholders in South Africa and beyond. Future studies should address methodological gaps, expand experimental research, and integrate economic and environmental analyses to support the decarbonisation goals of the maritime industry.

ABSTRACT

The ecotourism industry is one of the fastest-growing tourism sectors. Yet, research on its business and operational strategies remains limited. Lean and Green, an evolution of Lean philosophy, combines operational efficiency with environmental responsibility to deliver a holistic management approach. Therefore, this study aims to examine how Lean and Green can support organisational sustainability in ecotourism. A systematic literature review (SLR) identified relevant practices and their impacts on the triple bottom line (TBL). These findings informed the development of a Lean and Green Impact Matrix, mapping contributions across economic, environmental, and social dimensions. This framework offers a theoretical pathway for achieving sustainability in ecotourism and practical guidance for its application. The study deepens a theoretical understanding of Lean and Green within the ecotourism context. It lays the groundwork for future research into its practical implementation and contribution to sustainable organisational performance.

Keywords: Organisational sustainability; Lean and Green; Lean; Sustainable business practices; Ecotourism

1 INTRODUCTION

Organisational sustainability, also referred to as sustainable business practices (SBP), is the capacity of a business to operate in changing circumstances while simultaneously ensuring long-term success [1]. Additionally, it is the ability to meet the current needs of a business without compromising the ability to meet future needs [2]. Organisational sustainability attempts to address the triple bottom line (TBL) of sustainability—social, economic, and environmental wellbeing. This is a balance of the TBL of sustainability and how it is used to achieve a business that will not only survive but thrive and develop in the long term.

In the current economic climate, organisational sustainability has become increasingly relevant as a response to the increasing global threats of environmental degradation, socio-economic inequalities, and the climate crisis [3]. It is not purely about using less paper to save the trees, or reuse-reduce-recycle. Sustainability stands for the holistic approach to business that generates good publicity and healthy planetary habits, to ensure long-term sustainability [4]. Some of the benefits of SBP are increased customer satisfaction and increased market value, as an increasing number of consumers are showing an interest in eco-friendly products and services [4]. SBP can be approached in many different ways; however, to yield the best results, a holistic approach that addresses all three factors of a sustainable business is necessary.

Ecotourism is the combination of nature and tourism that focuses on providing the consumer with an experience of the natural environment and culture. It is focused on sustainably using the natural environment so that tourists might enjoy it. However, the sustainable environment is prioritised above economic growth. The purpose of any ecotourism organisation is to reach a state of sustainability using resource conservation, societal and cultural prosperity, and economic stability and growth [5]. With this being said, there is a growing interest in the ecotourism industry due to the change in tourist behaviour. More and more tourists are interested in sustainable travel options, making ecotourism uniquely suited.

One approach toward achieving organisational sustainability is the combination of Lean and Green (LG). Lean refers to the philosophy of continuous improvement of processes, the reduction of eight forms of ‘Lean’ waste, and the elimination of non-value adding practices in an organisation [6]. LG is an extension of this philosophy to include a focus on environmental sustainability, not only to create a “greener” operation but to use this additional focus further to improve the efficiency and economic performance of an organisation [7].

Currently, Lean and Green literature points primarily to the application of LG in a broader sense in manufacturing, service, or agricultural businesses. However, some writers recognise the need for sector-specific research regarding the implementation or approach of LG [8].

Thus, the primary focus of this paper is to identify how LG is relevant to the organisational sustainability and growth of businesses within the ecotourism industry.

2 LITERATURE REVIEW

2.1 Ecotourism

Ecotourism is defined as responsible travel to natural area that conserves the environment, sustains the well-being of the local people, and involves interpretation and education [9]. Ecotourism consists of at least five key characteristics [5, 10], which are as follows:

- It is a form of tourism.
- Attractions are primarily nature-based, but can include associated cultural resources and influences.

- Educational and learning outcomes are fostered.
- It is managed so that environmental and socio-cultural sustainability outcomes are more likely to be achieved.
- The importance of an operations financial sustainability is recognised (it must at least be financially viable). [5, 10]

The five characteristics are the requirements used to evaluate the applicability of this research to the ecotourism context.

2.2 Lean and Green

LG methodologies represent a strategic integration of Lean management principles, which prioritise waste reduction and operational efficiency, with Green practices that focus on minimising environmental impacts and fostering sustainability [11]. Lean principles, such as continuous improvement, value stream mapping, and systematic waste elimination, aim to optimise processes and enhance productivity [12]. At the same time, Green practices emphasise resource conservation, pollution mitigation, and eco-friendly operations [11]. The synergy between these approaches enables organisations to achieve operational excellence while simultaneously sustaining the environment [13]. For instance, Lean tools like Kaizen and 5S can be adapted to address environmental challenges, such as reducing energy consumption and waste generation, while green practices like water conservation and greenhouse gas reduction complement Lean's focus on process optimisation [14-16]. This integration not only enhances organizational performance but also aligns with broader sustainability goals, making LG a critical framework for modern business practices.

The TBL framework, encompassing economic, environmental, and social dimensions, is inherently connected to LG practices. Lean methodologies contribute to the economic dimension by improving profitability and operational efficiency [12], while Green practices address the environmental dimension by reducing ecological footprints and promoting sustainable resource utilisation [11]. Furthermore, social sustainability is supported through Lean's emphasis on employee engagement, workplace safety, and community wellbeing. By integrating LG practices, organisations can achieve balanced TBL performance, ensuring long-term viability and stakeholder satisfaction. Empirical evidence demonstrates that LG initiatives not only reduce costs and enhance product quality but also improve corporate reputation and address environmental and social responsibilities [2, 4, 13].

3 RESEARCH METHOD

This study employed a two-phase approach. Phase one (data gathering) took the form of a systematic literature review (SLR) to identify, evaluate, and synthesise relevant academic contributions related to LG for organisational sustainability. Phase one yielded the findings depicted in the PRISMA flow diagram illustrated in Figure 1. Phase two (data analysis) used content analysis to identify and investigate themes identified in phase one.

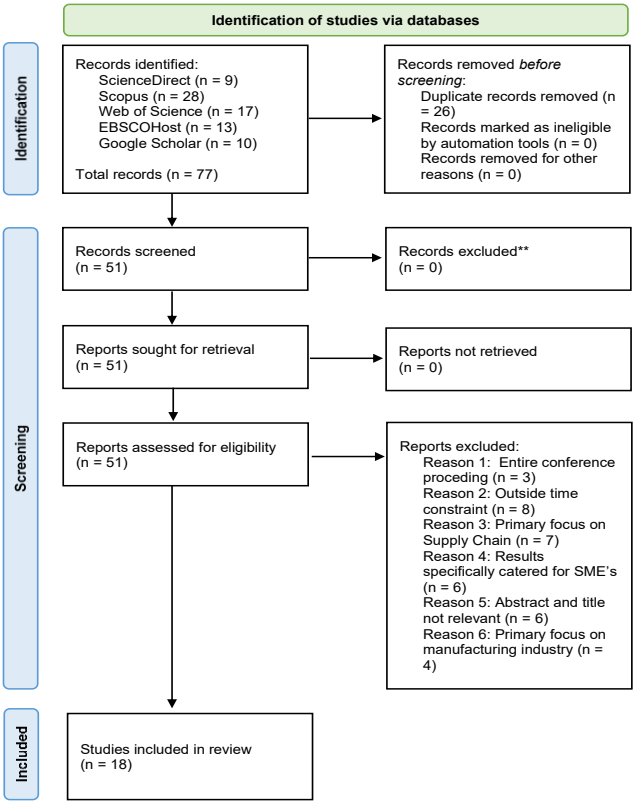

Figure 1: PRISMA Flow Diagram

3.1 Phase 1: Data gathering - Systematic literature review

The systematic literature review consists of three distinct stages: 1) Planning the review, 2) Conducting the review, and 3) Reporting the review [17]. The planning stage included a search protocol which defined the parameters of the literature review. The review protocol is seen in **Error! Reference source not found.**.

Table 1: Systematic literature review protocol

Purpose of the Study	The study aimed to identify the specific tools, methods, and strategies encompassed in Lean and Green that have an impact on organisational sustainability, and to evaluate how this is suitable for the ecotourism industry by relating the findings to the fundamental ecotourism characteristics.
Inclusion Criteria	• Literature on the use of lean and green management concepts to achieve organisational sustainability. • Literature with a primary focus on sustainable business practices. • Literature based on service organisations, ideally tourism organisations.
Exclusion Criteria	• Literature with a primary focus on manufacturing organisations. • Literature with a primary focus on supply chain and supply chain management • Literature with an inaccurate understanding of Lean.
Time frame	2016 - 2025
Search Databases	• Science Direct • Scopus • Web of Science • EBSCOHost • Google Scholar (For additional sources, the first 10 results were included for relevance)

Keywords	Lean & Green	Organisational sustainability keywords
	'Lean and green'	Organisational sustainability Corporate sustainability Sustainable business practices
Search string	"Lean" AND "Green" AND ("organisational sustainability" OR "corporate sustainability" OR "sustainable business practice")	
Quality Assessment Criteria	• Literature must be peer-reviewed • An accurate scientific method should be used • Correct knowledge and understanding should be prevalent	

The systematic review protocol seen in Table 1 was used to screen publications and identify the 18 papers that were included for full-text screening. The replicability of the research demonstrates its internal validity [18]. The thorough SLR protocol followed ensured that the study could be replicated if the exact steps are followed. The search yielded 18 eligible reports that adhered to the inclusion criteria and quality assessment criteria. A list of the included literature can be found in Appendix A.

3.2 Phase 2: Data analysis – Content analysis

The text-based data collected was subjected to a content analysis. The content analysis was based on a four-step inductive qualitative content analysis [30]. The four steps are as follows:

(1) Establishing an overview of the data material [30].
(2) Identifying and extracting meaning units of relevance to the study aim [30].
(3) Combining and condensing meaning units into descriptive categories [30].
(4) Generating explanatory themes by linking categorised meaning units [30].

This analysis was guided by the research questions posed in this research and used to identify the design requirements of a conceptual matrix explaining the detailed impact of LG on organisational sustainability in terms of the TBL.

- Research Question 1: What lean tools, methods, and strategies are identified in the text, and what is their impact on organisational sustainability?
- Research Question 2: What green tools, methods, and strategies are identified in the text, and what is their impact on organisational sustainability?
- Research Question 3: What combined 'lean and green' tools, methods, and strategies are identified in the text, and what is their impact on organisational sustainability?

Each paper was read and examined to critically assess the content to answer the three research questions. The content analysis resulted in eight themes. These themes, along with their elements, are displayed in Table 2. Column 1 provides the overarching 'Lean and Green' theme that is identified, while column 2 illustrates the specific practical elements that fall under each theme.

Table 2: Identified Themes

Lean and Green theme	Practical elements	References
Waste reduction	Lean waste elimination	[2, 4, 8, 14-16, 19, 21, 23-29]
	Reducing material waste	[2, 8, 16, 24, 26-28]
	Life cycle analysis	[24, 28]
	Reduced greenhouse emissions	[16, 24, 26-28]
	Responsible resources	[4, 14-16, 24, 26, 27]
Resource efficiency	Optimised resource utilisation	[4, 14-16, 24, 26-28]
	Streamlining processes	[4, 14-16, 24, 25, 27, 28]
	Sustainable value stream mapping	[15, 16, 24, 27, 28]

Lean and Green theme	Practical elements	References
	Sustainable resource practices	[4, 13-16, 19, 24-28]
Continuous improvement	Kaizen	[13-16, 24, 25, 27, 28]
	Problem-solving innovation (spaghetti diagrams, A3, visual process)	[15, 24, 25, 28]
	Defect detection and prevention (poka yoke, jidoka)	[15, 23, 24, 27]
	5S/ 7S	[8, 13, 15, 24, 25, 27]
Operational efficiency	JIT	[8, 14, 15, 23-25, 27]
	Kanban	[8, 15, 23-25, 27]
	TPM	[8, 14, 15, 23-25, 27]
Respect for people	Training	[13-15, 23, 25, 26, 28]
	Leadership commitment	[2, 13-15, 21, 25, 28, 29]
	Improved health and safety	[13, 15, 19, 21, 23, 26]

Green supply chain	Green logistics	[4, 19, 21, 23, 24, 28]
	Sustainable resource practices	[4, 13-16, 19, 24-28]
Integrated lean and green	Simultaneous implementation	[2, 14, 15, 27, 28]
	Aligning lean practices with circular economy goals	[15, 16, 27]
	Integrated frameworks	[13-15, 24, 28]
Customer and stakeholder engagement	Involving customers in sustainability initiatives	[2, 25, 28]
	Engaging stakeholders	[13, 19, 28, 29]

The themes are discussed in section 0. The themes are seen as combined LG methods, tools, and strategies. All the tools, methods and strategies identified, whether they were lean or green, were evaluated and used to create the combined list. No direct contradictions were seen; different papers aligned in terms of the overarching themes but differed in the practical elements mentioned. The practical elements did, however, support one another and were more of an expansion than a contradiction.

4 FINDINGS AND DISCUSSIONS

The study aimed to identify the specific tools, methods, and strategies encompassed in LG that have an impact on the organisational sustainability of an organisation, and to evaluate how this is suitable for the ecotourism industry and corresponds with the fundamental ecotourism characteristics. This section presents the findings in terms of the three research questions stated in Section 3.2. The research questions are closely related and are discussed collectively.

4.1 Themes and impact analysis

Columns 1 and 2 of Table 3 are an extension of the themes identified in Table 2. The impact matrix is used to illustrate the value of these themes in achieving organisational sustainability, as explained in columns 3 (social aspects), 4 (economic aspects), and 5 (environmental aspects).

Table 3: Lean and green impact matrix

Lean and Green theme	Practical elements	Social	Economic	Environmental
Waste reduction	Lean waste elimination	Improves workplace conditions by reducing clutter and hazards.	Reduces operational costs by eliminating inefficiencies.	Minimises resource consumption and waste generation.
	Reducing material waste	Reduces the strain on the local community in terms of waste removal.	Optimises material costs and improves profitability.	Decreases landfill waste and conserves natural resources.
	Life cycle analysis	Encourages sustainable product design, benefiting communities.	Improves product efficiency and reduces long-term costs.	Identifies environmental impacts across product lifecycles for mitigation.
	Reduced greenhouse emissions	Improves public health by reducing air pollution.	Reduces regulatory fines and energy costs.	Mitigates climate change and improves air quality.
	Responsible resources	Promotes ethical sourcing and community wellbeing.	Enhances brand reputation and reduces resource costs.	Ensures sustainable use of natural resources.
Resource efficiency	Optimised resource utilisation	Improves employee productivity and satisfaction.	Reduces operational costs and increases profitability.	Minimises resource depletion and environmental impact.
	Streamlining processes	Enhances teamwork and reduces workplace stress.	Improves efficiency and reduces production costs.	Reduces energy and material waste.
	Sustainable value stream mapping	Engages employees in sustainability initiatives.	Identifies cost-saving opportunities in processes.	Optimizes energy and material usage.
	Sustainable resource practices	Promotes community awareness of sustainability.	Reduces costs associated with resource inefficiencies.	Conserves resources and reduces environmental degradation.
Continuous improvement	Kaizen	Fosters a culture of collaboration and innovation.	Improves operational efficiency and reduces costs.	Reduces waste and enhances resource efficiency.
	Problem-solving innovation (spaghetti diagrams, A3, visual process)	Encourages employee engagement and skill development.	Identifies inefficiencies, reducing operational costs.	Minimises waste and improves process sustainability.
	Defect detection and prevention (poka yoke, jidoka)	Improves workplace safety and employee satisfaction.	Reduces costs associated with defects and rework.	Minimises resource wastage and environmental harm.
	5S/ 7S	Enhances workplace organisation and safety.	Improves efficiency and reduces operational costs.	Reduces waste and promotes sustainable practices.
Operational efficiency	JIT	Reduces stress on employees by aligning production with demand.	Minimises inventory costs and improves cash flow.	Reduces overproduction and associated waste.
	Kanban	Improves communication and teamwork.	Enhances workflow efficiency and reduces costs.	Minimises resource waste and energy usage.
	TPM	Improves equipment	Reduces downtime and maintenance costs.	Minimises energy consumption and emissions.

Lean and Green theme	Practical elements	Social	Economic	Environmental
		reliability and workplace safety.		
Respect for people	Training	Empowers employees and improves job satisfaction.	Enhances productivity and reduces turnover costs.	Promotes sustainable practices through education.
	Leadership commitment	Drives cultural change and employee engagement.	Aligns organisational goals with sustainability, improving profitability.	Ensures long-term environmental stewardship.
	Improved health and safety	Enhances employee wellbeing and reduces workplace accidents.	Reduces costs associated with health and safety incidents.	Promotes sustainable and safe practices.
	Lean and green culture	Fosters a collaborative and sustainability-focused workplace.	Improves operational efficiency and reduces costs.	Encourages eco-friendly practices and waste reduction.
	Alignment of organisational strategies with lean and green practices	Improves employee morale and stakeholder trust.	Enhances competitiveness and profitability.	Promotes long-term environmental sustainability.
	Promoting a top-down approach to drive cultural change	Encourages employee buy-in and collaboration.	Aligns organisational goals with sustainability, improving efficiency.	Ensures consistent implementation of eco-friendly practices.
Green supply chain	Green logistics	Improves community relations through sustainable practices.	Reduces transportation costs and improves efficiency.	Minimises emissions and environmental impact.
	Sustainable resource practices	Promotes ethical sourcing and community wellbeing.	Reduces costs associated with resource inefficiencies.	Conserves resources and reduces environmental degradation.
Integrated lean and green	Simultaneous implementation	Enhances employee engagement and collaboration.	Improves operational efficiency and reduces costs.	Optimises resource use and minimises waste.
	Aligning lean practices with circular economy goals	Promotes community awareness of sustainability.	Reduces costs associated with resource inefficiencies.	Conserves resources and reduces environmental degradation.
	Integrated frameworks	Encourages cross-functional collaboration and innovation.	Improves efficiency and reduces operational costs.	Promotes holistic sustainability practices.
Customer and stakeholder engagement	Involving customers in sustainability initiatives	Builds trust and improves customer satisfaction.	Enhances brand reputation and market competitiveness.	Encourages adoption of eco-friendly products and practices.
	Engaging stakeholders	Fosters collaboration and community support.	Improves organisational alignment with sustainability goals.	Promotes widespread adoption of sustainable practices.

Table 3 shows a summarised impression of the impact different Lean and Green elements have on the triple bottom line. Columns 3, 4 and 5 give a brief discussion of the effect each element has on each of the TBL pillars. The Lean and Green themes are discussed in more detail in the sections below.

4.1.1 Waste reduction

Literature emphasises waste reduction as a central theme and common goal of both Lean and Green efforts. Lean waste targets operational inefficiencies, such as overproduction, excess inventory, and defects, using methods like pull production, lot size reduction, and kaizen [2, 14, 15]. Material waste focuses on reducing resource consumption, emissions, and pollution through practices like energy efficiency, greenhouse gas reduction, and tools like life cycle assessment [24].

One way of interpreting the overlap between lean and green is that, instead of solely focusing on lean waste, the definition of waste can be expanded into lean waste and material waste [4]. Integrated frameworks like Green Lean Six Sigma [24] and the House of EcoLean [15] demonstrate that synergy can be achieved by addressing both types of waste for sustainable outcomes.

The research highlighted that lean management's role is in systematically reducing waste, enhancing efficiency, and achieving short-term sustainability benefits, while green practices address long-term environmental impacts [14]. It is also demonstrated how lean practices, such as continuous improvement and waste elimination, complement green initiatives like pollution prevention and resource reduction, leading to superior operational and environmental performance [4]. Similarly, lean methods such as 5S, value stream mapping, and total productive maintenance have been identified as effective tools for minimising waste and improving energy efficiency, with documented reductions in mixed waste and emissions, as well as improved overall sustainability [2, 8]. The House of EcoLean framework is introduced, which integrates lean principles like Kaizen and pull systems with ecological practices to optimise resource utilisation and eliminate waste, aligning operational efficiency with environmental sustainability [15].

Furthermore, Lean Six Sigma's use of tools like life cycle analysis and sustainable value stream mapping highlights its ability to eliminate defects and streamline processes, thereby reducing resource consumption and environmental impact [23, 24]. The LG combination highlights the alignment of lean production with circular economy goals, focusing on waste reduction through continuous improvement and resource efficiency, which advocates the use of LG for organisational sustainability [16]. Collectively, these studies demonstrate that waste reduction is not only a cornerstone of lean methodologies but also a critical enabler of environmental and operational sustainability.

4.1.2 Resource efficiency

Resource efficiency emerges as a critical theme across the included literature, underscoring its significance in achieving operational excellence and sustainability. Lean practices, such as value stream mapping (VSM) and enhanced value stream mapping (EVSM), systematically reduce waste and optimise resource utilisation [2, 4, 8, 14, 24]. Green practices complement these efforts by minimising environmental impacts through reduced water, material, and energy consumption, while promoting eco-friendly materials and sustainable production processes [2, 4, 24]. Frameworks like Green Lean Six Sigma (GLSS) and the House of EcoLean integrate lean tools with ecological principles, addressing both operational and environmental inefficiencies to enhance resource utilisation and sustainability outcomes [15, 24].

Sector-specific applications further illustrate the importance of resource efficiency in diverse contexts. In agriculture, Lean Green practices reduce chemical usage and optimise production processes, contributing to environmental sustainability and improved profitability [26]. Similarly, service industries leverage Lean tools such as continuous flow and work standardisation to enhance resource utilisation. Circular economy principles align with lean methodologies by emphasising regenerative systems and narrowing material and energy loops to minimise resource input and waste [16]. Integrated management systems (IMS) streamline processes across quality, environmental, and social dimensions, fostering resource efficiency [13]. Collectively, these approaches demonstrate how the integration of LG practices, alongside circular economy principles, can drive sustainable development by ensuring efficient resource use while mitigating environmental impacts [13, 14, 24].

4.1.3 Continuous improvement

Continuous improvement is consistently identified across the literature [2, 7, 10-12, 16, 18-20, 22-25, 27] as a critical mechanism for advancing organisational sustainability and achieving alignment with the TBL. Economically, continuous improvement drives operational efficiency by systematically reducing waste, defects, and costs [2, 11, 18, 21, 23]. Lean methodologies such as Kaizen and Total Productive Maintenance (TPM) are highlighted for their ability to enhance productivity and profitability [11, 18, 21, 23]. From an environmental perspective, continuous improvement integrates green practices, including waste reduction, energy efficiency, and pollution prevention, which collectively minimise ecological impacts [11, 12, 18, 21, 23]. Tools such as Value Stream Mapping (VSM) and Sustainable Value Stream Mapping (SUS-VSM) are particularly effective in identifying and optimising ecological aspects of processes [12, 18, 22].

The social dimension of sustainability is equally supported by continuous improvement practices, which foster employee engagement, training, and involvement, thereby enhancing workplace satisfaction and morale [11, 18, 23, 27]. Furthermore, these practices promote social equity by improving working conditions and contributing to community welfare [11, 18, 23, 27]. Collectively, methodologies such as Kaizen cultivate a culture of ongoing enhancements that align operational objectives with broader sustainability goals [11, 12, 18, 23]. By addressing the economic, environmental, and social dimensions of the TBL, continuous improvement emerges as a foundational strategy for ensuring long-term organisational resilience and competitive advantage [11, 12, 18, 23, 27].

4.1.4 Operational improvement

Operational improvement is consistently highlighted across the documents as a pivotal mechanism for advancing organisational sustainability and achieving alignment with the TBL, encompassing economic, environmental, and social dimensions. Economically, operational improvement drives cost efficiency, profitability, and resource optimisation. Lean methodologies such as Just-In-Time (JIT), Total Productive Maintenance (TPM), and Value Stream Mapping (VSM) are frequently referenced for their capacity to streamline processes, minimise waste, and enhance financial performance [11, 18, 21, 23]. For instance, JIT reduces inventory costs and improves responsiveness. At the same time, TPM ensures equipment reliability and mitigates downtime, thereby contributing to economic sustainability [11, 18, 21]. Furthermore, these practices enhance product quality and customer satisfaction [11, 18, 23].

From an environmental perspective, operational improvement facilitates ecological sustainability by mitigating environmental impacts through energy efficiency, waste reduction, and pollution prevention. Green practices embedded within operational processes, such as Sustainable Value Stream Mapping (SUS-VSM) and proactive environmental management, are demonstrated to reduce emissions and conserve resources, aligning

operational objectives with environmental priorities [11, 12, 18, 23]. For example, SUS-VSM identifies opportunities for reducing resource consumption and emissions, thereby supporting environmental sustainability [12, 22]. Socially, operational improvement enhances workplace conditions, fosters employee engagement, and contributes to community welfare, thereby advancing the social pillar of sustainability. Practices such as Kaizen and employee involvement promote inclusivity and collaboration, cultivating a culture of continuous improvement and enhancing workplace satisfaction [11, 18, 23, 27]. Collectively, the integration of LG practices into operational strategies emerges as a critical enabler for achieving long-term organisational resilience, competitive advantage, and alignment with sustainability objectives [11, 12, 18, 23, 27].

4.1.5 Respect for people

The principle of Respect for People (RFP) is integral to achieving organisational sustainability, as it emphasises employee empowerment, cultivates mutual trust, and promotes a culture of ongoing improvement [31]. This holistic approach, which balances human-centric and technical elements, reinforces organisational resilience and supports sustainable long-term growth.

The reviewed documents collectively underscore the critical role of respect for people, the human element, and employee involvement in advancing organisational sustainability and achieving the TBL, encompassing economic, environmental, and social dimensions [13, 20, 24, 29]. Employee engagement is consistently identified as a foundational element for the effective implementation of LG practices, fostering a culture of continuous improvement and collaboration. In the economic dimension, employee involvement enhances labour productivity and operational efficiency, contributing to cost reduction and profitability. For instance, Wu et al. [14] highlight that integrating lean practices with human resource initiatives, such as training and recognition, systematically reduces waste and improves profitability. Similarly, it is emphasised that the role of employee engagement in driving operational efficiency and reducing costs, thereby reinforcing the economic pillar of sustainability [8]. In the environmental dimension, employee involvement is pivotal in driving innovative solutions for waste reduction, energy efficiency, and pollution prevention. It is noted that Kaizen events and quality circles empower employees to identify and address environmental inefficiencies, contributing to the ecological pillar of the TBL [8]. Lizarelli et al. [25] further elaborate on how social lean practices, such as employee involvement and training, foster a culture of environmental responsibility, enabling organisations to achieve resource efficiency and reduce emissions.

Respect for people and human resource development are integral to aligning organisational goals with sustainability objectives, particularly in the social dimension. It is highlighted that social lean practices, such as leadership support and structured problem-solving approaches, improve workplace morale and inclusivity [23]. It is emphasised that leadership and management practices that prioritise respect for people create an inclusive and supportive environment, enhancing employee satisfaction and fostering a sense of shared responsibility for sustainability goals [29]. The importance of training programs and awareness initiatives in equipping employees with the skills and knowledge necessary to implement LG practices effectively [24]. Across the reviewed literature, the human element emerges as a vital enabler for achieving organisational resilience, competitive advantage, and alignment with the TBL. Employee involvement in lean systems enhances labour productivity and operational efficiency [11]. The role of employee engagement in driving both operational and environmental improvements is of high importance [18, 23]. Foo et al. [29] underscore the importance of leadership practices in creating a culture of respect for people. Collectively, these findings demonstrate that respect for people and employee engagement are indispensable for achieving organisational sustainability.

4.1.6 Green supply chain

The integration of LG practices within supply chain management and logistics is consistently identified across the reviewed literature as a strategic approach to advancing organisational sustainability and achieving the TBL—economic, environmental, and social dimensions. These practices emphasise waste reduction, resource optimisation, and environmental stewardship, fostering synergies that enhance operational efficiency while mitigating ecological impacts. It is highlighted that the influence of lean practices, such as pull production and lot size reduction, on green practices, which subsequently improve sustainable performance measures [7]. Similarly, the role of LG practices in enhancing supply chain performance by reducing greenhouse gas emissions, optimising resource consumption, and strengthening corporate reputation is underscored [25]. This idea further develops green supply chain management (GSCM), emphasising its capacity to reduce environmental impacts while simultaneously improving operational efficiency and ensuring compliance with regulatory standards [20].

The integration of LG logistics also demonstrates its significant contribution to the TBL. LG logistics practices, such as waste elimination, standardisation, and visual management, enhance economic performance by reducing operational costs and improving service delivery [26]. Environmental benefits are further realised through reduced emissions, increased energy efficiency, and sustainable resource utilisation, which proposes a Green Lean Six Sigma framework for optimising logistics processes [22]. Social benefits are also emphasised. The role of LG logistics in fostering employee engagement and improving workplace conditions is also noted [23]. The ability to create sustainable competitive advantages by aligning operational efficiency with environmental and social objectives is also mentioned [12]. Collectively, these findings illustrate that LG supply chain and logistics practices are integral to achieving the TBL and driving long-term organisational sustainability.

4.1.7 Integrated lean and green

The integration of LG practices, their simultaneous implementation, and the development of integrated frameworks are consistently identified as pivotal strategies for advancing organisational sustainability and achieving the TBL. The "House of EcoLean" framework is introduced, which systematically combines lean methodologies, such as Kaizen and 5S, with ecological principles, including resource optimisation and waste reduction. This structured integration not only enhances operational efficiency but also minimises environmental impacts [12]. Similarly, it is proposed that the Green Lean Six Sigma (GLSS) framework, which integrates lean principles, green practices, and Six Sigma methodologies, be used to address sustainability challenges [24]. The framework demonstrates significant improvements in operational efficiency, ecological outcomes, and long-term sustainability [22].

Wu et al. (2018) highlight that the combined application of LG practices yields both immediate operational advantages and long-term sustainability outcomes, such as enhanced profitability, reduced environmental impacts, and improved corporate reputation [11]. This notion is further corroborated by the demonstration that lean practices facilitate the adoption of green practices, resulting in superior performance across the TBL [2]. The study emphasises that the integration of LG practices enhances organisational competitiveness by reducing waste [2]. These findings collectively underscore the importance of aligning LG methodologies to achieve comprehensive and multidimensional sustainability objectives. The role of such frameworks within service industries is explored, highlighting their capacity to incorporate critical factors such as leadership commitment, employee engagement, and strategic alignment [28]. These elements collectively drive improvements across the TBL, ensuring long-term sustainability and resilience [26].

4.1.8 Customer and stakeholder engagement

Customer and stakeholder engagement is consistently identified as a pivotal factor in advancing the organisation's sustainability and achieving the TBL, encompassing economic, environmental, and social dimensions. The importance of auditing tools in evaluating corporate social responsibility (CSR) and stakeholder engagement is stressed, highlighting their role in fostering trust, regulatory compliance, and community support, which are essential for sustainable practices [19]. Similarly, the influence of customer demand and stakeholder pressure in driving the adoption of green and lean practices is emphasised [22]. These practices align the organisation’s objectives with broader sustainability goals.

The significance of stakeholder engagement, which advocates sustained communication and ethical relationships as foundational elements of Green Lean Six Sigma (GLSS) frameworks, is expanded [26]. Such practices are posited to enhance customer satisfaction while ensuring strategic alignment with stakeholder expectations, thereby contributing to sustainability across the TBL. Collectively, these findings underscore the critical role of customer and stakeholder engagement as a strategic enabler of organizational sustainability.

4.2 Ecotourism application

The application of LG in the ecotourism context is discussed based on its relevance to the five characteristics of ecotourism businesses identified in section **Error! Reference source not found.**.

(1) Ecotourism is a form of tourism.

LG is a holistic management approach for various organisations, including manufacturing and service organisations [25]. Thus, LG could theoretically be applied to tourism. The LG approach considers the various aspects of business, regardless of the type of business. It can be beneficial in the tourism context since it considers client satisfaction as a primary goal and as the most significant ‘value’ in the delivery of a service or product. Additionally, it focuses on the sustainability elements of the business and how to improve them and monopolise it in such a way that the triple bottom line will be benefited.

(2) Attractions are primarily nature-based but can include associated cultural resources and influences.

The LG approach focuses on cultural elements by addressing the social responsibility of the organisation, as well as the internal social standing by looking at corporate culture and employee involvement. The LG approach pays special attention to the human element, as discussed in the Lean philosophy [4]. Respect for people considers not only the internal culture of the staff and stakeholders but is expanded to include the external culture as it pertains to the social responsibility of the business [25]. This speaks to the social element of the triple bottom line.

(3) Educational and learning outcomes are fostered.

Specialised training is highly important in the LG approach as it is key in the implementation of the LG methods [14, 16]. Thus, LG aids in the training of staff, but also in ensuring an overall understanding of the organisation and its operations throughout the business. This allows for learning internally. Additionally, it fosters deeper understanding of the conservation efforts of the business and how it is achieved and why it is important. Which allows education staff to better inform tourists of the full extent of their role in the experience and how it affects the natural environment.

(4) Ecotourism is managed so that environmental and socio-cultural sustainability outcomes are more likely to be achieved.

LG offers an approach that prioritises each of the pillars in the TBL; all elements are equally important. The TBL focus ensures a symbiotic relationship where all of the factors are interdependent[21]. It emphasises the dependence of all three elements on one another and how no one can sustainably exist without the others [11].

(5) The importance of the operation's financial sustainability

Again, there is a focus on achieving organisational sustainability throughout the organisation. However, the lean contribution uniquely focuses on the financial gain in an organisation and its importance in creating sustainable economic growth [11]. Lean and Green enables an ecotourism business to operate efficiently and sustainably, contributing positively to conservation efforts while also increasing productivity and profitability [14].

The LG approach focuses on the fundamental characteristics of an ecotourism organisation. It is focused on establishing a positive TBL while simultaneously ensuring cost reduction and efficient operations. The identification of specific LG elements and their impact on the TBL shows the relevance of LG for organisational sustainability, but also how the ecotourism philosophy of a positive TBL might be well served with the implementation of LG.

5 CONCLUSION

Prior work in this field has focused on Lean and Green in a more general sense. For example, the different approaches to Lean and Green in manufacturing or service industries. This study focuses on a more sector-specific use of Lean and Green, interpreting the various elements of Lean and Green to determine an approach specifically for the organisational sustainability and sustainable business practices of ecotourism businesses. The systematic literature review conducted allowed for the identification of the main themes or areas of focus when attempting the implementation of LG, for organisational sustainability. This revealed a list of themes and the practical elements that contribute to the triple bottom line elements, and in turn, the sustainability of an organisation.

The findings further identify the relationship between LG and organisational sustainability by creating a conceptual Lean and Green impact matrix to understand better the impact of the different practical elements on the three pillars of the triple bottom line. The incorporation of Lean and Green into the triple bottom line framework shows the versatility and range of LG for all the elements of organisational sustainability and sustainable business practices. Therefore, this study highlights how LG impacts an ecotourism business in terms of holistic sustainability. The academic implication of this study is the conceptual understanding of LG and its impact on the triple bottom line and organisational sustainability. Additionally, it provides a blueprint for practical tools and elements for implementation in an organisation.

6 RECOMMENDATIONS FOR FUTURE RESEARCH

A theoretical contribution is made by measuring the impact matrix against fundamental characteristics of ecotourism to show the applicability; however, a more in-depth understanding of LG elements in ecotourism operations and processes would be beneficial to further motivate the value. Therefore, further research might explore the specific implementation of LG in the ecotourism context.

Although the fundamental characteristic of ecotourism is considered, no detailed explanation of the workings of an ecotourism business is provided. Thus, by gaining an understanding of the specific operations and inner workings of an ecotourism business, a better practical contribution to the implementation and application of LG in such a business can be achieved.

ABSTRACT

Manufacturing companies must operate efficiently and adopt dynamic technologies to meet evolving product demands. This study, conducted at a South African filtration company, highlights how industries dependent on filtration must adapt quickly to changing needs driven by climate change regulations and ongoing growth. Qualitative research in the form of interviews, transcription, and recordings is used. The induction technique and Atlas Ti software were used for analysis. The Business Model Canvas is used to determine whether the company has dynamic capabilities. The findings indicated that the interviewees believed the filtration company has dynamic capabilities, but sufficient training is required for employees.

Keywords: Qualitative Research, Business Model Canvas, Dynamic Capabilities, Technology Management, Filtration Industry

1 INTRODUCTION

Globalisation requires organisations to meet various customer demands in shorter time spans and greater variations. Manufacturing companies are measured by the value they deliver to the customers, and they must understand the measurements and adapt their business structure accordingly [1]. It is therefore important that companies investigate their processes and implement improvements where needed to remain competitive.

Market requirements can change at any time, and this can affect the technology and processes of a manufacturing company. There should be a strategic alignment between market requirements and operational capabilities to avoid losses to the organisation [2]. To remain competitive, companies must respond rapidly to market changes, and effectively coordinate and redeploy internal and external competencies [3].

The invested technology, supply chain, production processes, and labour skills should be flexible enough to adapt to any short-term or long-term capacity changes. Capacity constraints must be identified and improved to determine if new technologies are required on certain production lines [4].

Emerging technologies locally and abroad can become a threat to the existence of companies. Companies must therefore identify the solutions for current and future Industrial revolutions and their impact on technology requirements [5]. A technology framework can be used to ensure the selected technologies are linked to the business strategy [6].

The pace at which new technologies are adopted will be dependent on how quickly a company wants benefits. Some benefits of adopting new technologies are difficult to quantify, and therefore, manufacturing companies could take longer to adopt the innovation [7]. Due to cost implications and risks, companies might decide to extend the existing technology's life by upgrading it. A company might also decide that the risk and costs of change are low and therefore invest in completely new technology.

Manufacturing companies must have the means to create dynamically enabled technology capabilities that can enable value creation systems [3]. Digital transformation refers to the ability of companies to create value in all aspects of the business through technology, and consequently to respond swiftly to changes in the market [8]. Digital transformation cannot be ignored by manufacturing companies as it dominates industries globally, and demand for it is increasing. Challenges to digital transformation can be ignored if it is structured correctly to address the shortcomings [9]. All staff need to be trained on new technologies, and they must be informed that a company is aligning itself with a global technology demand. It is critical that gaps in skills be identified and that this is addressed as part of the strategy. To determine the required approach, the strategic goal should be measured against the technology capabilities. Key performance indicators should be used to measure success and to align people and processes [9].

Customer value creation drives a manufacturing company to analyse and improve its existing business offerings. The value can be measured by speed of service, price, design of products, or customer experience. Manufacturing companies must have dynamic capabilities to remain competitive and to improve on their value offerings to customers. This can be achieved by the collaboration of various input mechanisms between the internal and external stakeholders [10]. The internal capabilities (people, skills, and resources) are used to create the required value [11]. The contribution of the entire organisational structure (people, groups, and departments) is critical in creating value [12]. The Business Model Canvas (BMC) is a tool used to investigate the impact of various business units on value creation. It allows companies to highlight and improve on shortcomings.

Manufacturing companies should measure their internal performance to prevent customer dissatisfaction. They can measure themselves on efficiency, effectiveness, and adaptability. Efficiency can be interpreted as the resources that were expected to be consumed and those

that were consumed. Measurements can be done on the spending of resources or maintenance equipment, inventory management, or how well the space is utilized [13].
Effectiveness is a measurement of whether manufacturing companies are doing the right thing at the right time with the right quality. Effectiveness can be measured by process defects or reworks, or products that were returned to the manufacturing plant. Effectiveness can impact the quality of the Maintenance Equipment, labour productivity, and employee morale [13].
Adaptability refers to how sensitive and flexible a company can be when changes occur in the external environment. An adaptable company aims to dominate the market instead of benchmarking the processes of competitors [13].
Manufacturing companies should consider the external environment when implementing changes as external factors can influence the way the internal resources are structured, and highlight the strengths and weaknesses of a manufacturing company [14]. The type of industry, size of a manufacturing company, market share, location, and degree of competitiveness can all be influenced by the external environment [15]. The greater its interdependence, the more sensitive a company will be to activities in the external environment (Ghicajanu, 2019). Manufacturing companies should list the factors in the external environment that have the greatest influence on its internal environment. These factors should have planned responses to mitigate any potential disasters [14]. However, the attitude of the leadership towards the required changes will impact the speed of the process and it is therefore critical that the leadership are made aware of the advancements in the external environment and the impact these could have on a manufacturing company [15].

1.1 Objectives and Research Questions

The research in this paper is based on a manufacturing company in the filtration industry. The paper determines a manufacturing company's ability to respond to external changes. The concepts of dynamic capabilities is used to produce recommendations for organisational changes that will be beneficial to a company [3].
The study answers the following Research Questions:

1) What are the technological challenges experienced in the Filtration Industry?
2) How is performance defined and measured?
3) How can dynamic capabilities be applied to the current technologies?
4) What is the value versus benefits of the current technologies adopted?
5) How is the technology aligned to the market strategy?

1.2 Research Roadmap

Chapter 1 discusses the background, objectives and research questions of the study. This is followed by Chapter 2 which details the literature explaining the various concepts that was studied. This is followed by Chapter 3 which provides the proposed model followed for analysis. Chapter 4 explains the research methodology. Chapter 5 discusses the results and Chapter 6 provides the collective conclusions and recommendations. Figure 1.1 below shows the roadmap for the Article.

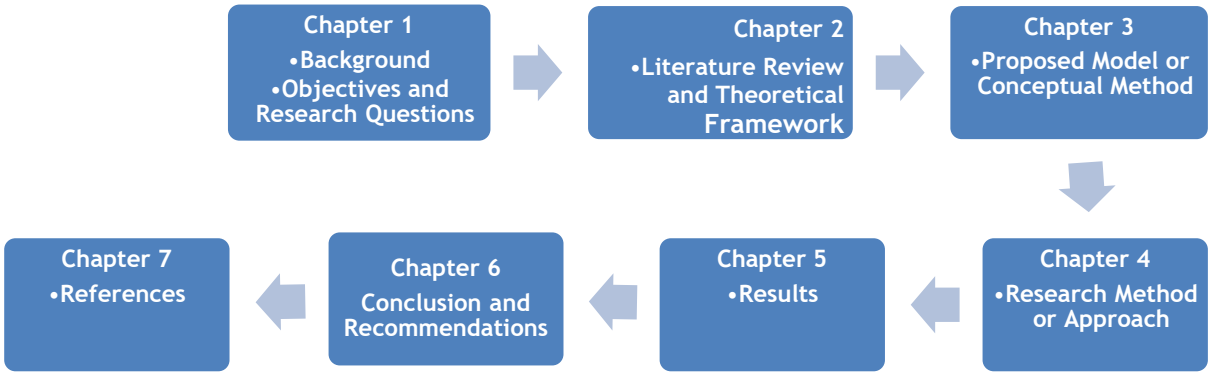

Figure 1.1 : Research Roadmap

2 LITERATURE REVIEW AND THEORETICAL FRAMEWORK

This chapter assesses the tools that can be used to create value for the customer. It discusses value creation and the role of dynamic capabilities in creating value. It also discusses strategy and how this should be aligned with the technology.

2.1 Value and Value Creation in Manufacturing Companies

The existence of Manufacturing companies depends on value creation [16]. Stakeholders include everyone with an interest in the company and can affect it negatively or positively by mobilising resources to impact the productivity of the business [17]. The company must reassure its stakeholders that they will receive value creation. This will convince them to invest further time and resources into the company [16].
Customers are interested in the value that is created in the form of quality and price of the products they are purchasing. They are interested in the continued existence of the company to ensure they can purchase the desired products in the future. Suppliers are also interested in the continuity of the business and thus need value in the form of long-term orders. Employees are interested in value in the form of benefits like education, training, compensation package, and other medical and insurance-related benefits [16]. The company must therefore improve its strategies to create value for all its stakeholders.

2.2 Dynamic Capabilities perspective on Value Creation

Dynamic capabilities refer to the process whereby managers alter their resource base and integrate and reconfigure them to generate new markets or add value to existing markets [18]. Dynamic capabilities are formed when the manufacturing company exploits its internal and external competencies to address the changing environment [3]. The manufacturing company's culture, values, and their collective ability to quickly implement changes play a big role in its dynamic capabilities [19]. The steps in implementing dynamic capabilities are (1) to sense and shape opportunities and threats, (2) to seize opportunities, and (3) to maintain competitiveness through enhancing, combining, protecting and, if needed, through reconfiguring the business enterprise's intangible and tangible assets [5]. The manufacturing company must learn (1) what customers want, (2) what new technologies might allow, (3) what aspects of the business model are working, and (4) whether the current strategy is effective [19].

2.3 The Role of Capabilities in Value Creation

A company's capabilities can be defined as its ability to deploy its resources (both tangible and intangible) to perform an activity that improves performance [20].
The manufacturing company's capabilities can allow it to create new products and respond to market changes [21].

Figure 2.1:Organisational capability framework, adapted from [22].

The organisational capability framework (Figure 2.1) illustrates the various groups of capabilities that can be formed.

- Resources: These enable the desired outcome and includes facilities, infrastructure, equipment, and physical tools, finance and other assets.
- People: These are the skills, abilities, expertise, and tacit knowledge of the people who interact with the resources for a specific purpose.
- Processes: These organise the execution of the activities through decision making, they enable the interaction between the elements and the resources to realise the desired outcome. The processes are captured in routines, procedures, intellectual tools, methods, models and explicit knowledge [23].

2.4 Operational Capabilities

Operational Capabilities enable the manufacturing company to execute its main operational activities. These capabilities allow a firm to perform an activity on an on-going basis using more or less the same techniques on the same scale to support existing customers [24]. It is important to note that the purpose and outcome of dynamic and operational capabilities are different. Firstly, dynamic capabilities are the manufacturing company's ability to reconfigure its operational capabilities and thus allow the company to adapt and evolve. Secondly, dynamic capabilities are used to extend or modify the current resources in different ways, such as alter the operational capabilities [24].

2.5 Systems View on Value Creation

The International Council on Systems Engineering (INCOSE) defines a system "as an integrated set of elements, subsystems, or assemblies that accomplish a defined objective. These elements include products (hardware, software, firmware), processes, people, information, techniques, facilities, services, and other support elements. " [12]
The systems life cycle processes is illustrated in Figure 2.2. This describes the inputs-process-output (IPO) diagram which shows key inputs, process activities and the resulting outputs [12].

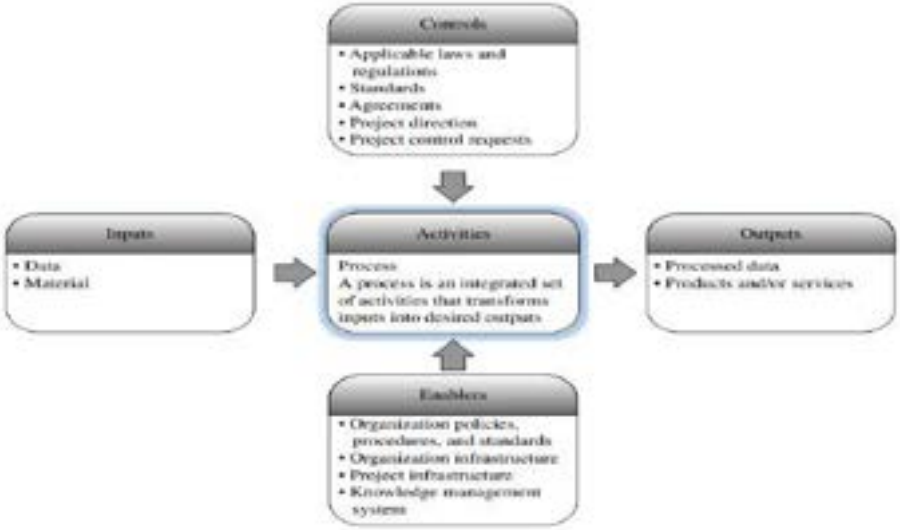

Figure 2.2: Sample of IPO Diagram for Systems Engineering Processes [12].

It is important to understand the systems view when investigating dynamic capabilities during the research. The various system processes of the manufacturing company can be complex, and the inputs will differ for the various operations. The research model takes this into account when determining a solution.

2.6 The Role of Dynamic Capable Technology in Creating Value Systems

Technology is "the knowledge, products, processes, tools, and systems used in the creation of goods or in the provision of services." [11]. Technology can therefore be seen as creating value in the manufacturing company. The use of technology in value creation plays a role in productivity and can lead to the evolution of entire industries [25]. Technology creates value when it is used optimally in a manufacturing company to increase global competitiveness. In the model below (Figure 2.3), Scenario A illustrates that there was a high investment in technology, but low economic growth. This could be due to the technology not being in line with the Business Strategy. In Scenario B, the investment is low, but the economic growth is high. This could be due to cheap labour and acquiring technology outside the country [22]. It is therefore important to ensure that technology is aligned to the business strategy and that the value of all investments is precalculated to prevent losses.

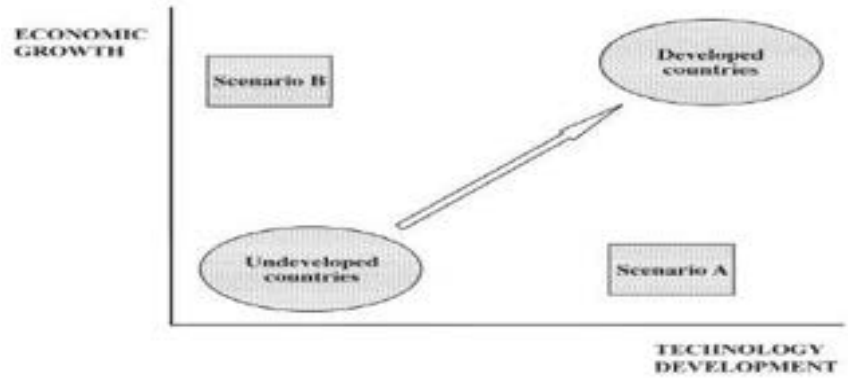

Figure 2.3: The ideal technology growth path [22].

2.7 Management Framework View on the company

The Technology Management Framework (TMF) as illustrated in Figure 2.4 is a tool that can be used by manufacturing industries to create value.

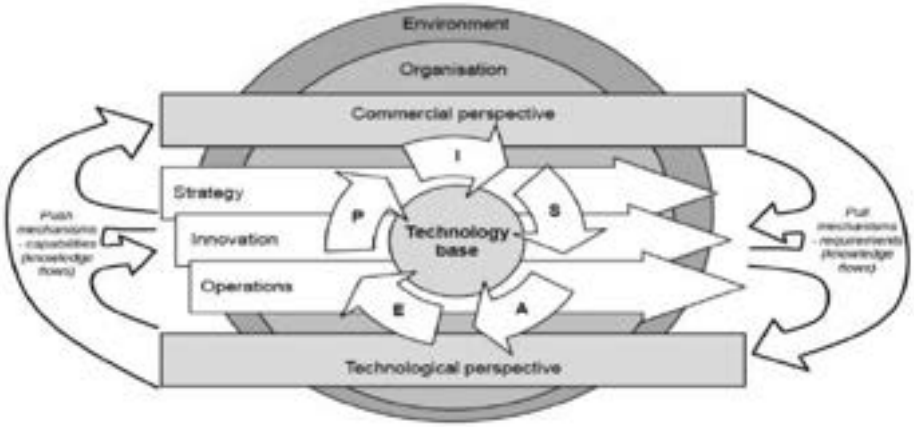

Figure 2.4 : Technology Management Framework [6]

There must be a knowledge flow between commercial and technological perspectives in the manufacturing company to achieve a balance between market pull and technology push [6].
The management of technology can be separated into five processes [26]:
Identification, Selection, Acquisition, Exploitation and Protection. The first process is to Identify the specific technologies, both present and future that may add value to the manufacturing company. The second process is the selected technologies that aligns with the strategy to create future business and is value adding [26]. The third process is the acquisition and implementation of the selected technologies in the manufacturing company and benefits are reaped. The fourth process is the exploitation of technologies by converting them into marketable products or realisation their value through sale or joint venture. The fifth process, that of protection occurs when the manufacturing companies incorporates features into their products that safeguards the product knowledge and thus ensure the company maintains ownership of the products in the long-term.
The framework focuses on three core business processes which is strategy, innovation, and operations. Strategy refers to the overall corporate and business objectives and direction. Innovation refers to the development of new products and services as well as improving strategic and operations processes. Operations is concerned with the flow of resources within the manufacturing company, as well as project management activities associated with strategy and innovation processes [6].

2.8 Aligning Strategy with Technology and Value Adding

Strategic management pertains to initiatives to create, enhance and sustain capabilities regarding the manufacturing environment, and to reach the company's objectives [27]. Strategic management can be done in line with the systems view and the technology management framework view that crosses different hierarchies.

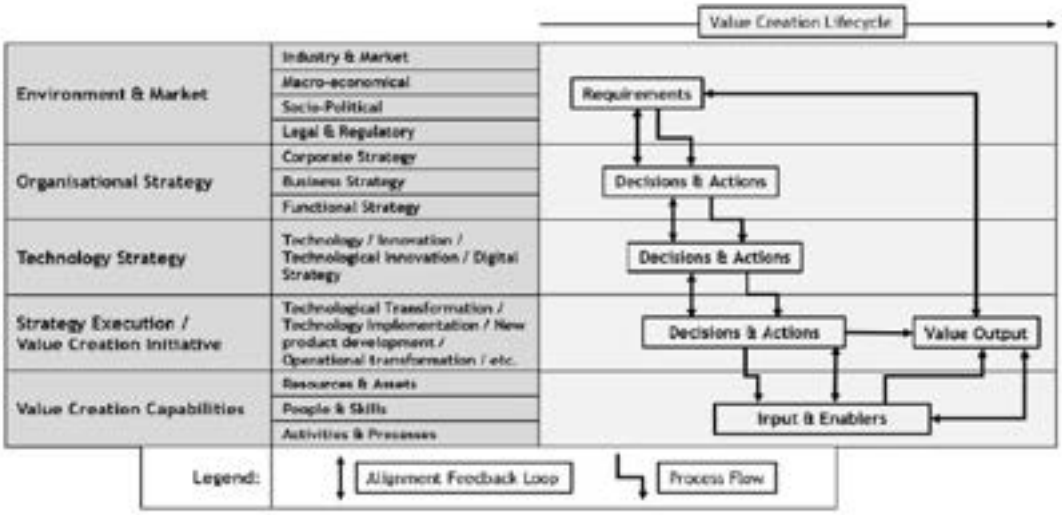

Figure 2.5 : A representation of strategic alignment in an organisation's value-creation system [23]

The technology strategy is a key factor for a manufacturing company to remain competitive as it will enable the company to remain competitive [25]. The manufacturing company needs to verify which markets it will be able to reach with its existing technologies and decide on a technology strategy that enables it to compete in desired markets. This is illustrated in Figure 2.5.

2.9 Dynamic Capabilities and the link to Strategic Management

Changes within the internal and external environment will impact the strategy [11]. Manufacturing companies can be placed in strategic groups, which means that they are competing for the same customers, product and geography. In this way, the company can determine who its rivals are and investigate strategic improvements that can be made to increase competitiveness [11]. The Technology Balance Sheet (TBS), as illustrated in Figure 2.6, highlights the processes as the value-adding activities required to produce the products. The technologies are the capabilities required to execute the process. The products fulfil various markets. The Technology Balance Sheet(TBS) answers questions on the technology and processes that are linked to the various products and whether it is viable to maintain those technologies and processes in the long-term [28]. The research will investigate the dynamic capabilities of the various technologies used during the processes.

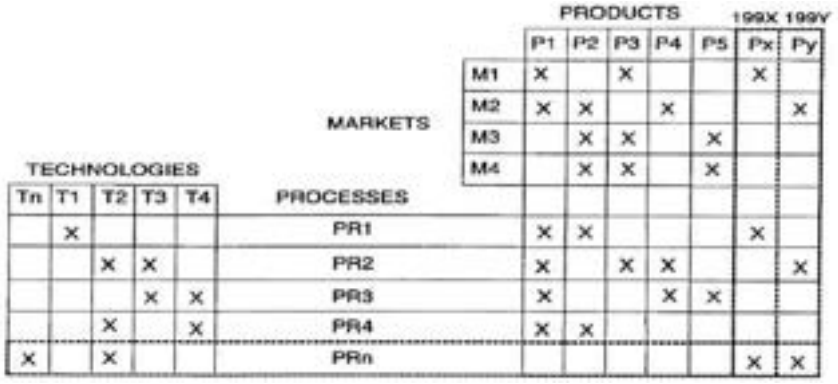

Figure 2.6: Technology Balance Sheet [28]

2.10 Poor Performance

Business performance is defined as the company's ability to satisfy customers' needs. The performance of Quality, Cost, Delivery, and Flexibility are some factors that can be used to identify business performance [13]. It is imperative that the manufacturing company performs well enough to satisfy its customers and maintain its global position. The customer desires value from the manufacturing company and only pays for the value that is generated. The concept of Lean Manufacturing and Value Stream Maps can be used to identify where the waste in the system is [29]. These are the items the customer is not paying for. There are nine wastes identified in this research, transport, defect, inventory, motion, behaviour, unutilized talent, overproduction, overprocessing and waiting [30].

3 PROPOSED MODEL OR CONCEPTUAL METHOD

3.1 Business Model Canvas

The proposed model for the research is the Business Model Canvas (BMC) as illustrated in Figure 3.1. The model helps manufacturing companies identify the interrelationships between the current internal operations and how it contributes to creating value. The model seeks to align key partners, key activities, key resources, customer relationships, customer segments, customer value proposition and costs to create value both for the internal and external stakeholders.

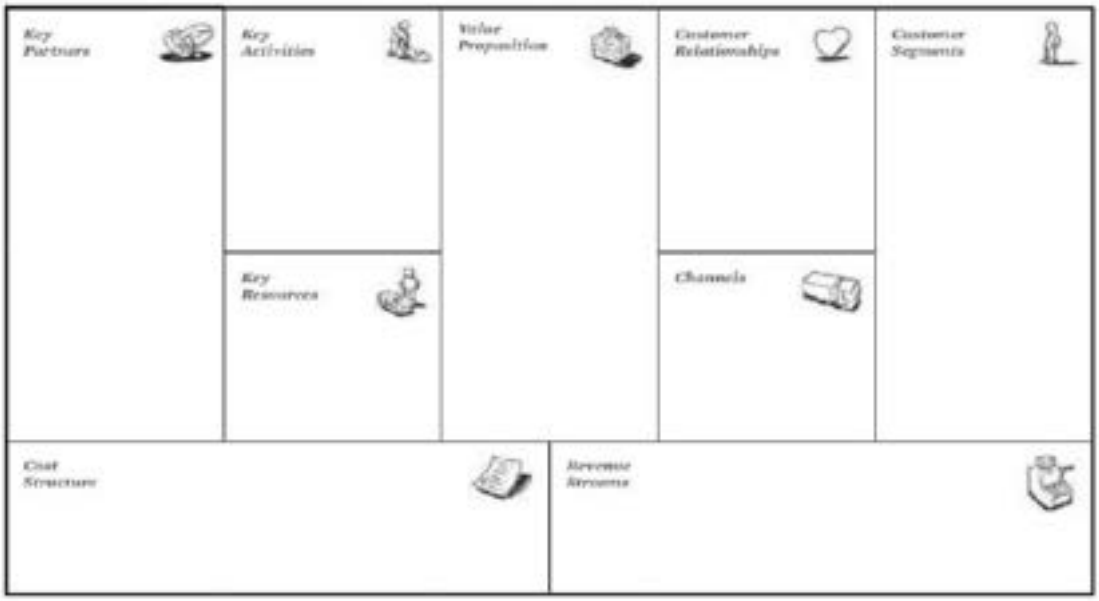

Figure 3.1 : Business Model Canvas [31].

3.2 Key Partners

Key partners are the network of suppliers and partners that make the business model work. Partnerships are formed to reduce risks by sharing infrastructure or outsourcing certain functions. Partnerships can also form to expand on capabilities that the manufacturing company does not have [31]. Types of partnerships can include strategic alliances between non-competitors, coopetition (which is strategic partnerships between competitors), joint ventures to develop new businesses, and buyer-supplier relationships to ensure reliable supplies.

3.3 Key Activities

Key activities are the fundamental activities that a manufacturing company must perform to guarantee that its business model will run successfully. These activities form part of the value proposition to the customer. In manufacturing companies, this could be the manufacturing processes, operations, consulting services to customers, or updating its ecommerce site. These will all be value-adding activities to the customer, and each must be assessed to determine whether it is optimal. The tools used during key activities should be investigated to determine possible improvements.

3.4 Key Resources

These are the resources that will be used to add value to the customer and reach new markets. These can be physical, financial, intellectual, or human centric. The paper investigates the physical assets such as manufacturing equipment, computers etc. The intellectual assets include knowledge, computer technology systems etc. Human resources are the critical employees with the high skillsets who work for the company. The financial resources can be profits generated, credits, stocks, or financial guaranties.

3.5 Value Propositions

Value proposition creates value for customer segments by presenting a unique offering to that segment. This could be related to cost, performance, newness, convenience, risk, accessibility, design, price, customisation and helping customers achieve their objectives. Performance of products or services can be improved to create value to the customer. Customisation is when products or services are tailored to the customer's needs. This can add enormous value to the customer as their immediate needs are met. Lower prices on products can be a value adding capability to customers who are price sensitive. The manufacturing company's brand can add value to the customer, and it is therefore worth protecting. It is important that value offerings are borne in mind when the manufacturing company analyses its processes and outputs, to meet the customer's demands.

3.6 Channels

Channels refer to the contact points between the manufacturing company and the customers. There are five phases that channels can go through: awareness, evaluation, purchase, delivery and after- sales. Awareness is the aspect of how the company raises awareness about its products. Evaluation is when the company helps customers to weigh up the various value propositions of the company. Purchase refers to how the company assists customers to purchase its products. Delivery refers to how the company delivers value to its customers. Afters-sales describes the support given to customers after they have purchased products. Channels can be the sales team, online web sales or stores owned by the company. Indirect sales can be partnering stores, websites or warehouses.

3.7 Customer Segments

Manufacturing companies can group customers into segments according to their common needs, behaviours, or other attributes. They may also serve a diverse customer base that contains various unrelated customer segments with differing needs and problems. The mass market refers to a large group of customers with similar needs and problems. The niche market is a specific group of customers that the manufacturing company can cater for, their needs will direct the value proposition, distribution channels and type of relationship offered.

3.8 Revenue Streams

Revenue is the profit that manufacturing companies can generate from each customer segment. There are several ways a manufacturing company can generate revenue, and these can include selling assets, leasing assets, or licensing of intellectual property.

3.9 Cost Structure

Cost structure can focus on either cost driven or value driven models. Manufacturing companies can focus being value-driven and ensure that customers receive premium value propositions and high degree of personalized services and products.

3.10 Customer Relationships

Customer relationships refer to the type of relationship that the manufacturing company establishes with specific customer segments. These relationships may be intimate, indirect or community based.

3.11 Model development

Table 3.1: Relevant Technology for Business Model Canvas

Technology Capabilities	Business Model Canvas
• Technology capabilities to serve key partners	• Key partners
• Technology capabilities in key activities • Technology capabilities in key resources • Technology capabilities to enable value • Technology capabilities in various channels • Technology capabilities in cost structure • Technology capabilities to generate a revenue stream	• Key activities • Key resources • Value proposition • Channels • Cost structure • Revenue streams
• Technology capabilities to foster customer relationships • Technology capabilities for the various customer segments	• Customer relationships • • Customer segments

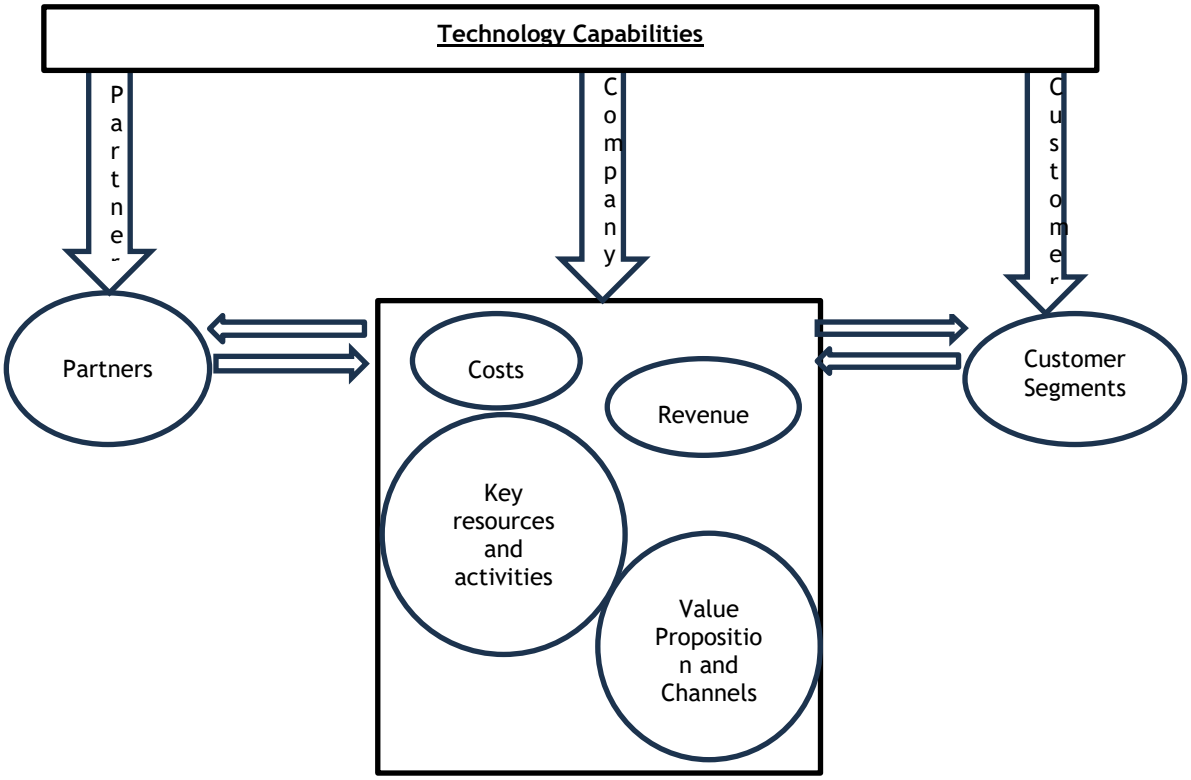

Figure 3.2 : Technology Capability for Business Model Canvas

The above model in Figure 3.2, based on the Business Model Canvas is used in the research. It is used to investigate the technology capabilities at the various interactions of the business. These are the technologies used by key partners. It will also investigate the technologies used during key activities, key resources, value propositions, channels, costs, revenue streams, customer relations, and customer segments. The dynamic capabilities of the technologies are investigated to determine where improvements can be made. Dynamic Capabilities do not view routines and business models as unchangeable; these are viewed as capable of being changed with the correct strategy and investments. Routines and business processes can be transformed to become high performance processes [19].

4 RESEARCH METHOD OR APPROACH

The research uses qualitative data techniques in the form of interviews, transcriptions and recordings. Qualitative research is a research strategy consisting of interpretive material practices that make the world visible. It seeks to interpret the meaning that a natural setting brings to people [32]. Qualitative research considers experiences, interactions, and documents of the study. A major part of qualitative research is based on text and writing from transcripts to interpret the data and then presentation of the findings and the research as a whole [33]. The research uses the analytical inductive technique. Induction approach is where a theory evolves based on empirical observations concerning the area of focus. It takes the context in which the events are taking place into account and will therefore use a small sample of each event [34]. Multiple data sources will be used to improve triangulation. Triangulation combines the theories of all the sources of the data to ensure biases are overcome. It is used to increase the credibility and validity of research findings. Credibility refers to the trustworthiness of the research and validity refers to the extent the study accurately reflects the situation [35].
It is not possible to obtain data from the entire population of a manufacturing company, hence a sample was taken. Stratification sampling of data is used to separate data into strata. This

can be based on location, plant, department, and expertise. This will ensure that the data represent the population more accurately [34].

Interviews with filtration manufacturing experts were conducted using qualitative data techniques to explore real-world challenges identified in the literature and global context. This approach allows for deeper insights through genuine feedback and real scenarios, especially given the unclear nature of top manufacturing challenges. Differences in departmental technology needs, employee skills, and emotional readiness mean that not all adapt equally to change. Investigating current technological capabilities and addressing knowledge gaps is essential, as process owners best understand their limitations and needs for improvement.

Five hypotheses had to be investigated as stated below:

1.Hypothesis1: There are technological challenges experienced in the filtration industry

2.Hypothesis 2: The technology in the company can directly influence the performance of the company by allowing faster process time and improve quality and therefore create more value for the customer.

3.Hypothesis 3: The value of the current technologies can be assessed by the benefits that can be obtained by using them. These benefits can lead to an increase in value to the customer.

4.Hypothesis 4: The current technologies must have dynamic capabilities to respond faster to the external requirements.

5.Hypothesis 5: The technology must be continuously aligned with the market strategy to create value-adding benefits.

5 RESULTS

5.1 Interviewee Information

A total of twelve Interviews were conducted in various departments.

Table 5.1: Interviewee's Years of Experience and Specialties

Interviewees	Years of Experience	Department	Specialty
1	32 years	Production	Production Manager
2	18 years	Production	Production Specialist
3	2 years	Engineering	Junior Engineer
4	14 years	Engineering	Senior Controls Engineer
5	21 years	Health and Safety	Sr Environment Safety Specialist
6	7 years	Information Technology	IT Service Specialist
7	27 years	Information Technology	Business Analyst
8	15 years	Planning and Supply Chain	Production Planner
9	22 years	Warehouse	Warehouse Manager
10	17 years	Quality	Quality Technician
11	5 years	Project Management	Project Manager
12	5 years	Procurement	Procurement Analyst

5.2 Hypothesis 1: There are technological challenges experienced in the filtration industry.

The hypothesis was confirmed through interviews, revealing several technological challenges within the organisation. These include system-related issues beyond employees' control, limitations in employees' technological capabilities, and difficulties in team collaboration due to technology. Such challenges can hinder task completion, delay operations, and pose risks

to the business, especially through interdepartmental information-sharing constraints. This emphasises the critical role of technology in delivering value to filtration industry customers and the need to monitor employee experiences to address and mitigate these issues.

Table 5.2: Number of Interviewees Experiencing Technological Challenges

Technological Challenge	Number of Interviewees
System Challenges	9
Technology Capability Challenges	6
Technology Challenges within Key Activities	8

Research question 1 was therefore answered by the challenges displayed in this table.

5.3 Hypothesis 2: The technology in the company can directly influence the performance of the company by allowing faster process time and improve quality, and therefore create more value for the customer.

The hypothesis was confirmed, with all interviewees agreeing on the need to upskill employees in technology, tailored to their preferred learning methods. Upskilling enhances employee capability, efficiency, and adaptability to current and future technologies. Most interviewees also agreed that effective technology use improves product quality, positively impacting both employee and company performance. Key risk factors identified were technology usage and product quality, emphasizing that employee comfort with technology is essential for maintaining high standards and delivering customer value. Research question 2 is answered in this hypothesis because performance is influenced and can be measured by the employee's use of the technology. The performance can decline if the employee is not comfortable with the technology.

5.4 Hypothesis 3: The value of the current technologies can be assessed by the benefits that can be obtained by using them. These benefits can lead to an increase in value to the customer.

This hypothesis was proven to be true. The data revealed that all twelve of the interviewees believed the technology has benefits for the company and its customers. A total of nine employees indicated that technology has benefits to employees. The benefits to the customers are due to the transparency of systems and the immediate communication available via modern technology. The organisation benefits from the real-time tracking of information and the increased speed of processes. The benefit to employees includes less paperwork and faster processing of information. This highlights the fact that there is value gained by using technology. The organisation can remain a leader in filtration due to a smart selection of technologies used, which adds value to its customers. However, all these benefits are high risk; customers must benefit to stay satisfied, employees must benefit to be productive, and the company must benefit to remain profitable. Research question 4 is answered in this hypothesis as both the benefits and the value of the current technology are mentioned.

5.5 Hypothesis 4: The current technologies must have dynamic capabilities to respond faster to the external requirements.

This hypothesis was proven to be true. The data indicated that the organisation is fluid and can adapt quickly to change. A total of eight interviewees were positive about changes that can occur quickly within the organisation. The data also indicated that employees view change as an opportunity and beneficial to the organisation. They will cooperate when given sufficient training during a change. It also shows that when the requirements are given beforehand, the process change will be rapid. This highlights the fact that the organisation has dynamic capabilities to respond to external requirements. There are, however, instances where internal changes involve risks. These can include the running of additional tests, government

approvals, Increased personnel to accommodate changes and international approvals that may be required. Ignoring these risks could prove to be disastrous.

Table 5.3: Department Feedback on Processes Adapting to Change

Department	Processes can change quickly.	Processes can take a long time to change.
Production	2	
Engineering		2
Health and Safety		1
IT	1	1
Planning and Supply Chain	1	
Warehouse	1	
Quality	1	
Project Management	1

Total	8	4

Research question 3 is addressed in this hypothesis. The interviewees indicated that dynamic capabilities can be applied to internal processes and technologies, which at times might involve risk that must be considered.

5.6 Hypothesis 5: The technology must be continuously aligned with the market strategy to create value-adding benefits.

This hypothesis was proven to be true. All twelve interviewees agreed that the company can assess gaps in the market as well as assess whether it is aligned with the customer's needs. A total of nine interviewees agreed that the company is in line with market trends in society. The data shows that the technology enables the organisation to compare its value-adding offerings to those of competitor products and the future requirements of the customers. The sales team can identify the gaps in the market and address them. The technology allows transparency as customers can view processes and products related to them. The customer can warn the company of product life spans and new, planned replacement products. This highlights the fact that technology plays a crucial role in the organisation's market strategy to create value for its customers. There is a risk that the company could lose out on future business if the company's strategy does not include technology that is aligned with the customer. Research question 5 is answered in this hypothesis, which shows how the technology is aligned with the market strategy.

6 CONCLUSION

6.1 Conclusions

The company must know its capabilities to determine how it will deliver value to the stakeholders. Capabilities are defined as the resources, skills, facilities and equipment, processes and routines, tools and manuals that are needed to get the job done [19]. Dynamic capabilities are important to create value for the stakeholders and thus ensure that the company will continue to exist [16]. The Business Model Canvas can be used as a strategic model to determine the dynamic capabilities within a company. The company must identify its technology challenges and remove the obstacles for employees so that they can be productive. This could also have a positive influence on the quality of products. The company's technological decisions must be aligned with their market strategy and should be followed by sufficient training of employees to bring about the change. The culture of adopting and

innovating can take time but a positive attitude and support from the company can make the transition easier and quicker.

The research questions were addressed by the investigation of each of the hypotheses. The objective of the paper, to determine a filtration manufacturing company's ability to respond to external changes, was met by the results of the hypotheses.

6.2 Recommendations for Further Studies

- Project Life Management Software in the filtration industry can be investigated for faster changes to processes.
- Pursuing Digitisation in both local and international filtration industry and its effect on Dynamic capabilities.
- Map the various customer bases that are dependent on the filtration industry and determine how the value creation compares for each customer. This can be used to rate the amount of effort that is put into creating dynamic capabilities.
- Compare the requirements for dynamic capabilities in South Africa's filtration industry with those of global companies.
- Explore whether the automotive industry will continue to seek dynamic capabilities despite the move towards electric vehicles.

Compare the attitude and education of the leadership in global manufacturing companies to those in South Africa regarding dynamic capabilities and the impact it has on productivity

ABSTRACT

The increase in fleet management has necessitated the adoption of innovative solutions to enhance efficiency, reduce costs and improve safety. However, the rapid advancement of Artificial Intelligence (AI) and the Internet of Things (IoT) presents transformative opportunities for fleet management. Fleet operations face challenges in effectively integrating these technologies, leading to suboptimal performance and increased costs. In this context, this study aims to investigate the impact of integrating AI and IoT on operational efficiency, cost reduction, and sustainability in fleet management. Utilising a mixed-methods approach, case studies were conducted, and data were collected from fleets that have implemented AI-driven predictive maintenance and IoT-based telematics. This study used a mixed-method approach. Quantitative data were collected from telematics and predictive maintenance systems across the sampled fleets, including variables such as fuel consumption, downtime, and route efficiency. Qualitative data were gathered through semi-structured interviews with fleet operations coordinators to capture perceptions of AIoT integration. The two datasets were triangulated to strengthen the validity of the findings. Results indicate a 30% reduction in vehicle downtime and a 15% decrease in fuel consumption, attributed to optimised routes and proactive maintenance. These results underscore the significance of adopting AIoT solutions to achieve smarter, greener, and safer fleet operations.

Keywords: fleet management, artificial Intelligence, internet of things, predictive maintenance, vehicle downtime

1 INTRODUCTION

AIoT integrates AI and IoT to create intelligent self-learning systems that analyse and respond to data autonomously [1]. AIoT represents the convergence of AI and IOT, enabling devices to learn from data and make autonomous decisions and context-aware systems that enhance operational efficiency and user experience [2]. AIoT spans sectors such as agriculture, health care, and smart cities, providing advanced solutions like remote patient monitoring and traffic optimisation [1, 3]. Fleet management is the administration and coordination of a company's vehicle fleet. It involves a wide range of functions that facilitate the efficient, cost-effective, and compliant operation of commercial vehicles[4]. This process is vital for businesses that rely on transportation, logistics, delivery services, or any form of mobility to conduct operations [5]. Large amounts of multi-modal data from various sources, including GPS modules, engine control units (ECUs), fuel sensors, and environmental monitors, are essential to AIoT-based fleet management systems. The diversity of data formats, sampling rates, and communication protocols is one significant issue noted in the literature that makes it more difficult to integrate data into AI models [6]. Furthermore, the dependability of predictive analytics is diminished by data redundancy, noise, and incompleteness brought on by malfunctioning sensors or network outages [7]. According to studies, inadequate pipelines for pre-processing data also lead to less-than-ideal results for route optimisation and maintenance scheduling [8].

In recent years, fleet management has shifted from ordinary to data-driven management systems through the integration of AI and IoT, particularly when dealing with complex data. AI and IoT are two of the most transformative technologies in the modern digital era [9]. Fleet management is complex, as fleet managers always face challenges in optimising routes, leading to increased fuel consumption, longer delivery times, and higher emissions. Traditional systems rely heavily on human oversight and static rules, often leading to inefficiencies. The vast amount of data generated by fleet operations can be difficult to manage and analyse, making it hard for fleet operators to make informed decisions. Analysing a lot of data, ensuring compliance with regulations and controlling costs whilst maintaining customer satisfaction is a very big challenge.

To overcome these challenges, the integration of AI and IoT has accelerated innovations across industries such as healthcare, transportation, manufacturing, and agriculture. This integration allows data collected by IoT devices to be analysed and acted upon in real time, often without human intervention [10]. The key capabilities of AIoT in fleet management include real-time vehicle tracking and diagnostics, predictive maintenance based on machine learning models, fuel efficiency monitoring and optimisation, automated driver behaviour analysis and dynamic route planning and traffic adaptation. Despite the recent success in integrating AIoT, fleet operators often face challenges in integrating innovative solutions with existing systems and managing change within the organisation, which also hinders the adoption of new technologies.

This study seeks to explore the impact of AIoT on operational efficiency, cost reduction, and enhancing fleet safety and sustainability in one of the municipalities in South Africa within the Limpopo Province. Through case studies and data analysis, the benefits of AI-driven predictive maintenance and IoT-based telematics were investigated. The research seeks to answer the following research questions:

RQ1: To what extent does the integration of AIoT improve operational efficiency in fleet management?

RQ2: How does the adoption of AI-driven predictive maintenance and IoT-based telematics influence cost reduction in fleet operations?

RQ3: What role does AIoT integration play in promoting sustainability in fleet management practices?

To address the research questions, a detailed literature review was conducted, and secondary data obtained from the fleet management company were analysed. Existing research on the fleet management industry typically revolves around understanding, improving, and innovating operational efficiency, cost-effectiveness, and sustainability.

The remainder of the paper is structured as follows: Section 2 provides a review of relevant literature, Section 3 outlines the methodology, Section 4 presents the results, and Section 5 presents the findings and concludes the paper.

2 LITERATURE REVIEW

This section discusses the existing literature on AIoT in fleet management and AIoT in other transport management services. The increasing complexity of fleet management in the Municipality has necessitated the adoption of innovative technologies to optimise operations, improve delivery of essential public services, fuel consumption monitoring and GPS-based vehicle location.

2.1 Literature Survey on AIOT in Fleet Management

Recent studies emphasise the transformative potential of these technologies, such as AI and IoT, in the realm of fleet management. Several frameworks have been proposed that leverage AI and IoT to enhance fleet efficiency, safety and sustainability. For example, one framework employs real-time data streams, predictive analytics, and automation technologies to promote fleet efficiency, improve safety protocols, and reduce environmental impact, though fuel efficiency was not considered in the study [11]. Another study monitors the key performance metrics of heavy vehicles, such as fuel consumption, route deviations, driving behaviour, breakdown incidents, and maintenance status [12-18]. In the context of Bengaluru, a straightforward framework has been developed for IoT-enabled visualisation and predictive analytics tailored to fleet management [19]. A novel approach combining AI, IoT and autonomous vehicles aims to optimise route planning, improve traffic signal coordination, and support predictive demand management delivery services[20]. Additionally, a methodology was developed to offer a structured framework for researchers aiming to implement intelligent Fleet Management Systems in mining operations to boost efficiency, safety, and productivity in mineral extraction [21]. Another IoT and AI-based Smart Fleet Management framework that enhances efficiency, safety, and sustainability [22]. It leverages real-time data and predictive analytics, incorporates ADAS to detect risky driving, and uses AI to forecast fuel use, emissions and fleet corrosion to reduce the carbon footprint. An in-depth analysis of IoT-driven solutions further suggests that smart transportation infrastructure could revolutionise contemporary roadway systems by making them into interconnected, efficient and sustainable frameworks [23]. Furthermore, a novel vehicle management system using Arduino UNO integrated with sensors was developed to enhance fleet safety and efficiency [24]. This technology monitors driving behaviour, ensures safe parking, and enables real-time tracking and maintaining cargo conditions to support compliance and quality control. The IoT-based vehicle emission monitoring system integrated with gas and dust sensors with an ESP-32 microcontroller and cloud analytics was developed to measure, analyse, and optimise vehicle carbon emissions and fuel consumption [25]. The reviewed literature highlights growing interest in the integration of AI and IoT in monitoring fuel consumption, the behaviour of the driver and the gas emissions.

2.2 The Literature Survey on AIoT

An overview of how artificial intelligence and machine learning contribute to the development of automatic incident detection aimed at reducing road accidents was explored [26]. A port

management system utilising advanced prediction and classification algorithms was developed to accurately estimate ship stay delays and durations [27]. A study explored how AI and Big Data Analytics can improve supply chain and sustainability, lower greenhouse gas emissions, logistics and transportation [28]. The Internet of Vehicles from three key perspectives: Mobile Edge Computing, AI and the benefits of integrating both was explored [29]. The research examines the architecture and implementation technologies involved and compares the applications of Mobile Edge Computing and AI in IoT with existing methods. A study examined how AI can be used to tackle traffic congestion in urban areas[30], energy management systems [31]. The literature reveals that AIoT is growing in other fields for monitoring and diagnosis of systems.

2.3 The Gaps identified in the literature

From the reviewed literature, the following key research gaps were pinpointed: Most studies focus on the modification of existing AIoT systems in fleet management. Little effort has been made in evaluating the existing AIoT systems in terms of profit or loss in the business operations. Based on the current state of fleet management in South Africa, there is a shortage of long-term studies on fleet performance, cost savings and driver behaviour. Most reports and studies focus on market share rather than performance comparisons between local and international fleet management providers. There is a need for independent studies comparing fuel consumption, route deviations, driving behaviour, breakdown incidents, and maintenance status. This paper focuses on a detailed analysis of fuel consumption in the municipality.

In summary, this review highlights the transformative potential of AIoT technologies across various sectors, including transportation. It sets the stage for understanding why AIoT is particularly promising for fleet management. The literature review makes a compelling case for why evaluating AIoT in fleet management, especially within the South African context, is timely and necessary. It aligns with the research questions by demonstrating Aiot's potential to improve operational efficiency and supports the hypothesis that AIoT can reduce costs and foster sustainability. The review also outlines several limitations of traditional fleet systems, and these challenges justify the need for intelligent, data-driven solutions, which AIoT can provide.

3 METHODOLOGY

Microsoft Excel is still a commonly used tool for data analysis, validation, and reporting, even though Artificial Intelligence of Things (AIoT) platforms for fleet management optimisation frequently make use of sophisticated analytics environments like Python, R, or cloud-based dashboards. According to published research, Excel's ease of use, familiarity, and integration potential make it an essential stage in AIoT data workflows, especially for businesses moving from manual fleet monitoring to completely automated analytics [32]. The study uses the following functions: mean and average to summarise the dataset with a single representative value and understanding around the central tendency of the data, standard deviation to quantify the amount of variation of a set of data points around its mean and the sum to determine the total value or quantity of fuel usage in litres and in rands. Using a mixed-methods approach, the purpose of this research is to conduct an in-depth analysis of the fuel expenditure, the fuel quantity, the rand per KM, the top 10 spenders and weekend fuel usage for three months. The data was obtained from a Teltonika FMC tracking device. The Teltonika FMC tracking devices are equipped with Onomondo IoT SIM cards to capture vehicle data. The tracking devices feed data into a Teltonika Fleet Management System, which is used to collect, visualise, and analyse telemetry in real time. It has software which enables: GPS-based vehicle location tracking, fuel consumption monitoring, driver behaviour analysis, engine diagnostics, and maintenance scheduling.

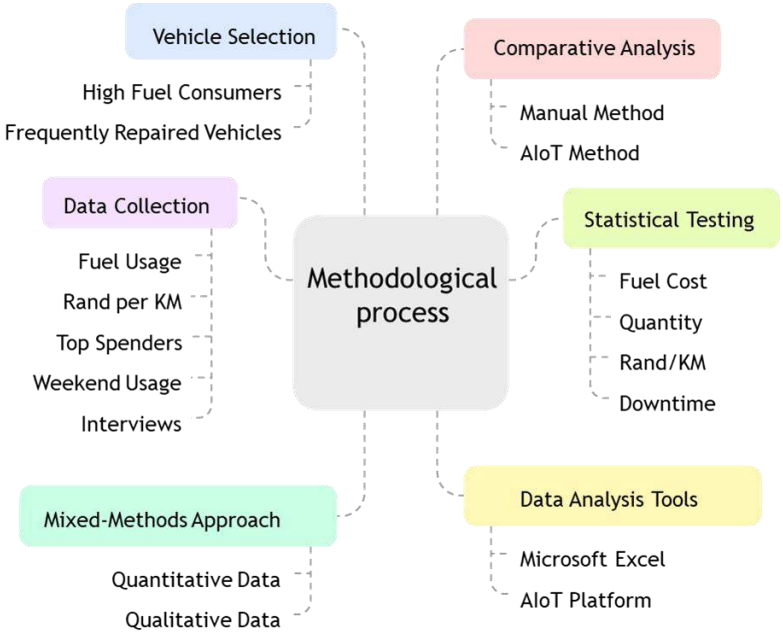

Figure 1. Methodological Process Summary

This study focuses on the fuel consumption monitoring for municipal vehicles, and the data collected includes the fuel usage and the consumption rates. The fleet consists of specialised heavy-duty and utility vehicles, including: BELL 670 Moto Graders, UD Trucks, Compactors, Mercedes-Benz (MBenz) Utility Vehicles, Komatsu Machinery, Excavators, BELL TLBs (Tractor-Loader-Backhoe. These vehicles operate on both rough (rural and undeveloped areas) and suburban roads across the rural municipality. Route allocation depends on the departmental function emergency services respond citywide, while maintenance and utility services follow scheduled or reactive service routes, covering key zones in both urban and peri-urban environments. A focused analysis was conducted on 10 high fuel-consuming vehicles per month to identify fuel inefficiencies and misuse.10 vehicles are undergoing frequent repairs and maintenance to assess wear patterns and predict failures using AIoT-based diagnostics. These 20 units were selected for their operational cost impact and are key to demonstrating the value of predictive optimisation. Each vehicle is a mobile node in a broader Smart City strategy, powered by AIoT for optimised service delivery. While fuel cost and volume remained consistent between March and May, the cost per kilometre increased significantly in April due to a marked reduction in distance covered, caused by vehicle downtime, route changes, operational restrictions, and call-outs.

4 RESULTS

By following the aforementioned research methods, data from the quarterly fuel management report were analysed. The results provide details of the fuel operations for each vehicle over 3 months. In March and April, the manual method was used, and in May, the AIOT-based system was used to analyse fuel usage and consumption for 10 vehicles

4.1 The Total Cost of Fuel

Figure 2 shows that the total cost of fuel spent for the Quarter was for May, and the lowest was for April. The difference between the 3 months was R120 634,77 (March & April) & R243 767,12 (April & May).

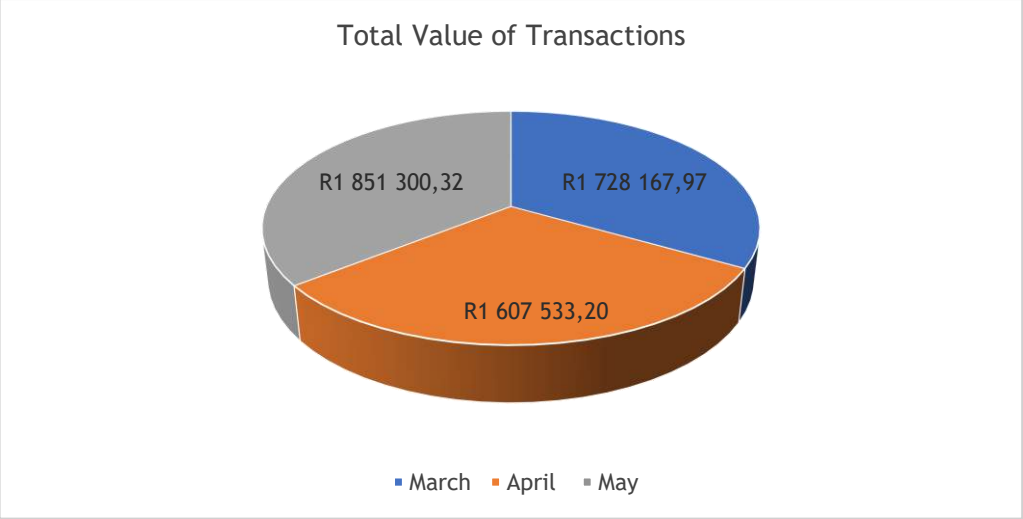

Figure 2: The total cost of fuel per month

Although May had the highest fuel expenditure, a deeper analysis shows that it was the most effective month, given that more working days were experienced in May (22 working days) in comparison to April (17 working days). The aforementioned does not include fuel utilisation on weekends.

4.1.1 Total Expenditure on Weekends

Figure 3 demonstrates that out of the total fuel expenditure for the weekends in March **64,39%** was spent on a Saturday **& 35,60%** was spent on a Sunday. For April, **R200 288,21** was spent on a Saturday, & **R109 324,03** was spent on a Sunday, & lastly for May, **58,98%** was spent on Saturday & **41,02%** was spent on a Sunday.

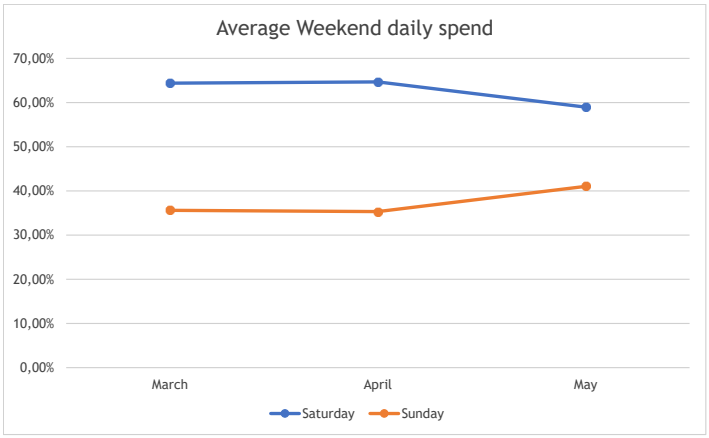

Figure 3: The total expenditure on weekends

4.2 The Total Quantity of Fuel

As presented in Figure 4, the highest total fuel quantity spent for the Quarter was for May, and the lowest was for April. The difference between March & April was 3 388,88 litres. May fuel quantity increased by 11,436.48 litres compared to April.

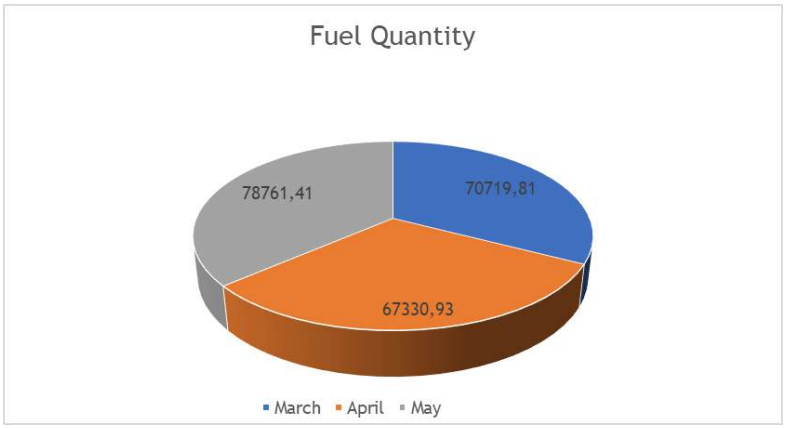

Figure 4: The total quantity of fuel consumed per month

Although April had the lowest fuel expenditure, a deeper analysis shows that it was the most ineffective month in terms of the amount of fuel used, given that fewer working days were experienced in April due to public holidays (17 working days) in comparison to May (22 working days).

4.3 The Total Rand per KM

Figure 5 indicates the Rand per KM for March, April and May, excluding vehicles with a single transaction. A higher amount of fuel was spent in May compared to March and April.

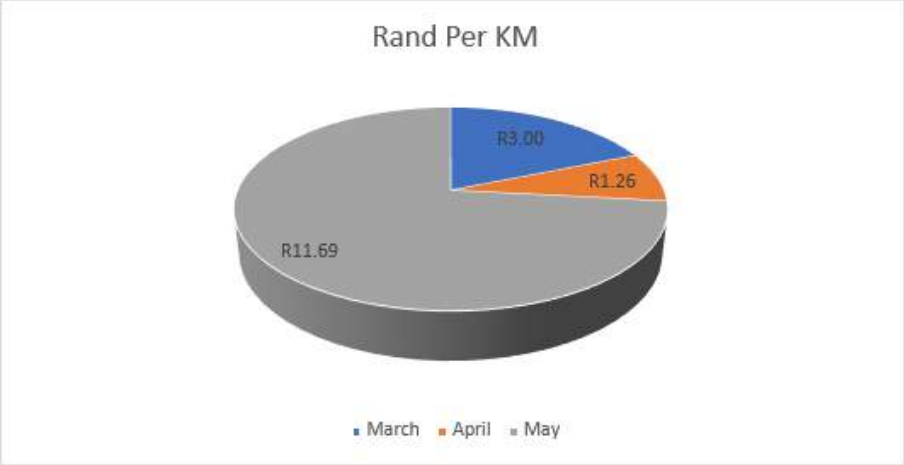

Figure 5: The total Rand per kilometre

4.4 Top Ten Spenders

The top 10 spenders for April cumulatively were 37.5% of the total fuel expenditure of April. This is a significant increase of 21.3%, which is over double the March top 10 expenditure. This should be further investigated as there is evidence of a concentrated use of fleet and not significant diversification of vehicles being used. The aforementioned could result in accelerated wear & tear of vehicles as well as increased maintenance costs. The top 10 spenders for April cumulatively were **~37.5%** of the total fuel expenditure of April. This is a significant increase of **21.3%,** which is over double the March top 10 expenditure. This should be further investigated as there is evidence of a concentrated use of fleet and not significant diversification of vehicles being used. The aforementioned could result in accelerated wear & tear of vehicles as well as increased maintenance costs. The top 10 spenders for May cumulatively were 18.6% of the total fuel expenditure of May. This is a significant reduction

of 18,9% in comparison to April, which still indicates that April had the highest consumption compared to both March and May fuel consumption.

4.5 The Actual Budget Versus the Monthly Expenditure

This section provides a comprehensive analysis of the actual budget versus the monthly expenditure for fuel consumption by highlighting the key variances and trends. Figure 6 compares the planned and actual spending for March.

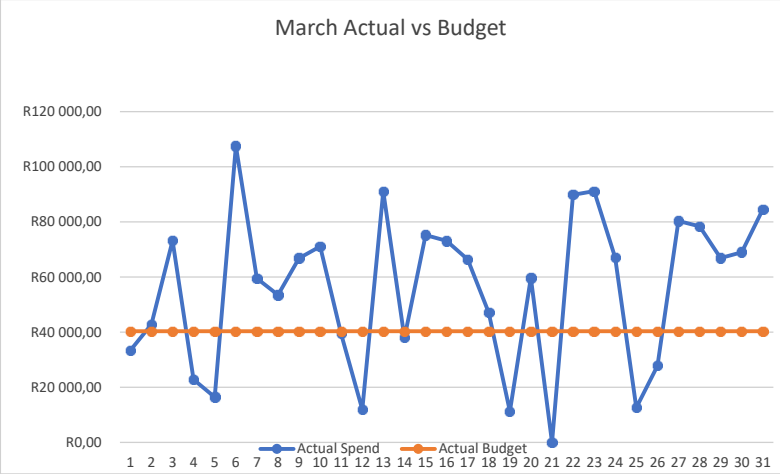

Figure 6: March Actual Cost Versus the Actual Budget

It is evident from Figure 6 that **R1 250 000** is insufficient as per the actual spend which s compared to the actual budget for March only on the 1st,4th,5th,12th,14th 19th,21st,25th & 26th (9 days out of 31 days) was there a saving & most of the days where there was a saving were weekends (4th, 5th, 12th, 19th,25th & 26th)for the rest of the days during March there was an over spend of the budget. Figure 7 compares the planned and actual spending for April. It is evident from Table 1 that R1 250 000 is insufficient as per the blue graph labelled actual spend which shows the actual spend per day compared to the actual budget for April only 13 days was there a saving & most of the days where there was a saving or breakeven were weekends & holidays (1st,2nd, 7th, 8th,9th,10th, 15th, 16th,27th, 29th & 30th)for the rest of the days during April there was an over spend of the budget.

Table 1: The Top Ten Spenders for March, April and May

Vehicle ID	Sum of fuel quantity(L)			Sum of value of transaction (Rands)			Sum of number of transactions		
	March	April	May	March	April	May	March	April	May
Vehicle 1	494,02			R12 000,00			2		
Vehicle 2	1522,53		1030,98	R36 754,45		R24 000,00	6		4
Vehicle 3	1030,39	2100,98	2351,51	R24 999,39	R50 475,81	R54 422,66	6	6	7
Vehicle 4	1276,23			R31 000,00			4		
Vehicle 5	897,15	2584,05	2068,02	R21 530,95	R61 448,14	R51 926,87	6	16	13
Vehicle 6	684,59		811,57	R16 574,15		R23 500,00	4		5
Vehicle 7	1303,12			R30 213,70			4

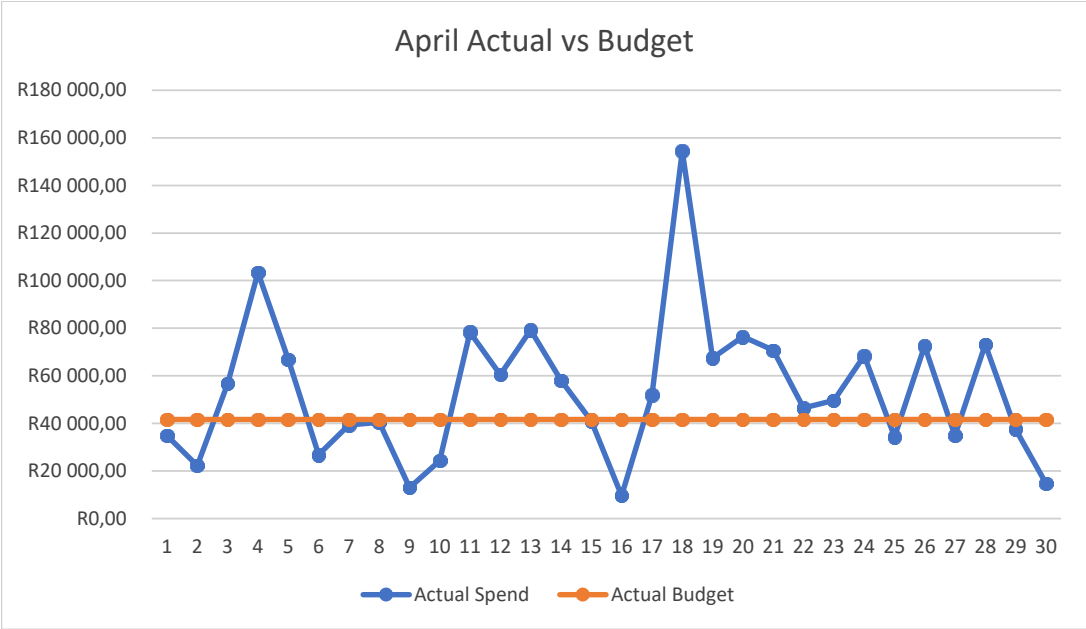

Figure 7: April Actual Cost Versus the Actual Budget

It is evident from Figure 8 that **R1 250 000** is insufficient as per the blue graph labelled actual spend which shows the actual spend per day compared to the actual budget, for May only 5 days was there a saving & most of the days where there was a saving or breakeven were weekends & holidays (1st, 7th ,14th, 27th & 28th) for the rest of the days during May there was an over spend of the budget.

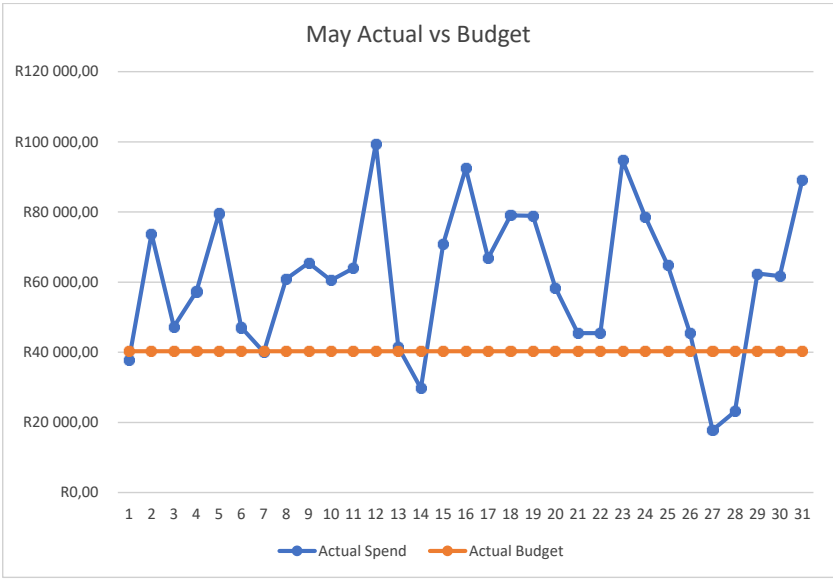

Figure 8: May Actual Cost versus the Actual Budget

The analysis of the vehicles shows that average downtime decreased from 20 hours before AIoT adoption to 14.3 hours after implementation, representing an overall reduction of approximately 30%. While individual vehicles displayed slight variations in the percentage reduction, the trend was consistent across the sample. This confirms that the introduction of predictive maintenance and IoT telematics significantly improved fleet availability. The results

provide strong evidence that AIoT integration can minimise unplanned downtime and enhance operational efficiency in fleet management.

Furthermore, the reduction in downtime is not only statistically significant but also operationally meaningful, as fewer breakdowns and service interruptions translate directly into cost savings and improved customer satisfaction. Compared with previous studies, this result exceeds the 20–28% reduction range typically reported in the literature, highlighting the competitive advantage of the strategies applied in this context. These findings strengthen the argument for greater adoption of AIoT systems in fleet management, especially for high-consumption vehicles where the potential benefits are most pronounced.

Table 2: The Vehicle Downtime (Hours) Before and After AIoT Adoption

Vehicle ID	Downtime Before(hrs)	Downtime After(hrs)
Vehicle 1	20	14.3
Vehicle 2	18	12.6
Vehicle 3	17	11.9
Vehicle 4	19	13.5
Vehicle 5	22	15.4
Vehicle 6	16	10
Vehicle 7	21	14.7
Vehicle 8	23	16.1
Vehicle 9	18	12.6
Vehicle 10	20	13
Mean	19,4	11,5
Stdv	**2,221110833**	**2,12132**
P-value	**0,048874504**	

As presented in Table 2, a paired t-test for the top 10 high consumption vehicles showed a significant reduction in downtime after AIoT implementation. Mean before is 19.4; SD is 0.048875. Then the mean after is 11.5; SD is 2.12132; p-value is 0.048875.

5 DISCUSSION

This study provides insights into the fuel management data from March to May, highlighting clear trends in both expenditure and operational efficiency. As presented in section 4, in March, there was moderate fuel usage and cost, with an indication of uneven vehicle usage, and it was limited with a relatively small fleet and low activity level. In April, while having the lowest working days (17), a disproportionately high fuel expenditure was recorded due to overutilization of select vehicles, inefficient routing, and increased weekend activity primarily related to water tankers and graders for funeral used for funeral support. In May, there was the highest fuel quality and cost, but also the highest number of working days (22). More importantly, it displayed notable operational efficiency, including the call-out fee as well, marked by better distribution of fleet use, fewer top spenders, and lower rand-per-kilometre ratios. Although May had the highest fuel spent, it also had more working days. There was a better fleet rotation with top 10 spenders accounting for only 18.6% of the total, compared to April's 37.5%. Also, considering the cost of the fuel, if a call-out job needs to be attended, and improve weekend fuel control. The fuel in May is spent more effectively, resulting in higher productivity and lower wastage. The AIoT-based tracking system and optimisation system were implemented at the start of May. This time, the company started to have more accurate tracking of vehicle usage, reduced idle time and unauthorised use and improvements in fuel allocation and route optimisation, as shown in Table 3.

Table 3: The Top Ten Spenders for May

Aspect	Manual Method (April)	AIoT Method (May)
Vehicle usage	Concentrated use, poor rotation	Better distribution
Tracking accuracy	Limited insights, post-use reporting	Real-time monitoring and alerts
Fuel efficiency	Low due to misuse	High due to higher usage
Total expenditure	Lower quantity but inefficient usage	Higher quantity but efficient allocation

Given the current economic issues in South Africa, inflation is at an all-time high, resulting in fuel costs increasing over time. At the start of the current quarter, Petrol 93 & 95 were at R22,65 & R22,95 respectively & Diesel 0,05%, 0,005% (wholesale) R21,63 & R21,72 respectively. At the end of the quarter, the fuel prices are Petrol 93 & 95 are R22,30 & R22,63 respectively, and Diesel 0,05%, 0,005% (wholesale) R19,31 & R19,69 respectively. In this case, it is favourable to fuel costs, but that is not always the case; this also contributed to the higher cost in May. As presented in Table 4, a 15% reduction in fuel consumption in this study aligns with the 12–18% range reported by [33] in North American freight fleets. However, the 30% downtime reduction exceeds the 20% improvement reported by[6], which aligns with proactive maintenance strategies applied in this study's context.

Table 4: Comparative Results of AIoT and Related Fleet Management Systems from Literature and Industry Sources

Study/Source	**Context**	**Technology Used**	**Fuel Savings (%)**	**Downtime Reduction (%)**
[33]	US freight fleets	IoT telematics + AI route optimisation	18	25
[34]	Manufacturing & logistics	Industry 4.0 IoT + AI predictive analytics	10	22
[35]	Global mixed fleets	AI telematics platform	15	28

Through cost reductions, accelerated return on investment, and competitive differentiation, AIoT systems generate significant operational gains in efficiency, safety, compliance, and asset utilisation. However, the size of the fleet, the operational environment, and the organisation's preparedness to incorporate AIoT into current processes all affect how much of an impact there will be. Adoption success necessitates striking a balance between technological prowess, reasonable financial expectations, and effective change management techniques.

Despite the valuable insights this study generated, the study has several limitations. The study was conducted over a three-month period(March to May), which may not capture seasonal variations in fuel consumption or vehicle usage. The analysis focused primarily on fuel consumption, cost per kilometre and top spenders. Other performance indicators, such as vehicle emissions, maintenance frequency, driver safety incidents or customer service response time, were not included. The research was limited to one municipality in South Africa. For further work, the IoT-based telematics could also be expanded to other fleets such as the ambulances, fire brigades, police vehicles and the garbage collection vehicles. The system is supposed to predict the vehicle status and the shortest routes. There is a need to expand the research to other municipalities with denser traffic patterns or different vehicle types. There is also a need to conduct a longitudinal study over 12 months or assess the sustainability of AIoT benefits across seasons and operational cycles. Compare multiple municipalities to assess scalability and contextual differences.

6 CONCLUSION

This study presents a comprehensive analysis of manual and IOT fleet management within a municipality located in one of the provinces in South Africa. In this study, the main emphasis was on fuel consumption. The research evaluated the total cost of fuel for March, April and May, including both weekdays and weekends for the three months. The fuel quantities utilised

in these three months were analysed. The top ten high users of fuel were selected and analysed. A comparison between the budgeted expenditure and the actual spending for each month. AIoT integration in fleet management led to a 30% reduction in vehicle downtime and a 15% decrease in fuel consumption. These improvements highlight the operational and economic benefits of predictive maintenance and IoT telematics. Compared to previous literature, these results align with reported fuel savings of 12–18% by [33], but exceed downtime reductions of 20-31%. Future research should investigate long-term impacts, scalability across fleet types, and the human expertise required for system sustainability. From this analysis, it has been noted that the adoption of AIOT for fleet management optimisation in the municipality has the potential to significantly increase efficiency. Fleet managers can optimise routes to reduce fuel consumption and enhance overall fleet performance.

ABSTRACT

SME bakeries face increasing pressure to improve sustainability while remaining competitive. Integrating farming and baking operations offers a pathway to achieve this by producing key ingredients on-site and reusing waste streams to close resource loops. However, designing such integrated systems is complex, requiring alignment between farm outputs, bakery demand, and circular economy principles. This study addresses these challenges by developing a Circular Economy Framework to guide the integration of farming and bakery processes. The framework highlights the interrelationships between production, waste reuse, and by-product transformation, offering SMEs a structured approach to balance environmental, economic, and operational goals. Grounded in the research onion paradigm, the study establishes the foundation for a future Circular Economy Decision Support System. Beyond improving efficiency and profitability, the framework contributes to food security and sustainable manufacturing practices, enabling SME bakeries to transition from survival strategies toward long-term resilience and competitiveness.

Keywords: SME, bakery, circular economy, decision support system, sustainability

1 INTRODUCTION

A substantial segment of the global food industry is represented by baked goods, which indicates the global demand for baked goods. From breads and pastries to cookies, cakes, and confectionery, they significantly contribute to global food production, although specific percentages vary by region and product type [1]. The global consumption patterns are shaped by cultural traditions, economic conditions, dietary habits, and demographics [1]. For example, rising urbanisation and lifestyle changes have driven a demand for packaged baked goods such as breads and snacks [1]. Baked goods remain essential in meeting dietary preferences worldwide by holding a significant market share in the global food industry, despite the regional variations and diversity in products [1]. This highlights the need for further investigation into the broader impact of bakeries on society.

Bakeries generally operate under two main bakery business models, namely wholesale bakeries and retail bakeries [2]. Wholesale bakeries supply other businesses such as grocery stores, restaurants, cafés, and other food establishments by focusing on producing and distributing large quantities of baked goods [2]. In contrast, retail bakeries sell directly to the customer by offering freshly baked items such as bread, pastries, cookies, cakes, etc. [2]. Retail bakeries can take a variety of forms, including online bakeries that ship products nationwide, home bakeries operating from residential kitchens, bakery cafés offering a sit-down experience, mobile bakery food trucks, counter-service bakeries with small walk-in storefronts featuring a counter or bakery display case, etc. [2]. This paper focuses specifically on retail bakeries operating as small and medium-sized enterprises (SMEs).

The South African Department of Small Business Development defines a small and medium-sized enterprise (SME) as an independent business entity, together with its branches or subsidiaries and including cooperative enterprises, that can be managed by one or more owners and operates predominantly in any sector or subsector of the economy [3]. In accordance with the Standard Industrial Classification the criteria for a micro, small, and medium enterprise in the manufacturing sector are stated as micro having 0 to 10 employees with a total annual turnover of less than R7 million, small having 11 to 50 employees with a total annual turnover of less than R17 million, and medium having 51 to 250 employees with a total annual turnover of less than R170 million [3]. In South Africa, the number of SME bakeries increased following the deregulation of the baking subsector, which began in 1991 and removed requirements such as bakery registration and retail price controls [4]. These changes led many wholesale (industrial) bakeries to scale down, and created space for the growth of smaller bakeries [4].

To describe South Africa's bakery sector's profile, a detailed national industry survey that recorded employment by bakery type was conducted [4]. **Error! Reference source not found.** s ummarises the data. When comparing these results to the SME definition from the South African governmental document of 2019, it is evident that most baking enterprises in South Africa can be classified as SME bakeries since the majority have fewer than 250 employees.

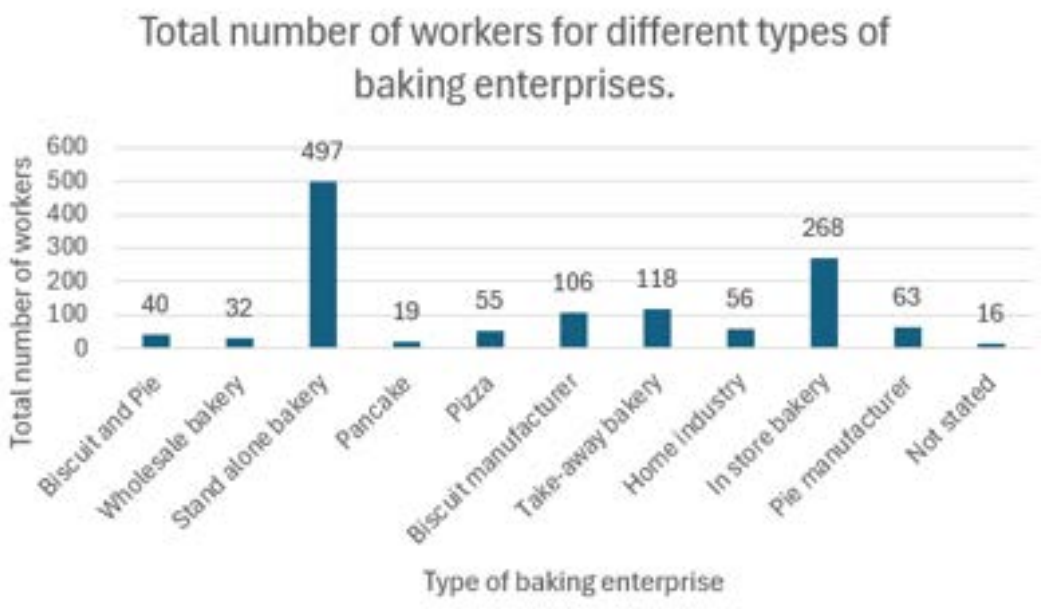

Figure 1: Total number of workers for different types of baking enterprises [4]

This shows a shift in focus from large wholesale bakeries to SME bakeries in South Africa. Furthermore, most entrepreneurs start their businesses as SMEs [5]. Thus, it is important to investigate SME bakeries, as this sector can create new opportunities for job creation and contribute to food security [4].

However, for SME bakeries to remain viable in the long term, these enterprises must not only contribute economically but should also address broader social and environmental responsibilities. This brings into focus the concept of organisational sustainability. Organisational sustainability can be understood as the organisation's contributions in supporting balanced sustainability in the economic, environmental, and social dimensions over various time periods, such as short-term and long-term periods [6]. This involves consistently embedding sustainability considerations into all the key areas of the organisation, including operations, strategic planning, internal systems, performance monitoring, etc. [6].

The concept of sustainability is commonly framed on three pillars, namely environmental, economic, and social [7]. The model typically implies a balance or trade-off between competing yet equally valued goals across these three categories [7]. The way an organisation manages these areas, as well as the pace and nature of the organisation's transformation efforts, plays a crucial role in shaping its sustainable performance [6]. Inputs, such as materials and resources that carry economic, environmental, and social implications, are converted into outputs, including products, services, and waste, all of which also hold value in those same dimensions [6]. The effectiveness of this conversion process is measured by how efficiently and responsibly the organisation uses its resources to achieve its objectives [6]. Furthermore, organisational sustainability is influenced by both tangible and intangible factors, such as infrastructure, workforce, cultural values, stakeholder relationships, and supply chain dynamics, each of which interacts to support or challenge the pursuit of long-term sustainability goals [6].

In the context of bakeries, core processes, such as mixing, baking, cooling and packaging, rely heavily on ovens, refrigeration units, and electric mixers, regardless of the variation in size and operation. These processes consume large amounts of energy, contributing to operational costs and environmental impact. Bakeries also generate various types of waste, including food waste from overproduction or unsold goods, as well as packaging materials. Food waste is seen

as a complex global problem that is increasingly drawing attention from both international and national scientific, professional, and policy-making communities [8]. Reducing food waste not only conserve valuable resources and lowers production costs, but it also serves as a meaningful way to promote responsible habits and attitudes toward waste reduction in future generations [8].

SME bakeries in South Africa face various challenges that restrict their ability to function effectively and efficiently. The 2002 study on the development of SME bakeries in South Africa used a survey to perform a SWOT analysis, determining the strengths, weaknesses, opportunities, and threats of this industry [4]. This study, presented in the current paper, focuses on the weaknesses and threats to identify the challenges SME bakeries face. The key weaknesses identified included high input costs, a lack of both technical baking skills and business and entrepreneurial skills, insufficient financial backup and support leading to cash flow problems, poor knowledge and understanding of market forces and product marketing, and a lack of confidence and business knowledge [4]. The key threats identified included competition that poses a significant risk to SME bakeries due to prevailing socio-economic circumstances, limited growth in the saturated South African baking industry, meaning that every new SME bakery could be taking an opportunity from another small, medium or large bakery, and the perceived high cost of ingredients compared to consumer price expectations [4].

Based on the challenges outlined above, it is evident that bakeries are struggling with both environmental and economic sustainability. Thus, the problem to be addressed is that SME bakeries struggle to achieve economic and environmental sustainability.

One potential solution lies in adopting circular economy (CE) principles. The circular economy is a regenerative economic system emphasising a fundamental paradigm shift to replace the traditional end-of-life concept with strategies focused on reducing, reusing and recycling materials throughout the supply chain [9]. The aim is to promote value maintenance and sustainable development, which creates environmental quality, economic development, and social equity to the benefit of the current and future generations [9].

Figure 2: Graphical representation of the circular economy (CE) definition [9] provides a graphical representation of this circular economy definition.

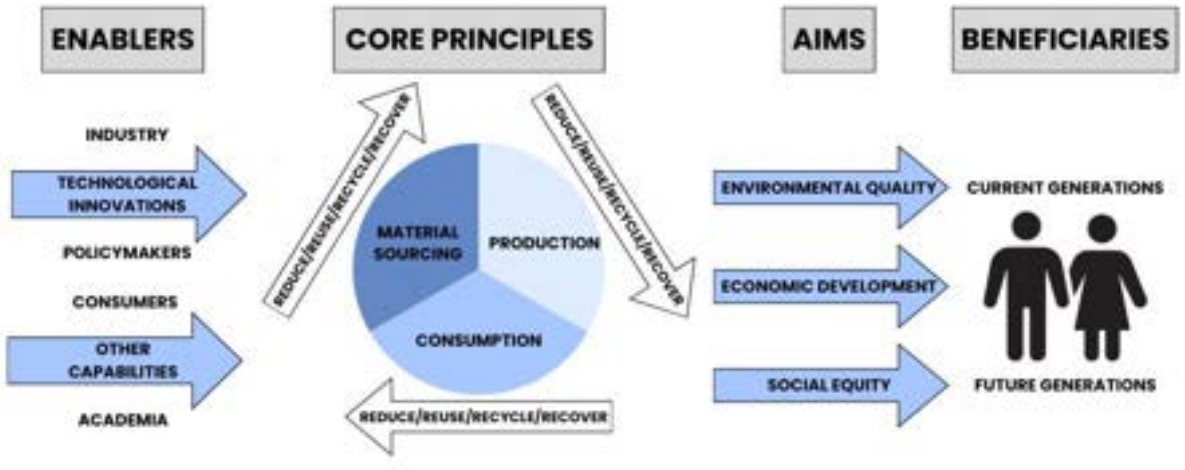

Figure 2: Graphical representation of the circular economy (CE) definition [9]

SME bakeries can greatly benefit from circular economy practices, which aim to reduce waste and pollution, keep materials in use for as long as possible, and restore natural systems. A potential solution to address the economic and environmental sustainability challenges of SME

bakeries lies in integrating a smallholding farm with an SME bakery. This could enable the development of a more sustainable bakery-food system by optimising resource use, shortening supply chains, reducing food loss and waste, and promoting sustainable practices across the production, processing, distribution, and consumption stages [10]. Globally, agricultural waste is generated daily from sources such as crop residues, agro-industries, livestock, and aquaculture [11]. Smallholding farms with livestock, crops, aquaculture, etc., also generate agricultural waste that is often underutilised. Bakery waste can be used in several valuable ways. Such as, turning it into bioethanol, a type of renewable energy, which can be used to power farm operations and reduce the use of fossil fuels [12]. Bakery by-products can also be used as animal feed, thereby lowering feed costs, maintaining animal health and performance, and reducing environmental harm ([13];[14]). In addition, the use of proper tracking systems helps ensure food safety and builds trust in circular food systems. Some studies have shown how food waste from onions and tomatoes can be added to bread without affecting its taste or quality. These ingredients improve the bread's health value and create new income opportunities for small producers ([15];[16]). These examples show that circular economy solutions are practical, low-cost, and suitable for smallholder farms. Since both bakeries and farms generate waste, this integration could be further strengthened through a circular economy whereby the bakery waste and the farm waste are repurposed for the farm and in return, the farm supplies the bakery with selected ingredients that are feasible to produce locally. Instead of relying on ingredients brought in from suppliers, baking and farming processes can be integrated to produce essential materials such as grains, dairy, eggs, and oilseeds. Waste from both farming and baking processes can then be reused within the system, helping to close the loop and reduce environmental impact as well as promote economic performance.

However, starting an SME bakery integrated with farming processes is complex. The system design must ensure that customer demands are met while effectively aligning farm outputs with bakery production, all within a framework of sustainability and profitability. This involves determining what can feasibly be produced on the farm, identifying which waste streams are suitable for reuse, and deciding how they can be transformed into valuable by-products to support a circular economy. It also requires evaluating and selecting the most beneficial uses for these by-products. Without practical decision support systems (DSS), SME bakeries often lack the knowledge and guidelines needed to implement such an integrated system successfully. However, before a DSS can be designed, a framework is required, indicating the different elements and the interrelationships between them.

Therefore, this study aims to design an SME bakeries circular economy framework (SME-CE framework) for integrating farming and baking processes.

Future research will then be able to use the CE framework to design a complete circular economy decision support system (CE-DSS) for integrating bakery and farming processes.

2 NARRATIVE LITERATURE REVIEW

2.1 Circular economy

The circular economy is much broader than just the definition provided in Section 1 and will be further investigated in this section. Although the circular economy now encompasses more than the original 3Rs, it is still fundamentally governed by the three core principles of reduce, reuse, and recycle [17]. These 3Rs are also promoted by the Ellen MacArthur Foundation, which developed the ReSOLVE framework to provide guidelines for implementing circular economy principles [18]. This framework was initially designed to target business strategies, but it consists of a versatile structure that applies to many sectors [18]. Although its application within agricultural systems remains relatively limited, it holds significant potential in the context of food system sustainability [18]. In agriculture, there is a growing emphasis

on transitioning from high-output, low-efficiency operations toward processes that prioritise nutrient recycling and closed-loop systems [18].

Error! Reference source not found. illustrates the principles of the ReSOLVE framework, a long with the objective of each of the principles [18]. These principles will serve as the design requirements to ensure that the circular economy concepts are applied to the design of the framework.

Table 1: The circular economy principles of the ReSOLVE framework [18]

ReSOLVE framework		
Symbol	**ReSOLVE principle**	**Objective**
R	Regenerate	Implement active recovery, the use of green technology, and the preservation of already-existing natural spaces to maintain and repair the health of natural ecosystems.
S	Share	Reduce the demand for individually owned products through product-sharing.
O	Optimise	Increase efficiency in production processes by cutting away unnecessary waste.
L	Loop	Valorise end-of-life waste products by reusing and upcycling.
V	Virtualise	Develop and adopt virtual technologies to replace wasteful processes, where possible.
E	Exchange	Shift towards purchasing more sustainable and longer-lasting products when replacing products at the end of their life.

2.2 Bakery product categories

Baked goods can be classified based on various factors, such as the ingredients used, texture, production methods, etc. In the book, Baking Problems Solved, the baked goods are grouped into categories, namely bread and other fermented products; cakes, sponges and muffins; biscuits, cookies, crackers and wafers; and pastries [19]. This classification helps to distinguish between the unique characteristics of each type of baked product. This classification will be used in the first phase of designing the framework.

2.3 WWF Terrestrial Ecoregions

The world can be categorised from different perspectives, such as land, aerial or aquatic. When focusing specifically on terrestrial landscapes, the most recent and widely accepted framework is the Terrestrial Ecoregions model developed by the WWF's Global 200 initiative. This model presents a globally consistent framework of 867 terrestrial ecoregions [20].

Although the intended purpose was to guide conservation efforts, these ecoregions were defined through the collaborative work of over 1000 experts, including biogeographers, taxonomists, conservation biologists, and ecologists worldwide, based on the foundation of classical biogeography [20].

Ecoregions are relatively large land areas characterised by a distinct assemblage of natural communities and species, with boundaries approximating the original extent before significant human-driven land-use change [20]. The WWF terrestrial ecoregions map provides a comprehensive global and regional coverage [20]. It builds on existing biogeographic knowledge and reflects the distribution of a range of diverse fauna and flora [20]. Ecoregions are classified within a system of biogeographic realms and biomes [20]. The combination of classifying ecoregions into 14 biomes and eight biogeographical realms allows for meaningful comparisons between regions and facilitates the identification of representative habitats and species groups [20].

Figure 3 illustrates the WWF terrestrial ecoregions map with the eight biogeographical realms as Oceania, Nearctic, Neotropic, Antarctic, Palearctic, Afrotropic, Indo-Malay, and Australasia

as well as the 14 biomes listed as tropical and subtropical moist broadleaf forests; tropical and subtropical dry broadleaf forests; tropical and suptropical coniferous forests; temperate broadleaf and mixed forests; temperate coniferous forest; boreal forests or taiga, tropical and subtropical grasslands; savannas and shrublands; temperate grasslands, savannas and shrublands; flooded grasslands and savannas; montane grasslands and shrublands; tundra; mediterranean forests, woodlands and scrubs; deserts and xeric shrublands; mangroves [20].

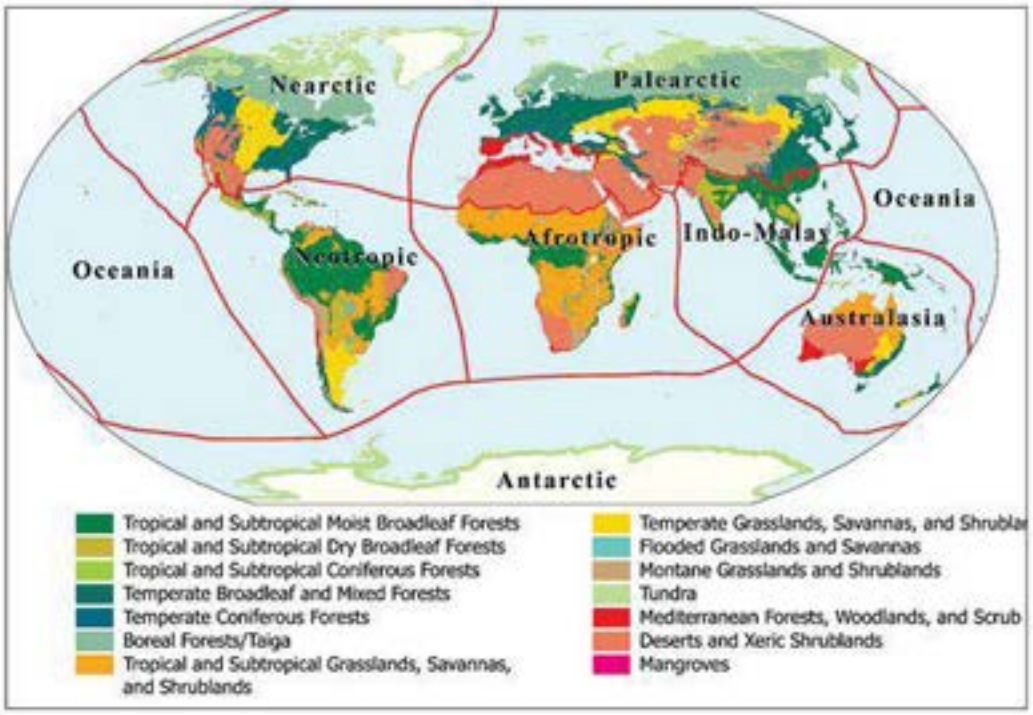

Figure 3: The WWF terrestrial ecoregions map [20]

These 14 biomes of the WWF terrestrial ecoregions will be used in the second phase of designing the CE framework.

3 METHOD

The method section of this study is divided into two subsections, namely the research paradigm, which guided the study, as well as the research method, which details the different phases the study followed.

3.1 Research paradigm

The research onion paradigm was adopted for this study and contextualises the research process through six layers, each representing a step that progresses from the outer layer inwards [21]. These layers guide researchers through a structured approach, from the initial philosophical stage to the final data collection techniques [21]. Figure 4 visually presents the research onion methodology by highlighting each of the six layers together with the possible choices for each layer.

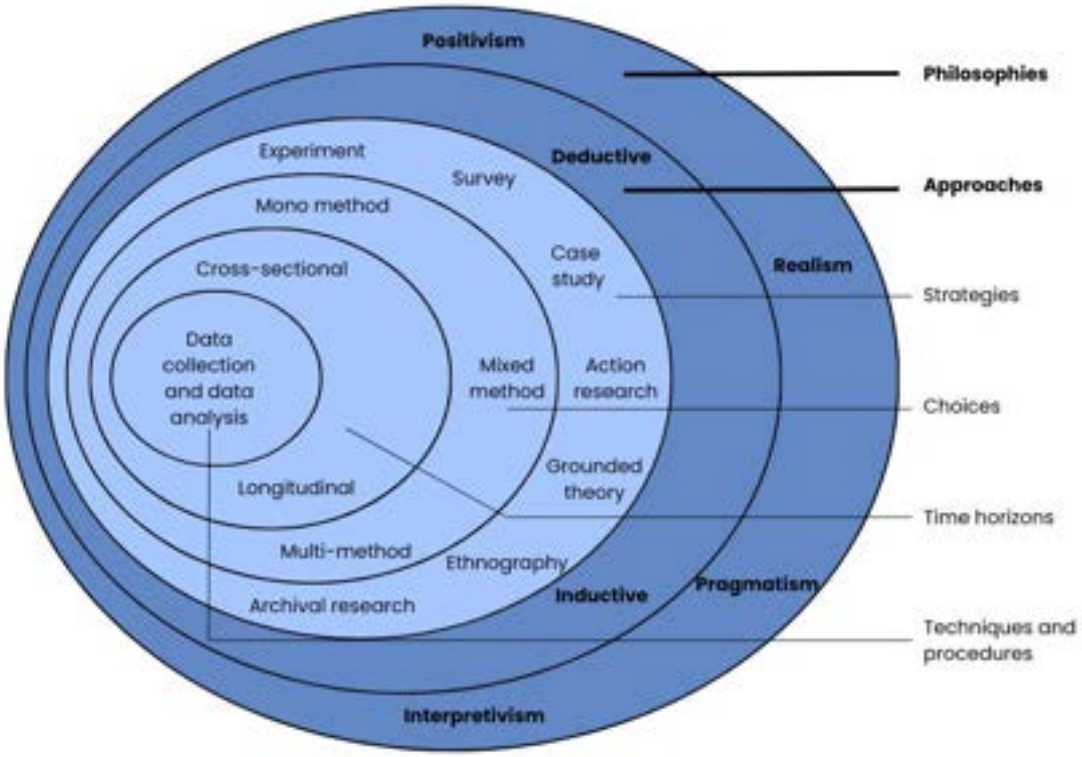

Figure 4: Illustration of the research onion methodology [22]

3.1.1 Research philosophy

This study adopted pragmatism as the research philosophy, as it aimed to design a practical CE framework for SME bakeries based on the insights gathered from literature. Pragmatism is guided by the principle of choosing methods and perspectives that best answer the research question, rather than being confined to a single philosophical stance [22].

The three elements that form the foundation of selecting a research philosophy include ontology, epistemology, and axiology, which influence how research is approached and conducted. Each of these is discussed in the context of pragmatism to justify the selection for this study. Ontology refers to the nature of reality from the researcher's perspective [22]. From a pragmatic perspective, reality is seen as external and multiple, with the view selected based on what best enables answering the research question [22]. Epistemology refers to what is seen as acceptable knowledge from the researcher's perspective [22]. Pragmatism accepts either or both observable phenomena and subjective meanings as sources of credible knowledge, dependent upon the research question [22]. It focuses on practical, applied research by integrating different perspectives to interpret the findings [22]. Axiology refers to the role of values in research from the researcher's perspective [22]. Under pragmatism, researchers values play a key role in interpreting results, where both objective and subjective viewpoints are considered valid [22].

The emphasis lies in the usefulness and applicability of the CE framework to SME bakeries, which aligns strongly with the pragmatic focus on real-world solutions. By adopting a pragmatic worldview, this study remains open to various forms of knowledge and prioritises practical outcomes. The goal is not only to understand current CE practices in theory, but to design a CE framework that can be implemented in real-world SME bakery operations, making pragmatism the most suitable philosophical approach for this study.

3.1.2 Research approach

An inductive research approach was applied to this study as it aimed to design a CE framework for SME bakeries by identifying patterns and insights from qualitative data, rather than testing an existing hypothesis [22].

An inductive research approach requires a close understanding of the research context, involves the collection of qualitative data, offers flexibility to adapt and refine the focus of the study as new insights are identified, and requires the researcher to play an active role in interpreting the data and shaping the outcome [22].

In this study, a close understanding of the challenges faced by SME bakeries and the application of the circular economy to SME bakeries was required to design the proposed CE framework successfully. Therefore, the inductive research approach aligns with the goal of this study to design a practical model based on the qualitative knowledge found in the literature.

3.1.3 Research strategy

Action research focuses on research in action to collaboratively address organisational challenges in partnership with those directly involved [22]. Thus, this study adopted an action research strategy, as it focused on research in action to address organisational challenges, specifically the economic and environmental sustainability challenges of SME bakeries, by providing a feasible solution. The process followed an iterative action research cycle by looping between reviewing literature to inform the design, progressing with the design until new information needs are identified, and then returning to the literature again to gather the required insights. This cycle was repeated as necessary. Since this study aimed to integrate available literature on circular economy applied to SME bakeries integrated with farming operations, this strategy offered flexibility and creativity to identify and establish the relationships and patterns in the literature with the design of the CE framework.

3.1.4 Methodological choice

A methodological choice was made to use a monomethod with the collection and analysis of qualitative data in this study. A mono method refers to using a single data collection technique and a corresponding analysis procedure [22]. This study only used qualitative data collected from literature, where qualitative refers to any data collection technique or data analysis procedure that generates non-numeric data [22].

3.1.5 Time horizon

The time horizon for this study was chosen as cross-sectional, as it was the study of a particular phenomenon, namely the circular economy in SME bakeries, at a particular time [22].

3.1.6 Data techniques and procedures

Data collection and analysis techniques included searching for relevant literature through the Scopus database and Google Scholar by means of an iterative narrative literature review to develop the design requirements and to inform the design phase of the CE framework.

3.2 Research phases

The research phases represent the three phases of the study. Table 2 explains the research phases by referring to the objective for each phase.

Table 2: Research phases

Research phases		
Phase	**Description**	**Objective**
1	Narrative literature review	• Identify the gap and support the problem. • Collect data on circular economy, biomes, bakery categories, etc. • Develop design requirements for the CE framework.
2	CE framework design	• Integrate the collected data. • Design a CE framework.
3	CE framework verification	• Ensure that the CE framework complies with the design requirements.

4 DESIGN

As stated previously, it is evident that bakeries place significant strain on both environmental and economic sustainability. However, starting an SME bakery integrated with farming processes to support economic and environmental sustainability is complex and without practical decision support systems, SME bakeries often lack the knowledge and guidelines needed to implement such an integrated system successfully. Thus, the CE framework was designed towards assisting bakery owners in successfully identifying and aligning potential farming and bakery processes.

4.1 Design requirements

The ReSOLVE principles were developed by the Ellen MacArthur Foundation, as outlined in Table 1. These are adopted as the design requirements to guide the integration of CE principles into the framework. To ensure relevance and practicality, only those ReSOLVE principles that align with the specific phase of the CE framework will be applied during the design process.

4.2 Designing the framework

The CE framework was designed in phases to accommodate its subsystems. At this stage, it consists of three subsystems, each designed in a separate phase. For the purpose of this paper, only the first two phases are completed, while future research will address the remaining phase. Phase 1 focuses on the bakery component of the CE framework, while Phase 2 addresses the farm component. Phase 3, which will be developed in future work, aims to integrate the farm and bakery processes through a decision support system. This system will allow users to input available space and generate balanced configurations of farm and bakery operations. For example, it will provide guidance on the appropriate ratios between livestock (e.g., cows and chickens), crop production, and bakery capacity to ensure that the overall system design is feasible and aligned with spatial and operational constraints.

4.2.1 Phase 1

The first phase of designing the framework was classifying the products produced in the bakery. In Section 2.2, the different bakery product categories were listed.

4.2.2 Phase 2

The first part of the second phase of designing the framework was presenting global biomes to classify the region in which a bakery is located, considering factors such as climate and growing patterns.

The second part of phase 2 used this information in combination with the bakery product categories of the first phase. For each category, the most-used ingredients were determined through a sampling method involving five randomly selected recipes per category. An ingredient was considered frequently used if it occurred in at least three out of five recipes. For example, within the "breads" category, the sample recipes included white and brown bread (representing basic yeast-leavened bread), sourdough bread (representing artisan rustic

bread), brioche (representing enriched bread containing fat, sugar or eggs), and pita bread (representing flatbread). This approach ensured that a diverse range of sub-categories were captured when identifying the most-used ingredients within each primary category. Ingredients were then classified according to the biomes in which they can grow or thrive. The system distinguished ingredients and by-products that can feasibly be produced on a smallholding farm from those requiring external sourcing. The CE framework also provides the bakery owner with guidance on ingredient sources and potential by-products for each ingredient.

5 THE CIRCULAR ECONOMY FRAMEWORK FOR SME BAKERIES

The functionality of the CE framework will be explained separately for each phase.

5.1.1 Phase 1

Figure 5 illustrates phase 1 of the CE framework, which begins by guiding the bakery owner in classifying the products produced in their bakery into the five primary bakery product categories. A bakery owner can choose between breads, cakes, muffins, pastries, cookies, biscuits, and speciality items.

	Product					
1. Determine and classify the products to be produced in the bakery according to the bakery product categories to identify the most-used ingredients for the bakery.	**Bakery product categories**	**Breads**	**Cakes & Muffins**	**Pastries**	**Cookies & Biscuits**	**Speciality Items**
	Definition of each category	Leavened baked goods made primarily from flour, water, and yeast or sourdough. Usually savory and consumed as a staple food.	Sweet, tender, and moist baked goods made with flour, sugar, fat, and eggs, often leavened with baking powder or soda. Meant for individual or group servings and often decorated or flavored.	Baked goods made with a higher fat content dough, often flaky or tender, and may be filled or topped. This includes laminated doughs (like croissants) and shortcrust bases (used in tarts and pies).	Small, flat, often sweet baked goods made from dough or batter, portioned before baking. Usually crisp or chewy, with a long shelf life.	Dessert-style items that don't fit cleanly into cakes, cookies, or pastries. These often include no-bake items, layered desserts, or modern refrigerated treats.
	Examples	White bread, whole wheat bread, rolls, baguettes, sourdough, focaccia.	Chocolate cake, cupcakes, loaf cakes, muffins, red velvet cake.	Croissants, Danishes, éclairs, pies, quiches, tarts.	Chocolate chip cookies, shortbread, rusks, biscotti, ginger snaps.	Brownies, peppermint crisp tart, fridge tarts, mousse cups, marshmallows.

Figure 5: Phase 1 of the framework

5.1.2 Phase 2

The next step (Figure 6) is for the bakery owner to determine the region the bakery will operate in and classify the region according to a specific biome, using, for example, the ArcGIS WWF Terrestrial Ecoregion interactive map (available at: WWF Terrestrial Ecoregions Of The World (Biomes)). Users can search for their city or region and identify the biome classification by clicking on the map, which assigns the location to one of 14 global biomes.

	Biome number	Biomes	Colour
2. Determine the region the bakery falls in and classify the region according to a specific biome by using the ArcGIS WWF Terrestrial Ecoregoin Interactive Map to identify the ingredients grown in the specified region.	1	Tropical and subtropical moist broadleaf forests	
	2	Tropical and subtropical dry broadleaf forests	
	3	Tropical and suptropical coniferous forests	
	4	Temperate broadleaf and mixed forests	
	5	Temperate Coniferous Forest	
	6	Boreal forests / Taiga	
	7	Tropical and subtropical grasslands, savannas and shrublands	
	8	Temperate grasslands, savannas and shrublands	
	9	Flooded grasslands and savannas	
	10	Montane grasslands and shrublands	
	11	Tundra	
	12	Mediterranean Forests, woodlands and scrubs	
	13	Deserts and xeric shrublands	
	14	Mangroves	

Figure 6: Phase 2 Part 1 of the framework

Once the products produced in the bakery were categorised into the five primary bakery product categories and the region the bakery will operate in was classified according to a specific biome, the CE framework then guides the bakery owner to determine the most-used ingredients for each of the primary bakery product categories that can be produced in the specific biome (Figure 7). Furthermore, the CE framework then identifies potential sources and highlights potential by-products that may be incorporated into a CE strategy for each most-used ingredient. The bakery owners are advised to source the ingredients that cannot feasibly be produced on the farm (due to the biome that the farm is located in) from local suppliers. When looking at Figure 7. The input from the bakery owner will be the bakery product categories chosen in the first phase, as well as the biome determined in part 1 of the second phase. The output from the CE framework is the most-used ingredients that are marked with an X for each of the bakery product categories. The framework also provides the source of each of the most-used ingredients and the by-products produced for each of the most-used ingredients. The applicable biomes for each of the most-used ingredients are indicated by the coloured dots, which correspond to the colours used in Figure 6.

Part 3 of phase 2 of the CE framework will be addressed in future research, which will provide a comprehensive guide to the optimal uses of the possible by-products produced on the farm as well as the bakery, ensuring effective use within the SME bakery integrated with the farming operations.

Product								
Bakery product categories	**Breads**	**Cakes & Muffins**	**Pastries**	**Cookies & Biscuits**	**Speciality Items**			
Most-used ingredients per category	X	X	X	X		Cake wheat flour	Soft wheat	Bran Germ
	X		X			Bread flour	Hard wheat	Bran Germ

Figure 7: Phase 2, Part 2 of the framework

6 VERIFICATION

The conceptual model will be verified by checking compliance with the circular economy principles of the ReSOLVE framework that served as the design requirements. Table 3 shows a verification checklist that justifies why the model is verified.

Table 3: Verification checklist

Verification checklist		
Symbol	**ReSOLVE principle**	**Justification**
R	Regenerate	• Part 3 of Phase 2 of the CE framework will provide a comprehensive guide to the optimal uses of the possible by-products produced on the farm and in the bakery. • Rainwater harvesting and boreholes are also advised to support sustainable water usage.
S	Share	• This CE framework helps with knowledge sharing in the community. • Excess ingredients produced will be shared with the community.
O	Optimise	• Phase 3 of the CE framework will be a tool designed to balance the bakery and farm processes to match demand and avoid overproduction.
L	Loop	• Bakery and farm by-products are worked back into the farm. • Farm products are used as the ingredients for the bakery.
V	Virtualise	• This CE framework is a virtual technology that is designed to support decision-making in integrating bakery and farming processes to support environmental and economic sustainability.
E	Exchange	• Some of the by-products can be used to generate renewable energy instead of fossil fuels. • The use of local suppliers is advised rather than long-haul distribution chains.

Thus, the CE framework is verified as complying with all the design requirements.

7 CONCLUSION

The circular economy framework (CE framework) guides the design of a circular economy decision support model.

Without practical decision support systems, SME bakeries often lack the knowledge and guidelines needed to successfully implement an integrated system by aligning farm and bakery processes to support economic and environmental sustainability. By combining circular economy principles with both farming and bakery operations, the CE framework for SME bakeries provides a strategic framework towards mitigating these challenges. This study starts to address the critical challenges faced by SME bakeries, particularly the lack of technical, entrepreneurial, and operational skills that hinder their ability to operate efficiently, as well as the environmental sustainability challenges.

The CE framework offers a practical guideline towards aligning bakery operations with on-site farming activities. The model serves as a foundation for designing future circular economy decision support systems for SME bakeries integrated with farming processes.

The CE framework not only provides support towards economic growth and food security, but also contributes towards the broader goal of developing sustainable manufacturing practices in the bakery sector.

The contribution of this study lies in establishing a foundation for aligning bakery operations with smallholder farming activities through a circular economy lens. While the CE framework is only the first step, it demonstrates how integrated bakery–farm systems can close resource loops, reduce external dependencies, and strengthen food system resilience. Importantly, it

highlights a pathway for SME bakeries to move beyond survival strategies towards long-term sustainability and competitiveness.

8 FUTURE RESEARCH

The CE framework presented here should be viewed as a stepping stone toward a CE decision support system for SME bakeries. Future research should expand the integration phase, test the framework in real-world contexts, and validate its performance through scenario modelling.

Future work should focus on applying the CE framework to design a circular economy decision support system for SME bakeries (SME-CE-DSS). This system should allow users to input available space and generate balanced configurations of farm and bakery operations. For example, it should provide guidance on the appropriate ratios between livestock (e.g., cows and chickens), crop production, and bakery capacity to ensure that the overall system design is feasible and aligned with spatial and operational constraints.

The decision support systems should also enable SME bakery owners to make informed decisions regarding ingredient sourcing and regional agricultural feasibility. This could reduce the dependency on external inputs, lowering costs and promoting environmental sustainability.

ABSTRACT

To explore the application of the Submerged Scraper Conveyor (SSC) so that the learnings from the publications and industry can be adopted in the local plant for an uptime enhancement using system dynamics tool in the future. Studies from 1989-2024 were identified and key themes considered included maintenance strategy adopted, type of technology that was applied, type of industry, technologies used to remove ash and its application trends. Energy sector dominated the studies. Different SSC technologies were identified and some of them were not available in the South African power plants. SSC technology application was mainly for boiler residues removal. Original Equipment Manufacturer - Magaldi© had damage tolerant SSC Superbelt© for the adverse coarse ash conditions. Maintenance strategy must incorporate operating speed, coal quality and risk-based inspection for a dynamic schedule. Research output in this sector was increasing due to the negative effect of SSC failures on the boiler uptime.

Keywords: Submerged Scraper Conveyor, Coarse Ash, Plant

1 INTRODUCTION

In South Africa, most of the electricity is generated from the coal source and this was mainly driven by the abundance of this resource. Power generation in a coal-fired plant requires coal, oxygen and fire for combustion to take place in the boiler [1]. One of the by-products of this process is ash, the amount of ash produced hinges on the quality of coal, and this is largely driven by the calorific value (CV) of the coal [1]. Ash that is produced is classified into two categories, namely coarse ash (15%) and fly ash (85%). Coarse ash is collected at the bottom of the boiler through the Submerged Scraper Conveyor (SSC) while fly ash is collected through the Electrostatic precipitators (ESP) onto the hoppers. Below in figure 1 is high level illustration of the boiler plant process.

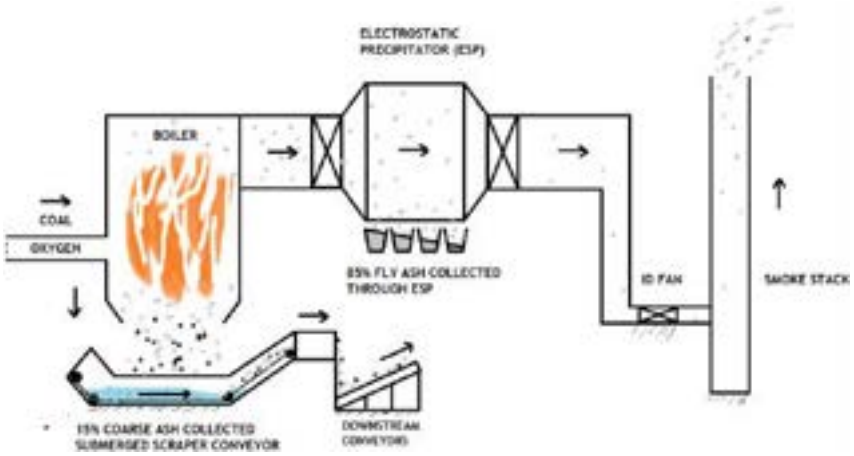

Figure 1: Coarse ash (SSC) and Fly ash (ESP) collection systems in a coal-fired power plant.

Eskom [2] produces 34 million tonnage of ash per annum, cement industry consumes about 3.4 million tonnage of fly ash per annum from the coal-fired power plants while coarse ash is disposed at the dumping sites or ash dams. Eskom [2] has recently constructed a 759 m heavy-duty road made of ash at Kusile Power station through its research, testing and development initiative to minimise CO_2 emissions by reducing reliance on conventional cement. Fly ash is collected through the electrostatic precipitators (electrical filters) or fabric filter plants whereas coarse ash is collected through the submerged scraper conveyor (SSC) and downstream conveyors. SSC is located at the bottom of the boiler as shown in figure 1 and it makes use of water to quench hot coarse ash followed by pulling out ash from the trough via the dewatering slope through the chain-fight bars conveyor system into the downstream conveyors.

During boiler operation, soot starts to settle on the boiler tubes and walls, this ultimately reduces the boiler heat transfer to the steam. To prevent decrease in the boiler efficiency, soot blowing of the boiler tubes and walls takes place after regular intervals in the boiler with the objective to retain the tubes clean so that maximum heat transfer to the steam pipeline takes place. It is normally after this process that molten slags/clinkers are dropped onto the SSC trough filled with water, at times chain-flight bars system get to be damaged during the impact thus leading to power generation interruption. Once the SSC has failed in this process, boiler continues to dump coarse ash on the damaged chain-flight bars system and if the ash is not removed fast enough, boiler operation must be reduced or shut down after maximum of about 8 hours. SSC is not allowed to be kept idling while coarse ash continues to be dumped onto its armoured conveyor as extended downtime led to overload of the chain system. Hydraulic drive system is designed to carry certain amount of coarse ash load otherwise unit must be shut down and ash on the conveyor removed manually using shovels and yellow plant.

Boiler downtime in a power plant has been reported to be the biggest contributor to the total plant downtime [3] and SSC plant had significant impact. SSC is composed of the key critical plant items such as chain-fight bars system, hydraulic drive system, hydraulic take-up, structural supports, water trough, two-way chute with grizzly screen, control and instrumentation equipment, etc. Figure 2 below shows some of these plant items that are attributable to the high boiler plant downtime and key components with their operating lifetimes.

Figure 2: Submerged Scraper Conveyor, Source: adapted from [4] and [5].

Table 1: SSC major components and its description.

SSC components	Approximate lifetime	Description
Chain, Chain links and chain guide idler wheels	6 years	Transfer of the rotational power from one sprocket to another
Sprockets and Mid-wear sprockets	3 years	To transmit power
Flight bars	12 years	To scrap coarse ash from the trough into the second conveyor
Non-drive bearing, drive-end bearing, housing and bearing supports	12 years	To provide smooth rotation of the idlers and provide protection from dust ingress
Wet idlers, dry idlers (return tray), dry idler bearing fixed/Plummer block and dry idler bearing	6 years	To guide and support the chain
Drive power pack, drive shaft, drive pump, drive hydraulic motor, hydraulic filters	2 years	To provide hydraulic power or oil flow to drive the take-up unit. Dust ingress reducing the life of plant items, etc.
Agitation pump and sump pump	3 years	To prevent ash settling at the bottom of SSC in the trough.
Control and Instrumentation	3 years	Speed control during the start, Maximum Control Rating (MCR) operation, soot blowing and long-standing time.
Two-way discharge chute with Grizzly louver system	3 years	Option to dump into the conveyor or into the skid during emergencies.
Structural supports	6 years	Alignment of gearboxes, pump, motors, etc.
Trough	3 years	To contain water, dust suppression and cool down the hot coarse ash from the boiler.

Wieczorek [6] has conducted a study on the chain and sprocket friction nodes. In this study, the identified nodes where high abrasive wear was taking place (see figure 3) was found on the actual SSC chain that was recently replaced at the power plant (see figure 4). Decreased wall thickness in this chain links represented its weakest spot hence preventive maintenance was applied to avert power generation disruption.

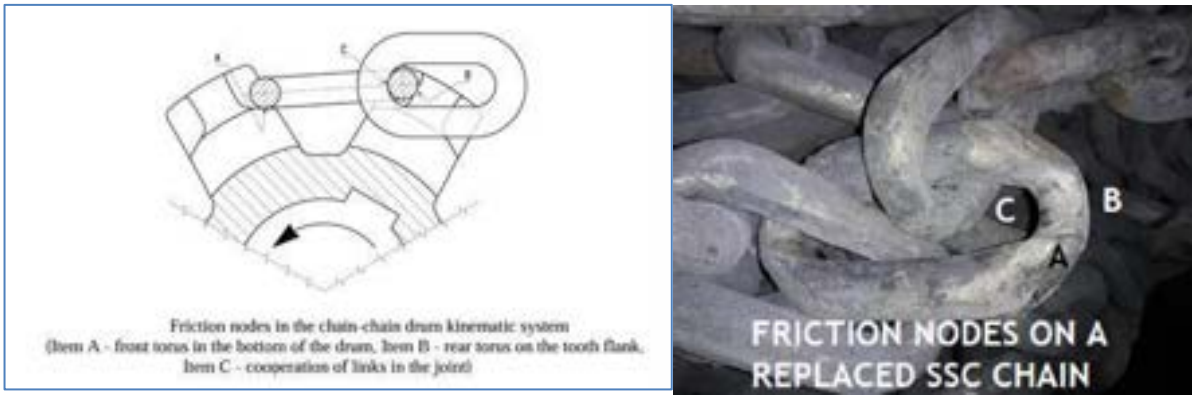

Figure 3: Abrasive wear of a chain in contact with sprocket (left), Source: Wieczorek [4] and typical abrasive wear profile in a coarse ash SSC chain (right).

2 RESEARCH OBJECTIVES

The researcher was tasked to improve the health of the dust and ash plant in a coal-fired power plant and a need was identified to learn from the work of the researchers who have travelled this route of solving submerged scraper conveyor (SSC) problems in the industry. One of the most important components needed to optimize dust and ash plant uptime and surpass customers' expectations was a healthy SSC plant amongst others. Therefore, the objective of the study was:

- To explore the application of the SSC studies in the industry so that the learnings from the publications can be adopted in the power plants for an enhanced uptime using system dynamics tool in the future.
- To present a summary of the systematic literature review findings for industry practitioners, researchers, and policymakers - offering insights into the potential benefits and challenges associated with the application of submerged scraper conveyor system.

The findings of this study will be integrated in the future study to build the dust and ash plant maintenance model (Electrostatics precipitator, mixed ash conveyors, fly ash bunkers, overland conveyors, stacker, spreader, etc.) using the system dynamics tool with the aim to identify the leverage points in the total system for an enhanced plant uptime.

3 RESEARCH QUESTIONS

Based on the stated background, systematic research methodology has been adopted to learn from the SSC research work that had been conducted in the past. This study seeks to answer the following question:

- What are the characteristics in the published SSC plant studies that can be transferred to the South African power plants with the aim to enhance dust and ash removal system performance?

In addition to tackling this question, the study shall characterise the studies by paying attention to some of the themes in table 2.

Table 2: Relevant topics for the SSC system SLR study.

Topic of interest in the included SSC studies	Description
Industry Sector	This denotes the field in which SSC technology is applied.
Type of SSC technology	Technological enhancements that have been included in the original SSC technology with the aim to exceed customers' needs and stringent environmental laws.
Maintenance Strategy	SSC system's reliability depends on several variables. The change in these variables triggers maintenance manager to repair the plant at certain time and after it has processed certain amount of coarse ash in tons. Refer to table and figure 3 above.
Type of Residues	It refers to the type of residue that has been produced in a particular process (eg.: boiler combustion, etc.)
Type of Research Instruments	This refers to the type(s) of instruments that were applied in the SSC studies.
Type of publication	This is a measure of the included SSC studies' academic health status as they are required to be rigorous, reliable and peer reviewed.
Country and continent generated publications	This indicator offers the SSC researchers locations that are actively advancing the technology under review. This could help in cases where benchmarking must be undertaken in the future.

4 RESEARCH METHODOLOGY

Through a comprehensive study of the 36 articles, systematic literature review approach was adopted in this analysis to find out the factors that contribute to the best performing submerged scraper conveyor plant. The study was based on the work conducted by various researchers dating from 1989 to 2024 and met the criteria. Google scholar databases and other sources were indexed on the 2nd of February 2025 to extract relevant scholarly journals, conference papers, reports, theses and books that were applicable for operation and maintenance of SSC plant. Data was coded and extracted from the included studies to synthesize and appraise the results, describe how the SSC was applied in practice, and highlight any gaps or discrepancies. An explicit and repeatable search approach was employed throughout the investigation process, and studies were either included or excluded, based on the criteria illustrated in figure 4 below. The advantages and disadvantages of this methodology were known; hence research controls were put in place to eliminate bias and replicability crisis.

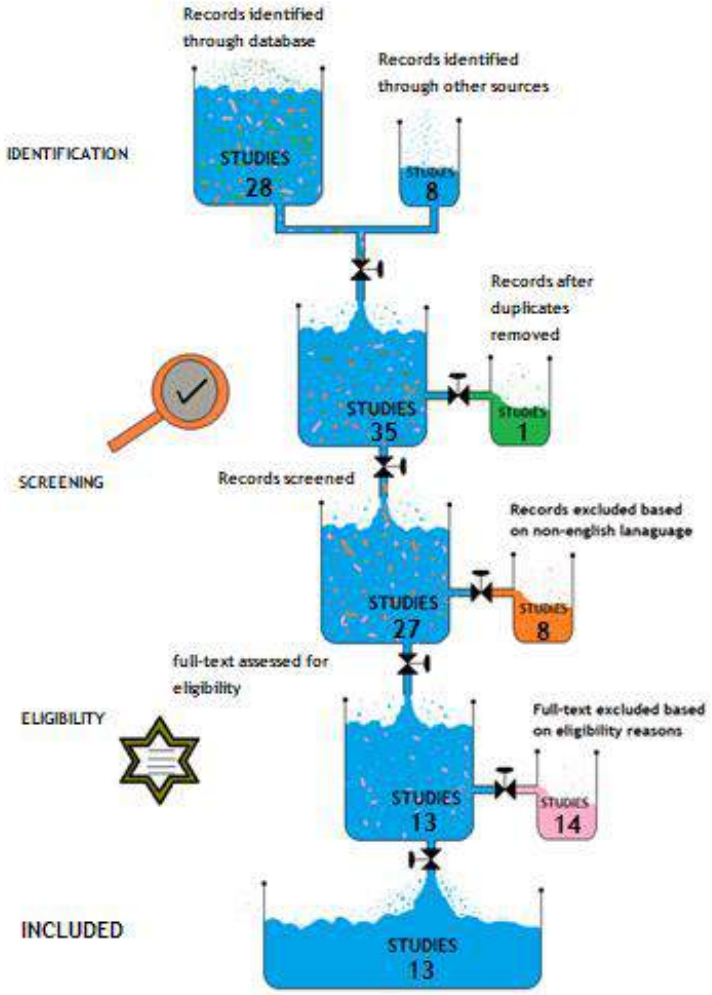

Figure 4: Systematic review flow diagram, Source: adapted from [7].

5 SEARCH STRATEGY AND SELECTION PROCEDURE

After going through a modified Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA), 23 studies that didn't fit the inclusion criteria were eliminated from the study. All the articles that satisfied the requirements were examined and categorized using qualitative data analysis [7]. Thematic analysis was done according to Braun and Clarke [8] framework as shown figure 5, this involved "a method for recognizing, analysing, and presenting patterns (themes) within the data". Section 6 provides an overview of the thematic analysis' findings, while Appendix A contains the specific findings. The search term *Submerged Scraper Conveyor* was used to obtain relevant articles. The unstructured SSC studies considered prevented a meta-analysis execution as the studies' objectives were diverse, inconsistent and did not follow PRISMA guidelines.

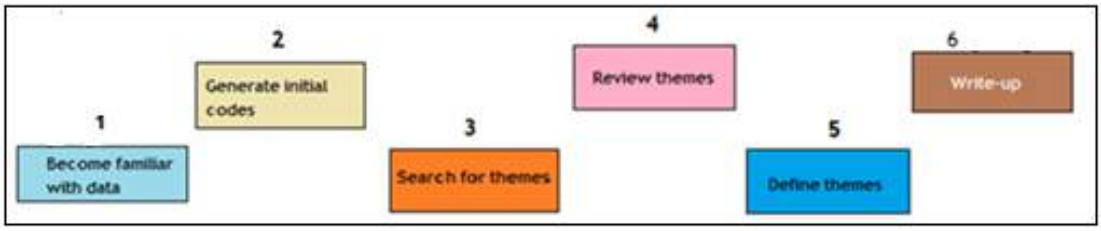

Figure 5: Framework for doing thematic analysis. Source: adapted from [8] and [9].

6 STUDY CHARACTERISTICS [25] TO [38]

To address the research question, an initial review of the 13 submerged scraper conveyor articles was conducted without applying thematic filters. Thereafter, top 6 themes that distinguished themselves as the best submerged scraper conveyor issues were characterised and analysed and the results are captured section 6.1 to 6.6 below.

6.1 Original Equipment Manufacturers and Type of technologies on SSC plant

The type of technology that was employed in the South African power plants' SSC was basic and it had reached maturity. It included some of the following: *chain and sprockets, hydraulic power package, slurry agitation system, control and instrumentation system, structural supports, etc.* The conveyed coarse ash no longer matched its original quality because tied coal mines were depleted, and new coal sources were introduced, and this was negatively affecting performance of this plant. The original equipment manufacturers (OEM) of these plant items included some of the following:

Table 2: Common OEMs of SSC components in the South African power plants.

Plant item	Original Equipment Manufacturers
Chain	RUD®, PEWAG®, HEKO®, GZ Material Handling® and EDD®
Chain Links	RUD®, PEWAG® and HEKO®
Idlers	RULA
Sprockets	RUD® and HEKO®
Flight bars	Steinmuller®, Actom® and Eskom manufactured
Hydraulic drive and pumps	Hytec/Rexroth® and Hydraulic Hagglund®
Bearings	FAG®, SKF® and TIMKEN®

The five (5) papers in this study were based on the works of OEMs across the globe and eight (8) papers were not linked to the OEMs as shown in figure 5. Power plant operators of the SSC had OEMs such as Babcock and Wilcox [4], RULA [10], Kawasaki (Babcock Borsig AG) [11], CISCA [12], HEKO [13], Martin [14] and Aumund [15]. Although the OEMs were prominent in the power generation industry, they were not represented in the academic publications sampled—a gap potentially attributable to the study's sample size and database selection.

Magaldi® emerged as the leading OEM for SSC turnkey solutions and their products were not seen during the fieldwork in the local power plants. Magaldi® had also invented Magaldi Superbelt® (see figure 6) that was described as "Damage tolerant by the OEM" as it could deal with the harsh environment that SSC was exposed to, these included clinkers or boiler parts that were falling onto the chain-flight bars thus leading to extended plant downtime. OEMs in table 2 above did not design the SSC as a package but specialized in the design and manufacturing of the individual components.

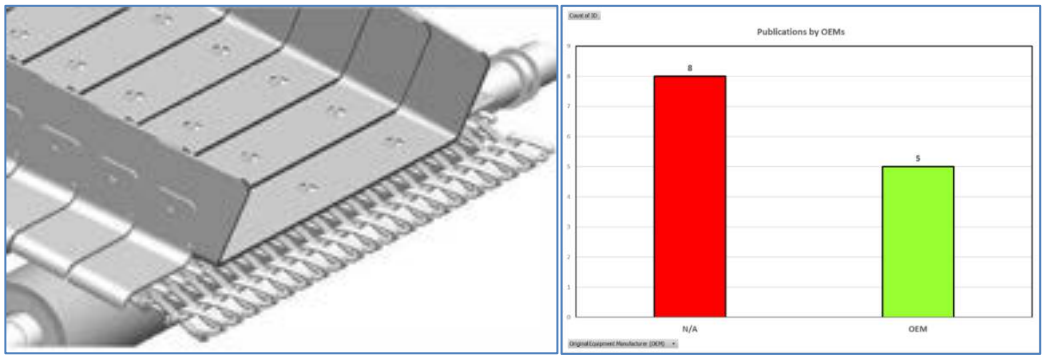

Figure 6: The Magaldi Superbelt®, Source: [16] (Left) AND Figure 7: Publications produced by the SSC OEMs in the studies (Right).

Additional technologies that were identified in the studies included: MAP Magaldi Ash combustor®: "*To comply with new requirements on co-firing of the boilers, Environmental concerns about water scarcity and reliability Wet Bottom Ash System (WBAS)*". and MAC Magaldi Ash Cooler®: "*To enhance the quality of ash through reduction of unburnt carbon content with MAR® system that ensures the "valorization" of the bottom ash. Elimination of water using to quench hot ash. Elimination of the ash ponds*". The remainder of the articles covered a common SSC, and they were based on known SSC technology that was found in the local power plants (see figure 7 and 8).

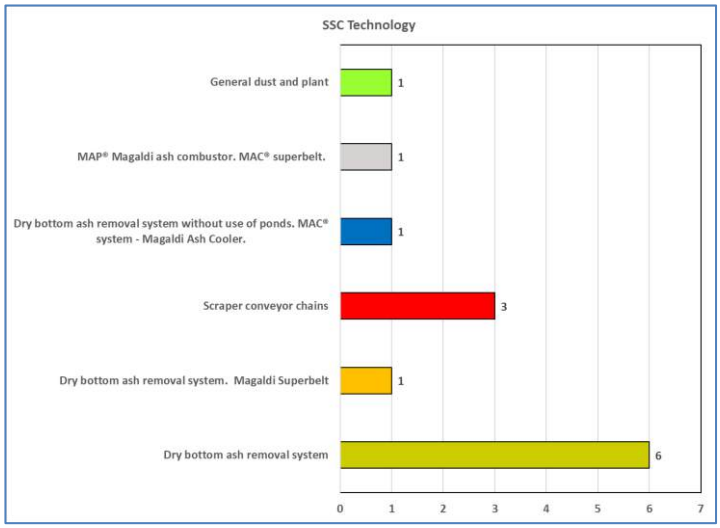

Figure 8: Technologies identified in the studies.

6.2 Maintenance strategy of SSC plant

Outage philosophy of the power plant was mainly driven by turbine plant running hours and this drove boiler plant outage philosophy. Arrival of the risk-based inspection (pressure equipment regulation) has extended boiler inspection from 36 months to once in 9 years and this has also disrupted submerged scraper conveyor maintenance strategy as some of the maintenance interventions were following the 36 monthly inspections. The second disruption to the SSC was reported by Mahlangu [17] as poor quality of coal that was unstable (figure 9). Ash with high abrasive index has negative effect on the lives of the plant items that its maintenance strategy was based on ideal coal quality. The third disruption in operation of the SSC was the high operating speed [17]. Mahlangu [17] argues that SSC plant items failed prematurely thus forcing major overhaul to be done before the authorized schedule (see figure 9).

Design	TM	IM	CV	GCV	Nett CV	Ash	Vol	Sulphur
	%	%	MJ/Kg	MJ/Kg	MJ/Kg	%	%	%
	(ar)	(ad)	(mf)	(ar)	(ar)	(mf)	(mf)	(mf)
Original	9.3	4.3	25.18	22.18	22.06	22.4	24.5	1.37
Current	8	4.1	20.98	19.3	18.46	31.48	19.29	1.45

Figure 9: Coal quality changes from the original to the current supply at Power Plant P, Source: [17].

Mahlangu [17] argues that changes in the quality of coal that is fed to the boiler is one of the maintenance schedule disruptors as shown in figure 9 and 10. One of the parameters which is not covered in this figure is called Abrasive Index (AI). Raask [18] and Meintjes [19] argue that the higher the value of this parameter the greater the wear rate of the chains, guides, sprockets, etc.

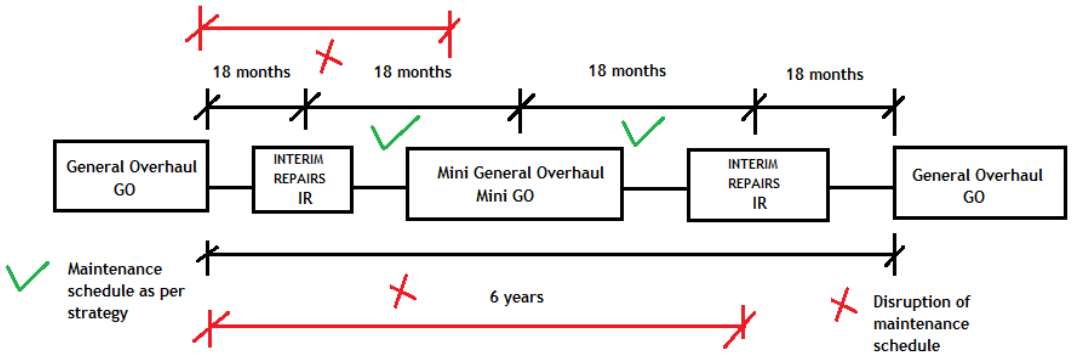

Figure 10: Boiler maintenance cycle – no outage disruption vs. disruption scenario.

Koloane, *et al*. (2025) [20] conducted an extensive systematic literature review on the railway defects and tools used to manage them. Railcar online track health monitoring tool was used to assess the irregularities in the railway tracks so that maintenance management can arrest rail/wheel defects timeously for enhanced rail system with increased uptime and this type of intervention was suitable to manage similar damage mechanisms that were at play in the SSC (see figure 11).

Figure 11: Submerged Scraper Conveyor with "online track health monitoring" tool, Source: Adapted from [21].

Twenty-three percentage of the studies that were considered in this focused on the maintenance strategy to improve SSC plant health (see figure 11-left) and higher proportion in the studies of the power plant operators did not publish their experience or sampling methodology was deficient.

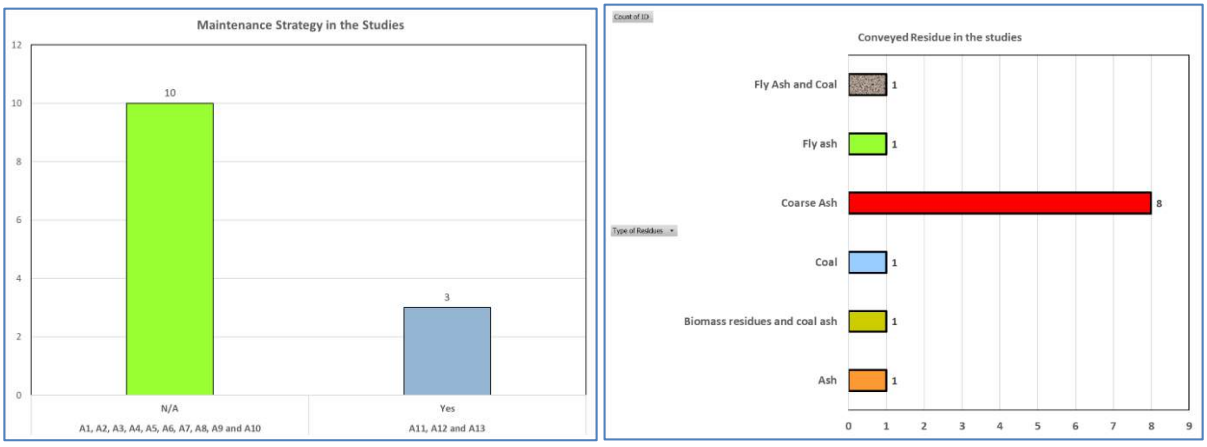

Figure 11: Included studies with maintenance strategy (Left) and Type of residue that was conveyed (right).

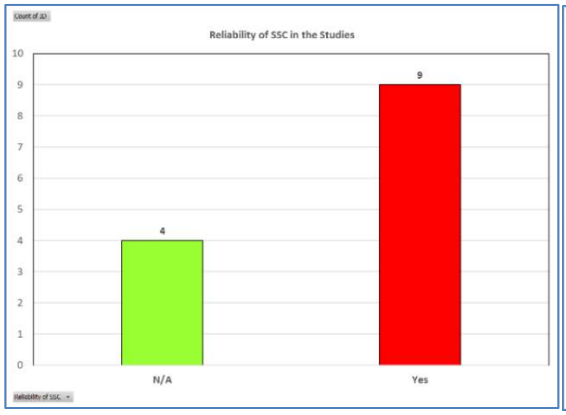
6.3 Reliability of SSC plant

According to Ryan [22], reliability is the "*probability of an SSC fulfilling its intended function during its life cycle*". Unreliability in this plant can be caused by several factors such as: *corrosion of the structural supports, fatigue of the load bearing members, ash ingress into the hydraulic system (grinding paste), clinkers or slag or boiler parts falling onto the chain-flight bars, master link failure, overloading of the chain due standing time (backlog), etc.* Sixty-nine percentage of the included studies were focused on the reliability of the SSC plant while eighty-five percentage of the studies were coal-fired power plant based (figure 12). This highlighted the importance of reliability of the SSC plant items. van Alphen [23] found that over a period of 5 years, 180 MWh load losses was attributed to slagging in the boiler, this took place when the slag (clinkers) was dislodged and fell onto the tubes thus causing dent and damages or when gas flue distribution is changed to such an extent that certain areas in a boiler experiences high localized erosion rate or reduction in heat transfer in steam pipelines due reduced thermal conductivity by the slag.



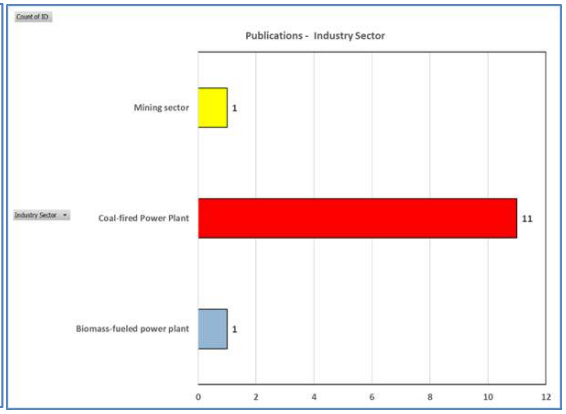


Figure 12: Studies that focused on the reliability of the SSC (Left) AND Figure 13: Industry sectors that were included in the studies (Right).

SSC downtime failure in the power generation industry sector is referred to as Unplanned Capability Loss Factor (UCLF), when SSC fails it directly translates to power generation *opportunity loss* that is called Mega-Watt Hour (MWh) load loss. This is a product of an energy sent out capacity of that unit and the amount of hours that SSC was on downtime.

$$\text{Total SSC MWh loadloss} = \sum_{i=1}^{n}(\text{MWh}_1 + \text{MWh}_2 + \cdots \text{MWh}_n) \quad \text{.....1}$$

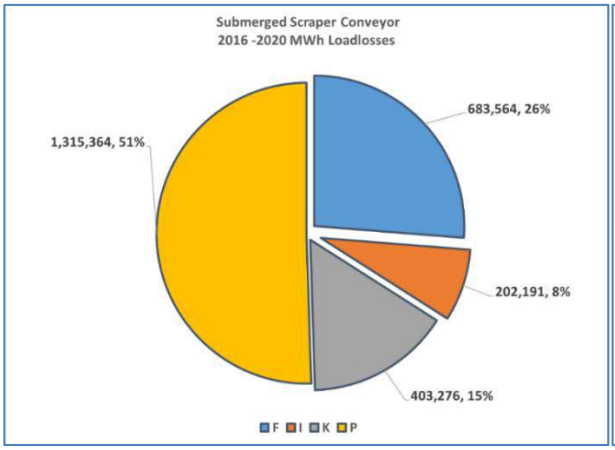
Typical example:

Power generating Unit has a maximum sent out capacity of 600 MW, during failure the loss could be ether full or partial. SSC fails due to an overloaded chain, and this leads to unit shutdown and SSC recovery time is 48 hours. Below is the MWh load loss calculation due to this incident.

$$\text{MWh}_1 = 600\ \text{MW} \times 48\ \text{hours}$$

$$= 28\,800\ \text{MWh}$$

Mahlangu [17] has reported that submerged scraper conveyors at the power plant P in 2016 (4%) and 2017 (17%) had contributed 4% and 17% of the UCLF respectively. The author found during the fieldwork, 2 604 394 MWh load losses were incurred due to the unreliability of SSC in power plants F, I, K and P between 2016-2020 (see figure 14).



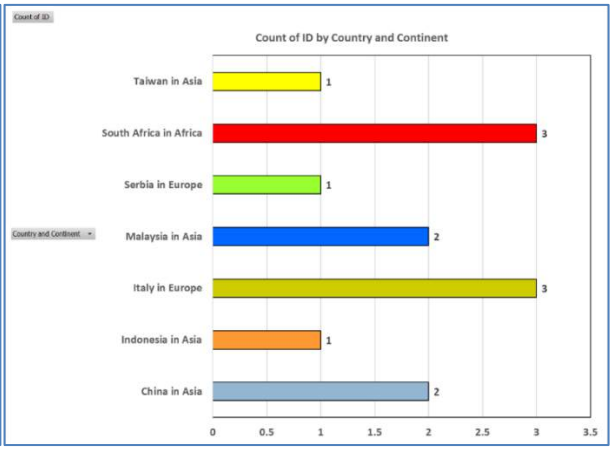


Figure 14: Submerged Scraper Conveyor MWh Load losses 2016-2020 (LEFT) AND Figure 15: Authorship by country and continent in the studies under review (RIGHT).

6.4 Authorship by country and continent in the SSC studies under review.

Most of the studies (46%) were based on the research work that was conducted by the Asian academics. This was followed by the European research studies (31%). South African researchers contributed 23% of the work based on the sample and this indicated a need for more local research that can be easily transferred to the industry (see figure 15).

6.5 Type of SSC publications in the included studies

Majority of the SSC research publications (39%) were based on the conference proceedings that was disseminated through peer-reviewed mechanism (see figure 16). Journal publications constituted 31% of the studies, this is often considered reliable and rigorous form of academic communication. Production from the academic institutions through theses provided 39%, these were mainly done to address practical problems that power plants experienced as academic literature was silent in their unique problems. One case study (7.8%) was included in the SSC studies, this was based on the Magaldi Ash Cooler technology to optimize the slag removal system and to minimize the impact of the air-cooled dry bottom ash removal system on the thermal efficiency of the Baoding Qingyuan Thermal Power Plant located in North China.

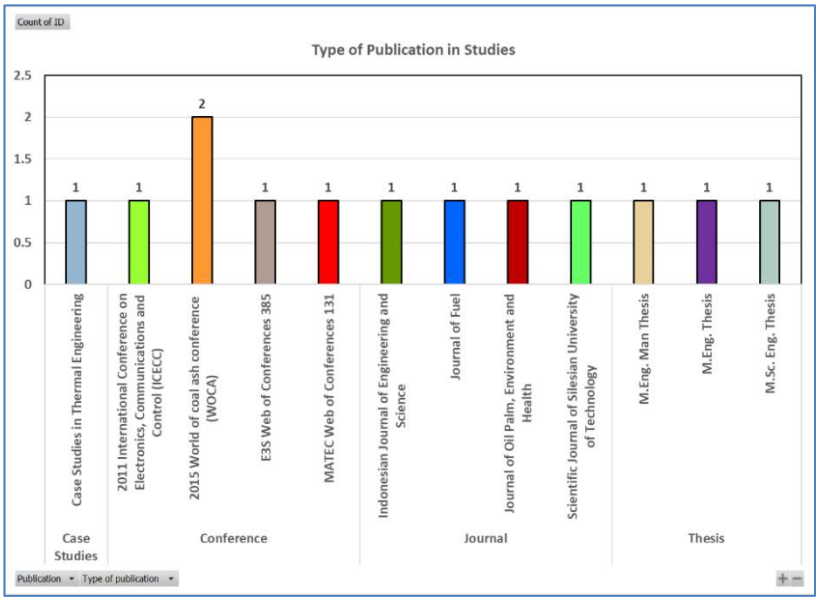

Figure 16: Number of publications in the SSC studies under review.

6.6 Publications trends of SSC

Submerged scraper conveyor publications (see figure 17) indicated a relatively upward trend (1989-2024) based on the 13 included studies and this highlight the importance of the SSC in the industry in general as more and OEMs and power plants owners realise the relationship between plant reliability and happy energy customers.

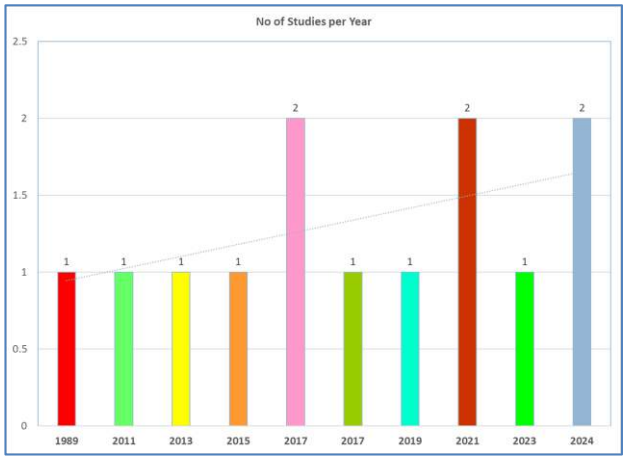

Figure 17: Publication trends in the studies under review.

7 LEARNINGS FROM THE INCLUDED SSC STUDIES

Table 3 below provides a summary of the systematic literature review and learnings that are important for the future dust and ash plant SD model and SSC industry practitioners.

Item	Study findings	Notes for SSC practitioners
Industry Sector	Power plant sector (85%) was the most dominant area where SSC technology was applied. Learnings from the other power plants with SSC could help to enhance the plant uptime and retain the environment green.	There was a need for the power plant operators, academics and designers to combine forces and intensify sharing of the operational experiences so that race could be won against low plant uptime and environmental pollution.
Type of SSC technology	SSC technology had progressed, and South African power plants were using old technology that was prone to failures and not damage tolerant. Magaldi® was identified as a proponent developer of technology that addresses production, reliability, environmental and thermal efficiency issues.	South African power plants to conduct benchmarking exercise with the Malgadi© and Asian counterparts to learn from their successes and implement learnings in their power plants.
Maintenance Strategy	The studies (77%) have put emphasis on the effective SSC maintenance strategy, operating speed of the SSC had negative effect on the items' life [17]. Maintenance schedule was disrupted by high abrasive index of the coal burnt in the boiler [18] and [19]. A need to integrate this factor on the maintenance strategy was identified. SSC plant maintenance schedule must be based on the abrasive index of coal burnt in the boiler versus the operational lifetimes of the SSC items listed in table 2 above. Introduction of the risk-based inspection has disrupted boiler maintenance schedule (SSC plant).	For an effective maintenance strategy and increased uptime of the SSC, maintenance planning must evolve with changing plant input dynamics (i.e. operating speed, abrasive index, risk-based inspection, etc.).

Item	Study findings	Notes for SSC practitioners
Type of Residues	Ash (92%) was the most common product. Industry in general made use of SSC to collect and transport coarse ash to the dumping site.	SSC can be applied to convey other products beside ash.
Original Equipment Manufacturer (OEM)	The studies (39%) were based on OEM papers. Malgadi© was found to be the most active OEM on SSC plant and they offered state-of-the-art and turnkey solutions. Original Equipment Manufacturers (OEMs) for South African power plant SSCs were dispersed, and none focused on resolving systemic issues to mitigate MWh load loss. The lack of academic publications on these influential OEMs in the sample might be explained by the study's limited databases or sample criteria.	Malgadi© was recommended for the turnkey solution with latest technology. There was a need for the various SSC OEMs to collaborate so that they can jointly develop a turnkey solution that will eliminate the load losses. Sample of the SSC studies to be increased and based on multiple databases in the future for a more representative sample of the research work that has been done in the power generation industry across the globe.
Reliability	Reliability of the SSC is vital as its failure has direct impact on power plant MWh produced. SSC plants in the included studies (100%) did not have redundancy system hence a need for highly a reliable plant. SSC chain, flights, guides, sprockets and structural supports failures were catastrophic hence a need to be subjected to an online monitoring as practiced in the rail industry [21] for an increased reliability.	To achieve zero MWh load losses, the SSC components must operate with 100% reliability.
Publications	South African researchers contributed just 23% of the analysed publications. Consequently, many domestic power generation issues have not undergone rigorous global peer scrutiny that could help enhance industry performance.	Increased scholarly publications by South African power professionals would enable knowledge-sharing with international experts (e.g., Malgadi's team) helping to optimize local plant performance.

8 LIMITATIONS

This research was based on the publications between 1989 and 2024. This study was designed with an English-centric perspective and indexed in Google's database as well as additional repositories. This provided the 36 studies, but it might have missed any other significant research that was published elsewhere or in languages other than English. Future research should therefore be aware of English-based and aim to incorporate studies from regions previously thought to be underrepresented as most of the included studies were Asian-based and this region's researchers were not English-centric. This strategy may involve seeking out SSC studies that apply different analytical methods and utilizing language translation for international research. The abstracts for some of the studies were not comprehensive to provide vital details of their studies hence a need was identified to study the entire article versus using abstracts as recommended by PRISMA. The replication difficulties may be attributable, at least in part, to methodological flaws arising from potential author bias in these studies [24].

9 CONCLUSION

Majority of the included studies (92%) were based on the power generation industry.

Original Equipment Manufacturers have advanced SSC technology to target production losses while improving reliability, environmental compliance, and thermal efficiency. The invention of Magaldi Superbelt® could have tremendous positive effect on the plant availability as falling objects will not damage the SSC and stop power generation.

Studies (77%) highlighted the importance of an effective SSC maintenance strategy. This requires a dynamic maintenance schedule that respond to the changes like operating speed, coal quality and risk-based inspection demands.

Coal procurement must stick to the quality that the boiler plant was designed for so that SSC maintenance strategy or planned maintenance schedule interruptions could be eliminated, and MWh load losses are kept at zero.

The studies (39%) were based on OEM papers. Malgadi© emerged as the most active OEM on SSC plant and they offered state-of-the-art and turnkey solutions. Original Equipment Manufacturers (OEMs) for South African power plant SSCs were dispersed, and none focused on resolving systemic issues to mitigate MWh load loss. The lack of academic publications on the influential South African power plants OEMs in the sample might be explained by the study's limited databases or sample criteria.

SSC chain, flights, guides, sprockets and structural supports failures were catastrophic hence a need to be subjected to an online monitoring for reduced load losses.

South African researchers contributed just 23% of the analysed publications and this denied the international scientific community an opportunity to scrutinise local problems and provide solutions that could help enhance industry performance for happy energy customers. The included studies were disseminated through peer-reviewed mechanism hence considered reliable and rigorous. These indicated an upward trend in publications that proved a need to address the SSC plant problems.

10 COMPETING INTERESTS

The authors declare that they did not have competing interests.

11 ACKNOWLEDGMENTS

The Ph.D. candidate would like to thank the University of South Africa (Unisa) for funding this research and Eskom for granting the candidate a permission to conduct research in their power plants.

ABSTRACT

This study explores the techniques used in detecting outliers, with specific application in trade misinvoicing. A Systematic Literature Review was conducted to identify relevant studies from 2010 to 2024. Themes considered included identifying techniques used to detect outliers in solving quality control problems, techniques used to identify and quantify customs trade misinvoicing, the industries in which these techniques are applied, and the advantages and limitations of the current techniques utilised. In the customs environment, two primary techniques were identified: the Partner Country Method and the Price Filter Method. Several quality control techniques were explored for their applicability in the customs trade context. The study highlighted similarities and differences between various techniques. Classification and learning-based methods, such as isolation forest and neural networks, were found to be effective in detecting outliers indicative of quality control issues. The identified potential techniques will be evaluated for their suitability and applied in future research.

Keywords: quality control, trade misinvoicing, outlier detection

1 INTRODUCTION

According to Walsh [1] the World Trade Organization (WTO) agreement established rules for the valuation of imported goods that must be applied by all member countries. Countries that are signatories to the WTO are required to adhere to this valuation agreement, but complying to the provisions of this agreement has often proved challenging as it includes the introduction of modern principles of tax and customs administration, such as self-assessment. Self-assessment implies that traders complete the customs declaration form which includes estimating the value and tariff classification of the goods, as well as calculating the duties and taxes owed. The customs administration only verifies the information based on risk assessment techniques which can include random sample selection. The process relies on traders' honesty and accuracy in making a proper declaration. However, this is not always the case.

Globally, customs authorities face challenges with the incorrect declaration of goods, known as *trade misinvoicing*, and South Africa is no exception to this issue. Muryawan [2] defines trade misinvoicing as the practice of knowingly submitting an invoice that misrepresents the value of goods being imported or exported. It can manifest itself as imports or exports under or over-valuation. The risks of trade misinvoicing are shown in the table below.

Table 1: Trade Misinvoicing risks, Source: Adapted from Muryawan [2].

Financial Inflows	**Import Under-Invoicing**	• To evade Customs duties or VAT taxes • To avoid regulatory requirements for imports over a certain value.
	Export Over-Invoicing	• To exploit subsidies for exports. • To exploit drawbacks (rebates) on exports.
Financial Outflows	**Import Over-Invoicing**	• To shift money abroad • To reduce income tax liability. • To avoid anti-dumping duties.
	Export Under-Invoicing	• To shift money abroad • Income tax evasion.

Theoretically, commodities that are misinvoiced will have a unit price that is different from the unit prices of other similar commodities. These can be referred to as outlier unit prices.

The reference pricing tool was introduced by the South African Revenue Services (SARS) since 2009 to detect undervaluation of customs values on imported goods [3]. This tool aims to detect goods declared at unit prices significantly lower than the norm. However, it has faced criticism for causing unnecessary delays and hindering trade, which conflicts with SARS' mandate of facilitating legitimate trade through customs and excise services.

This has necessitated the need to investigate other advanced techniques for detecting the misinvoicing of goods. This research study aims to review and document the available literature on various outlier detection techniques, identify the industries where they are most commonly applied, and determine the types of data required for their application. The findings from this systematic review will offer valuable insights into the techniques that can be explored to enhance the current methods used for estimating trade misinvoicing.

1.1 Applications of outlier detection

Historically, observations that deviated from a hypothesized distribution of a data set were often discarded as erroneous. However, this approach was problematic because not all of these observations were incorrect; some could indicate extreme or rare events [4]. This necessitated a need for more formal statistical techniques for identification of observations that might be excluded notwithstanding the fact they bear useful information. To this day, practitioners continue to formulate and define new techniques for detecting and handling outliers. However, no standard quantifiable outlier detection method is universally applicable

across all domains. Different techniques are suited to different environments, making outlier detection domain dependent [5]. In addition, the techniques used depend on the type of data under study, as the same method might not be applied to both numerical and categorical data types [6].

Outlier detection is applicable in various environments, including:

- **Manufacturing and Supply Chain**: *Investigating product deviations* [7].
- **Stock market**: *Analysis of daily stock market returns [8].*
- **Medicine**: *Identifying potential health problems* [9].
- **Sports**: *Detecting high testosterone levels in women* [10].
- **Finance / Fraud detection**: C*redit card fraud detection* [11].
- **Aviation**: *Detection of aircraft engine rotation defect* [12].

2 RESEARCH OBJECTIVE

This systematic review aimed to investigate the techniques employed in outlier detection and evaluate their applicability within the customs trade environment. Optimizing tax revenue collection hinges on maximizing tax compliance. To achieve customs tax compliance, a tax authority must ensure that all legitimately declared goods enter and leave the country through proper border control. However, it is crucial to balance border protection with the smooth movement of goods to prevent losses due to delays at ports of entry (POE). By employing advanced outlier detection techniques, a tax authority can minimize unnecessary delays at POE, that can disrupt traders' businesses, by targeting only dishonest traders while maintaining border protection and control. Thus, through modified Preferred Reporting Items for Systematic Reviews and Meta Analyses (PRISMA) of the studies, the study's goal was to identify modern techniques and map their characteristics that contribute to the optimal tax collection. Based on the learnings gained from this study, techniques were evaluated for their applicability in the customs industry with the objective of selecting a tool that can be used by a tax authority to enhance the current methods.

3 RESEARCH METHODOLOGY

Google scholar was indexed between 1 March and 8 June 2025 to extract relevant articles, conference papers, books and theses that were applicable to this topic. Google Scholar was chosen as an appropriate search engine as it collates results from across the internet and is free to use [13]. Some of the articles searched through Google Scholar were only fully accessible through Elsevier, Taylor and Francis, SAGE Journals, Sabinet, Research Gate, Springer Academic Journals, Wiley Online Library and Science Direct using the University of Kwa-Zulu Natal platform.

After that, information was coded, taken out of the manual, and studies were included to summarize and evaluate the findings. This analysis mapped around 221 articles covering the outlier detection techniques, customs trade misinvoicing detection and quality control techniques to identify outliers. Throughout the inquiry, a clear and consistent search strategy was used, and studies were either included or excluded in accordance with a specific inclusion and exclusion criteria. Since this methodology's benefits and drawbacks were well understood, study controls were implemented to ensure that bias was eliminated. In addition to its strengths, there were several limitations to be mindful of. The researchers presented country-specific examples, which were open to their interpretation and might be a little subjective [14].

3.1 SEARCH STRATEGY AND SELECTION PROCEDURE

Article selection was based on the titles, abstracts and year of publication. The review considered eligible articles that contained the following criteria:

- The method of inclusion covered topics such as, outlier detection techniques, customs trade misinvoicing detection techniques and quality control techniques, to identify outliers.
- A purposive sampling technique was used for this study as follows:
    - The first 15 pages of search results containing outlier detection techniques were reviewed to ensure enough articles were analysed to determine the prevalence and industry application of outlier detection.
    - The first 5 pages of search results containing customs trade misinvoicing detection techniques were reviewed to enable a customs-specific analysis in case the initial search did not yield any relevant applications in the customs environment.
    - The first 20 articles containing quality control techniques were reviewed to determine the extent to which outlier detection techniques are used for quality control purposes.
- Additionally, the search was limited to the criteria above due to time constraints.
- Only articles that described the technique or method used were included in the selection criteria.

3.2 Inclusion and exclusion criteria

Date of publication was restricted from January 2010 to 31 December 2024. A search string containing outlier detection techniques, customs trade misinvoicing detection techniques and quality control techniques to identify outliers was developed for no specific industry. No restrictions were placed on the language used in the article. The query search string used was:

"*outlier detection techniques*"; "*customs trade misinvoicing detection techniques*" *and*

"*quality control techniques to identify outliers*"

Research data was evaluated and reported using the adapted Preferred Reporting Items for Systematic Reviews and Meta Analyses (PRISMA) systematic literature review criteria [15]. Figure 1 depicts the methodology that was employed. When the abstract lacked information that was necessary for this study, the authors went back and read the complete article to extract value from the chosen articles. It was rather challenging to choose the right search terms because there was a scarcity of systematic research in the studies on *outlier detection techniques, customs trade misinvoicing detection techniques, and quality control techniques*. A total of 221 articles were found for the systematic review; to choose the final articles to be included in this review, a practical screening was carried out using the criteria setting and the flow diagram in Figure 1. After eliminating articles with a cost attached to them, irrelevant articles, articles whose pages could not be found, had pending Research Gate requests or were in foreign languages, 178 articles were selected and analysed.

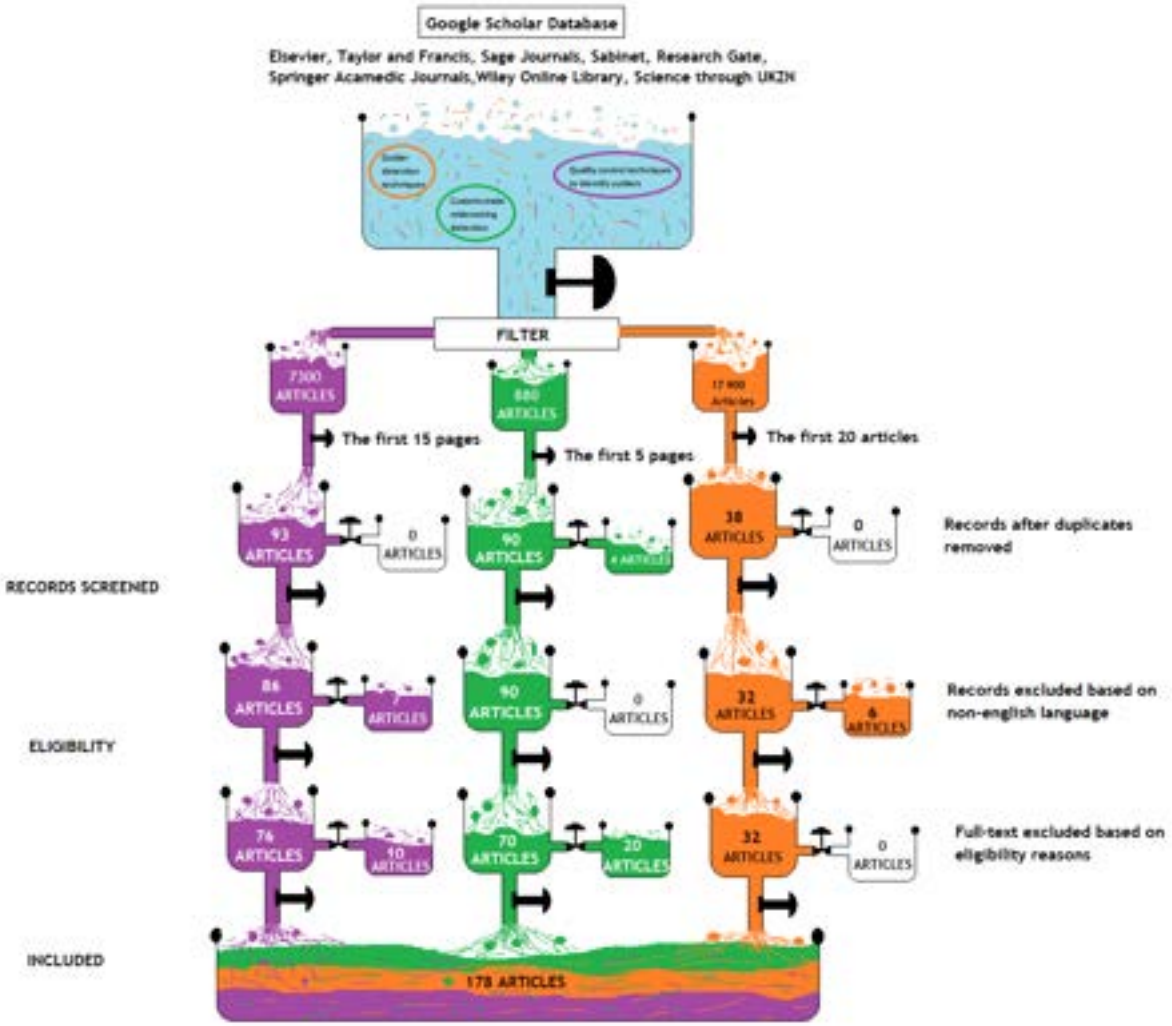

Figure 1: Flowchart illustrating the different stages of paper selection, Source: adapted from Page *et al.* [15]

4 STUDIES SELECTION

The study's articles went through a two-stage filtering process, which excluded 43 articles that did not meet the inclusion criteria. Qualitative data analysis was used to scrutinize and categorize all papers that met the criteria [16]. Braun and Clarke [28] define thematic analysis as "a method for recognizing, analysing, and presenting patterns (themes) within the data."

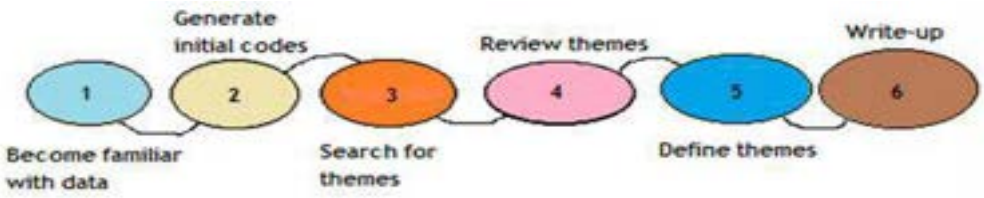

Figure 2: Framework for doing thematic analysis. Source: adapted from [15] and [17].

The results of the thematic analysis are outlined under section 5. The studies varied significantly and did not adhere to PRISMA guidelines, which made it impossible to conduct a meta-analysis as it is commonly practiced in the medicine field [18].

5 STUDY CHARACTERISTICS

5.1 Definition of variables

The variables analysed in this systematic review are:

- **Categories of Outlier Detection Techniques**: *Supervised, Unsupervised, Semi-supervised, Statistics-based, Distance-based, Density-based, Clustering-based, Classification-based, Ensemble*
- **Outlier Detection Techniques**:
  - **Supervised**:
    - **Classification-based methods**: *Decision trees, Support Vector Machines (SVM), Neural networks, Random forests, Logistic regression*
    - **Ensemble methods**: *Gradient boosting machines (GBM), AdaBoost*
    - **Deep Learning Classifiers**: *Convolutional Neural Networks (CNNs) for image anomalies, Recurrent Neural Networks (RNNs) for sequential data.*
  - **Unsupervised**
    - ***Distance-based methods*: *k-nearest neighbour(k-NN), Local Outlier Factor (LOF),* Angle-based OD algorithm (ABOD)
    - ***Density-based methods***: *Density-Based Spatial Clustering of Applications with Noise (DBSCAN), Isolation Forest*
    - ***Clustering-based methods***: *k-means, Hierarchical Clustering*
    - ***Statistical methods***: *Z-score/Modified Z-score, Gaussian Mixture Models (GMM), Minimum Covariance Determinant (MCD), Bayesian networks*
    - ***Subspace and Projection Methods***: *Candès' Robust Principal Component Analysis (RPCA), Kernel PCA*
  - **Semi-supervised**
    - *One class SVM (OCSVM), One-Class Neural Networks, Gaussian Mixture Models trained on normal data only, Isolation Forest trained mostly on normal data*
- **Data Type**: *Type of data used in each technique (categorical, numerical, images)*
- **Industry**: *The industry where the analysis was conducted.*
- **Relevance/Irrelevance**: *The relevance of the study was assessed with respect to whether any outlier detection techniques were used or discussed in the study. Articles where outlier detection techniques were not mentioned were excluded.*
- **Country**: *The country where the study was conducted or the country of origin of the author(s).*
- **Continent**: *The continent where the study was conducted or the continent of origin of the author(s).*
- **Publication date**: *The date when the article was published.*
- **Type of publication**: *Whether the publication is a journal article, conference paper, book, working paper, report, PhD dissertation, Master's thesis, discussion paper or policy paper.*

Information on the objective of the study, from whom the data was collected, study period and on whether the data used was primary, secondary, synthetic or simulated was also collected.

5.2 Industries where outlier detection techniques are applied

Table 2 illustrates the primary applications of outlier detection techniques. The highest percentage of articles (25%) discussed these techniques in a general context, without focusing on any specific industry. Given the specific search criteria of "customs trade misinvoicing detection techniques," a notable portion of the articles (23%) focused on customs trade. Articles related to the Telecommunication and Medicine industries were relatively higher, at 12% and 7%, respectively. Additionally, 4% focused on data streaming environments, 3% on Production and 2% each on Internet of Things (IoT), biology, data mining, finance, chemistry and geography. Articles focusing on agriculture, environmental engineering and traffic industries were two, respectively. Other industries that applied outlier detection techniques included construction, satellite, crime, education, oil fields, food, software measurement, universities, human mobility, video surveillance, entertainment, cybersecurity, machine learning, crowdsourcing, geology, surface measurements, geomechanics and health, with one article each.

The above-mentioned results emphasise the importance of multi-disciplinary research approach as outlier detection solutions could have been developed in the other fields.

Table 2: Industries where outlier detection techniques are applied.

Industry	N	(%)
General	45	25%
Customs Trade	41	23%
Telecommunication	21	12%
Medicine	12	7%
Data Stream	8	4%
Production	5	3%
Internet of Things	4	2%
Biology	4	2%
Data Mining	4	2%
Finance	4	2%
Chemistry	3	2%
Geography	3	2%
Agriculture	2	1%
Environmental Engineering	2	1%
Traffic	2	1%
Other	18	10%
Grand Total	**178**	**100%**

5.3 Ten (10) sampled industries with applied techniques

Table 3 present ten sampled industries from this study, highlighting the applied outlier detection techniques. Among the 41 eligible articles on customs trade, only three outlier detection techniques are covered, which is fewer compared to other industries. Additionally, statistics-based techniques, the Partner Country Method (PCM), and the Price Filter Method (PFM) are discussed in 33 of the 41 articles (80% of the customs trade articles). Machine learning algorithms are mentioned in only 3 of the 41(7%) customs trade articles. The remaining articles focus on techniques such as declared value versus assessed value, domestic factors to predict export and import misinvoicing, mismatching score index, DATE, gravity model of international trade, and any divergence between the value of imported shipments declared by firms and their value assessed by customs officials, which are mostly statistically

based techniques. There is limited application of other advanced techniques in the customs trade environment.

Table 3: Ten sampled industries with applied outlier detection techniques

Food	Medicine	Production	Cyber Security	Data Mining	Data Stream	Finance
1. Statistics	1. ABC based OD technique	1. Statistics	1. Statistics	1. Clustering	1. Clustering	1. Rule-based
2. Density	2. Linear Discriminant Analysis	2. High dimensional data approaches	2. Distance	2. Classification	2. Classification	2. Clustering
3. Distance	3. Statistics	3. OCSVM	3. Density	3. Statistics	3. Statistics	3. Classification
4. Clustering	4. Classification	5. DBOD	4. Clustering	4. Proximity	4. Distance	4. Model-based
5. Deviation	5. Clustering	6. LDBOD	5. Classification	5. Distance	5. Density	5. Statistics
6. Subspace	6. Density	7. ABOD	6. Information Theoretic	6. Density	6. Information Theoretic	6. Depth

4. LOF			4. Clustering	3. PCM and PFM		12. Unsupervised dimension reduction
5. ABOD			5. K-nearest			
			6. LOF			

NB: Distance-based OD (DBOD); Local density-based OD (LDBOD)

5.4 Data type applied in the outlier detection techniques

Table 4 lists the data types most frequently found in the literature reviewed. Numerical data (65%) is the most frequently found in literature, followed by studies where the techniques were not applied on any data at 31%. Few studies employed categorical data (2%), a combination of categorical and numerical data (1%) and only 1 study applied the techniques in images. Since customs trade data is inherently numerical, it facilitates the seamless application of many of these outlier detection techniques.

Table 4: Data Type

Data Type	N	(%)
Numerical	116	65%
No data	56	31%
Categorical	3	2%
Numerical and Categorical	2	1%
Images	1	1%
Grand Total	**178**	**100%**

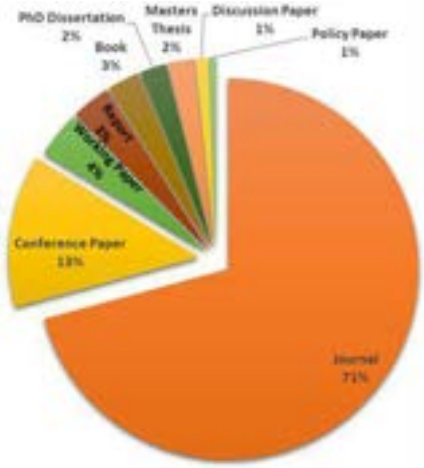

Figure 3: The proportion of papers reviewed per type.

5.5 Application of outlier detection techniques by publication type

As illustrated in Figure 3, most of the reviewed articles were from journals (71%), followed by conference papers (13%), working papers (4%), reports and books (3% each), PhD dissertations and Master's theses (2% each) and discussion papers and policy papers (1% each).

The articles considered in this study have a high percentage of journal publications (71%) that are mostly published in peer-reviewed journals. Publications in journals are frequently seen as trustworthy and exacting medium for scholarly discourse. The high number of conference papers (13%) suggests that research on outlier identification strategies is frequently shared and presented at conferences. The importance of graduate-level academic research is highlighted by the inclusion of theses (4%). In conclusion, journal papers predominate in the distribution of research on outlier identification strategies, highlighting the need of thorough peer review.

5.6 Authorship of outlier detection techniques: Country and Continent

The country with the highest percentage of authors was India (22%), followed by the USA (15%) and China (4%), as shown by Table 5. Figure 4 shows that the highest percentage of articles were from Asia (44%), Europe (22%), North America (19%) and Africa (9%).

Table 5: Authorship Country

Author Country	N	(%)
India	39	22%
USA	27	15%
China	8	4%
Netherlands	6	3%
Canada	6	3%
France	6	3%
United Kingdom	6	3%
Thailand	4	2%
Tunisia	4	2%
Malaysia	4	2%
Other	68	38%
Grand Total	**178**	**100%**

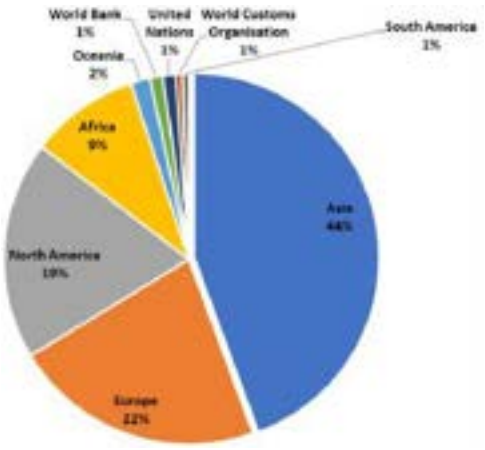

Figure 4: Continent of the authorship

NB: Other include Australia, Singapore, Pakistan, Iran, Italy, Iraq, Korea (3 respectively), World Bank, Indonesia, Ethiopia, Egypt, Germany, Turkey, South Africa, Portugal, United Nations, Spain, Vietnam, Switzerland, Ghana, Morocco (2 respectively), Saudi Arabia, Nigeria , Jordan , Slovakia ,Hungary, Finland, Austria, Denmark, Ukraine, Sri Lanka, Burundi, Sweden, Russia, Malta, World Customs Organisation, Belgium, Algeria, Mexico, Poland (1 respectively).

5.7 OUTLIER DETECTION TECHNIQUES BASED ON METHODOLOGICAL REVIEW

Outlier detection techniques with referred classifications are graphically displayed in Figure 5 below. From all the listed literature, none discuss all the outlier detection techniques comprehensively. Some focus on one technique [19] while others focus on several techniques [20], [21]. There is a need for global classification of all the outlier detection techniques.

5.7.1 Statistical based outlier detection techniques

Statistical based techniques can be broadly categorised into parametric, non-parametric and hybrid approaches. Common parametric techniques include Gaussian-based techniques like the Z-score and Grubbs' test [23],[24] and non-parametric techniques include techniques such as Kernel density estimation models, box plots, interquartile ranges and histograms [23],[25],[26]. Hybrid statistical approaches are less frequently used but combine parametric and nonparametric methods [23].

5.7.2 Nearest neighbour outlier detection techniques

Nearest neighbour outlier techniques are divided into distance-based, density-based, depth-based and deviation-based methods. Distance-based techniques, such as the Mahalanobis distance, grid-based approximate average outlier detection (GAAOD), subspace outlier degree (SOD), ABOD, k-th nearest neighbour and resolution-based outlier factor are discussed by García *et al*. [27], Samara *et al*. [22], Singh and Upadhyaya [28] and Rana *et al*. [29]. Density based techniques include the LOF [27], [24], local outlier correlation integral (LOCI), relative density factor (RDF), influenced outlierness (INFLO), connectivity-based outlier factor (COF) and local outlier probabilities (LoOP) [30],[25], among others. Depth based techniques, such as Isometric Depth (ISODEPTH) based outlier detection and Frequency Domain Clustering (FDC) (fast algorithm) and deviation-based techniques are discussed by Kriegel *et al*. [31], Zhang, *et al*. [19] and Singh and Upadhyaya [28].

5.7.3 Clustering based outlier detection techniques

These techniques can be categorised into distance-based (partitioning clustering methods), hierarchical, density-based, grid-based and clustering methods for high dimensional data. Distance based techniques include k-means, CLARANS, CLARA and PAM. Hierarchical clustering methods include MST, CURE and CHAMELEON. Density based techniques feature density-based spatial clustering of applications with noise (DBSCAN), DENCLUE, clustering-based LOF and Euclidean distance. Grid-based techniques include STING, Wavecluster and Dcluster. Techniques for high dimensional data include CLIQUE and HPStream [25],[26],[21].

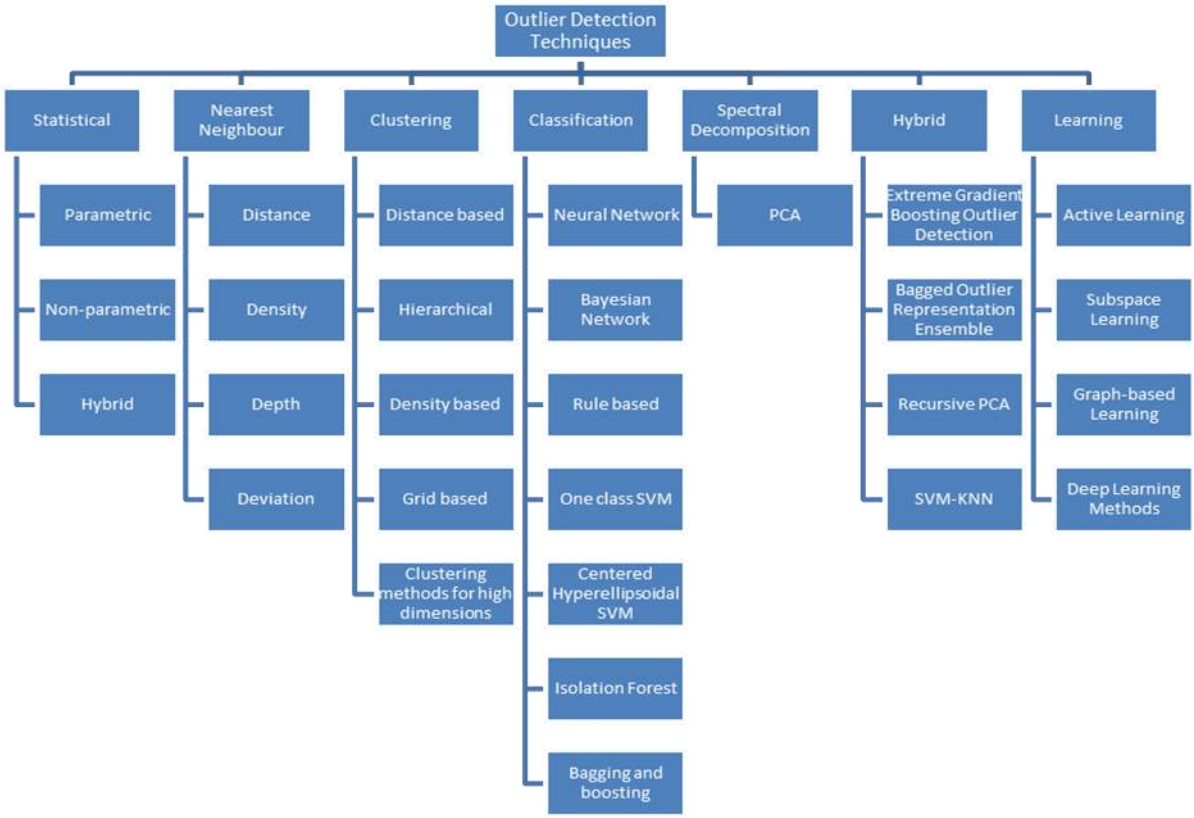

Figure 5: Taxonomy of outlier detection techniques, Source: adapted from Samara *et al*. [22]

5.7.4 Classification based outlier detection techniques

Neural networks, Bayesian network, rule-based techniques, SVM, isolation forest and bagging and boosting are some of the techniques discussed [23],[32],[33],[34]. Adaptations of the SVM including centered hyperellipsoidal SVM (CESVM), distributed hyperellipsoidal one class quarter-sphere SVM (QS-SVM), hyperellipsoidal neighbourhood outlier factor (ENOF) and spatial-temporal attribute one class quarter-sphere SVM (STA-QS-SVM) are discussed by Samara *et al*. [22] in the context of wireless networks.

5.7.5 Spectral decomposition techniques

Principal Component Analysis (PCA) as a technique for outlier detection is thoroughly discussed by García *et al*. [27], Zhang *et al*. [19], Samara *et al*. [22] and Singh and Upadhyaya [28]. Additionally, Pawar *et al*. [11] apply PCA in credit card fraud detection.

5.7.6 Hybrid techniques

These techniques are derived from two or more models. They include Extreme Gradient Boosting Outlier Detection (XGBOD), Bagged Outlier Representation Ensemble (BORE), Recursive PCA and SVM-KNN are discussed [23], [25],[8].

5.7.7 Learning based techniques

These techniques encompass active learning, subspace learning, graph-based learning, and deep learning methods. They are discussed in detail by Samara *et al*. [22], Wang *et al*. [35] and Pawar *et al*. [11], among others.

6 ADVANTAGES AND DISADVANTAGES OF DIFFERENT OUTLIER DETECTION METHODS

The advantages and disadvantages of the different outlier detection techniques are summarised in Table 5A-5E, as well as the appropriateness of the techniques in different environments.

Table 5A: Advantages and disadvantages of outlier detection techniques

Technique	Advantages	Disadvantages	Suitable Industries	Unsuitable Industries
Statistical based	They are mathematically sound and can correctly identify outliers if a correct probability distribution is determined and used [22], [27], [35], [19].	Prior knowledge of data distribution is not always available or not easy to obtain, so parametric models are not helpful [22],[35].	Telecommunications (Wireless Sensor Networks [39],[40],[41])	Sensor data applications (parametric techniques) [22], [19].
	Non-parametric techniques are more flexible and autonomous as they do not make any assumptions about the data distribution [27]. They use temporal correlation to detect outliers [22].	Available data may be insufficient to estimate the true distribution of the data especially in high dimension [29],[35].	Medicine (health monitoring [42], [28], [29]); Text data [28],[29]	Multivariate data (non-parametric techniques) [22], [27],[35].
	• After construction, they do not need the actual data on which the model is based [27]. • Outputs can be used directly for forecasting [29]. Low time and computational complexity [29], [43].	Non-parametric models are unsuitable for real-time applications [22], [27]. It is no easy to determine the optimal size of the bins to construct the histogram [19], [43].	Finance [8]; Data Stream [44], [43]; IoT [38]	N/A
	• Histogram-based techniques are efficient for univariate data and easy to implement [27], [27]. • Boxplots have no strict assumptions regarding the data generating processes and the underlying probability distributions of the data making it more flexible to be used and implemented in practical settings [21].	• Histogram-based techniques cannot capture the interactions between different attributes of multivariate data [27], [35],[19]. • Non-linear regression-based techniques returns binary results and not the outlier score [29].	Production [29]; Image Processing [28],[29], [45]; Customs Trade [20]	N/A
	Non-linear regression-based techniques have the real-time ability to detect outliers in data streams [29].	Non-linear regression-based techniques are computationally time consuming [29].	N/A	N/A
	The ordinal data can be changed to an appropriate value for processing which results in improved processing time for complex data [35].	N/A	N/A	N/A
	Easier to implement even though limited to specific problems [35], [43].	N/A	N/A	N/A

Table 5B: Summary of advantages and disadvantages of outlier detection techniques

Technique	Advantages	Disadvantages	Suitable Industries	Unsuitable Industries
Clustering based	• Do not require prior knowledge of data distribution [22], [27], [35], [19]. • The testing phase is quick because the number of clusters is a small constant that needs to be compared with each test data value [22], [27].	• Requires thresholds for minimum size and distance [29] • The effectiveness of these techniques depends on their ability to capture the cluster structure of normal instances [27].	Data Mining [22],[26], [19]; Telecommunications (Wireless Sensor Networks) [41],[46],[47]	Multivariate data (High computational costs) [22], [27], [19].
	Suitable for incremental data, as new data can be added to clusters and tested for outliers after learning the clusters [22], [27], [35], [19],[30].	• Not effective in adapting to ongoing changes in data streams over time [27]. • Low performance in small dataset [29]. • Outliers may affect the initial formation of clusters [19].	Computer Network Intrusion, Finance, Human Behaviour [48]; Finance [48], [43], [11]; Image Processing [11],[43], [28]	Resource-constrained sensors due to the computational cost [22].
	• Can be used on several data types [29]. • Unsupervised [22].	• Suffer from the choice of an appropriate parameter of cluster width [19], [43]. • Sensitive to the number of clusters chosen [29].	IoT [49], [50], [51]; Medicine [29],[48], [52]; Data Mining [53]	Cannot handle changes in the IoT data over time [22].
	Low computational complexity [29], [43].	Some clustering algorithms force assignment to groups, which can lead to outliers being assigned to a large cluster and being considered as normal instances [27].	Data Streams [35]; Text data [28],[29]; Spacecraft [29]	N/A

Table 5C: Advantages and disadvantages of outlier detection techniques

Technique	Advantages	Disadvantages	Suitable Industries	Unsuitable Industries
Nearest Neighbour based	• Straightforward and can be applied to different data types [22], [27], [29], [35],[30]. • Do not need supervised learning [22]. • Effective in detecting outliers in data with nonlinear patterns [27].	This technique has the problem of choosing suitable input parameters. Therefore, incorrect choice of the threshold will give a high false-negative rate of outlier detection [22], [29], [19].	Data Mining [22],[19]; Data Stream [54], [55], [56],[30]; Medicine [28],[43]; Text data [43] Image Processing [28], [45]	• INFLO and MDEF cannot resourcefully handle data streams [35]. • Lack of scalability in the context of IoT [22].
	Density-based techniques do not need any prior assumption about the data distribution [22], [27], [35], [19], [30].	• Density based techniques are not entirely efficient as some approaches may be sensitive to variations in the local density of data points [27], [43]. • The detection accuracy is variable and unpredictable [22].	Telecommunications (Wireless Sensor Networks) [46],[57], [28]; Machine Learning [22],[19]	• Density based techniques cannot handle high dimensional data when the outlier scores are closely related to each other [35]. • Multivariate dataset (high computational costs) [22],[27], [35], [19].
	Distance-based approaches scale better in multi-dimensional space as they have a robust theoretical foundation, and they are computationally efficient when compared to statistical methods [35].	The performance of distance-based techniques declines due to the curse of dimensionality [35].	N/A	Some distance-based techniques cannot deal with data streams because it is difficult for them to maintain the data distribution in the local neighbourhood and in finding the kNN [35].
Classification based	Unsupervised which means that they do not need prior knowledge of labelled training data [22], [27], [19].	Computation cost is greater than that of statistical and clustering techniques [22], [27], [29], [19].	Telecommunications (Wireless Sensor Networks) [19],[23], [58], [19]	Unsupervised which means that they do not need prior knowledge of labelled training data [21], [27], [19].
	• Do not have an explicit statistical model or estimated parameters [22], [27]. • Suitable for a multidimensional data set [22].	• New training is needed for new data values [22]. • High classification accuracy [22]. • Returns binary results and not the outlier score [34].	IoT [59]; Image Processing [28],[29]; Suitable for muti-dimensional dataset [22], [27].	• Do not have an explicit statistical model or estimated parameters [22], [27]. • Suitable for a multidimensional data set [22].
	• Optimal and maximum detection of outliers [22], [27]. • Multi-class approaches apply powerful algorithms that can differentiate instances of various classes [22].	SVM requires parameter selection which can limit the capacity of the solution and increase the need for human intervention [22], [19].	Machine Learning; Data Mining [19]; Finance [29], [11]; Text data; Medicine [28],[29]	• Optimal and maximum detection of outliers [22], [27]. • Multi-class approaches apply powerful algorithms that can differentiate instances of various classes [22].

Technique	Advantages	Disadvantages	Suitable Industries	Unsuitable Industries
	• Quick test phase since test instances only need to be compared with the precalculated model [22]. • Higher accuracy on structured data [29].	• Bayesian network techniques have difficulties in learning an accurate classification model when there are many variables [22], [19]. • Bayesian network techniques have limited capability in handling multivariate datasets [22].	N/A	• Quick test phase since test instances only need to be compared with the precalculated model [22]. • Higher accuracy on structured data [29].

Table 5E: Advantages and disadvantages of outlier detection techniques

Technique	Advantages	Disadvantages	Suitable Industries
Spectral Decomposition	• Can be used with a huge, multivariate dataset [22], [27]. • Can operate in unsupervised mode [22]. • Capture the normal pattern of the data and detect outliers optimally [22].	It is difficult to find suitable components that capture the regular data pattern and have high computational costs [22], [27], [19].	Telecommunications (Wireless Sensor Networks) [60],[61],[62], [19]; Finance [11]
Hybrid	• Can implement an optimal solution [22]. • More stable and give better predictive models [35].	• High computational costs [22]; Poorly developed. Selecting the right meta-detectors is a difficult task [35].	Telecommunications (Wireless Sensor Networks) [23], [61], [62]
	Suitable for outlier analysis in high dimensional data [35].	The outlier analysis can be very complex to evaluate due to the combination of a smaller sample space and its unsupervised nature [35].	Data Stream [24], [35]; Data Mining [35], [54]; IoT [63], [25], [32]
Learning based	Can generalize fragmented, noisy, limited data [22], [27].	Not suitable for the resource-constrained sensors [22]	IoT [22],[64],[65]; Image Processing [28],[29]
	No need for new training for the system when adding new data or rules [22], [27].	High computational costs and memory consumption e.g. subspace learning [22], [27], [35].	Telecommunications (Wireless Sensor Networks) [66],[67],[68]
	Rule-based techniques, providing a clear understanding of the detection process, flexibility to adapt to different contexts and can incorporate expert knowledge [22], [27].	Developing a model from a fuzzy system requires fine tuning and prior simulation before being operational [22].	Finance [28], [29], [11]; Medicine [28],[29]; Text data [28],[29]

7 EVALUATION TECHNIQUES FOR OUTLIER DETECTION METHODS

Over the years, numerous outlier detection techniques and variations of existing methods have been proposed. Nevertheless, in the customs environment, application has been predominantly limited to statistical-based techniques, as revealed by this study. An outlier detection technique is required to maintain a high detection rate (DR) while keeping the false alarm rate (FAR) low [22]. The detection rate represents the percentage of abnormal data that are correctly classified as outliers and the false alarm rate represents the percentage of normal data that are incorrectly classified as outliers [69]. To evaluate the efficiency and effectiveness of outlier detection methods in Customs trade, the following measures can be considered [35]:

a) **Precision** – refers to the number of correct outliers m as a ratio of the whole number of outliers t.

b) **R-precision** – measures how accurately the top-ranked potential outliers identified by an algorithm correspond to the actual outliers in the dataset.

c) **Average precision** – denotes the average of the precision scores over the ranks of the outlier points. It combines recall and precision.

d) **Correlation coefficient** – denotes the statistical relationship between two variables

e) **Rank power (RP)** – ranks the true outliers at the top and the normal ones at the bottom.

f) **Receiver Operating Characteristic (ROC) curve** – a graphical plot that shows the true positive rate against the false positive rate. The true or false positive rate signifies the number of outliers ranked among the potential outliers in the top number of outliers in the ground truth. **Area Under the Curve**– this is the numerical evaluation performance of the outlier detection method. The larger the area under the ROC curve, the better the performance of the technique [19].

8 LIMITATIONS

This research was based on the publications between 2010 and 2024. It was carried out with English-speaking lenses and entered the Google database using various journal platforms. The google database provided the 178 studies, but it might have missed any other significant research that was published elsewhere or in languages other than English. Examples of studies that were overlooked due to the nature of the inclusion criteria include those that were conducted in Asian languages as majority of the articles were from Asia (44%). This might include searching for studies on outlier detection methods that utilize translation software for research in languages other than English [14]. The summaries for certain research projects lacked thoroughness. The authors needed to carefully assess these articles to identify relevant themes, as many of the research abstracts were deficient due to missing key findings. This potential author bias may lead to a flaw in the study, which could exacerbate the replication crises [40].

9 CONCLUSION

Outlier detection is fundamental to data cleansing processes, ensuring accurate data analysis for informed decision-making. In the customs environment, however, outliers may indicate deliberate misdeclaration of goods to evade taxes, exploit rebates, or facilitate capital flight. This results in billions of rands lost due to under and over-invoicing, which can negatively impact the growth of the South African economy.

This paper offers a thorough systematic literature review of current outlier detection techniques, highlighting the industries where they are predominantly utilized, the types of data most suitable for these methods and their respective advantages and disadvantages.

Furthermore, the papers were classified according to the geographical location of the author or the geographical location of the focus of the study. Finally, the evaluation methods used to determine the most efficient outlier detection techniques were discussed.

The study reveals that outlier detection techniques are extensively utilized across various industries, including telecommunications, medicine, data streaming, production, IoT, biology, data mining, and finance. It is evident from the study that in the customs environment, outlier detection methods are predominantly statistical based, such as the PFM, which is an adaptation of the interquartile range. Since customs trade data is numerical, it is well-suited for the practical application of these techniques, as they were primarily applied to numerical data (65%). Outlier detection techniques are widely applied in Asia, especially India, as well as in Europe and North America. Only 9% of the articles originated from Africa, highlighting the limited research conducted in this area within South Africa.

In future research, the identified outlier detection techniques will be evaluated using the aforementioned methods within the customs environment, considering the strengths and weaknesses of each technique.

10 COMPETING INTERESTS

The authors declare that they did not have competing interests.

ABSTRACT

Emissions arising from fossil fuel-derived products and waste disposal in landfills have prompted the development of sustainable alternative technologies. The adoption of bio-based chemicals contributes to the growth of a bioeconomy and requires the development of viable technologies that meet the market and industry requirements. The main goal of the research was to develop a methodical approach to assess the feasibility of manufacturing bio-based technologies within South Africa. Firstly, literature and market assessments were conducted, which identified pertinent bio-based chemicals and feedstocks used during the manufacturing process. Secondly, a framework consisting of eight themes and twenty-six criteria was developed, interviews were conducted with nine key stakeholders, and the market attractiveness of bio-based chemicals adoption in South Africa was determined using thematic network analysis. Lastly, pilot scale data will be used to explore the commercial scale feasibility of producing the key product of interest, bio-lactic acid, as part of future work.

Keywords: sustainability, sustainable supply chain, bioeconomy, feasibility study, stakeholder analysis framework, bio-based chemicals industrialisation

1 INTRODUCTION

The global chemical industry is undergoing a fundamental transformation driven by sustainability imperatives, regulatory shifts, and public demand for cleaner products. Bio-based chemicals, derived from renewable biological resources, offer an alternative route to conventional chemical manufacturing from fossil carbon thereby reducing industrial emissions. They also contribute significantly to the emerging global bioeconomy, a concept endorsed by institutions such as the Organisation for Economic Co-operation and Development (OECD) and the European Commission [1, 2].

In South Africa, a bioeconomy strategy was introduced in 2013 to support knowledge-based innovation in agriculture, health, and industry [3]. However, the industrial bioeconomy, particularly bio-based chemicals, remains underdeveloped. The sugar industry presents a potential opportunity to catalyse this sector. South Africa produces around 20 million tonnes of sugarcane annually, generating vast quantities of sugarcane juice, molasses, and bagasse. The waste and by-products from the industry are largely under-utilised or disposed of through low-value applications such as animal feed or combustion [4].

Simultaneously, South Africa faces several challenges: a reduction of industrial activity across key sectors, rising unemployment, and a high national carbon footprint compared to developed countries. A transition to green chemical manufacturing has the potential to contribute towards addressing these issues by localising manufacturing, creating new product value chains, reducing negative environmental impact, and reducing dependence on imported chemicals [5]. Realising this potential requires more than technical innovation, it demands an integrated approach that encompasses technical, social, economic, and governance dimensions [6].

Few studies have evaluated the feasibility of implementing bio-based technologies in South Africa, highlighting the importance of market and stakeholder needs analysis as a precursor to technology adoption, which informs drivers, barriers, and guides development [7-9]. Most research focuses on technical and sustainability performance, addressing challenges like scaling from laboratory to commercial production, feedstock selection, and end-of-life treatment [5, 10]. While there is literature on the market potential of bio-based platform chemicals, understanding the strategic dimensions of technology development is limited. Additionally, comprehensive feasibility studies that include stakeholder perceptions, technical bioconversion, and economic analysis are limited. To enhance the bioeconomy, feasibility studies on converting renewable feedstocks into valuable bio-products are essential.

The following research responds to the call for holistic feasibility assessments. It explores the viability of producing two potential bio-based chemicals, namely bioethanol and bio-lactic acid, from sugarcane derivatives in South Africa. Ultimately, through stepwise rationalisation, a full feasibility assessment is considered for lactic acid, with a techno-economic assessment premised on future work. Through an approach that links stakeholder input, pilot scale demonstration, commercial scale techno-economic modelling, and policy alignment, the paper aims to demonstrate a replicable model for sustainable chemical development in emerging economies.

2 GLOBAL MARKET FOR BIO-BASED CHEMICALS

2.1 Background

Globally, fossil-based energy sources account for most of the greenhouse gas (GHG) emissions, specifically CO_2, into the atmosphere [11]. Waste to landfills also contributes significantly to GHGs, with up to 19% of the global man-made emissions of methane emitted from landfills [12]. More than 30% of waste is disposed of in some form of landfill, and it is estimated that annual waste-related emissions will increase by up to 76%, or 2.7 billion tons of CO_2-

equivalent, by 2050 [13, 14]. Bio-based chemicals are increasingly positioned as substitutes for petrochemical products across industries including plastics, agriculture, textiles, and personal care [15]. Global market reports estimate the bio-based chemicals sector will exceed $120 billion by 2030, with key drivers being regulatory bans on single-use plastics, demand for low-carbon products, and bioeconomy investment policies [16, 17].

2.2 The different approaches to managing waste in developing versus emerging countries

Globally, waste management strategies differ between high-income (developed) and middle- and low-income (developing) countries. Developed nations typically have better recycling capabilities, yet their solid waste generation rates (kg/capita/day) are generally higher than those of developing countries [18]. The increasing complexity of waste poses risks to community well-being, leading to social, economic, and environmental challenges [18-20]. Developing countries face significant challenges, including poor waste management practices that harm human health and the environment [14, 21-23], inadequate infrastructure for growing waste volumes [21, 24], reliance on landfills, and issues with open dumping and burning [21, 22, 24, 25]. They also contend with problematic waste streams like organic waste and hazardous materials, and lower recycling rates, often relying on the informal sector [24-26]. Effective waste processing can mitigate socio-economic and environmental impacts, enhancing sustainability in economics, environmental protection, and social equity [18]. Waste management technologies for organic waste vary, ranging from basic composting to anaerobic digestion and high-temperature thermal destruction.

2.3 Global waste feedstock market for bio-based chemicals production

Many countries promote biomass production for industrial use to reduce reliance on petrochemical resources and reduce the negative impact on the environment. Biomass can replace petrochemicals in various bio-products, categorised into bio-energetic and non-bioenergetic materials. By 2027, it is projected that 19.2% of biomass will be used for energy, while 23.4% will be allocated for bio-based chemicals and materials [27, 28]. The COVID-19 pandemic temporarily affected biofuel demand, but it rebounded in 2021, with expectations for steady growth driven by transportation fuel needs. South America, Europe, and North America lead in renewable chemical production, with Brazil being the largest bioethanol exporter and the USA advancing in biorefining technologies [27, 28]. Major biomass feedstocks include crops, microbial sources, and waste, with crop-based biomass holding the largest market share in the USA, projected to grow significantly by 2026 [29]. Corn and sugar crops are key feedstocks for chemical manufacturing, while microbial and waste biomass markets are also expected to expand.

2.4 The South African waste sector and options for bioconversion into chemicals

The South African waste sector generates approximately 108 million tons of waste annually, with a significant reliance on landfilling, as only about 10% is recycled [30, 31]. As of 2011, 90.1% of general and hazardous waste was disposed of in landfills, often in uncontrolled dumpsites. Recent reports indicate a potential increase in waste diversion, although municipalities remain heavily dependent on landfilling [32]. The National Environmental Management: Waste Act mandates municipalities to implement alternative waste management strategies, but financial constraints hinder the adoption of new technologies [25]. The commercial and industrial sectors are responsible for their waste disposal, and it is therefore anticipated that stricter regulations on hazardous and other waste will be put into place.

Organic waste, including food waste, constitutes a significant portion of the overall waste (Figure 1), with estimates suggesting that 27% of available food is lost to waste [31]. Key by-products and wastes with potential for producing bio-based chemicals include fruit waste from

processing industries, sugarcane by-products such as bagasse and molasses, and forestry residues from timber and pulp production. These materials can be converted into valuable bio-based products, including biofuels, enzymes, biopolymers, bioactive compounds (such as antioxidants), and bioplastics. The South African waste economy is increasingly focusing on alternative waste treatment solutions, driven by public concerns over plastic pollution and the implementation of Extended Producer Responsibility (EPR) regulations [32]. The waste hierarchy emphasises waste prevention, reuse, and recycling, necessitating technological innovations to improve environmental outcomes (Figure 2).

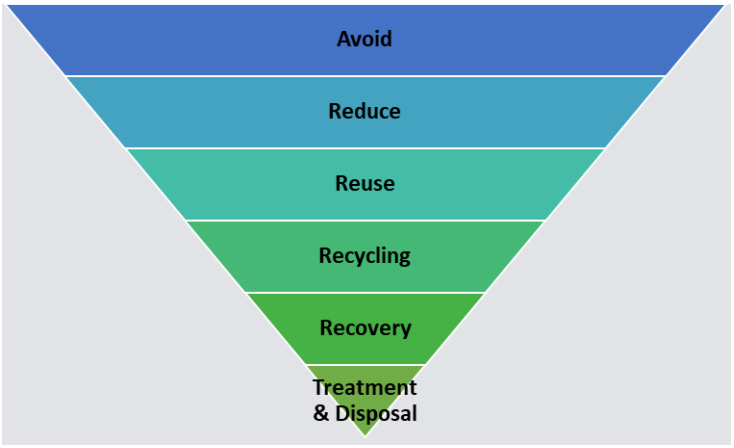

Figure 2: Waste hierarchy. Source: [22]

2.5 Potential options for bio-based chemical manufacturing in South Africa

Globally, bio-based chemical and polymer production is significant, estimated at 50 million tons per annum and valued at over $5.4 trillion [29]. Bioethanol and lactic acid are featured among the top 25 sugar platform chemicals (Table 1).

Bioethanol is widely adopted as both a transport fuel and an industrial solvent. It is produced primarily by yeast fermentation of glucose from sugarcane, corn, or lignocellulosic hydrolysates [33]. Lactic acid, a carboxylic acid produced by lactic acid bacteria, has multiple end uses: as a food preservative, pH regulator, and feedstock for polylactic acid (PLA)—a biodegradable plastic [34].

In South Africa, there is substantial potential for manufacturing bio-based chemicals from various feedstocks, particularly through fermentation processes. The role of microbes in producing bio-based chemicals is crucial, with fermentation techniques having evolved to produce a range of valuable products, including amino acids, organic acids, and industrial

enzymes. The global market for microbial products is expected to reach $346.3 billion by 2027 [35]. South Africa's biomass base is underexploited despite its diversity and volume. The sugar industry, in particular, offers ready infrastructure and logistics systems that could be adapted for biorefining. It is estimated that approximately 26 million tons of lignocellulosic biomass is available annually, which can meet a significant portion of the country's liquid fuel requirements as bioethanol equivalent [36]. However, there are limited pilot-scale demonstrations and no commercial-scale bio-based chemical facilities currently operating in the country [4]. Past techno-economic studies in sub-Saharan Africa have focused primarily on biofuels, while assessments of bio-based chemicals have been fragmented and rarely include stakeholder dimensions [37].

Target chemicals for commercialisation in South Africa include lactic acid and polylactic acid, bioethanol, acetic acid, n-butanol, succinic acid, furfural and sorbitol, which have shown promising market potential and can be derived from lignocellulosic biomass or sugar by-products such as sugarcane bagasse, molasses and agricultural residues. Of the chemicals indicated, lactic acid and bioethanol are prominent contributors to the non-energetic bio-products market [28]. The integration of synthetic biology in optimising microbial processes and expanding feedstock options further supports the growth of the bio-based chemicals sector in South Africa. Overall, the focus on bio-based chemicals presents a significant opportunity for economic development and sustainability in the region. Technology Readiness Levels (TRLs) offer a framework for assessing commercialisation potential. Bioethanol and lactic acid are both classified as TRL 6–8 in international roadmaps [33], indicating readiness for scale-up beyond the laboratory. However, barriers remain in terms of downstream purification, infrastructure costs, and market readiness [28].

3 METHODS

The research employed an integrated multi-phase approach to assess the feasibility of bio-based chemicals production in South Africa (Figure 3). The approach was designed to align actual policy and market requirement with scientific experimentation and economic evaluation. The research included four phases: (1) Market and literature assessment, (2) Stakeholder needs analysis, (3) Pilot scale demonstration and process selection (pre-feasibility), (4) Process modelling and techno-economic assessment (TEA) for commercial application, premised on future work. This phased approach allows for triangulation between stakeholder needs, technical performance, and economic constraints, enabling a comprehensive feasibility evaluation.

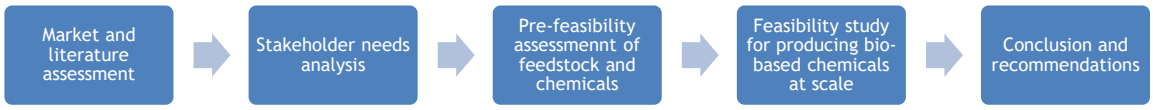

Figure 3: Research approach. (Author's own source)

3.1 Market and literature assessment

Two reviews were conducted as part of the market and literature assessment. The first review focused on the global waste market, highlighting bio-based products as potential replacements for petroleum-based products, and specifically examined the South African waste market to identify available municipal, industrial, and agricultural by-products and waste biomass for conversion into higher-value products. The second review addressed the bio-based chemicals market, detailing the global market for bio-products, the role of microbes in their production, and the introduction of renewable chemicals derived from 'green chemistry' processes. It described relevant bio-products, such as biopolymers and bio-based alcohols, along with their global market values, and introduced bio-based platform chemicals as essential building blocks for various applications. The overarching goal of these reviews was to establish a connection between industrial by-products and waste biomass, and industry-relevant bio-based chemicals.

3.2 Stakeholder needs analysis

The research method involved a qualitative assessment of the industry need for bio-based chemicals in South Africa, focusing on identifying key criteria, conducting stakeholder assessments, and analysing drivers and barriers to adoption. Following a literature review, a framework consisting of 8 factors and 26 criteria was developed to guide the assessment. The 8 market-relevant factors included business opportunity, business forces, product value chain, competitiveness, supply chain readiness, financing, governance, and policy [37-44]. The primary data was obtained through semi-structured interviews conducted with nine representatives from academia, industry, and government, using a questionnaire with 26 structured and open-ended questions. In parallel, a market analysis was conducted using global and local industry data to identify platform chemicals with high commercial and technical potential (secondary data). The qualitative data analysis involved using a hybrid coding approach, starting with a deductive coding scheme based on the framework, followed by an inductive approach to identify new criteria. *Atlas.ti* software was employed for coding

and analysis, merging codes and deriving relationships within themes, with the final coding scheme established through systematic triangulation to evaluate both primary and secondary data (Figure 4). The total number of extracts from the stakeholder interviews that align to specific codes (groundedness), were summarised for each theme or sub-theme. Bioethanol and lactic acid were selected for further evaluation due to their alignment with stakeholder interest, market potential, and compatibility with South Africa's sugar industry.

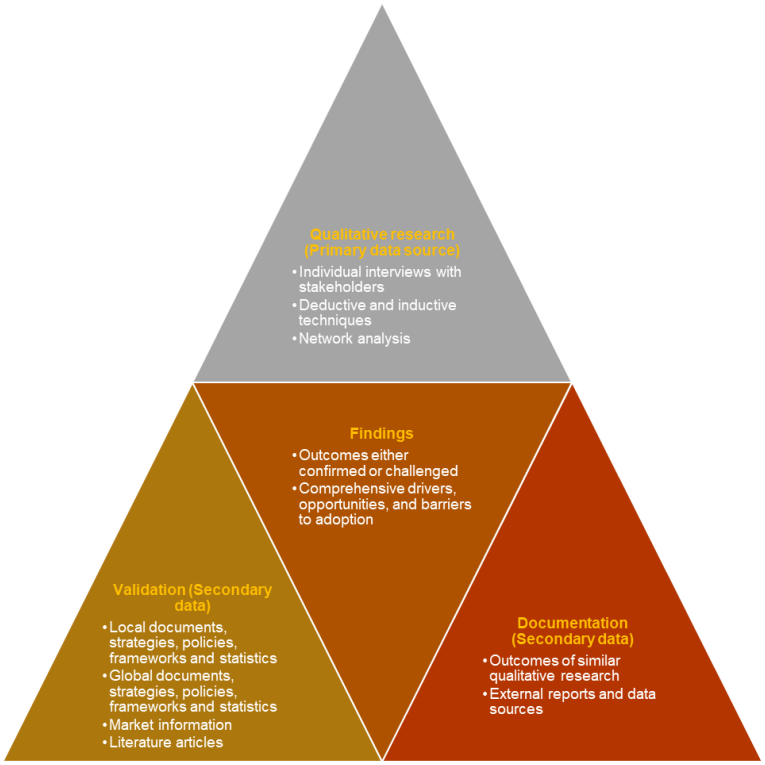

Figure 4: Systematic approach for evaluation of primary and secondary data. (Author's own source)

3.3 Pilot scale demonstration and process selection

Synthetic feedstocks, namely glucose and xylose, and industrial feedstocks, sugarcane juice and molasses were tested under laboratory conditions against various microbial strains to produce bioethanol and lactic acid. The industrial feedstocks were selected based on market assessment and feedback, their relative abundance and availability, carbohydrate content, and existing collection infrastructure. The laboratory testing was conducted from 0.2 to 30 L scale. The process performance metrics included sugar utilisation (%), ethanol or lactic acid yield (g/g), and productivity (g/L/h). The top-performing strains were scaled up to a 30 L stirred-tank bioreactor (pilot scale) operated under batch or fed-batch conditions. Parameters such as pH, temperature, and agitation were controlled to replicate near-industrial conditions. Pilot scale runs were used to assess process robustness, adaptation to variable feedstock quality, and operational control requirements. The selected lactic acid process generated the mass balance data for use in the upstream process modelling and TEA (future work), and validated the selected molasses feedstock and *Lactobacillus* strain performance in a controlled environment.

3.4 Process modelling and techno-economic assessment (TEA)

The selected 30 L pilot scale process was based on the fed-batch process to produce lactic acid using molasses feedstock. The pilot scale process will be modelled in Excel, using actual input parameters, and forms the baseline for the TEA. The annual production rate of lactic acid production facilities varies from a few thousand to about 140 000 tons per annum [45]. More recently, larger production facilities with production capacities above 75 000 tons per annum have been established [46]. The biggest producers of the lactic acid final product include NatureWorks LLC, Purac, Galactic, and Cargill. NatureWorks LLC is currently leading the lactic acid polymers market; their lactic acid plant in Blair (USA) has a production capacity of 180 000 tons per annum [47, 48]. A lactic acid production facility with annual commercial scale capacities of 92 000 tons per annum of the lactic acid intermediate, and 8000 tons per annum of the biomass by-product will be selected for techno-economic analysis.

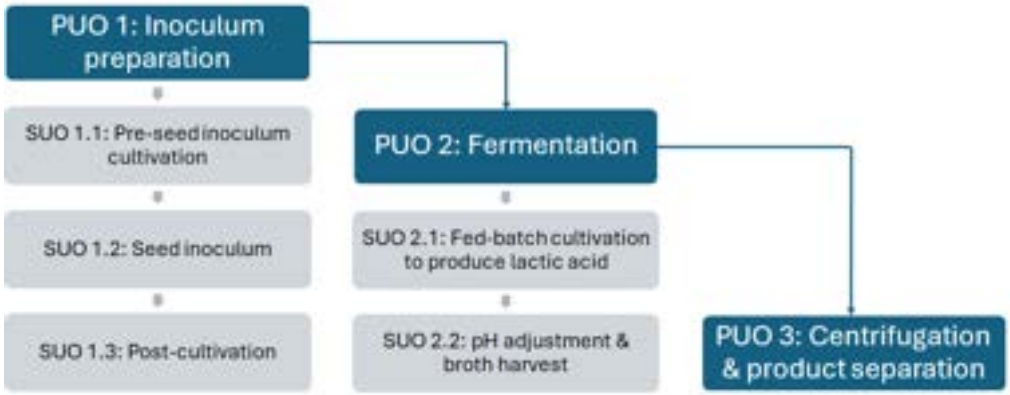

Figure 5: Simplified process flow diagram to produce the lactic acid intermediate product and biomass by-product. PUO indicates process unit operation. SUO indicates sub-unit operation. (Author's own source)

The TEA aims to evaluate commercial viability under realistic economic and operational assumptions. The model incorporates capital expenditure (CAPEX), operating costs (OPEX), product pricing, and product recovery estimates. Mass and energy balances will be estimated based on pilot scale data and existing process design literature [37, 49]. NPV, IRR, ROI and payback periods will be calculated for lactic acid under baseline and optimistic scenarios. The analysis will also include sensitivity tests for key variables: feedstock cost, product market price, debt to equity ratio etc.

This holistic approach ensures that each phase of the assessment informs the others: stakeholder feedback shaped technical selection criteria, laboratory results informed process and preliminary economic modelling, and TEA outcomes will be validated against investor and policymaker perspectives. The following methodology provides a blueprint for bio-based feasibility studies that aim to move beyond fragmented technical or economic assessments.

4 RESULTS AND DISCUSSION

4.1 Stakeholder needs analysis

Using network analysis, key products such as bioethanol, lactic acid and acetic acid were identified. Following the qualitative content analysis, sixteen codes were derived deductively, and forty-four codes were derived inductively. Using the codes and level of groundedness, market drivers and barriers to adoption were then identified and discussed for each theme and supported by literature. Stakeholders identified strong alignment between bio-based production and national sustainability priorities. Bioethanol was seen as viable for fuel blending mandates and industrial solvents. Lactic acid's role in bioplastics and various

other applications made it strategically relevant. The drivers and barriers to adoption across the eight key themes are summarised (Table 2).

These insights demonstrate that stakeholder perceptions provide critical data that influence project feasibility. Embedding the eight key themes into the broader feasibility frameworks enables the development of policy and business models that supports the innovation ecosystem. The study highlights the potential for growth in South Africa's bio-based chemical industry, driven by global trends and local opportunities. However, significant barriers remain, including regulatory enforcement, market pricing, and competition from established industries. Institutional investment and supportive policies are crucial for fostering a robust bioeconomy.

Table 2: A summary of key drivers and barriers to adoption across eight key themes according to stakeholders in the field of bio-based chemicals

Theme	Drivers	Barrier
Business Opportunity for Bio-based Products	Global demand for bio-based chemicals and the presence of international companies in South Africa can stimulate local industry growth. There is a growing interest in bioethanol, lactic acid, acetic acid, and other bio-based chemicals, presenting opportunities for localisation and technology development.	Limited export potential and competition from established global producers hinder the growth of local bio-based industries. The emerging nature of the industry, lack of investment in feasible technologies, and limited awareness of bio-based products restrict market potential.
Business Forces	Local and global environmental regulations, along with pressure from stakeholders and partners, drive the adoption of bio-based chemicals.	Enforcement of local regulations is weak, and limited legislation regarding feedstock utilisation and biodegradable materials poses challenges.
Product Value Chain	The potential for high-value products from bio-based intermediates and the strengthening of markets for products like furfural and bioplastics.	Challenges in technology development to convert intermediates into higher-value products limit market opportunities.
Competitiveness	The availability of biomass in South Africa provides a competitive edge for bio-based chemicals.	Competition from global producers and imports, along with limited local production capacity, restricts market entry for new players.
Supply Chain Collaboration	Opportunities exist for utilising sugarcane by-products and establishing frameworks for bioethanol and sustainable aviation fuel (SAF) production.	Lack of reliable data on feedstock availability and supply-side constraints hinder effective supply chain management.
Finance	Interest in diversifying into bio-based chemicals is present, with potential for product diversification in bioethanol, SAF, and biopolymers.	Securing investment during the conceptual phase is challenging and limited financial feasibility studies result in low investor interest.
Policy	Existing policies and frameworks provide a foundation for bio-based technology development, with some regional collaboration noted.	Policies are often limited in scope and enforcement, particularly outside of biofuels and bioplastics, necessitating a review and expansion to support a broader range of bio-based technologies.
Governance	Access to innovation agents and existing operational tools for scaling up technologies are available, which can aid in the production of bio-based products. Some operational governance mechanisms are in place, such as protocols and equipment that can be utilised for manufacturing.	Effective regulatory frameworks for the dissemination and implementation of global strategies and comprehensive local frameworks are limited. There is limited assessment of the equipment and infrastructure needed for economies of scale. Strong industry partnerships and global technology providers are currently insufficient.

4.2 Pilot scale demonstration and process selection

Based on the initial assessment of the feedstock, molasses was considered a preferred feedstock for chemical production. No pre-treatment of the molasses is required, the only requirement is that the molasses is diluted with water prior to fermentation as described by [50]. The performance of the upstream processes using molasses feedstock to produce bioethanol and lactic acid intermediates were compared.

Both upstream processes demonstrated effective conversion (> 90%) of molasses into the intermediate products. However, the lactic acid process achieved a higher average maximum fermentation yield (0.960 ± 0.00469 g/g) and productivity (2.92 g/L/h), compared to the bioethanol process with a yield and productivity of 0.672 ± 0.0814 g/g and 0.849 ± 0.103 g/L/h, respectively. Furthermore, 99.27% of the molasses substrate used in the lactic acid process was converted to the lactic acid product. Bioprocesses with high yields, productivities and conversion efficiencies, such as the lactic acid process, have the potential to be more profitable.

While there was no significant difference in the direct cost of production between bioethanol and lactic acid, lactic acid is considered a higher value product. Based on global market trends, the selling prices for purified ethanol and lactic products were 10.78 and 22.64 Rand/kg, respectively [51, 52]. However, based on local market prices [53-57] and an assumption that 50% of the production cost can be attributed to downstream processing [58-61], the selling prices for ethanol and lactic acid intermediate products were estimated to be 28.05 and 48.10 Rand/kg, respectively. The lactic acid process demonstrated superior performance in the laboratory, illustrated by a fermentation yield greater than 0.95 g/g, and has the potential to generate higher profits based on the market price, and global and local market demand.

The findings suggest that adopting a fed-batch cultivation strategy using molasses can enhance lactic acid yields and productivity, making it a viable option for industrial-scale production.

4.3 Process modelling and techno-economic assessment (TEA)

This section presents a preliminary reflection on the techno-economic framework applied in this research, which forms the final phase of the integrated feasibility approach. The model is intended to yield financial estimates, as well as demonstrate the interdependencies between technical, market, and economic-related variables, and inform iterative development of the commercial scale system.

The approach taken integrates insights from stakeholder interviews, pilot scale data, and literature-based assumptions to construct a representative cost model for lactic acid production. The sensitivity analysis will be deliberately included as a dynamic tool to assess how variations in key input parameters impact financial performance. The principal contributors to this analysis will be:

- The fermentation equipment cost, which escalates in cost based on the scale of operation and is a key cost contributor.
- Feedstock cost, which is a critical variable due to its influence on operating costs and its volatility across harvest cycles.
- Lactic acid production rate, which directly affects raw materials utilisation and other operating costs.
- Product price assumptions, which are based on local market pricing for lactic acid products.

Incorporating stakeholder feedback into the TEA can ensure that technical thresholds, such as required yield or market price, are validated against investment expectations and policy realities. The model could also be used to explore scale-up potential by estimating performance at different production capacities. While final TEA outputs are still being refined, this approach offers a replicable methodology for early-stage techno-economic assessment that considers both process performance and the evolving commercial landscape.

5 CONCLUSIONS AND RECOMMENDATIONS

This research presents an integrated, multi-dimensional approach for assessing the feasibility of bio-based chemical production in South Africa. It demonstrates that bioethanol and lactic acid can be effectively produced from sugarcane derivatives, such as molasses, using locally available microbial strains and potentially existing agro-industrial infrastructure. Through pilot-scale trials, high fermentation yields, and conversion efficiencies were achieved.

Stakeholder engagement revealed that there is strong alignment between bio-based chemical production and national development priorities. However, several cross-cutting barriers must be addressed: fragmented policy mandates, inadequate financing instruments, high price point of bio-products, and infrastructural deficits. Performance data confirmed that while ethanol is close to market readiness, the performance and profitability of the lactic acid process was superior. However, further optimisation of the lactic acid process is required, particularly in downstream purification and market development. The strength of this research lies in its integrated methodology—linking stakeholder insight, technical feasibility, and economic performance into a unified framework. The research's integrated methodology offers several advantages over traditional feasibility assessments, such as:

- Triangulated insight: Based on the outcomes of the process modelling and techno-economic assessment positioned for future work, the research will combine stakeholder input, actual pilot scale data, and financial data, allowing for cross-validation of assumptions.
- Adaptability: The research approach can be applied to other bio-based chemicals or feedstocks.
- Policy relevance: Embedding governance and policy barriers into the approach creates more implementable recommendations.
- Risk reduction: It highlights technical and institutional bottlenecks early in the process, which reduces the risk of project failure.

Previous studies have either focused narrowly on process optimisation or high-level lifecycle analysis without engaging stakeholders or modelling the economic feasibility [5, 62]. This research fills that gap and demonstrates how to align pilot scale performance data, market needs, and economic viability to support decision-making.

To advance sustainable chemical manufacturing in South Africa, the following are recommended:

- Establish demonstration-scale biorefineries co-located with sugar mills.
- Define profitable product value chains for intermediate and final products as well as by-products.
- Launch a national bio-based technology and investment roadmap, and develop policy and frameworks aligned to the roadmap.
- Develop skills programmes in bioprocess engineering and green manufacturing, which will contribute toward strengthening of the bioeconomy.

- Facilitate public-private partnerships to de-risk projects at an early-stage.

This feasibility framework provides a model for other developing economies seeking to transition to low-carbon, local technologies through bio-based innovation.

ABSTRACT

Accurate numerical simulation of wet ball mill loads is challenging due to the need for integrating solid and liquid-based algorithms. We introduce a novel computer framework that combines Discrete Element Modelling (DEM) and Computational Fluid Dynamics (CFD) to address this issue. The grinding media is modeled using a Lagrangian approach, treating particles according to Newton's laws and Hertzian contact law, implemented via the open-source platform LIGGGTHS. The slurry phase is described by the Navier-Stokes equations and solved using finite volume method, incorporating a solid phase volume fraction. The coupling of DEM and CFD is facilitated through buoyancy and drag forces. Our simulations validate the framework against experimental data, showing a close alignment within 10% margin for load positions. While the model exhibits minimal sensitivity to slurry viscosity, it indicates that shoulder positions increase with mill speed. Continued refinement, especially in drag force modeling, is necessary to enhance grinding process optimization.

1 INTRODUCTION

Comminution, the process of reducing ore to finer sizes for easier beneficiation, relies heavily on ball mills in various industries [9]. These mills pulverize materials through the action of loose crushing bodies, with grinding balls cascading and cataracting within the mill [4]. The load position, described by the toe and shoulder angles, can be determined mathematically or through physical measurements [29, 28, 1, 20, 11].

Studying ball mills involves experimentation and computer-based engineering simulation. [1, 2] Experimentation provides real-world data but is costly due to the need for specialized instruments [19, 7, 30, 31, 32]. Engineering simulation offers a more affordable alternative, though it requires model calibration to ensure accuracy [10, 6]. While dry milling simulations are well-established [27, 8, 21], wet milling simulations lag in development [27, 19, 7]. Wet grinding is popular in ore processing because it helps to control the viscosity of the slurry and reduce energy consumption [5, 3]

This research aims to develop a numerical model framework using an open-source package to simulate dynamic load behavior in wet ball mills [1]. It models the interaction between balls and slurry using Discrete Element Modeling (DEM) and Computational Fluid Dynamics (CFD). [4, 5] Computational Fluid Dynamics (CFD) refers to the use of numerical methods and algorithms to analyze and simulate fluid flow and the associated physical processes within fluids. The model is validated against experimental data from laboratory and pilot mills [19, 7, 30, 31, 32, 1, 6] The paper's structure includes an introduction, literature review of DEM and CFD, methodology, results, and conclusions.

2 LITERATURE REVIEW ON COMPUTATIONAL MODELLING OF MULTIPHASE GRANULAR SYSTEMS

Recent studies [6, 35, 36] have successfully applied the Discrete Element Method (DEM) to comminution modelling, showcasing its effectiveness in simulating the behaviour of grinding media [25, 26, 36,16, 37, 6, 23, 17, 24, 18, 33]. Originally introduced by [2] for molecular dynamics, the principles of DEM were further developed by [12]. This numerical technique discretizes dynamic events into time steps, allowing for detailed analysis of particle interactions.

By utilizing Newton's second law (Equation 1) and kinematic equations, DEM calculates particle positions and orientations, while changes in angular momentum are governed by Euler's second law (Equation 2) [34]. Although DEM excels in dry milling simulations, modelling wet milling requires a deeper understanding of fluid dynamics and the spatial positioning of the slurry in relation to the media charge. To address these challenges, Computational Fluid Dynamics (CFD) is often integrated, enhancing the modelling of complex interactions in wet milling scenarios.

$$F = m_i \frac{d^2\vec{x}_i}{dt^2} = \sum \vec{f}_{ij}^{\,p-p} + \vec{f}_i^{\,f-p} + \vec{f}_i^{\,ext} \quad \textbf{(1)}$$

$$I_i d\overrightarrow{\omega_i} = I_i \frac{d^2\vec{\omega}_i}{dt^2} = \vec{M}_i\left(x_i, v_j, \varphi_j, \omega_j\right) = \sum_{j \in CL_i}\left(\vec{M}^t{}_{ij} + \vec{M}^r{}_{ij}\right) \; for\; j = 1, \dots, N \quad \textbf{(2)}$$

Where $\sum \vec{f}_{ij}^{\,p-p}$ is sum of particle–particle interaction forces acting on particle i

F is the sum of different forces that act on the particle i

x_i is the particle position

φ_j is the angular position.

ω_j is the rotational velocity of the particle

v_j is the translational velocity of particle

$\vec{f}_{ij}^{\,p-p}$ is particle-particle interaction forces.

$\vec{f}_i^{\,f-p}$ is fluid-particle interaction forces in multiphase systems. This term is ignored in pure DEM simulations.

$\vec{f}_i^{\,ext}$ are external forces acting on particle i due to uniform or non-uniform external fields such as gravitational and magnetic fields

$\vec{M}_i$ is sum of different torques that act on particle i

Key forces in Discrete Element Method (DEM) simulations include gravitational forces, contact forces from collisions, and solid-solid interactions like electrostatic, Van der Waals, and cohesive forces [13]. The behaviour of grinding media can be modelled using two approaches: the soft sphere and the hard sphere. The soft sphere approach more accurately reflects the practical behaviour of milling charges, making it preferable for realistic simulations compared to the hard sphere formulation.

2.1 Computational modelling of grinding media and slurry phase in wet ball milling

Multiphase granular systems can be effectively modelled by integrating the Discrete Element Method (DEM) with Computational Fluid Dynamics (CFD) within a unified framework. This approach typically employs DEM to represent the solid phase while utilizing CFD to analyse liquid flow patterns [23, 21]. By leveraging the strengths of both techniques, this integrated modelling enhances accuracy and reliability.

To simulate wet milling effectively, it is essential to have a thorough understanding of fluid dynamics and the slurry's positioning relative to the media charge. CFD, a sophisticated technique, is grounded in three fundamental principles: conservation of mass, Newton's second law, and conservation of energy. These principles are articulated through integral or partial differential equations, depending on the chosen flow model. CFD methods are categorized into Eulerian and Lagrangian approaches. The Eulerian method analyses fluid flow at fixed spatial locations, while the Lagrangian method tracks individual fluid particles as they move through space and time.

Recent advancements have led to hybrid CFD-Discrete Element Method (CFD-DEM) models that effectively represent multiphase granular systems. These models focus on fluid-particle interactions and their applications in wet ball milling. Accurate modelling of fluid flow in such systems typically involves solving the continuity equation (Equation 3) and the Navier-Stokes equations (Equation 4), forming a robust foundation for simulations in this domain. This integration not only improves the accuracy of simulations but also facilitates better predictions of system behaviour under various operational conditions.

$$\frac{\partial \alpha_f}{\partial t} + \nabla\left(\alpha_f u_f\right) = 0 \qquad \textbf{(3)}$$

$$\frac{\partial (\rho_f \alpha_f u_f)}{\partial t} + \nabla\left(\rho_f \alpha_f u_f\right) = \nabla\rho - f_p + \nabla.\left(\alpha_f \tau\right) + \rho_f \alpha_f g \qquad \textbf{(4)}$$

Where α_f is the volume fraction occupied by the fluid, ρ_f is the fluid density, u_f velocity of the fluid, τ is the stress tensor for the fluid phase and f_p represents the momentum exchange with the particulate phase. When both the granular and fluid phases are incompressible, [24] showed that the mass conservation equation could be written as follows:

$$\nabla.\left(\alpha_f u_f + \alpha_s u_s\right) = 0 \qquad \textbf{(5)}$$

Where α_s is the volume fraction occupied by the solid phase, u_s velocity of the solid phase.

The coupling of CFD and DEM—known as CFD-DEM coupling describes the interactions between the solid and fluid phases through the exchange of momentum and interaction forces. In this framework, the fluid phase is characterized by pressure, velocity, temperature, and species concentration distributions, while the solid phase is described by particle size, position, velocity, temperature, and concentration. This innovative approach enables the simultaneous resolution of solid particle interactions, fluid flow dynamics, and particle-fluid interactions [21, 23, 34]. Key steps in the CFD-DEM coupling process have been thoroughly outlined by [14, 15, 21]. The procedure begins with the DEM solver calculating the positions and velocities of solid particles. These results are then transmitted to the CFD solver, which identifies corresponding cells in the CFD mesh for the particles. The volume fraction and average velocity of the particles are calculated, followed by the determination of fluid forces acting on the particles based on their volume fraction. Finally, the momentum exchange between particles and fluid is computed by averaging all particle-fluid forces within each CFD cell. The resulting data is then sent back to the DEM solver, allowing it to update particle dynamics for the next time step, while the CFD solver adjusts fluid velocity according to local conditions and momentum exchanges.

This coupling approach improves the accuracy of multiphase modelling and deepens our understanding of interactions within granular systems. For instance, authors like [27] proposed a one-way coupling method to simulate the dynamics of a wet ball mill, emphasizing how slurry affects the motion of individual grinding balls. They incorporated drag and buoyancy forces into their model, detailing these forces using Equations 6 and 7.

$$F_D = C_d a \rho_s \frac{{v_r}^2}{2} \quad \textbf{(6)}$$

Where F_D is the drag force.

C_d is the drag coefficient.

a is the area of grinding media.

v_r is the relative velocity between a ball and suspension.

The buoyant force, on the other hand, was given by Equation 7

$$F_B = V_B \rho_s \quad \textbf{(1)}$$

Where F_B is the buoyant force and V_B is the volume of a ball.

2.2 Summary

The literature review on the application of the Discrete Element Method (DEM) to comminution modelling reveals several critical gaps and areas for further investigation. Despite advancements in simulating dry milling processes, comprehensive studies addressing the unique challenges associated with wet milling remain sparse. The integration of DEM with Computational Fluid Dynamics (CFD) has improved the accuracy of simulations; however, the complexity of interactions in wet environments necessitates further refinement, particularly concerning the dynamic behaviour of the slurry and grinding media interactions [24, 45]

One notable gap is the need for more sophisticated models that capture fluid-particle interactions and their resultant effects on milling efficiency. Existing studies primarily focus on the solid phase while neglecting intricate fluid dynamics in slurry phases, significantly affecting the grinding process [43]. Additionally, recent literature indicates that fluid dynamics modelling, including the effects of varying liquid media on particle behaviour, is often oversimplified. This leaves out crucial parameters such as the influence of temperature, pressure variations, and shear conditions [41]. Hence, future research should develop dynamic

models that incorporate detailed hydrodynamic forces acting on grinding media and their effect on particle size reduction and distribution.

Moreover, past studies often face challenges related to high computational demands when implementing CFD-DEM coupling strategies. Current methodologies may incur extensive computational costs that limit their application in industrial contexts. Therefore, addressing computational efficiency while enhancing the fidelity of the simulation models for wet milling processes represents a significant knowledge gap. Future exploration could focus on optimizing algorithms or employing more efficient numerical approaches to mitigate these computational challenges [42].

Also, the experimental validation of DEM models remains inadequate, particularly in the context of wet milling. While several studies successfully simulate the behaviour of grinding media under various conditions, there is a critical lack of empirical data to substantiate these findings [44]. Integrating experimental results with simulation data can provide verification and improve the robustness of predictive models, thus enhancing their practical applications.

In summary, while recent advances in DEM applications have significantly contributed to understanding dry milling processes, there is substantial opportunity to refine modelling approaches for wet milling scenarios. Areas requiring further research include enhanced fluid-particle interaction modelling, reducing computational demands for simulation fidelity, and linking theoretical models with experimental data to validate findings.

3 METHODOLOGY

The research methodology consisted of three main stages. First, the physical processes occurring in a typical ball mill were translated into mathematical equations. To simulate the dynamic behaviour of the grinding media, a series of computer scripts based on LIGGGHTS were developed, incorporating these equations. Next, an OpenFOAM script was created to include the liquid phase representing the slurry. Finally, the numerical model was iteratively refined and calibrated using available experimental data.

3.1 Computational modelling of grinding media and slurry phase in wet ball mill

In this paper, the Discrete Element Method (DEM), a set of numerical techniques extensively used in modelling particulate systems was applied to model the dynamic behaviour of grinding media. The behaviour of grinding media was modelled using the soft sphere approach, which closely represents the practical behaviour of the mill charge as compared to the hard-sphere formulation. Each ball was treated as a distinct particle, governed by Newton's second law of motion applied at the centre of mass of each particle (Equation 1). Euler's second law of motion is used to describe changes in angular momentum (Equation 2). This is called the Lagrangian approach [34]. In terms of describing the motion of balls in the ball milling system, the dense charge is assumed to experience long and multiple contacts between particles. Based on this, the DEM model was built around the assumptions that particles retain their original shape after a collision, collisions are inelastic, instantaneous, and repulsive and finally collisions occur between a pair of particles at any point in time. Interaction forces were assumed to obey the Hertzian contact law. Each particle interacts with nearby particles through particle-particle contacts, which are formed or broken at each time step [9]. The contact force is expressed by Equation 8.

$$F_r = (k_n \delta n_{ij} - \gamma_n v n_{ij}) + (k_t \delta t_{ij} - \gamma_t v n_{it}) \quad \textbf{(8)}$$

Simulations were run using custom virtual Linux® based, Ubuntu 20.04 LTS machine hosted on a Windows® Dell Precision M6700 personal computer, with Intel® Core (TM) i7-3740QM Quad (four-core), 8 Logical Processers, 2.4 GHz, and 16 GB RAM. The mill geometry was developed using Blender version 2.9, an open source and CAD software. The files were then exported as

.stl format into LIGGGHTS for simulation purposes. Converting the Blender files to .stl files has an advantage that this format describes the surface geometry only. Attributes common to other CAD models like colour, texture, material types are not represented in the .stl file of this mill. This feature also allows one to set suitable material properties for various scenarios under investigation in the input script.

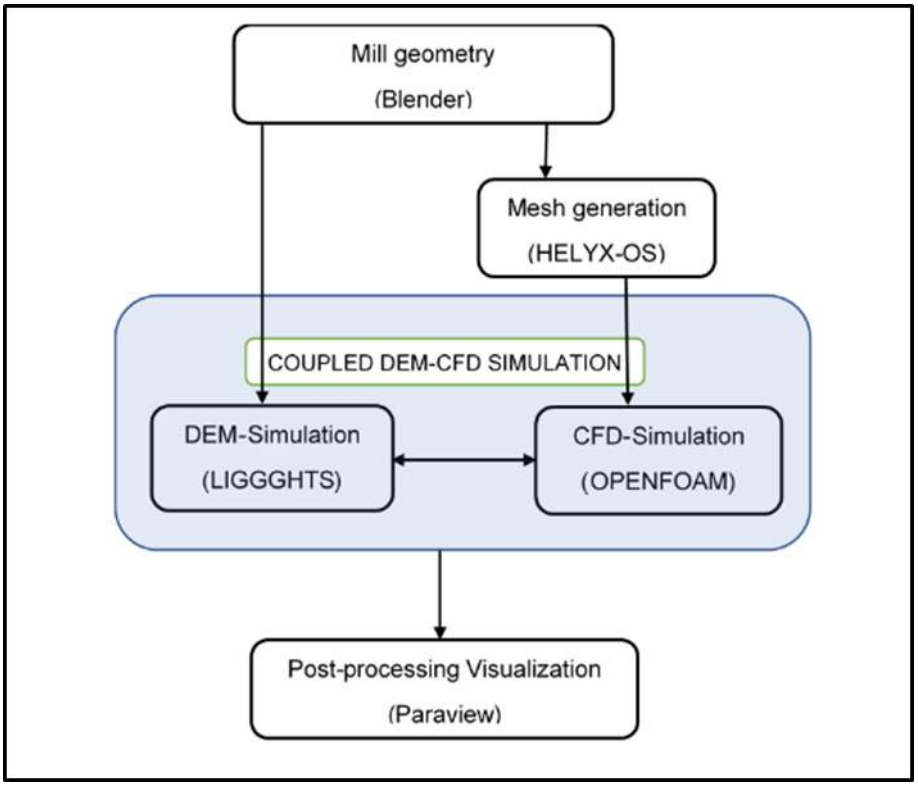

Figure 1: CFD-DEM coupled simulation workflow

The open-source DEM solver LIGGGHTS was utilized to simulate dry milling experiments, offering the advantage of no licensing requirements and the ability to modify the source code. A LIGGGHTS input script involves four main steps: initialization, defining particle variables, setting simulation parameters, and running the simulation. During initialization, essential data such as atom types, units, and boundaries are specified. Particle variables, including the computational region and grinding media properties, are defined next, with media mass calculated based on mill volume and ball filling. In the third step, the contact model, timestep, and mill rotation are set, followed by running the simulations where grinding media particles are generated and settled in the mill. Mill rotation is initiated, and output data is written to a designated directory for visualization. The challenge then was to incorporate the fluid phase using a suitable CFD platform. The fluid flow field was described by Equation 4 and solved using the finite volume method (FVM) with a coupled CFD-DEM solver called cfdemSolverPiso. The PISO algorithm was chosen for its effectiveness in facilitating data exchange between the DEM and CFD solvers.

The two-way coupling was implemented by the buoyancy force drag model given in Equations 6 and 7. In this case, the grinding media affects the fluid by adding the mass and velocity of the DEM particles to the forces in the governing fluid equations. On the other hand, the flow of fluid over the DEM particles creates a drag force on the DEM particles

The wet milling set of experiments using a pilot and laboratory mill, presented by [19] were simulated. In this case slurry filling (U_s) was varied from 0 to 3.0. Slurry dynamic viscosity (μ) was also varied between 1 and 10 mPa·s Load position as described by the shoulder, toe

as well as slurry pool angular positions were measured and recorded. Mill speed was varied from 65 to 85% of critical speed. The volume of the slurry (V_{slurry}) was determined as a function of the interstices in the grinding media charge.

4 RESULTS

In this section findings from coupled CFD-DEM simulations which seek to establish the load profile are reported. Results on the voidage and velocity profile, media shoulder, toe and slurry pool angular positions under varying simulated conditions are presented.

4.1 Void fraction and Velocity profile of mill the charge

The void fraction represents the fractions of different phases in the cell. One would expect that in the mill charge region the void fraction is very close to zero. This is because this is the region with the highest concentration of grinding media. This region is denoted by the blue colour in Figure 2 (a).

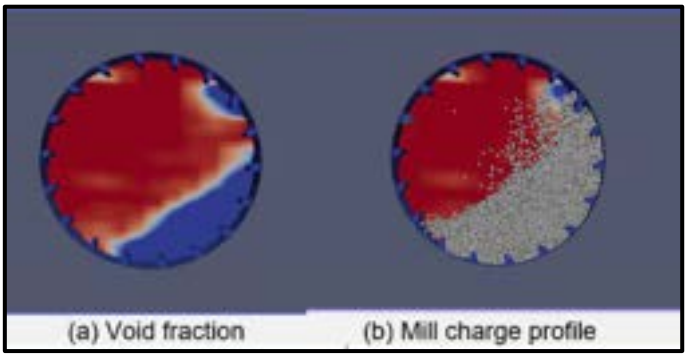

Figure 2: Depicting void fraction or amount of interstices in grinding media charge

To determine the amount of slurry in the charge, the volume of interstices within the grinding media was estimated. The void fraction data was recorded from Paraview® facility as shown in Figure 3(a).

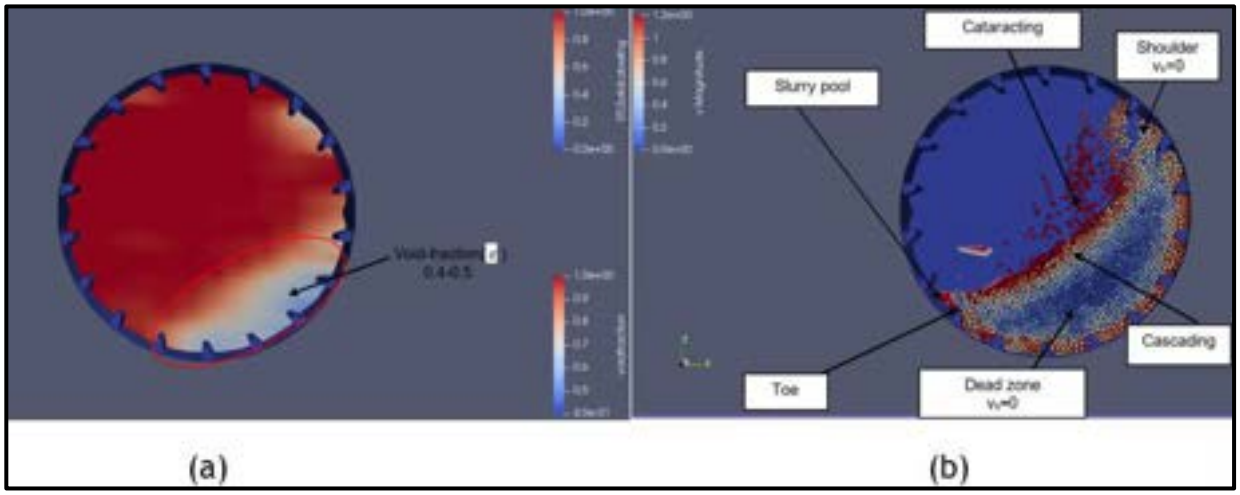

Figure 3: Estimate of void fraction in grinding media charge

It can be observed that the voidage (ε) ranges from 0.4 around the dead zone region to about 0.5 in the cascading region. Thus, a value of 0.4 voidage (ε) was used in this paper. This value of the voidage was found to be a good estimate as other researchers have recommended [19, 39].

The media velocity was profiled as shown in Figure 3 (b). This comparison was useful in assessing the capability of the coupled CFD-DEM simulation to mimic the behaviour of a wet mill charge. **Error! Reference source not found.** shows the velocity (u_S) profile of the media obtained at a mill speed of 67.4% critical speed, 20% ball filling and slurry filling (U_s) of 1.0. The velocity profile shows that the load charge experiences a high velocity in the peripheral areas of the mill charge. That is to say, higher velocity of the load is experienced by the grinding media along the mill shell and along the cataracting region of the charge. **Error! Reference source not found.** presents the velocity estimates of the different load regions as compared to the expected values (see legend in Figure 3 b).

Table 1: Velocity profile of mill charge

Region	Expected (u_S)	Actual
Cataracting	$u_S > 0$	≈1-1.2m/s
Cascading	$u_S > 0$	≈0.8-1m/s
Dead zone	$u_S \approx 0$	≈0.0m/s

The velocity profile extracted shows that grinding media in the cataracting region has the highest velocity (above 1m/s) while the media in the dead zone region has the lowest. This profile is a good fit for a dynamic mill charge [38].

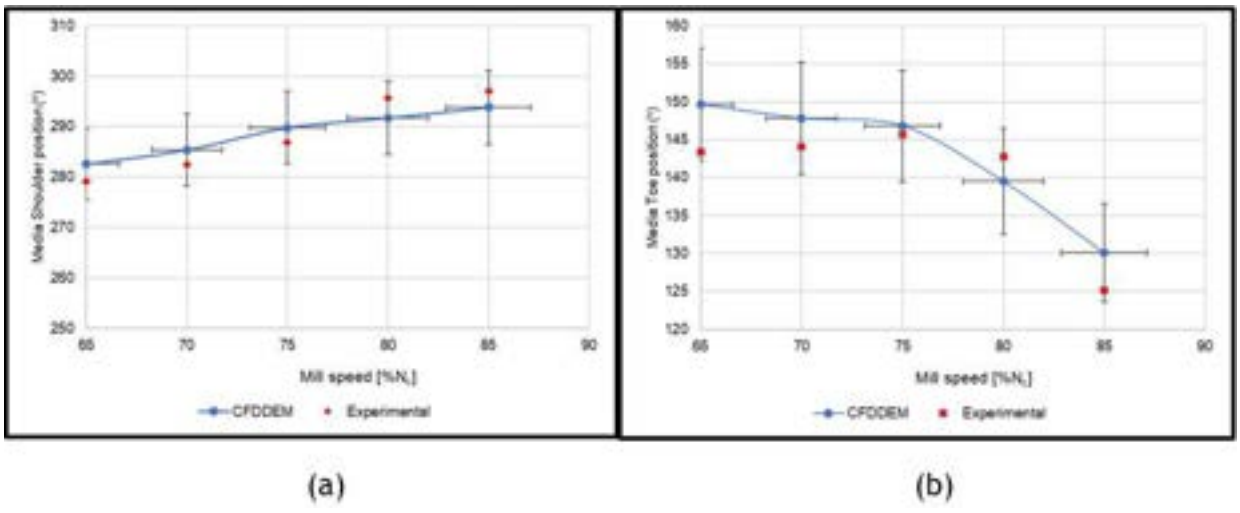
4.2 How slurry presence affects mill load dynamics

The presence of slurry affects both mill load dynamics and kinetics. Thus, it is key that a wet ball mill simulator should be able to adequately mimic the mill load behaviour under wet conditions. In this section, findings on the effects of mill speed, degree of slurry filling, and viscosity on load position are presented.

4.2.1 Effect of mill speed on the angular position of mill load

In the wet milling simulations, the mill speed was varied from 65% to 85% of critical speed. The media shoulder tends to rise steadily with increasing mill speed. When compared to the

experimental results this increase in the shoulder location is more gently. The experimental results fall within an error margin of 5% of CFD-DEM shoulder position (see Figure 4).

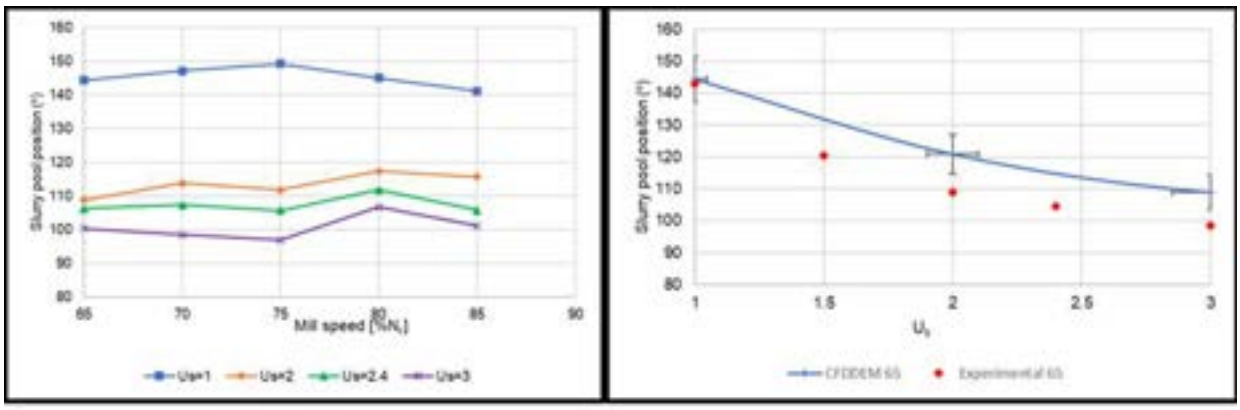


(a) (b)

Figure 4: Angular position of media shoulder with error bars compared to experimental results

At mill speeds lower than 75% of the critical speed the CFD-DEM shoulder position is higher than the experimental results and as the mill speed was increased the simulation shoulder location became lower than the experimental results. This trend is similar to dry mill

simulations and may be a consequence of centrifuging load. A similar plot was also done for the toe position as shown in Figure 4 (b). As for the CFD-DEM toe, its position is higher than the experimental toe although close to 5%. This shows that CFD-DEM produced simulations which are reasonably close to the actual experimental value.



(a) (b)

Figure 5: Angular position of slurry pool with varying mill speed and (b) Slurry pool location with varying slurry filling

The effects of mill speed on the position of the slurry pool with respect to media charge were evaluated. Six slurry fillings evenly selected from the experimental range were investigated. Figure 5 (a) shows a plot of the slurry pool location as the mill speed was varied from 65-85% of critical speed at a specified slurry filling. At slurry fillings of below 1, the slurry pool could not be observed. This is not surprising since the amount of slurry introduced could be adequately accommodated in the grinding media interstices. As slurry filling was increased beyond 1, it was then possible to observe the slurry pool. Two main observations can be made from Figure 5 (a) with regards to the slurry pool. The first one relates the location of the pool to the slurry level. An increase in the level of slurry generally resulted in a decrease in the pool position. It can be observed that for all mill speeds considered, a higher slurry filling results in a lower angular pool location. In a physical wet mill, as more slurry is introduced into the grinding media, the excess cannot be accommodated hence, it collects on the toe side of the mill charge and forms the slurry pool. It is expected that increasing the amount of the slurry present will lead to a corresponding increase in the pool level, resulting in a lower angular pool position.

The second observation relates the pool position to the mill speed. At higher slurry fillings, (i.e., above 2) a pattern of some sort can be realized from the data. An increase of 3°-10° was observed between 65% and 80% of critical speed as a consequence of an increased slurry uptake by a dilated media charge. At speeds higher than 80% of critical there is a reduction in the pool location triggered by centrifuging media. It is reasonable to presume that the slurry pool location was marginally influenced by mill speed within the range examined. The location of the slurry pool from the coupled CFD-DEM simulations was compared with that from the experimental work on a pilot mill [19]. Figure 5(b) shows a plot of the two sets of results at a mill speed of 65% of critical speed.

Except for the slurry filling of 1, the simulation pool location is generally higher than the experimental values. It is not quite clear why this trend exists, but it may be a consequence of the mesh used. Due to the limited computational ability of the computer used in this thesis a single mesh was implemented which may have resulted in a not fully developed fluid field. However, a similar trend can be observed between the two sets of results.

4.2.2 Effect of slurry filling on the angular position of mill load

The results of dry milling simulation as represented by DEM simulations were plotted. Figure 6 shows a plot of the angular position of media shoulder and toe at a constant mill speed of 75% critical speed and slurry level between 0 and 3.

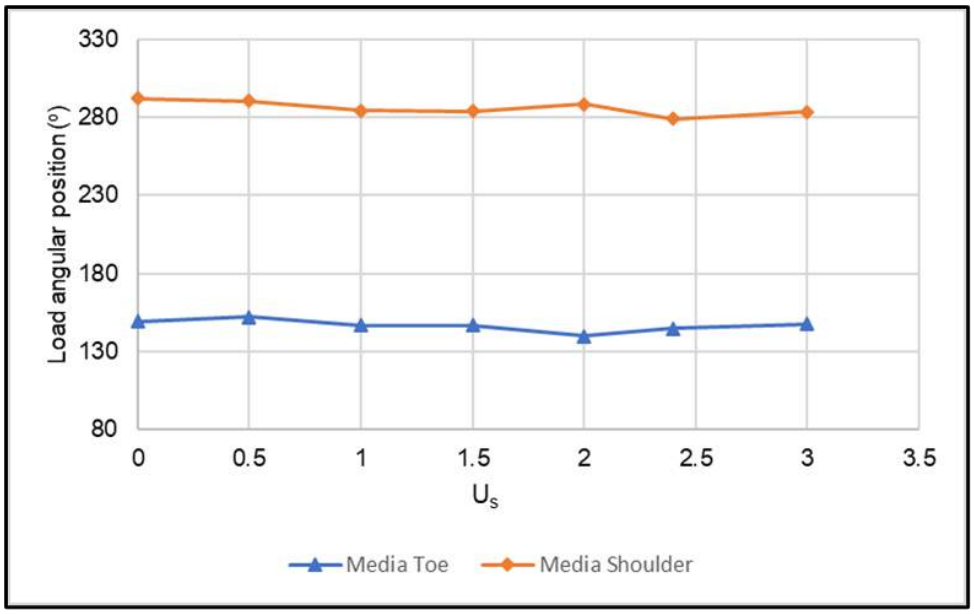


Figure 6: Angular load position with varying slurry filling

The angular position of the media shoulder varied between 279° and 293°. The shoulder position decreased from 293° to about 284° when the slurry filling was increased from 0 to 1, followed by a slight increase up to a slurry filling of 2. From Figure 6 it is not possible to establish a definite pattern of the behaviour of the shoulder position as slurry loading changes.

Regarding the toe of the media charge, the data evidence shows that the toe angle is generally constant for slurry fillings up to 2. The toe angle then gradually increases by 8° for slurry fillings of approximately between 2 – 3. This behaviour can be explained by the velocity profile of the slurry. The slurry velocity approaches the mill rotational speed near the shell but decreases as one moves farther away from the shell towards the centre of the mill. At low slurry loading a small amount of slurry flows in the direction of rotation of the mill. As a result, only a few layers are subject to the effect of the mill shell. Consequently, the media charge in the toe region tends to rise in the region where the cataracting balls fall and this translates into a decrease in the media toe angle.

With an increase in slurry loading, the number of layers affected by the shell rotation is much increased. This makes the balls less free to move and more subject to mill rotation, consequently the media toe increases. The slurry also creates some lubrication effects which prevents the media toe from going much higher. This explains the marginal increase in the toe angle similar trends can be observed in some empirical studies [19].

4.2.3 Effect of slurry viscosity on the angular position of mill load

Slurry rheology and load behaviour are crucial for mill performance, significantly impacting grinding efficiency [26, 19]. This study examined how the coupled CFD-DEM model responds to changes in slurry viscosity, focusing on its influence on load orientation in a laboratory mill. Slurry filling (U_s) was varied from 0 to 3.0, while viscosity (μ) was adjusted between 1 mPa·s and 10 mPa·s due to computational constraints. Data on pool, toe, and shoulder positions of the media were collected for comparison with an empirical model. Results indicated that

viscosity levels did not affect the shape of the media charge, as shown in the simulation snapshots Figure 7.

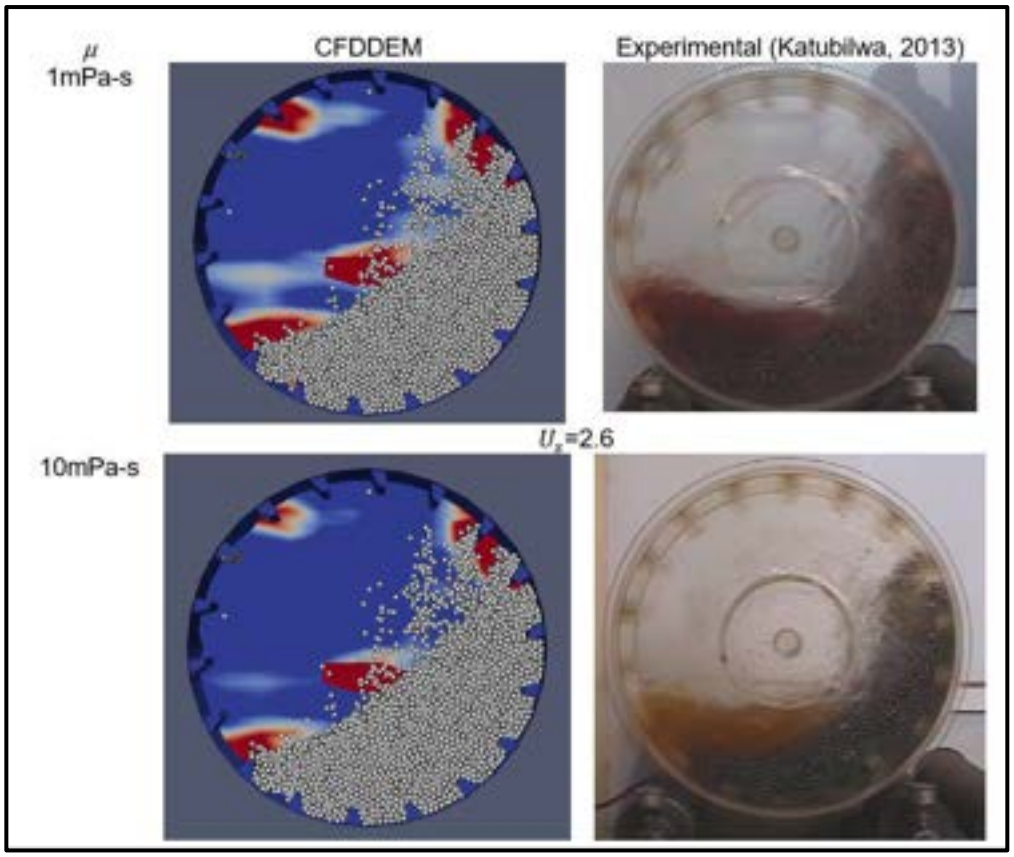

Figure 7: Comparison of coupled CFD-DEM and laboratory mill

The media shoulder had a variation of about ±10o regardless of the level of viscosity. On the other hand, the toe position is initially constant, and then consistently increases at slurry filling of 1 and beyond before steadily increasing with increasing slurry filling (see Figure 8)

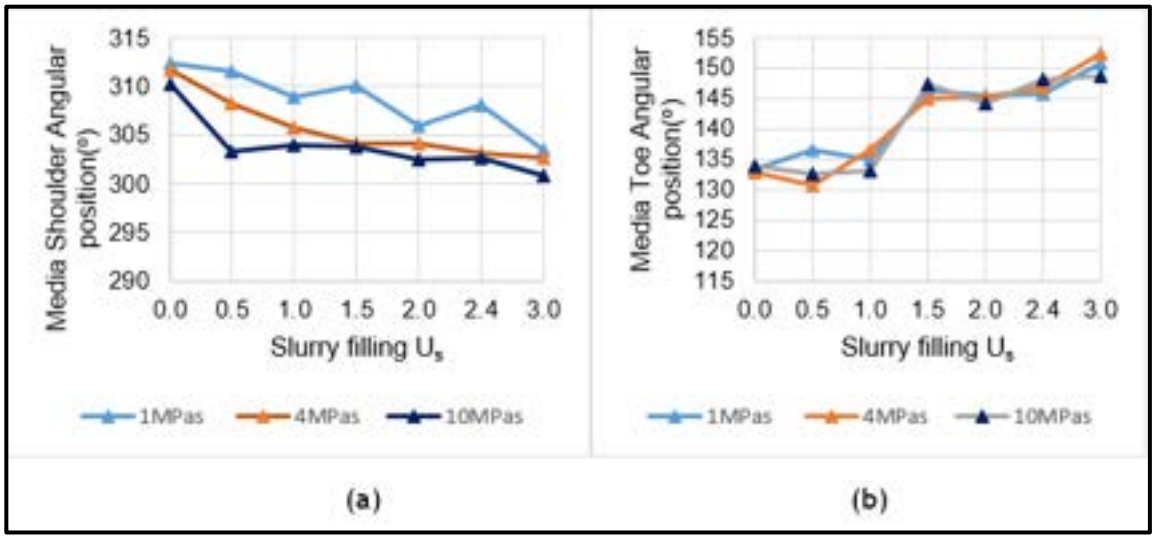

Figure 8: Angular position of media toe as a function of slurry viscosity and filling

The location of the slurry pool was plotted in Figure 9. For a specific filling degree of slurry, it seems slurry viscosity does not affect the position of the pool. However, the data pattern

suggests that the angular location of the slurry pool decreases with increasing slurry filling. In the coupled CFD-DEM simulation it seems that mill charge dynamics is not affected by the slurry rheology. Regardless of the change in pool level with slurry filling, the shape of the media charge position remained constant. And for the same filling degree of slurry, viscosity appears to have a limited effect on the position of the pool. Findings reported in this section show similar patterns to the experimental findings reported by [19 and 40]. However, it was not possible to verify that there is more cataracting for low viscosity as compared to higher viscosity.

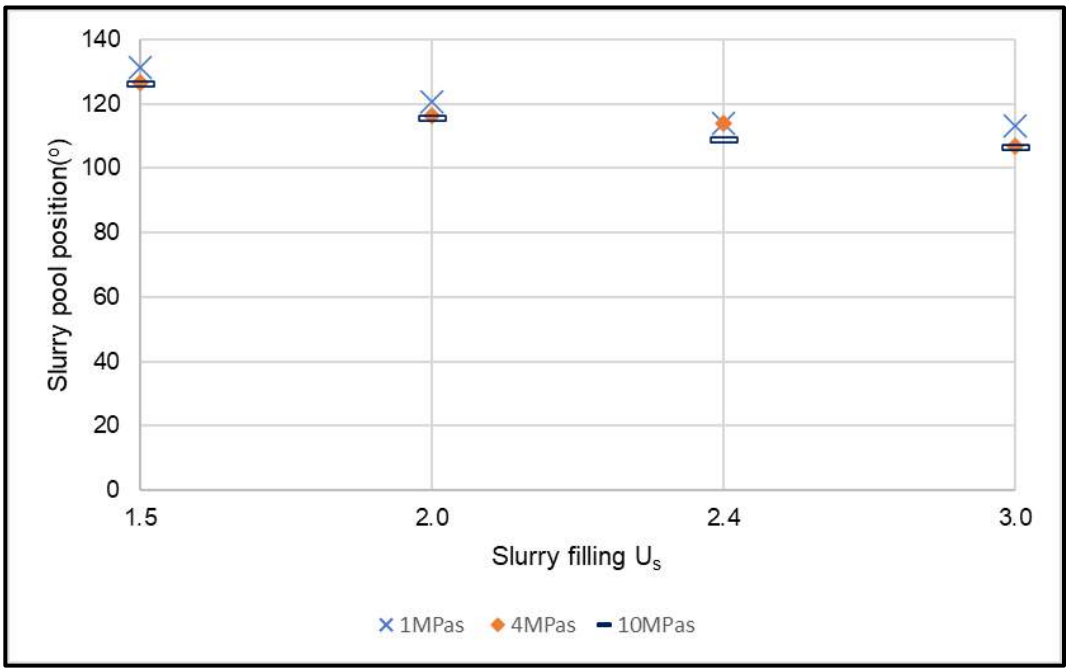

Figure 9: Angular position of slurry pool as a function of slurry viscosity and filling

4.3 Summary

This section presents comprehensive findings derived from coupled Computational Fluid Dynamics (CFD) and Discrete Element Method (DEM) simulations that were conducted to delineate the load profile within a wet ball mill. The key results elucidate critical metrics such as the void fraction and velocity profiles of the mill charge. Notably, our analysis shows that the void fraction varies between 0.4 in the stagnant 'dead zone' and 0.5 in the more dynamic cascading region, underscoring the heterogeneous nature of the charge distribution within the mill.

The velocity profile analysis reveals that the grinding media within the cataracting region experience peak velocities exceeding 1 m/s. This observation serves to confirm the robustness of the simulation model in replicating the dynamic behaviour characteristic of wet milling processes. Furthermore, we investigated the effects of operational parameters, including mill speed, slurry filling levels, and viscosity, on load dynamics. Our findings indicate that an increase in mill speed results in a noticeable elevation of the media shoulder position, with experimental validations showing a close alignment within a 5% margin of error—a testament to the reliability of the simulation framework employed.

Additionally, the study found that increasing slurry filling levels correspondingly lowered the position of the slurry pool, illustrating the intricate balance between these parameters. Conversely, variations in viscosity exerted a relatively minor influence on the overall dynamics of the milling environment, suggesting that other factors may play more significant roles under different operating conditions.

In summary, these findings contribute valuable insights into the interplay between grinding media and slurry interactions in wet milling environments. The data generated from this research enriches the existing body of knowledge, providing a basis for optimizing milling processes and advancing predictive modelling techniques in mineral processing applications.

5 CONCLUSION

This research has successfully demonstrated the application of coupled Computational Fluid Dynamics (CFD) and Discrete Element Method (DEM) simulation techniques in replicating the complex motion of the wet ball mill charge. Through a detailed examination of the velocity profiles within the mill, we have identified critical findings, particularly noting that the cataracting media achieves peak velocities during its descent from the shoulder region of the mill. This insight is invaluable not only for advancing theoretical models but also for practical evaluations relating to the wear mechanisms of grinding media, which is a crucial factor in optimizing the lifespan of milling equipment and improving operational efficiency.

The current findings have also provided a deeper understanding of the dynamics governing mill charges, facilitating a more nuanced evaluation of the forces exerted on grinding media. Furthermore, this study delves into the impacts of slurry filling and viscosity on load position, and the correlation of these parameters with results from existing pilot and laboratory experiments reinforces the validity of our computational approaches. This alignment with empirical data serves to bolster confidence in the use of CFD-DEM simulations as predictive tools in mineral processing applications.

Despite the promising results, it is essential to acknowledge the inherent limitations faced during this study. The computational power available restricted the simulation of a full spectrum of experimental conditions, potentially limiting the generalizability of our findings. Moreover, the use of a coarse mesh may have impaired the comprehensive development of the fluid flow field, which is crucial for capturing finer interactions within the slurry dynamics. These limitations highlight the necessity for enhanced computational resources and the pursuit of mesh refinement in subsequent research endeavours.

In conclusion, while this study lays a significant foundation for future research integrating CFD-DEM simulations in ball milling processes, it simultaneously charts a path forward that necessitates improvements in computational methodologies. Future investigations should focus on more sophisticated simulations that can encapsulate the full complexity of grinding environments, thus further enhancing our understanding of and ability to manipulate the factors influencing grinding efficiency and media performance. Emphasis on collaborative efforts between computational advancements and experimental validations will not only enrich the understanding of milling phenomena but will also propel innovations in mineral processing technologies.

AN EMPIRICAL STUDY ON THE EFFECT OF NUMBER AND VARIETY OF MULTIPLE TEAM MEMBERSHIP ON INDIVIDUAL PERFORMANCE

W.A.F. Du Plessis[1] and K-Y. Chan[2*]

[1,2]Department of Engineering and Technology Management,

ABSTRACT

Multiple team membership (MTM) is common in modern organizations, with individuals working in multiple teams simultaneously. The number of teams varies, as does the variety in tasks and geographic dispersion. The number and variety of MTM influences performance, with research suggesting an inverted U-shaped relationship—low MTM underutilizes employees, while high MTM leads to overload. Task variety typically harms performance due to switching difficulties. However, this study found a U-shaped relationship between number of MTM and planning performance in the South African context. Additionally, task and geographic variety positively impact communication, counterproductive work behaviour, skills development, and innovative performance. MTM remains an emerging field with limited and inconsistent empirical data, making further research essential.

Keywords: Multiple team membership, Individual performance, Geographical dispersion variety, Task variety

1 INTRODUCTION

In many engineering disciplines, employees contribute to various teams performing different projects and tasks [1]. This is inevitable in multi-project work settings as human resources are assigned to other teams to balance workload through scheduling [2]. Previous studies conducted in Sweden found that 77% of respondents worked on multiple projects simultaneously [3]. Individuals can be assigned to several teams as part of their job description. Within each team, variety can exist. The number and variety of an individual's MTMs influence their performance.

Being in various teams is known as multiple team membership (MTM), where an individual can simultaneously hold any number of memberships [4]. MTM is defined as "a situation in which individuals are concurrently members of two or more teams within a given period of time." [4] or as "…membership interdependencies across teams." [1]. MTM is an emerging research field that limits relevant research papers on theory and evidence despite the increased interest in the topic in recent years [1]. MTM can be conceptualised in terms of number and variety in the literature.

The relationships between MTM (in terms of number and variety) and individual performance have mixed findings, and there is limited empirical evidence in this area. To solve the problem stated, the objective of the study is to examine the relationship between MTM (number and variety) and individual performance. Furthermore, the research aims to answer the following questions:

- What is the effect of number of MTM on individual performance?
- What are the various categories of MTM variety?
- How does variety of MTM affect individual performance?

Based on the literature review in the next section, these two direct relationships and their interaction in MTM have yet to be researched extensively. The direct relationships are the number of MTM to individual performance and the variety of MTM to individual performance. Some studies might contradict or describe different ranges of the same theory based on positivism. Expanding the empirical evidence base allows a better understanding of the underlying theory to be discovered and further explored. If the relationship can be better understood, its advantages can be exploited, and its adverse effects can be reduced to promote individual and subsequent team and organisational performance.

2 LITERATURE REVIEW

In this section, extent theory and research are explored to provide insights into the problem statement and to establish what is known about the relationships between MTM and individual performance. Firstly, individual performance and metrics are defined and related to the MTM context. The number and variety of effects of MTM on individual performance are explored.

2.1 Individual performance

Individual performance can be conceptualised either as a behavioural action or as an outcome [5]. Commonly used indicators and methods of measure from literature and industry are discussed in this section. Individual performance and its metrics must be defined to understand the effects that MTM will have.

Productivity is defined as working to achieve an organisation's goal [6]. This infers that the measurements for performance for firm performance are suitable for individual performance as individuals' collective performance fuels company performance. Goldratt and Cox [6] state that a firm aims to make a profit. Therefore, individuals that make up the firm should have the same goal in mind. According to Pretorius [7], three measurements should be considered when determining if and how well the firm is reaching its goal. The three measurements are

throughput, inventory, and operational expenses. By increasing throughput, profitability is increased. Likewise, the reduction in inventory and operating expenses will also increase profitability. These three measurements should be used to assess the combined effect of assets, employees, and processes.

The analogy of Goldratt and Cox [6] above relates to individuals. The individual's contribution to the firm's throughput, inventory and operational expenses can be used to measure their performance [7]. Studies measuring individual work performance (IWP) list three aspects, namely, task performance, contextual performance and counterproductive work behaviour (CWB) [8,9]. These three aspects are related to the three former measurements [6], [7] in Table 1.

Table 1: Task performance

Work Aspect [7]	Description [7]	Unit of Measure [7]	Relationship to Profit [7]	Relation to IWP [9]
Throughput	The revenue generated by work done over a set period.	Revenue per time	Positive	Task Performance
Inventory	The cost expended on work that has yet to be delivered.	Revenue	Negative	Contextual Performance
Operational expenses	Costs incurred to support the throughput of work.	Cost per time	Negative	CWB

2.2 Number of MTM

As researched in a previous study, the number of memberships impacts individual performance [10]. Number of MTM is defined as the "…number of team memberships held by individual members within that same time period." [4].

Based on the literature reviewed, the relationship between the number of MTM and individual performance has a curvilinear or inverted U-shape, as proposed by O'Leary et al. [4], is generally accepted but not proven extensively as described by Chan [2] and Margolis [1] as they note a lack of empirical evidence in the field. This relationship represents low performance at low numbers of MTM and is driven by a positive relationship of increasing performance as the number increases. The positive relationship is the result of a more comprehensive knowledge base [11], balancing capacity [12], and utilising idle time [4] as the number of MTM increases. Furthermore, low performance at high numbers of MTM is driven by a negative relationship where individual performance decreases as the number of MTM increases. The negative relationship is the result of switching costs [4], attention fragmentation [13] and work overload [3,4]. Between the extremes of high and low MTM is a plateau where the positive and negative effects of moderate MTM numbers result in limited changes in individual performance [4]. This plateau is the optimal number of MTM where individual performance is at its best. The location of the optimum number of MTMs is an open debate, with suggestions ranging from one to nine projects [1].

Other studies discovered contrary results, revealing that the relationship between the number of MTM and performance is not necessarily curvilinear. In the study by Fodor, Curşeu and Meslec [11], no differences were found in individual performance (individual learning in estimation tasks) between single team and MTM settings. Moreover, a longitudinal study suggests that employees perform better at higher numbers of MTM [10], thus not a curvilinear relationship.

With these varying results, the authors have proven the relationship at different parts of the same curve. The authors do not necessarily contradict each other but describe various parts of the same continuum from a positivist approach. Therefore, for this study, the literature reviewed on the number of MTMs is generalised to have an inverted U-shape relationship with individual performance.

2.3 Variety of MTM

Variety of MTM describes the general uniqueness of tasks being performed across MTM [14]. Variety can be divided into several categories, such as geographic dispersion [4], the individual's role [14], heterogeneity or task variation [15]. Geographic dispersion or proximity measures the physical distance between group members [16]. The proximity of teams can influence team and individual performance as interactions range from face-to-face to virtual communication and handover. Low proximity or highly dispersed teams can show enhanced creativity compared with their collocal counterparts [17]. Moreover, distance teams can need help effectively communicating ideas and instructions, which hinders performance, especially with a team needing more cohesion [16].

Repetitive tasks can lead to a lack of motivation, resulting in lower performance [18]. Therefore, higher variety will increase performance by increasing individual motivation. Conversely, repetitive tasks have fewer switching costs than various task types, leading to higher performance. This concept is illustrated using machine setup and breakdown as an analogy by The Goal [6]. O'Leary et al. [4] support this view of a negative relationship. For this study, the literature review on variety and MTM is generalised to have a negative relationship with individual performance cross-sectionally. The effect of variety of MTM has a negative relationship with individual performance.

2.3.1 Geographic dispersion variety

Geographic dispersion measures the physical distance between team members of different teams in MTM [16]. According to a study by Yao and Robert [17], dispersed teams need more effective communication and creative performance. However, team cohesion and effective multimedia communication reduce these negative impacts as individuals are less exposed to group pressure and social convention and more likely to share ideas in virtual team and work settings [19]. Moreover, as the number of sites or locations where an individual's team functions increases, the difficulties in communication, coordination, and switching costs also increase [4], [20]. This paper defines a site as a building [20]. Geographic dispersion can also be determined by area. For instance, a team can be spread internationally or confined to a single city [21].

2.3.2 Task variety

Task differentiation or heterogeneity is a form of variety of MTM, as Snijder [15] described. The task can vary in nature depending on the individual's job description and working environment and can include activities of design, research, administration, physical work, project management, and collaboration. Snijder used two main categories namely explorative and exploitative. Explorative tasks include design, research, development, and training. These tasks primarily concern growing, improving and expanding existing knowledge and methods. Exploitative tasks include project management, physical work, and manufacturing. These tasks focus on the effective use of existing knowledge as part of the day-to-day operations of a firm. Snijder's study revealed a negative relationship between task heterogeneity and individual performance. Bertolotti *et al.* [22] found that individuals struggle to adapt to new tasks during switching, significantly if the functions differ. Project management tasks require quick responses intermittently, whereas design and development tasks require long periods of uninterrupted concentration. A notable difference here is the duration of the task concentration effort. Increased task variety may induce overload and reduce individual performance [23].

3 HYPOTHESES

A predictor or independent-dependant model (Figure 1) is used in this study without moderator factors and is primarily based on the adapted models of O'Leary *et al.* [4] and Snijder [15].

The independent variables identified are number, geographic dispersion variety, and task variety within an individual's MTM. The dependent variable is individual performance, broken down into task performance, contextual performance, and counterproductive work behaviour.

Hypothesis 1 arises from the literature study. The number of MTM is expected to have a curvilinear or ∩ relationship with individual performance [2], [4], [22]. At low numbers of MTM, individual performance is expected to have a positive relationship due to reduced standing time and resource balancing [4], [12]. At higher numbers of MTM, individual performance is expected to have a negative relationship due to increasing switching costs and cognitive fragmentation [4].

H1: There is a curvilinear (inverted-U shaped) relationship between the number of MTM that an individual has and individual performance.

Hypothesis 2 arises from the literature study and is a summation of its components. The variety of MTM is expected to have a negative relationship with individual performance, as depicted in **Error! Reference source not found.**. The main factor for this negative relationship is switching costs between different types of teams [4], [15], [22].

H2: The higher the variety of MTM an individual has, the lower the individual performance.

Hypothesis 2 is further broken down into its components with a hypothesis for each aspect of variety covered in the literature study. Hypothesis 2.1 is based on the study by Yao and Robert [17] and predicts a negative relationship between geographic dispersion variety and individual performance. This negative relationship results from increased switching costs, less effective communication, and lower creative performance as team dispersion variance increases [17].

H2.1: The higher the geographic dispersion variety amongst an individual's MTM, the lower the individual's performance.

Based on the studies of Bertolotti *et al.* [22] and Snijder [15], hypothesis 2.2 is created and suggests a negative relationship between task variety and individual performance. This relationship is driven by elevated switching costs between tasks that differ in nature [15], [22].

H2.2: The higher the task variety amongst the individual's MTM, the lower the individual's performance.

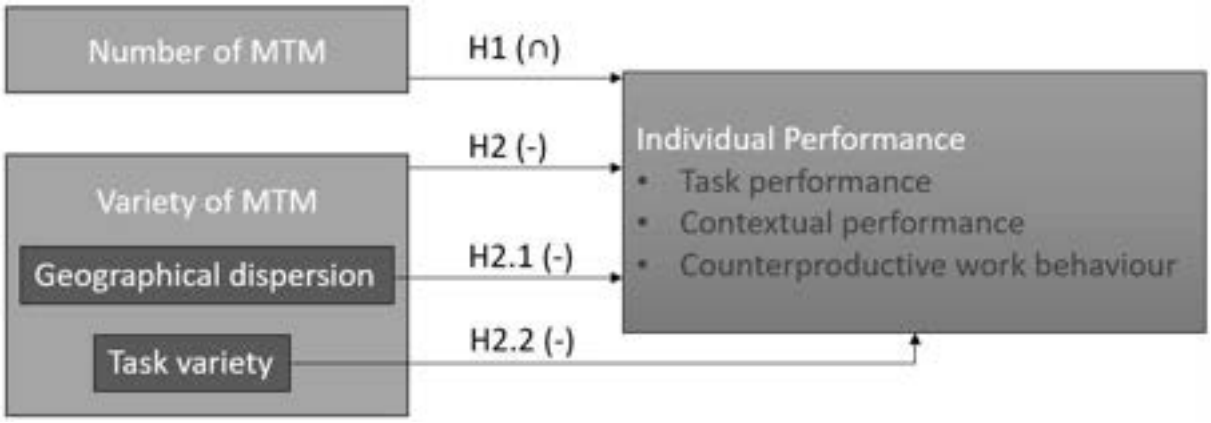

Figure 1: Conceptual Model

4 RESEARCH METHOD

A quantitative approach is selected for the study based on the ability to establish relationships between independent and dependent variables [24]. An online questionnaire was used to gather data from the study respondents. Non-probability techniques of convenience and

snowball sampling are used to collect the research data [24]. A link to the questionnaire was sent out via email and WhatsApp to all the author's personal contacts deemed suitable for the study (convenience). To expand the respondents further, a request was added to forward the survey (snowball) to others who also fall within the requirements for the research [24]. Working professionals in South Africa are the target group.

A sample size of 107 is needed to test the partial correlation of individual predictors [25]. This is the target number of responses for the study. The target population for the survey is graduate professionals in South Africa. The author used personal contacts to send out invitations to the target group as described by convenience sampling [24]. At the end of the questionnaire, respondents are asked to relay it to their network of similar participants, as described by snowball sampling [24]. Research ethical clearance was obtained from University of Pretoria's EBIT Research Ethics Committee before the research commenced.

Demographic or categorical variables are included in the data set to categorise specific trends within the data [26]. The sample consists of professionals from various industriesm with average industry experience of 11.6 years from 44% females and 67% males. Ordinal and continuous scales are used for these variables. The ***number*** of MTM is determined by asking the respondents to indicate their three-month average of MTM [4]. The site index from O'Leary measures the ***geographic dispersion variety*** between an individual's teams. The site index is the number of sites per team [20]. If a team has more sites, it is more geographically dispersed. Likewise, there is no geographical dispersion if a team has a single site. Questions from Morgeson and Humphrey [23] on ***task variety*** are adapted to suit the MTM context. ***Individual performance*** is measured based on the individual work performance questionnaire developed by Koopmans *et al*. [8] which measures three aspects: task performance, contextual performance and counterproductive work behaviour.

5 RESULTS

5.1 Factor analysis of individual performance

The following factors of individual performance as proposed by Koopmans et al. [8] and Ramos-Villagrasa et al. [9]:

- Task performance: (Items 1 – 5)
- Contextual performance (Items 6 – 13)
- Counterproductive work behaviour (Items 14 – 18)

Factor analysis is conducted to test if the sample in this study shows the same factors (i.e. task performance, contextual performance and counterproductive work behaviour) of individual performance as proposed by Koopmans et al. [8] and Ramos-Villagrasa et al. [9]. The extraction method used is principal component analysis with an unrestricted number of factors for Eigenvalues greater than 1. The analysis converged in six iterations using the Varimax method with Kaiser Normalization. Suitability for factor analysis is tested using the Kaiser-Meyer- Olkin Measure of Sampling Adequacy (KMO) and Bartlett's test of sphericity. The KMO result indicates an average partial correlation among the individual performance variables. The Bartlett's test significance result suggests high plausibility of the underlying factors. Given the favourable outcome of the KMO and Bartlett's test, the factor analysis identified five underlying factors of individual performance in Table 2 below.

Table 2: Rotated component matrix

Item	Item description	Component					Factor group
		1	2	3	4	5	
1	I managed to plan my work so that I finished on time.	.094	**.836**	-.034	.058	-.018	2
2	I kept in mind the work result I needed to achieve.	.131	**.502**	.136	.105	-.477	2
3	I was able to set priorities.	.139	**.618**	.145	.185	-.462	2
4	I was able to carry out my work effectively.	-.031	**.770**	.074	.161	.240	2
5	I managed my time well.	-.073	**.852**	.155	.022	-.071	2
6	On my own initiative, I started new tasks when my old task was completed.	-.030	.102	**.645**	.055	-.154	3
7	I took on challenging tasks when they were available.	.018	.211	**.742**	.122	.023	3
8	I worked on keeping my job-related knowledge up to date.	.137	.137	.215	**.842**	.107	4
9	I worked on keeping my work skills up to date.	.140	.173	.231	**.856**	-.072	4
10	I came up with creative solutions for new problems.	.102	.026	**.656**	.192	-.028	3
11	I took on extra responsibilities.	-.127	-.043	**.680**	.010	.350	3
12	I continually sought new challenges in my work.	.063	.021	**.740**	.131	.179	3
13	I actively participated in meetings and consultations.	.035	.074	.285	.098	**.755**	5
14	I complained about minor work-related issues at work.	**.669**	.010	.085	.153	-.241	1
15	I made problems at work bigger than they were.	**.684**	.111	.072	.337	-.138	1
16	I focused on the negative aspects of the situation at work instead of the positive ones.	**.759**	-.005	.063	.042	.063	1
17	I talked to colleagues about the negative aspects of my work.	**.831**	.118	.036	-.115	-.024	1
18	I talked to people outside the organisation about the negative aspects of my work.	**.719**	-.100	-.257	.090	.216	1

The five underlying factors identified in Table above are described in grouped items below:

1. Counterproductive work behaviour (Items 14-18): This factor group coincidences perfectly with the same group and name of Ramos-Villagrasa et al. [9]. The items all describe negative traits that reduce individual performance. As these items are reverse coded, the higher the value, the higher the individual's performance.
2. Planning (Items 1-5): This factor group aligns with the task performance group of Ramos-Villagrasa et al. [9].
3. Innovative performance (Items 6-7, 10-12): This group consists of initiation, creativeness, and thriving in facing challenges.
4. Skills development (Items 8-9): Keeping up to date with job-related skills and knowledge describes individuals' performance in terms of skills development.
5. Communication (Item 13): Active participation in meetings and consultations entails communication performance. These five underlying factors are used to compute new dependent variables further analysed in the following correlation and regression sections.

5.2 Correlations analysis

Spearman's correlation coefficients are calculated to account for ordinal data. There is an expected correlation direction; therefore, one-tailed significance is tested. Observations concerning independent and dependent variables from Table 3 is listed below. The results shown include only the correlations between dependent and independent variables. The number of MTM is mean-centred and squared to test for U-shape correlation.

- The number of MTM positively correlates with communication. This means that the higher the number of MTM, the higher the individual's communication performance will be.
- The number of MTM mean squared positively relates to planning. Therefore, the number of teams has a U-shaped relationship with planning. At a low number of MTM, the planning performance will decrease as the number of teams increases. With a higher number of MTM, the planning performance will increase as the number of MTM increases.
- Geographic dispersion variety positively correlates with counterproductive work behaviour. Since counterproductive work behaviour is reverse coded, the higher the geographic dispersion variety, the less counterproductive work behaviour will be and the higher the individual performance.
- Task variety positively correlates with innovative performance and skill development. As task variety increases, the innovative performance and skill development increases.

Table 3: Spearman Correlation (N=111)

Variables	Number of MTM	Number of MTM ^{2}	Geographic dispersion variety	Task variety
Counterproductive work behaviour	-.062	.081	.134	-.048
Planning	-.133	**.158***	-.054	.039
Innovative performance	.106	-.032	-.112	**.175***
Skills development	-.056	-.093	.011	.046
Communication	**.179***	.004	.090	.133

*p<0.05 (one-tailed)

5.3 Multiple regression analysis

Multiple regression analysis is done for each factor group of individual performance. Significant impacts between independent and dependent variables are discussed.

5.3.1 Counterproductive work behaviour (CWB)

The multiple regression analysis for counterproductive work behaviour as dependent variable showed no significant relationship between number of MTM and CWB as shown in Table 4

As for MTM variety, Geographic dispersion variety has a weak positive impact on counterproductive work behaviour ($\beta = 0.176$, $p<0.1$). With more variety in geographical dispersion, counterproductive work behaviour becomes more prevalent.

Table 4: Regression analysis: Counterproductive work behaviour to variety (N=111)

Variables	Dependent variable: CWB		
	Model 1	Model 2	Model 3
Constant	.434	.199	.762
Age	-.010	.009	.009
Gender	-.161	-.166	-.159
Qualification level	-.061	-.066	-.076
Industry	.039	.048	.054
Level of employment	.105	.102	.128

Experience	-.074	-.083	-.099

ΔF-value	.788	3.429*	1.325
VIF	1	1.007-1.052	1.112

*p<0.10; **p<0.05; ***p<0.01

5.3.2 Planning

At a low number of teams, the planning performance decrease as the number of teams increases (β = -0.426, p<0.05) as reported in Table 5. With a higher number of teams, the planning performance increases as the number of teams increases (β = 0.389, p<0.05). This shows a U-shaped relationship between number of MTM and planning performance.

Table 5: Regression analysis: Planning to number (N=111)

Variables	Dependent variable: Planning		
	Model 1	Model 2	Model 3
Constant	-.324	-.305	-.300

F-value	.755	.756	1.316
ΔF-value	.755	.774	5.026
VIF	1	1.092-1.189	3.387

*p<0.10; **p<0.05; ***p<0.01

5.3.3 Innovative performance

No significant impacts of independent variables are observed on the dependent variables.

5.3.4 Skill development

There are no significant results for the number of MTM and skill development. On the other hand, task variety has a weak positive impact on skill development (β = 0.188, p<0.1). As task variety increases, skill development increases. The results are shown in Table 6 below.

Table 6: Regression analysis: Skill development to variety (N=111)

Variables	Dependent variable: Skill development		
	Model 1	Model 2	Model 3
Constant	.383	.322	-.601
Age	-.413	-.408	-.408

F-value	.887	.786	1.148
ΔF-value	.887	.220	3.543*
VIF	1	1.007-1.052	1.112

*p<0.10; **p<0.05; ***p<0.01

5.3.5 Communication

Number of teams has a weak positive impact on communication (β = 0.236, p<0.05) and contributed to ΔR^2 of 4.7% to the variance in Commumication as the dependent variable as shown in Table 7. As the number of teams increases, respondents are more likely to improve their communication skills.

There are no significant results for the variety and communication.

Table 7: Regression analysis: Communication to number (N=111)

6 DISCUSSION

6.1 Answering the research questions

The answers to the research questions are discussed below:

- *What is the effect of number of MTM on individual performance?*

The number of teams has a U-shape relationship and correlation with the planning aspect of individual performance. The number of teams negatively correlates with planning performance at low MTM. As MTM increases, the relationship becomes positive. Although this is only for the planning aspect of individual performance, it is the direct opposite relationship as proposed in the literature study [2], [4], [22]. It appears that people are bad at planning

from the outset. People tend to perform well when there is less need for planning and prioritising (presumably at a low number of teams). The possible lack of planning skills shows as the number of teams increases, as described by switching costs [4]. At a certain point, however, individuals are faced with the absolute need to plan and prioritise to avoid even lower performance. At this point, when they presumably learn to plan and prioritise effectively, the relationship turns positive, and performance increases as the number of teams increases.

The number of teams has a positive relationship and correlation with the communication aspect of individual performance. The correlation coefficient for Pearson (0.207) and Spearman (0.179) are both significant at the $p<0.05$ level. This indicates a weak but definite correlation. As the number of teams increases, individuals respond with higher levels of communicational performance.

- *What are the various categories of MTM variety?*

Four aspects of variety of MTM are identified in the literature review, of which only the first two have been included in the research model: task variety and geographical dispersion variety. Including all the aspects of variety explored in the literature will make the research too broad and convolute the data gathering and analysis. Thus, this study focused on the effects of task variety and geographical dispersion variety to simply the data collection and analysis.

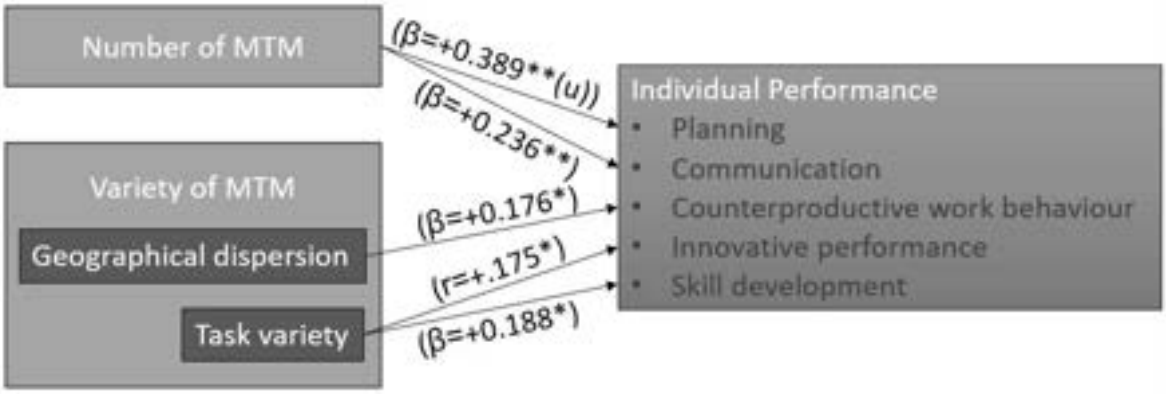
- *How does variety of MTM affect individual performance?*

Geographical dispersion variety positively affected individual performance in terms of counterproductive work behaviour (CWB). The more individuals are involved in teams with various levels of geographic dispersion, the less counterproductive work behaviour is observed and the higher the individual performance becomes. The discussion in the literature study suggested that geographic dispersion variety would have the opposite effect on individual performance. According to the literature, switching costs are expected to increase as the geographical dispersion variety increases, decreasing individual performance [4], [20].

Task variety has a positive correlation with innovative performance. As individuals are exposed to a wider variety of tasks, they tend to perform more innovatively. Task variety also has a positive relationship correlation with skill development. Individuals are likelier to focus on skills development in settings with greater task variety. This result differs from the literature study that proposed a negative relationship due to added switching costs [2], [4], [22].

6.2 Updated model

An updated model based on the results is presented below as a summary of the relational research answers (Figure 1). This model shows the newly discovered correlations and relationships between the number and variety of MTM and individual performance.



Regression values significance (ß): *p<0.10; **p<0.05

Correlation value significance (r): *p<0.05 (one-tailed)

7 CONCLUSION AND RECOMMENDATION

7.1 Theoretical implications and contributions

The underlying factors of individual performance differ in this study compared to the study by Koopmans *et al*. [8]. The tool proposed by Koopmans *et al*. [8] may not be generalisable for this sample, given the volatility of its underlying factors.

The number of teams has a U-shaped relationship and correlation with planning regarding individual performance. The other underlying factors of individual performance do not have a significant relationship with the number of teams. Moreover, a weak positive relationship is found between the number of teams and communication. The number of teams also positively correlates with communication. This means that the higher the number of teams, the higher the individual's communication performance will be. Conversely, the literature suggests that individual performance has an inverted U-shaped relationship with the number of teams [2], [4], [12], [22].

Contrasting findings are found in this study for the relationship between variety and individual performance. Negative relationships were expected based on the literature [4]. The results may be explained by the notion that greater involvement in teams with varying levels of geographic dispersion exposes individuals to diverse collaboration demands and accountability structures, which in turn reduces counterproductive work behaviours and enhances individual performance.

Geographical dispersion variety has a positive relationship and correlation with individual performance regarding counterproductive work behaviour. When individuals work across different numbers of sites per team, they tend to exhibit less counterproductive work behaviour, which improves their individual performance. Conversely, a negative relationship is observed by Yao and Robert [17]; switching costs, ineffective communication, and reduced creativity reduce individual performance as geographical dispersion variety increases.

Task variety has a positive correlation with innovative performance. Moreover, task variety has a positive relationship and correlation with skill development. As the variety of tasks increases, individuals are observed to perform better innovatively and develop their skills.

Conversely, the literature suggests that a negative relationship exists between task variety and individual performance. Switching costs are expected to elevate as task variety increases, which lowers individual performance [15], [22].

Effects of switching costs and cognitive fragmentation were not observed with either number or variety increases. The contrasting result of this report suggests that the field of MTM is sample-specific, and that generalisability is not readily achievable. This stems from the novelty of the research field and necessitates caution when interpreting results.

7.2 Managerial recommendations

In practice, managers are encouraged to exploit positive relationships to enhance the individual performance of their teams. Based on the results, individuals tend to perform better at a higher variety of tasks and geographical dispersion of teams. Therefore, employees should be exposed to different work aspects and work on different sites. Moreover, individuals with more teams tend to communicate better. Few negative effects are observed apart from the U-shape relationship regarding the number of teams and planning. Managers should aim to avoid the trough by keeping the number of teams limited or exposing their employees to many teams quickly.

7.3 Recommendations for future study

The findings of this research can be further explored to determine the justifications underpinning the results found concerning the list in the result summary section. Underlying factors may differ in each research setting and should be analysed case-by-case.

The number of teams is highly dependent on the specific work environment of the individual. As Bertolotti *et al.* [22] mentioned, project management requires quick intermitted responses and frequent switching, as development environments require longer concentration spans and fewer switching. With high switching, a higher number of teams can be possible, whereas with less switching, a lower team number can be expected. These two different settings need to be researched separately to compared. Task or setting type optimums can be explored between various industries.

Future research could examine potential interaction effects among the independent variables, as such analyses may reveal more nuanced relationships that are not captured through main effects alone. Investigating these interactions would contribute to a more comprehensive understanding of the model's dynamics and may offer deeper theoretical and practical insights into the phenomenon under study.

People might rate themselves as good biasedly, as observed in the result. This will skew the results toward the upper limit when a Likert scale is used with a self-appraisal. Qualitative methods should be explored using key performance indicators rather than self-assessments in organisation-specific settings. Using this approach may reduce the probability of biased data. Moreover, the sample is limited to South African professionals; therefore, the results cannot be generalised to other countries. Similar research in other contexts would enhance the generalisability of the model.

This study employed linear regression and correlation analysis, with the selection of these methods determined by the research questions and the nature of the dataset. Although these techniques allowed for a straightforward examination of the hypothesised relationships, more sophisticated approaches—such as social network analysis—may yield deeper and more nuanced insights.

ABSTRACT

A large number of knowledge workers across industries and occupations engage in multiple team membership (MTM). Given MTM's collaborative nature, understanding how relationships affect individual performance and learning is crucial. This study examines intra-organisational MTM using a social capital perspective, focusing on degree centrality and trust. The sample included 139 individuals from a South African petrochemical company, with 110 completed online questionnaires. It was hypothesised that degree centrality has a curvilinear relationship with performance and learning, but analyses did not support this. However, trust was found to positively impact both performance and learning. These findings suggest that fostering trust is more influential than expanding an individual's network size. Project managers should prioritise building trust in MTM environments to enhance individual outcomes.

Keywords: Degree centrality, intra-organisational MTM, individual learning, individual performance, trust

1 INTRODUCTION

1.1 Background

One prevalent assumption that has characterised much of the research on team composition is the belief that, at any given point in time, individual employees are exclusively affiliated with a single team. This conventional perspective may no longer be applicable since a substantial proportion of today's workforce, spanning diverse countries, industries, and occupations, engages in more than one team concurrently. In Europe and the United States, it is estimated that approximately 65-95 percent of knowledge workers are engaged in MTM [1]. O'Leary et al. [2] define MTM as *"a situation in which individuals are concurrently members of two or more teams within a given period of time."* Previous research has largely overlooked the underlying causes and resulting impacts of MTM, leaving uncertainty regarding whether MTM constitutes an effective and efficient work practice. For instance, multi-team members must allocate their time and efforts across multiple teams, frequently necessitating transitions from one team to another to manage competing demands on their time [2], [3]. Consequently, MTM can significantly complicate an employee's work schedule and task requirements.

On a more optimistic note, MTM may also provide individual employees with opportunities for unique personal and professional development, and self-expression [2], [3]. Engaging with multiple teams exposes individuals to diverse challenges, perspectives, and tasks, leading to the acquisition of a broader range of skills, knowledge, and experiences while allowing individuals to express their unique talents and capabilities [2], [4].

As the nature of MTM necessitates that employees collaborate with a diverse range of colleagues across various teams, it is necessary to understand the role that relationships play in the performance and learning of individuals within MTM settings. Carter and De Church [5] define relationships in the MTM context as "the interpersonal connections, interactions, and dynamics" that individuals foster and sustain when these individuals concurrently work across multiple teams within an organisation. Such relationships can considerably influence team effectiveness, information sharing, coordination, and the overall functioning of teams and the organisation [5], [6].

Chan et al. [7] define individual learning "as the behavioural focus organisational actors have on improving and mastering a task." A fundamental principle supporting the adoption of employees in MTM work arrangements is the anticipation that both the employees and their teams will derive educational advantages. In the MTM context, project members acquire information that can be exchanged among teams, serving as an asset to facilitate learning [7].

O'Leary et al. [2] define individual productivity as "the ability to create products or services that meet the expectations of key stakeholders in a given time period with a given set of human and other resources." Chan [8] posits that individual productivity may be viewed as a dimension of individual performance. The same stance is adopted in this research.

Social capital theory posits that an individual's social network, characterised by their interpersonal relationships with colleagues, encompasses valuable interpersonal assets that enhance their performance and learning [9], [10], [11]. This study adopts a social capital perspective to investigate the impact of relationships within intra-organisational MTM on individual performance and learning.

1.2 Research gap and problem statement

Analysis of the existing literature reveals that there is a deficiency in empirical research on how relationships within these MTM settings influence individual performance and learning. Previous scholars have primarily investigated the conditions and factors associated with MTM, with the majority of research concentrating on how MTM impacts individuals or teams [12],

[13]. Regarding the influence of MTM on teams, the predominant research focus has been on performance and productivity [14]. Research on the effects of MTM on individuals encompasses the examination of roles, creativity, and performance [15], [16], [17], with minimal empirical exploration of the influence of relationships within MTM on individual performance [1], [17], despite the potential for these relationships to impact individual performance significantly.

Despite the widespread occurrence of MTM within organisations, and the continuous organisational challenge of adapting and learning, there is a paucity of empirical research linking these two concepts [1], [18]. Addressing this gap is critical, as such relationships hold significant potential to facilitate individual learning.

1.3 Research objective and question

The objective of this study is to evaluate the extent to which relationship dynamics in intra-organisational MTM influence individual performance and individual learning. Given the objective, the research question is: How does the relationship dynamics of intra-organisational MTM influence the performance and learning of individuals?

2 LITERATURE REVIEW

2.1 Conceptualising MTM

Previous research [14], [19] has primarily concentrated on examining MTM at the team level, which might seem surprising given that MTM arises when individuals participate in multiple teams concurrently [2], [3]. Employees often exhibit significant variations (e.g., in the number of teams, depth of involvement, nature of team roles, time commitment, etc.) in the multitude of teams they are concurrently engaged in. However, these individual-level discrepancies are not adequately addressed in team-level conceptualisations [20], [21].

The investigations that have delved into the repercussions of MTM at the individual level depict MTM as a “double-edged sword” capable of both impeding and enhancing an employee's overall performance and well-being in the workplace [21]. To elaborate, the existing literature highlights areas of uncertainty concerning the impact of MTM on an individual's overall job performance, mental health, and the quality of the individual’s interpersonal workplace relationships [21].

2.2 Interpersonal consequences of individual-level MTM

MTM necessitates that employees collaborate with a diverse range of colleagues across various teams, and this collaboration can be influenced by specific interpersonal dynamics [2], [3], [22]. Pluut et al. [17] argued that each team affiliation brings about its own set of demands and expectations for an employee, consequently observing a positive correlation between the number of teams an individual is concurrently a part of and the individual’s perception of interpersonal demands.

Moreover, MTM imposes time constraints on an individual's participation within each team, potentially complicating their ability to fully comprehend the interpersonal expectations and demands of each co-worker [3], [23]. Additionally, the roles an individual plays in these multiple teams could be easily compromised due to the work performed across the multiple teams and reporting to different team managers [3], [23].

In contrast, Mortensen et al. [12] proposed that MTM offers employees the opportunity to establish meaningful relationships with co-workers across different parts of the organisation. Connectedly, O’ Leary et al. [2] argued that “MTM significantly enlarges an individual’s social network, leading to a more diverse range of contributions and adequate interpersonal connections that inspire learning.” Thus, MTM has the potential to magnify an individual’s interpersonal network among various teams within the organisation, potentially enhancing their accessibility to valuable information and knowledge.

This emphasis on the correlation between MTM and learning holds significance not only in academic discourse, but also in managerial practice. Learning serves as a foundational cornerstone for various organisational outcomes, including creativity, performance enhancement, innovation, competitive advantage, and, eventually, the longevity of the organisation itself [3].

Chan et al. [7] found that individuals who engage with both external and internal project teams are more inclined to concentrate on enhancing their skill sets and achieving proficiency in their assigned responsibilities. As a result, they expand their reservoir of expertise and gain insights from various project teams with which they are affiliated. Establishing strong connections with project teams within and beyond the organisation is evidently advantageous with respect to learning for individual team members.

The literature reviewed highlights MTM as an intricate work practice that can both complicate interpersonal relationships and foster productive and meaningful connections among multiple teams. This seeming paradox underscores the necessity for further research into the interpersonal implications of individual-level MTM.

2.3 Social capital perspective on the interpersonal consequences of individual-level MTM

Social capital theory posits that an individual's social network, characterised by their interpersonal relationships with colleagues, encompasses valuable interpersonal assets, such as knowledge, information, and instrumental and social support [10], [21]. Lin [24] defines social capital as an individual's capacity to access and utilise these resources. Social capital is a pivotal factor in employee performance since those with greater social capital can more readily tap into resources that enhance their performance outcomes [10], [11], [25].

In innovative, non-routine work environments, forging connections across organisational subunits provides access to diverse information, outlooks, political linkages, and expertise [24], [26]. Given this perspective, it is reasonable to contend that MTM can foster additional productive associations spanning various teams, thus bolstering the social capital essential for improved performance. MTM, by definition, necessitates collaboration with colleagues from multiple teams with varying specialisations [2], [21]. Consequently, MTM enables individuals to collaborate with a greater quantity of previously unacquainted clients, project leaders, and colleagues, thereby accessing significant resources inherent within diverse teams, and transmitting such resources across team contexts [27], [28], [29].

MTM might, for instance, expose an individual to novel sources of knowledge, which can stimulate their creativity [21], [30], [31], acquaint them with novel practices that could prove beneficial in other team environments, e.g., through sharing best practices [21], [32], and institute prospects for forging fresh and profound relationships with co-workers situated in diverse sections of the organisation [21], [33], [34]. In summary, MTM could represent a unique source of social capital, extending beyond an individual's sheer quantity of interpersonal connections [10], [21].

2.4 Dimensions of social capital

Social capital possesses diverse attributes. Putnam [35] advocated for a heightened research focus on elucidating the different dimensions of social capital. Within the examination of the impact of social capital on intellectual capital formation, Nahapiet and Ghoshal [36], Menike [37], and Fandiño et al. [38] organised its facets into three main clusters, namely, the structural, relational, and cognitive dimensions of social capital.

Structural social capital refers to the dimension of social capital associated with the characteristics of the social structure and the network of relationships in its entirety [36], [39]. The study of structural social capital often adopts a network approach, depicting

interaction patterns by examining the intensity of interactions among actors within a specific firm or organisational field [40], [41]. Various perspectives, such as degree centrality and network stability, are employed to analyse structural social capital [42]. Structural social capital fosters conditions that enable access to assorted parties for knowledge exchange and transfer, as well as opportunities for individuals to connect with peers who possess the desired knowledge or expertise [10], [43], [44].

Relational social capital constitutes a dimension of social capital primarily concerned with the attributes and virtues of personal relationships [9], [45]. This dimension encompasses the disposition and calibre of relationships formed via a series of interactions [42], [46] and manifests in behavioural characteristics like identification, shared group norms, trustworthiness, and obligations [10], [47]. Associability, the inclination to prioritise collective goals over individual goals, stands as a central aspect of relational social capital [42], [48].

The cognitive dimension of social capital refers to resources that facilitate shared conceptions, understandings, and frameworks of meaning among involved parties [36], [37], [39], [49].

This study focuses on the influence of only one element of the structural dimension of social capital, namely degree centrality, and only one element of the relational dimension of social capital, namely trust, in investigating the impact of relationships on individual performance and learning within intra-organisational MTM. This is because evaluating all the elements of all three dimensions of social capital would notably extend the questionnaire, potentially lowering the response rate, as indicated by Roszkowski and Bean [50] and Gaur et al. [51], who concluded that in empirical studies, shorter questionnaires received approximately 28 percent higher response rates compared to longer ones.

2.5 Degree centrality of network ties

Researchers in the field of social networks have long contended that certain connections for sharing information, referred to as network ties, can have varying levels of worth for an individual's performance [21], [26]. The core tenet of social capital theory posits that network ties grant access to resources [52]. A prominent theme in the literature emphasises social capital as a valuable source of informational advantages [32], [53], [54]. As individuals are situated within social structures, they are part of intricate networks of relationships [55], [56]. [57]. Each connection in an employee's network acts as a pathway for knowledge exchange [55], [58].

Degree centrality, which refers to the degree of connectedness to others within an organisation, conceptualises the social position based on the number of ties [55], [59]. Different network positions offer varying opportunities for knowledge sharing [55], [60]. Therefore, one's degree of network centrality serves as both an opportunity and a constraint for receiving information, accessing resources, and seeking advice or social support [55], [61]. Employees in more central positions possess numerous ties, granting them greater access and control, affording them increased opportunities to not only share knowledge but also accumulate valuable insights [55], [56]. Conversely, peripheral network positions provide limited opportunities for knowledge transfer or assimilation as employees with few ties may be perceived as outsiders within the social context, minimising their engagement in knowledge-sharing activities [55], [62].

The research portrays degree centrality as a vital aspect of social capital theory as it affects the flow of resources (particularly information) within networks and significantly impacts the efficiency and effectiveness of knowledge transfer. Hence, degree centrality represents the structural element of social capital examined in this study.

2.6 Trust

Misztal [63] and Nahapiet and Ghoshal [36] define trust as the belief that the "results of somebody's intended action will be appropriate from our point of view." Substantial research exists [9], [35], [64], [65], [66], [67], [68], [69] demonstrating that high levels of trust in relationships lead to increased willingness to participate in cooperative interaction and social exchange.

Putnam [66] and Sawhill [70] describe trust as a pivotal component of social capital. Sawhill [70] and Putnam [66] posit that trust promotes cooperation and that the greater the level of trust within a community, the better the probability of cooperation. Hence, trust represents the relational element of social capital examined in this study.

3 CONCEPTUAL MODEL

3.1 Influence of degree centrality within intra-organisational MTM on individual performance

Degree centrality can influence individual performance in various ways. In a social network, for example, individuals with a higher degree centrality are considered more popular or important, as they have more connections with other individuals. This can lead to increased opportunities for information exchange, resource support, and social support from colleagues, positively affecting work engagement and job satisfaction, and thereby influencing individual performance [71], [72].

The impact of the number of MTM on individual performance is a complex issue with both potential benefits and challenges. The more teams an individual is part of, the greater the opportunities to interact with different team members, potentially increasing the individual's connections and relationships within the network. This increased interaction can lead to higher degree centrality for individuals with multiple team memberships, as these individuals are likely to have more ties within the network compared to those with fewer team memberships. Therefore, there is a positive relationship between the number of MTM and degree centrality in a social network.

However, there are also potential negative effects associated with MTM, such as increased workload, coordination challenges, and resource blocking, which can hinder individual performance [6], [73]. The research suggests that at lower levels of MTM, the positive effects, like volume flexibility, may dominate, while at higher levels of MTM, the negative effects, like overwork, may become more prominent, leading to a decline in performance [6], [74]. Hence, the relationship between the number of MTM that an individual has, and the performance of the individual is curvilinear. As degree centrality is positively related to the number of MTM, the following hypothesis was formulated:

H1: The relationship between the degree centrality of an individual within intra-organisational MTM and the performance of the individual is curvilinear; the positive relationship increases at a decreasing rate and eventually turns negative.

3.2 Influence of degree centrality within intra-organisational MTM on individual learning

In a social network, individuals with higher degree centrality may have more opportunities to interact with others, leading to a greater willingness to disclose relevant information. This can positively influence their potential for information exchange and their ability to affect others in the network, thereby enhancing individual learning [75], [76].

Research suggests that MTM can positively influence individual learning by providing opportunities to engage in various tasks and projects, which leads to greater learning through exposure to diverse viewpoints and knowledge [7], [73]. As mentioned, research suggests that

at lower levels of MTM, the positive effects, like learning opportunities, may dominate, while at higher levels of MTM, the negative effects, like coordination neglect, may become more prominent, leading to a decline in learning [6], [74]. Hence, the relationship between the number of MTM that an individual has, and the learning of the individual is curvilinear. As degree centrality is positively related to the number of MTM, the following hypothesis was formulated:

H2: The relationship between the degree centrality of an individual within intra-organisational MTM and the learning of the individual is curvilinear; the positive relationship increases at a decreasing rate and eventually turns negative.

3.3 Influence of trust within intra-organisational MTM on individual performance

Studies conducted by Conlon and Mayer [77] and Morales-Sánchez [78] concluded that the readiness to trust others was positively correlated to the performance and behaviour of individuals employed in an agency simulation, suggesting that the readiness to trust others is linked to the performance and behaviour of individuals in an organisational context. Similarly, a study conducted by Ning and Jin [79] empirically supported the idea that an environment perceived as trustworthy by employees is linked to positive psychological conditions. This perception motivates individuals to invest more effort and personal resources in the organisation's work, leading to superior task performance. Based on the research above, the following hypothesis was formulated:

H3: Trust within intra-organisational MTM is positively related to individual performance.

3.4 Influence of trust within intra-organisational MTM on individual learning

Misztal [63], Nahapiet and Ghoshal [36] and Safari et al. [80] observed that trust enhances dialogue and communication, suggesting that trust may facilitate access to individuals for intellectual capital exchange, i.e., learning, and heighten expectations of value via such exchanges.

Research [68], [80], [81] indicates that high levels of trust lead to an increased willingness to take risks in interactions, potentially facilitating experimentation by integrating different types of information. Nahapiet and Ghoshal [36], Luhmann [82], and Safari et al. [80] have shown that trust enhances a system’s potential for managing diversity and complexity, factors crucial in developing new intellectual capital. Boisot [83] underscores the significance of interpersonal trust for knowledge development in environments characterised by high uncertainty and ambiguity. Based on the research above, the following hypothesis was formulated:

H4: Trust within intra-organisational MTM is positively related to individual learning.

Based on the hypotheses formulated, the following conceptual model was defined, as illustrated in Figure 1.

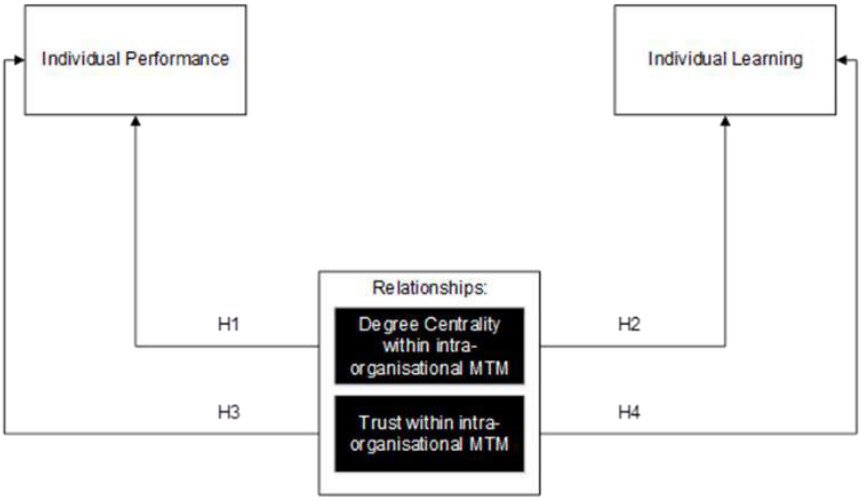

Figure 1:Conceptual Model

4 RESEARCH METHOD

4.1 Research design

This study was conducted as an empirical investigation involving the collection of primary data. Primary data was selected over the analysis of secondary data due to the limited empirical exploration of the impact of relationships within intra-organisational MTM on both individual performance and learning. Electronic questionnaires were employed to gather data on the concepts outlined in the conceptual model. Permission to collect data from the company, along with research ethics clearance from the University of Pretoria's EBIT Research Ethics Committee (reference number EBIT/121/2024), was obtained prior to the commencement of the study.

4.2 Sample and setting

The research was conducted within the Projects and Engineering department of a petrochemical company in South Africa which consists of 274 individuals. Within the Projects and Engineering department, there exists the Solutions and Delivery Hub divisions (comprised of 139 individuals) which employ MTM as a work design. The company was selected using convenience sampling, as the first author is employed there. The electronic questionnaire was completed by 110 of the 139 individuals, resulting in a response rate of 79.14%.

4.3 Data collection instruments[†]

4.3.1 Control variables

Age, education level, years of work experience and organisational tenure, were selected as control variables to account for potential confounding factors within intra-organisational MTM that could influence an individual's performance and learning. This selection was based on previous research conducted by Ng and Feldman [84], Deng et al. [85], Sturman [86], Ng and Feldman [87], Seibert et al. [88] and Cerasoli et al. [89].

[†] The comprehensive research instrument employed in this study is available from the authors upon request.

4.3.2 Degree centrality

Degree centrality within intra-organisational MTM was measured using two metrics. For the first measure of degree centrality, each respondent was asked to indicate the total number of teams within intra-organisational MTM the respondent had simultaneously been involved with in the past six months. A similar approach was adopted by Chan et al. [7], where the total number of MTM each respondent was extensively involved in was used as a measure of the number of multiple team memberships. For the second measure of degree centrality, each respondent was asked to indicate the total number of individuals the respondent had worked extensively with on a weekly basis in the intra-organisational project teams the respondent had been involved with in the past six months.

4.3.3 Trust

Trust within intra-organisational MTM was assessed using the Interpersonal Trust Scale (ITS) developed by McAllister [90] to measure trust between individuals in interpersonal relationships, particularly in the workplace. The ITS consists of eleven items, six of which assess cognition-based trust and five of which assess affect-based trust [90], [91]. The Cronbach's alpha in the original study conducted by McAllister [90] was 0.9 for the ITS [90], [91]. This research instrument was chosen as it has been used extensively in research to measure trust within organisational studies [91], [92], [93].

4.3.4 Individual performance

Individual performance was assessed using a modified version of Podsakoff and MacKenzie's [94] five-item scale for in-role job performance, as adapted by Janssen [95]. This scale specifically evaluates standard job performance, emphasising the employee's adherence to the organisationally defined role expectations [96], [97]. The Cronbach's alpha for the individual performance measures in the original study conducted by Janssen [95] was 0.85 [95], [97]. This research instrument was chosen as it has been used extensively in research to measure individual performance within organisational studies [97], [98], [99].

4.3.5 Individual learning

Individual learning was measured using the nine items developed by Sujan et al. [100]. This research instrument was chosen as it has been used extensively in research to measure individual learning within the MTM context [7], [101]. The Cronbach's alpha for the individual learning measures in the original study by Sujan et al. [100] was 0.81.

5 RESULTS[‡]

5.1 Reliability analysis

Reliability analyses were conducted on the research instruments employed to measure trust, individual performance, and individual learning, yielding Cronbach's alpha values of 0.821, 0.700 and 0.820, respectively. A study conducted by Hair et al. [102] concluded that the minimum acceptable value (i.e., Cronbach's alpha) to demonstrate sufficient internal consistency is 0.7.

[‡] The comprehensive set of results are available from the authors upon request.

5.2 Hypothesis testing

The hypotheses proposed in the conceptual model were tested using the statistical techniques of correlation and multiple regression analyses.

5.2.1 Correlation analysis

From the results of the Spearman's correlation analysis, the following was observed:

- The number of teams within intra-organisational MTM, has a negligible correlation with both individual performance (r = 0.029) and individual learning (r = -0.12).
- The number of individuals within intra-organisational MTM, has a significant weak positive relationship with individual performance (r = 0.227; $p < 0.05$) and a negligible correlation with individual learning (r = 0.083).
- Trust within intra-organisational MTM has a significant moderate positive relationship with individual performance (r = 0.324; $p < 0.01$) and a significant weak positive relationship with individual learning (r = 0.299; $p < 0.01$).

5.2.2 Multiple regression analysis

Model 1 examined the direct and linear relationships between the control variables, and the dependent variables, i.e., individual performance and individual learning.

Model 2 evaluated the additional influence of the first independent variable i.e., degree centrality, which was measured using two metrics, namely, the number of teams within intra-organisational MTM, and the number of individuals within intra-organisational MTM.

Model 3 evaluated the additional influence of the second independent variable i.e., trust within intra-organisational MTM, on the dependent variables. According to Miles [103] and Russo and Stol [104], a variance inflation factor (VIF) below ten suggests that multicollinearity is not a concern. The results of the regression analyses for both dependent variables yielded acceptable VIF values.

From the results of the multiple regression analysis, the following was observed:

- The number of teams within intra-organisational MTM has no statistically significant influence on individual performance in both Model 2 (β = 0.057) and Model 3 (β = 0.083).
- The number of individuals within intra-organisational MTM has a moderately significant weak positive influence on individual performance (β = 0.223; $p < 0.05$) in Model 2 but no statistically significant influence on individual performance in Model 3 (β = 0.149).
- The number of teams within intra-organisational MTM has no statistically significant influence on individual learning in both Model 2 (β = -0.072) and Model 3 (β = -0.044).
- The number of individuals within intra-organisational MTM, has no statistically significant influence on individual learning in both Model 2 (β = 0.154) and Model 3 (β = 0.071).
- Trust within intra-organisational MTM has a highly significant moderate positive influence on individual performance (β = 0.330; $p < 0.01$), and a highly significant moderate positive influence on individual learning (β = 0.366; $p < 0.01$).

As the number of individuals within intra-organisational MTM was observed to have a moderately significant weak positive influence on individual performance, the statistical significance of the negative slope of the hypothesised curvilinear relationship between degree centrality and individual performance was tested. However, the results from the multiple regression analysis for the negative slope of the curvilinear relationship concluded that the number of individuals within intra-organisational MTM has no statistically significant influence on individual performance (β = 0.046).

5.3 Discussion of results

Hypothesis H1 was not supported based on the results of the correlation and multiple regression analyses for both measures of degree centrality within intra-organisational MTM. This is inconsistent with previous research by Van de Brake et al. [6], Kao et al. [103], Badi et al. [104] and Lechner et al. [105]. The discrepancies in the research findings may be attributed to the specific context of the research within a petrochemical company in South Africa, where the nature of work and organisational culture might mitigate the negative impacts of high degree centrality on individual performance. This context-specific dynamic underscores the complexity of the relationship between degree centrality and individual performance, suggesting that different environments can yield varying outcomes. The significant weak positive relationship observed between the second measure of degree centrality, i.e., the number of individuals within intra-organisational MTM, and individual performance is consistent with an empirical study conducted by Ahuja et al. [106]. This consistency may stem from the shared focus on intra-organisational dynamics, where centrality facilitates access to information, resource mobilisation, and enhanced collaboration.

Based on the results of the correlation and multiple regression analyses for both measures of degree centrality within intra-organisational MTM, hypothesis H2 was also not supported. This is inconsistent with previous research by Van de Brake et al. [6], Rishani et al. [74] and Chan et al. [7]. The discrepancies in the research findings may be attributed to the unique characteristics of the study's sample. The petrochemical industry has distinct dynamics and challenges that may differ from those in other sectors, potentially affecting how team members interact and learn from one another. Furthermore, the organisational culture and external pressures (such as organisational changes taking place during the research study) might have impacted the relationship between degree centrality and learning. The aforementioned studies, which also examined individual-level MTM within the intra-organisational context, utilised larger and more diverse samples, providing a more generalised understanding of the relationship in different contexts.

Hypotheses H3 and H4 were fully supported based on the results of the correlation and multiple regression analyses for trust within intra-organisational MTM. This is consistent with previous research conducted by Conlon and Mayer [77], Morales-Sánchez [78], Ning and Jin [77], Nahapiet [81], Ring and Van de Ven [68], Safari et al. [80], and Luhmann [82] as discussed earlier.

The findings from Model 3 of the multiple regression analyses indicate that the influence of degree centrality within intra-organisational MTM on individual performance and learning becomes insignificant. This suggests that trust within intra-organisational MTM (an element of the relational dimension of social capital) has a more significant influence on individual performance and learning compared to degree centrality (an element of the structural dimension of social capital). This emphasises the importance of strong ties over mere structural connections in social networks. The distinction between strong and weak ties, as articulated by Granovetter [107] in his influential work and referenced by numerous researchers [21], [33], [108], [109], further supports the argument that relational elements of social capital, such as trust, are paramount. Strong ties, characterised by frequent interactions and emotional closeness, are crucial for providing support and fostering a sense of belonging [110].

6 CONCLUSION

6.1.1 Theoretical and practical implications

The literature reviewed suggests that despite the widespread occurrence of MTM within organisations, there exists minimal empirical exploration of the impact of relationships within

intra-organisational MTM on both individual performance and learning. This lack of empirical exploration is notable given the potential for these relationships to significantly impact both individual performance and learning. Hence, the results of this research study contribute to alleviating the scarcity of empirical exploration of the impact of relationships within intra-organisational MTM on both individual performance and learning.

Should project managers wish to enhance either individual performance or individual learning, the findings of this study suggest that the establishment of trust within intra-organisational MTM is of greater benefit than the size of an individual's network (i.e., degree centrality) within intra-organisational MTM.

6.1.2 Recommendations for future research

Despite the study's theoretical and practical implications, the study has some limitations that can guide future research. Firstly, the research was conducted within the Projects and Engineering division of a South African petrochemical company using self-reported questionnaires, which may affect the generalisability of the findings. Future research could consider extending the findings of the study to diverse professional environments in different countries and incorporate multiple data sources (e.g., interviews, observational data, or archival records) to enhance validity.

Secondly, the study concluded that only the second measure of degree centrality, i.e., the number of individuals within intra-organisational MTM, has a statistically significant weak positive influence on individual performance, while for the first measure of degree centrality, i.e., the number of teams within intra-organisational MTM, there were no statistically significant relationships observed. Additionally, no statistically significant relationships were observed between the degree centrality of an individual within intra-organisational MTM and the individual's learning for both measures of degree centrality. Existing research on the aforementioned relationships is mixed, suggesting that these relationships may be complex and influenced by various factors. Future research could therefore consider reproducing the findings of the study to better understand the nuances of these relationships. Moreover, this study employed linear regression and correlation analysis. The choice of statistical methods was guided by the research questions and the available dataset. While these techniques provided a clear test of the hypothesised relationships, complementary approaches, such as social network analysis, could offer further insights.

Lastly, due to practical constraints, only a restricted set of variables was included in this study, which examined how relationship dynamics in intra-organisational MTM influence individual learning and performance, focusing on two elements of social capital, namely degree centrality and trust. Other factors, such as temporal misalignment, context switching, and membership variety, for example, also influence individual performance and learning [2], [3], [7]. Future research could consider extending the findings of the study to include these factors, explore inter-organisational MTM, incorporate the team and organisational levels, and include other elements of social capital. Since trust emerged as the most dominant predictor, investigating its development in this industry is recommended to gain deeper insights.

ABSTRACT

The study outlines a systematic literature review that examines the historical progression and integration of design thinking into engineering education curricula. It emphasizes the importance of understanding how design thinking has been adopted, adapted, and institutionalized over time to foster innovation, creativity, and human-centered problem-solving skills among engineering students. The review analyzes scholarly sources from various databases, highlighting key trends, milestones, and pedagogical shifts from the mid-20th century to the present. It pays particular attention to the evolving definitions of design thinking, teaching strategies, and alignment with learning outcomes such as interdisciplinary collaboration and empathy. The findings reveal a shift from traditional technical instruction to more integrative, student-centered approaches, though challenges like curriculum design and faculty training persist. Overall, the review offers helpful suggestions for educators, curriculum designers, and policymakers to enhance the long-term viability and impact of design thinking in engineering education.

Keywords: Design thinking, Integration, Curricular development, engineering education, pedagogy

1 INTRODUCTION

Engineering plays a crucial role in global development, underpinning economic growth, social stability, and sustainable innovation [1, 2]. As UNESCO observes, "engineering drives social, economic, and human development" and is a "major factor in innovation [2]. Consequently, high quality engineering education **is i**mperative to address worldwide challenges. Major issues facing engineering education today include outdated curricula and teaching methods, as well as the need to develop students' problem-solving abilities, lifelong learning habits, and soft skills such as teamwork and communication [1]. At the same time, engineers must be prepared to tackle 21st-century challenges (e.g. climate change, global health, and digital transformation) with interdisciplinary and human-centred approaches. In this context, UNESCO stresses that enabling future engineers to "design solutions for local and global challenges" is critical [3]. Recent engineering education frameworks therefore emphasize holistic, systems-oriented thinking and alignment with the UN Sustainable Development Goals (SDG) [4]. For example, engineering curricula are increasingly moving toward hands-on, project-based learning (PBL) and interdisciplinary teamwork to foster innovation and address complex societal problems.

Design thinking (DT) has emerged as a prominent pedagogical strategy to meet these evolving demands. It is broadly defined as a human-centred, iterative problem-solving approach that prioritizes creativity and the use of multiple disciplines [5]. In practice, DT involves empathizing with users, rapid prototyping, and testing solutions to ensure effectiveness and innovation [5]. Leading engineering institutions have championed this approach: for instance, Stanford University adopted "design thinking" to combine creative and scientific cognition in its engineering programs [5]. This approach mirrors how designers work and is intended to equip students with flexible, designedly problem-solving skills [5].

1.1 Historical Evolution of Design Thinking in Engineering Education

A major paradigm shift has occurred with the introduction of DT into engineering education, moving away from conventional, theoretically oriented curricula and toward more hands-on, application-based learning opportunities. In the past, engineering education frequently ignored the creative and humanistic components of problem-solving in favour of a strong mathematical and scientific foundation. The emergence of DT as a formal methodology can be traced back to the mid-20th century when faculty at Stanford began introducing creative design practices into engineering courses [6]. In 1957, Professor John E. Arnold initiated a "design revolution" at Stanford, using psychology and systems thinking to teach engineers creative problem solving [7]. Soon after, Arnold and Robert McKim launched Stanford's Product Design program (circa 1958), emphasizing visual thinking, sketching, prototyping, and a human-centred approach to design [7]. By the 1970s and 1980s, the term "design thinking" appeared in the education discourse, reflecting a shift toward iterative, user-focused design processes. In the 1990s, Stanford formalized core design-thinking principles (e.g., need-finding, ambidextrous thinking, and iterative prototyping) as part of its engineering curriculum [8]. Notably, these practices extended beyond individual studios to embrace a "whole person" design mentality. In 2005, Stanford further codified this evolution by founding the Hasso Plattner Institute of Design (the d.school), an interdisciplinary hub focused on creativity and innovation in problem-solving [7].

This Stanford-led tradition helped inspire other institutions worldwide. By the early 21st century, many universities began embedding DT into engineering courses and programs. Leading engineering schools introduced first-year design courses, design clinics, and project-based modules that explicitly teach designedly habits of mind [5]. Empirical studies and reports note that such integration tends to improve student engagement and broaden skill sets [5]. In short, DT has evolved from an experimental pedagogy to a mainstream element of

engineering education, reflecting a historical trajectory from individual design courses (mid-20th century) to cross-disciplinary curricula (2000s onward) across the globe.

1.2 Problem Statement

Despite the evident interest in DT as an educational paradigm, its historical development and curricular integration in engineering remain underexplored. Existing literature often focuses on case studies of individual courses or projects rather than providing a unified historical account. As one review notes, there is a clear "need for a systematic review of the literature" on DT in engineering education to map its current state and future directions [5]. Without such a perspective, educators and researchers lack a comprehensive understanding of how DT has been incorporated into curricula over time and what milestones have shaped its adoption.

1.3 Objectives and Significance

This paper strives to fill the gap by conducting a historical literature review of DT integration in engineering curricula. Its objectives are to identify key steps and milestones in this evolution, to synthesize how the concept has changed in engineering contexts, and to highlight current trends and future opportunities. By bringing together disparate studies and historical records, the review will provide a global perspective on the ways engineering programs have responded to calls for creativity and innovation. The significance of this work lies in informing educators and policymakers: understanding the trajectory of DT integration can guide curriculum development and teaching practices that better prepare engineers to address complex global problems [5].

1.4 Research Questions

Building on the above background and objectives, this systematic review addresses the following research questions:

1. How has the concept of DT evolved, particularly within the context of engineering?
2. What are the key stages and milestones in the integration of DT in engineering education?
3. What are the current trends and future directions of DT in engineering curricula?

These questions will guide the historical analysis and literature synthesis in the ensuing review.

2 THEORETICAL BACKGROUND

DT has emerged as a significant paradigm in innovation-oriented education and practice, with roots spanning multiple disciplines, including architecture, industrial design, and business. The concept began to formalize in the mid-20th century when scholars and practitioners sought to understand and replicate the creative problem-solving processes of professional designers.

Historically, the foundations of DT can be traced to Herbert Simon's seminal work, The Sciences of the Artificial (1969), where he emphasized design as a way of transforming existing conditions into preferred ones [9]. Around the same time, architects and industrial designers began articulating methods of creative exploration, iterative prototyping, and user-centric design. Christopher Alexander made contributions through his work on design patterns and structure in architecture [10], while Robert McKim at Stanford developed visual and ideation-based methods in engineering and product design [11].

In the 1990s, companies like IDEO helped make DT more popular in the business world. They did this by promoting it as a structured, repeatable innovation process based on empathy,

ideation, and rapid prototyping [12]. The Stanford d.school model formalized this approach by breaking DT down into five main steps: empathize, define, ideate, prototype, and test [7].

Scholars have provided diverse definitions of DT over time. Brown refers to it as “a discipline that employs the designer’s sensibility and methods to align people’s needs with technological possibilities” [13], whereas Cross defines it as a distinct cognitive style and process linked to creativity in design [14]. Even though they all focus on different things, they all agree that DT encourages people-centred, iterative, and solution-focused ways of dealing with difficult problems.

DT is especially useful in engineering education because it focuses on innovation and user needs. As engineering issues become more connected to social, environmental, and ethical issues, there has been a growing call for teaching methods that encourage creativity, empathy, and working together across fields [15]. DT provides a structured framework for meeting these expectations, which is in line with educational goals like ABET outcomes and the development of skills for the 21st century [16].

So, the need for engineering to be innovative, useful in the real world, and focused on people has made it easier for DT to be used and grow in curricula around the world.

3. METHODOLOGY

3.1 Search Strategy and Inclusion/Exclusion Criteria

This systematic literature review (SLR) employed a comprehensive search strategy informed by the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines to identify significant scholarly articles regarding the incorporation of DT in engineering education. The search included peer-reviewed articles that were published between 1950 and 2025. To ensure a wide range of coverage across time and fields, only peer-reviewed journal articles and conference proceedings were included [17]. This meant that theses, reports, and grey literature, which are not peer-reviewed, were not included. The studies were selected for their examination of the utilization, instruction, or evolution of DT in engineering education, which corresponded with the research's aim to identify methodologies or the historical progression of DT within engineering educational contexts, in alignment with the research objectives.

3.2 Databases Used

The following electronic databases were utilized to retrieve relevant literature: IEEE Xplore, ERIC, ScienceDirect, Semantic Scholar, Scopus, and Google Scholar. These databases were selected for their extensive coverage of engineering education and interdisciplinary scholarly works, ensuring a comprehensive and diverse literature base.

3.3 Keywords and Search Terms

The search employed a combination of keywords and controlled vocabulary variations to capture the multifaceted nature of DT. The primary search terms included: "Design thinking", "engineering education", "curriculum development", "pedagogy", "innovation", "human-centred design", "problem-solving", and "history of design thinking". Boolean operators and truncation were used to refine the search strings, such as "design thinking" AND "engineering education" or "curriculum development" OR "pedagogy" to encompass related concepts and methodological approaches. In the end, with the help of the Publish or Perish software version 8.0, the following search string was used: "History of design thinking" OR "design thinking" AND "engineering education" AND "curriculum development".

3.4 Screening Process and Data Extraction Procedures

Initially, we imported all retrieved articles into Rayyan online systematic review software, which facilitated efficient and blinded screening by multiple reviewers, thereby minimizing selection bias. Title and abstract screening were conducted independently by three reviewers to assess relevance based on predefined inclusion and exclusion criteria. We included studies that explicitly discussed aspects of the evolution of the integration of DT within engineering curricula, its historical development, or pedagogical methods.

Table 1: Total number of articles from each database and the search terms used

Database	Search terms	Search string	No. of articles	Search date
Scopus	Primary search terms - title, abstract and keywords	"History of design thinking" OR "design thinking" AND "engineering education" AND "curriculum development"	24	01 June 2025
Google Scholar	Primary search items - title, abstract and keywords	"History of design thinking" OR "design thinking" AND "engineering education" AND "curriculum development"	184	01 June 2025
Symantic Scholar	Primary search terms - title, abstract and keywords	"History of design thinking" OR "design thinking" AND "engineering education" AND "curriculum development"	6	01 June 2025
Science Direct	Primary search terms - title, abstract and keywords	"History of design thinking" OR "design thinking" AND "engineering education" AND "curriculum development"	6	01 June 2025
IEEE Explore	Primary search terms - title, abstract and keywords	"History of design thinking" OR "design thinking" AND "engineering education" AND "curriculum development"	4	01 June 2025
ERIC	Primary search terms - title, abstract and keywords	"History of design thinking" OR "design thinking" AND "engineering education" AND "curriculum development"	7	01 June 2025

The search yielded a total of 224 articles. The study selection process followed a three-phase approach, as outlined below:

Phase 1: Removal of duplicates

Phase 2: Title screening

Phase 3: Abstract screening. Following this step, we selected 14 studies for full-text review and inclusion.

3.5 Prisma flow diagram

The screening process involved importing 224 articles from six databases into Rayyan online systematic review software, which facilitated efficient and blinded screening by multiple reviewers, thereby minimizing selection bias. The PRISMA flow diagram in Table 2 illustrates the stepwise approach for this review.

Table 2: Prisma flow diagram

Phase	Records Count
Records identified through database searching (IEEE, Scopus, etc.)	224
Duplicate removed	10
Records screened (titles/abstracts)	214
Records excluded (non-relevant, outside scope)	200
Full-text articles assessed for eligibility	14
Full-text articles excluded (low quality, insufficient data)	10
Studies included in final synthesis	8

Following screening, full-text articles were obtained and subjected to data extraction, which involved systematically recording information on the publication year, study context, methodological approach, specific pedagogical strategies used, key findings related to the evolution of DT, and reported outcomes. Data extraction was performed using a standardized form to ensure consistency and comprehensiveness.

3.5 Quality Assessment of Included Studies

The methodological quality and relevance of the included studies were evaluated using adapted versions of established appraisal instruments, specifically the Critical Appraisal Skills Program (CASP) checklists and the Joanna Briggs Institute (JBI) critical appraisal tools [18]. Assessment criteria encompassed the clarity of the research question, suitability of the study design, validity and reliability of data collection methods, and transparency of reported findings. To ensure consistent application of inclusion criteria, three reviewers independently screened each article and classified them as “Included,” “Excluded,” or “Maybe.” Discrepancies were addressed through a consensus meeting, during which reviewers discussed their assessments and resolved disagreements. Final decisions on contested articles were resolved through discussion.

4. FINDINGS: THE EVOLUTION OF DESIGN THINKING INTEGRATION

This section shows the results of the systematic literature review, which looks at how DT integration in engineering curricula has changed from the middle of the 20th century to now. The results, which are shown in Table 3, are arranged in chronological order to show the most important steps and milestones that have shaped the development of DT in engineering education.

Table 3: Main results of the selected studies

Reference	Summary	Historical Evolution	Key Stages and Milestones	Current Trends
[19]	COVID-19's impact on education and the shift to digital learning	Traditional → Online → Systemic reform	Online shift, tech use, mental health, policy support, AI/VR integration	Hybrid models, VR tools, curriculum reform
[20]	DT enhances 21st-century skills in education	Montessori to modern empathy-based approaches	Empathize, Define, Ideate, Prototype, Test	Integration in K-12 and higher ed, teacher training
[21]	Engineering education reform for global challenges	DT for innovation and leadership	Foresight, protovation, open authorship	Innovation focus, systems thinking, entrepreneurship
[22]	REEdI project uses DT for agile engineering curriculum	DT evolution from 1969 to 2018	Understand to Continuous Improvement (8 steps)	Industry-aligned, flexible, personalized learning

[23]	UK engineering education and DT integration	From 1980s design inclusion to modern standards	Empathize to Test (5 steps)	Student-centred, PBL, CDIO, discipline-specific DT
[24]	Experiential DT course for freshman engineers	Post-WWII to ethics-focused experiential learning	Empathy & Ethics to Testing	Real-world problems, early DT exposure, civic partnerships
[25]	Harvard School of Engineering and Applied Sciences (SEAS) as a model for multidisciplinary DT	Founded 2007, rapid growth, no departments	Curriculum reform, ES96/ES100, design integration	Interdisciplinary, innovation, entrepreneurial training
[26]	DT for curriculum innovation in higher ed	From 1960s design theory to business innovation	Immersion, Framing, Testing	Outcome-based, student-centred, constructive alignment

4.1 Chronological overview

Based on the information provided in the papers, here is a chronological overview of how DT has changed in engineering education. The chronological overview shows how DT has changed in engineering education over time.

4.1.1 Early Origins

DT in engineering education originated in the late 1980s, when design was recognized as a fundamental element of engineering curricula [23]. In the 1990s, there was a change from teaching engineering through hands-on experience to focusing more on scientific analysis and mathematical modelling [24].

4.1.2 2000s: Emergence of Design Thinking

In the early 2000s, DT began to gain popularity as a way to encourage innovation. Roger Martin from the Rotman School of Management was one of the first people to use it in business settings [26]. At this point, engineering education started to see DT as an important way of thinking that needed to be developed [23]. This acknowledgment resulted in the incorporation of DT principles into engineering curricula and the establishment of interdisciplinary programs.

4.1.3 Mid-2000s: Integration into Engineering Curricula

Some universities started to include DT more formally in engineering programs by the middle of the 2000s. For instance, Harvard's School of Engineering and Applied Sciences (SEAS) was founded in 2007 to focus on research that crosses disciplines and classes that do the same [25]. SEAS aimed to create "T-shaped" engineers who were experts in one field but knew a lot about many others [25].

4.1.4 2010s: Expansion and Refinement

There was a lot of growth in the use of DT in engineering education in the 2010s. A lot of programs started to focus on team-based problem solving and perspectives from different fields [24]. PBL became a model for future curricula, and it often used DT principles [23]. There was a stronger push for learning by doing in engineering classes [22]. User-centred design principles began to be included in engineering programs across the board [22].

4.1.5 Recent Developments

More recently, there has been a continued evolution of DT in engineering education. Programs are exploring the integration of DT with emerging capabilities in online learning, blended learning, and technologies like AR/VR [22]. There is an increased focus on partnerships with industry to inform engineering curricula and research agendas [22]. Recent approaches emphasize the development of soft skills, transversal skills, and a more holistic view of engineering education [22]. There is a trend toward more flexible, personalized learning

environments and the transformation of learning experiences into capabilities for students [23].

This evolution reflects a growing recognition of the need to prepare engineers who can address complex, multidisciplinary challenges in an increasingly technological and interconnected world.

4.2 Key stages and milestones

This section also examines the different approaches to DT that have been adopted in engineering education, such as the Stanford d.school model, the Double Diamond model, and other variations.

Based on the findings, thematically, highlight the key stages and milestones in the development of DT in engineering education.

4.2.1 Recognition of Design in Engineering Education

The late 1980s marked the beginning of design being considered an integral component of engineering curricula [19]. This recognition laid the foundation for the future development of DT in engineering education.

4.2.2 Shift Towards Analytical Focus

In the 1990s, engineering education experienced a shift toward scientific analysis and mathematical modelling, leading to a decrease in hands-on engineering education [24]. This change created a gap that would later be addressed by DT approaches.

4.2.3 Emergence of Design Thinking Methodology

In the early 2000s, Roger Martin from the Rotman School of Management [26] and others helped make DT a separate method. This method was first used in business settings, but it soon had an effect on engineering education.

4.2.4 Integration into Engineering Curricula

The founding of Harvard's SEAS [25] in 2007 was a big step forward. SEAS focused on research that crossed disciplines and courses that did the same. The goal was to make "T-shaped" engineers who were experts in one area and had a broad range of knowledge in others [25]. SEAS also aimed to foster a culture of innovation and entrepreneurship.

4.2.5 Emphasis on Multidisciplinary Approach

In the 2010s, engineering education put more and more emphasis on working together as a team and looking at problems from different points of view [24]. This change showed that people understood that complicated problems in society need solutions from many different fields. This change has continued to affect how engineers are trained and what kinds of problems they can solve.

4.2.6 Adoption of Project-Based Learning

PBL evolved into a model for future curricula, often using DT ideas [23]. Students got to practice using DT on real-world problems with this method. Students can learn how to think critically and solve problems by using PBL, which gets them ready for the challenges of the modern job market.

4.2.7 Focus on Human-Centred Design

Engineering programs started to include user-centred design ideas in all their classes [25]. This change made it clear how important it is to have empathy and understand what users want when designing something.

4.2.8 Integration with Emerging Technologies

Recent developments include the use of DT with new technologies like AR/VR and online learning platforms [22]. The goal of this integration is to improve the learning experience and get students ready for new technologies in the field.

4.2.9 Industry Collaboration

One important step in the development of DT in engineering education has been the growing emphasis on working with businesses [25]. The purpose of these collaborations is to make sure that engineering curricula and research agendas are relevant to real-world problems.

4.2.10 Emphasis on Soft Skills and Holistic Education

Recent methods have focused more on building soft skills, transversal skills, and a more complete view of engineering education [22]. This change shows that communication, teamwork, and adaptability are just as important as technical skills.

4.2.11 Curriculum Flexibility and Personalization

The latest trend in engineering education is to make DT more flexible and tailored to each student [23]. This approach seeks to convert learning experiences into competencies, equipping students for the various challenges they may encounter in their professional lives.

5. DISCUSSION

5.1 Trends and Future Directions

This section presents the findings of the literature review on DT education. It identifies key trends and patterns by examining how the findings change over time in the studies, rather than using a separate analysis. The analysis further explores the advantages and disadvantages of integrating DT into engineering curricula and discusses the implications of these results for future curriculum development and pedagogical approaches

A major trend is the use of DT in many different areas of engineering. Universities are designing programs that encourage people from different engineering fields and even non-engineering fields to work together [19, 22]. The purpose of this approach is to prepare students for the complex, interdisciplinary challenges they will encounter in their future careers [25]. When students learn about DT in their engineering classes, they acquire a range of skills. This analysis emphasizes the acquisition of foundational skills, including critical thinking, effective technical communication, and problem-solving abilities. This interdisciplinary approach fosters creativity and innovation, enabling engineers to better address the evolving needs of society. These findings significantly impact curriculum development by highlighting the importance of transitioning from traditional, isolated teaching methods to more collaborative and integrated approaches. Innovative teaching methods in engineering education play a crucial role in ensuring that graduates are equipped to tackle future challenges effectively.

An increasing number of engineering programs are incorporating PBL and experiential learning methods that are based on DT principles [23, 24]. These methods give students more advanced skills, including creative thinking and the ability to apply knowledge to complex, real-world problems [25]. As a result, students are developing technical competencies along with vital interpersonal skills, including effective communication, teamwork, and critical thinking. By fostering a culture of innovation and creativity in engineering education, schools are equipping their students with the adaptive skills required to succeed in a constantly evolving and increasingly complex world. Ultimately, the transition towards more collaborative and hands-on learning in engineering programs is cultivating engineers who are versatile, creative, and adept at addressing future challenges with confidence.

Engineering programs are putting more and more focus on human-centred design principles [22]. This trend shows that people are starting to realize that engineers need to be able to put themselves in the shoes of their users and understand their needs to come up with good solutions [24]. Engineering students are better prepared to solve real-world problems and come up with solutions that are not only technically sound but also meet the needs of the end-users when they learn about human-centred design. This method helps engineers think about the moral effects of their work and how engineering projects affect society. Because of this, graduates are ready to not only be great at their technical skills, but also to use their creative thinking and problem-solving skills to make the world a better place.

Engineering programs are looking into how to combine DT with new technologies like VR, AR, and online learning platforms [22]. The goal of this integration is to improve the learning experience and get students ready for new technologies in the field [25]. It also wants to help students be more creative, solve problems, and come up with new ideas.

More and more, universities are working with businesses to help them make decisions about their curricula and give students real-world design problems to solve [25]. These partnerships make sure that engineering education stays up-to-date and meets the needs of the industry [24]. This way, students are better prepared for the job market and can use what they've learned in real-world situations.

Recent trends indicate an increased emphasis on cultivating soft skills in conjunction with technical proficiencies [22]. DT is being used to help people learn important skills for the modern workplace, like how to communicate, work as a team, and be flexible [25]. Furthermore, partnerships with businesses give students valuable chances to meet people and find jobs after they graduate. As the need for well-rounded professionals grows, the focus on soft skills in engineering education becomes more and more important. Teachers are giving students the tools they need to do well in a competitive job market by using DT and other new ways of teaching. In general, these partnerships between schools and businesses are important for getting the next generation of engineers ready for the job market.

There is a movement toward more flexible and personalized learning environments in engineering education [23]. This approach allows for customization of the learning experience to meet individual student needs and interests while incorporating DT principles [26]. Furthermore, studies have demonstrated that this approach enhances student engagement and motivation.

In engineering education, there is a push for learning environments that are more flexible and tailored to each student [26]. This trend makes sure that DT is used in a way that fits with the goals of the program and the specific learning outcomes [26]. Ultimately, this results in graduates who are better prepared for the demands of the workforce.

This section also identifies emerging trends in DT education, such as the use of digital tools and technologies, the integration of DT with other disciplines, and the emphasis on social impact and sustainability. Finally, it proposes future directions for research and practice in DT education.

There is a growing emphasis on integrating sustainability and social responsibility into engineering curricula via design thinking methodologies [24]. This trend shows that more people are aware of how important engineers are in solving global problems [25]. This trend shows that more people are becoming aware of the important role engineers play in solving global problems. It also suggests that engineering education needs to be more complete.

To improve DT education, engineering programs are putting in place ongoing assessment and accreditation processes [21]. This trend ensures that curricula remain up-to-date and effective in preparing students for the evolving demands of the engineering This trend makes sure that

curricula stay current and help students get ready for the changing needs of the engineering field [21]. As a result, graduates are better prepared to do well in their careers and make a real difference in the field.

5.2 Potential Applications and Synergies of Design Thinking to Industrial Engineering domains

To further explore into the implications of the findings on the evolution of DT integration in engineering curricula, the exploration of potential applications and synergies of DT within Industrial Engineering (IE) domains like process design, systems thinking, and Lean/Agile educational practices is essential. This will allow us to bridge the gap between our findings and the specific interests of the IE community.

5.2.1 Process Design

DT's human-centered approach can revolutionize process design in IE. Instead of solely focusing on efficiency and cost reduction, incorporating DT principles can lead to more innovative and user-friendly solutions that better meet the needs of stakeholders. Additionally, applying DT to process design can enhance collaboration among cross-functional teams and improve overall project outcomes in IE domains. Focusing on efficiency metrics, DT encourages understanding the needs and pain points of the people involved in the process (workers, customers, etc.). Understanding users and creating prototypes can result in process designs that are efficient, user-friendly, and enhance overall satisfaction. DT can make sure that processes become more adaptable and responsive to changing needs.

5.2.2 Systems Thinking

DT's iterative nature complements systems thinking in IE. Design Thinking (DT) encourages looking at problems from a comprehensive perspective, which fits well with the systems approach. When IE professionals use DT principles, they can grasp the connections and dependencies in complex systems, resulting in more efficient and long-lasting solutions. The human-centered design approach encouraged by DT also emphasizes the importance of considering all stakeholders in a system.

5.2.3 Lean/Agile Educational Practices

DT can enhance Lean and Agile methodologies in IE education. DT's emphasis on iterative development and user feedback aligns with the core principles of Agile. By integrating DT into Lean and Agile courses, students can learn to develop solutions that are not only efficient and cost-effective but also highly responsive to user needs and market demands. DT can provide the "human-centered" lens that ensures Lean/Agile efforts truly deliver value.

5.2.4 Curriculum Innovation

DT can be used for curriculum innovation within IE programs themselves. The principles of immersion, framing, and testing can be applied to design more effective and engaging IE curricula that better prepare students for real-world challenges.

5.2 Limitations and Future Work

This SLR, while conducted rigorously using PRISMA guidelines and Rayyan software for blinded screening by three reviewers to minimize selection bias, is subject to certain limitations. First, the final synthesis included a relatively small sample size of eight studies. While our methodology clearly details the process of narrowing down 224 articles to this final set, this limited number may affect the generalizability of the findings. Second, there is potential for publication bias, as studies with positive or significant results are more likely to be published than those with null or negative findings. Finally, as a systematic review, this study relies on

secondary data, which refers to data collected by other researchers and may inherit the limitations of the original studies.

Future research could address these limitations through a meta-analysis incorporating a larger sample size and by conducting primary research to compare the influence of DT across different engineering subfields. The Rayyan results are available upon request to further demonstrate the strength of our screening process.

6. CONCLUSION

This systematic review underscores the evolving role of DT in engineering education, marking a shift from traditional, discipline-specific instruction toward more holistic, student-centered, and interdisciplinary approaches. The integration of DT has been catalyzed by technological advancements and global disruptions, notably the COVID-19 pandemic, which have accelerated the adoption of digital tools and blended learning environments.

Established frameworks such as the Stanford d.school model, known for its focus on human-centered design thinking, and the Double Diamond, a model for the design process, have provided structured methodologies that support curriculum innovation and pedagogical reform. Notably, DT's human-centered approach can revolutionize process design in IE by understanding the needs and pain points of workers and customers, leading to more adaptable and responsive processes. DT's iterative nature also complements systems thinking in IE, promoting a holistic view and sustainable solutions. Furthermore, DT enhances Lean and Agile methodologies in IE education by providing a human-centered lens that ensures value and responsiveness to user needs. DT can also drive curriculum innovation within IE programs through immersion, framing, and testing.

Looking forward, the movement toward flexible, personalized learning environments and cross-disciplinary collaboration presents significant opportunities for further development. Future research could address these limitations through a meta-analysis incorporating a larger sample size and by conducting primary research to compare the influence of DT across different engineering subfields. Addressing existing barriers through enhanced faculty development, improved assessment strategies, and the strategic use of technologies like artificial intelligence and virtual reality will be essential. Continued empirical research is necessary to evaluate pedagogical outcomes and ensure that DT remains a foundational element in preparing engineers to navigate complex, real-world challenges. The Rayyan results are available upon request to further demonstrate the robustness of our screening process.

Declaration of Generative AI and AI-assisted Technologies in the Writing Process

During the preparation of this work, the authors used QuillBot and Grammarly language and grammar checks. After using these tools, the authors reviewed and edited the content as needed and took full responsibility for the publication.

ABSTRACT

This paper investigates how design thinking (DT) practices influence the development of entrepreneurial self-assurance in engineering students. A qualitative meta-synthesis was used to highlight how DT supports confidence-building through adeptness, reflective feedback, uncertainty tolerance, and problem relevance. The findings indicate that DT supports students to reframe their identities and connect with uncertainty in meaningful ways. Lecturers are encouraged to incorporate DT as a structured yet flexible pedagogical tool that develops creative agency and self-belief. The study offers insight into how engineering education can better supported with the demands of innovation and entrepreneurial thinking in complex, real-world contexts.

Keywords: Design Thinking, Engineering, Entrepreurial mindset

1 INTRODUCTION

Design thinking (DT), emerged as a transformative methodology that is joining creativity and technical expertise. As Leem [1] advocates, DT encourages students combine inovative ideation with technical and analytical problemsolving skills, making it an ideal framework for interdisciplinary education in engineering and design. Panikar [2] confirmed that integrating DT into engineering education promotes an entrepreneurial mindset by allowing students to innovate under constraints and recognise opportunities. DT is seen as an iterative and human-centred approach to problem-solving. As shown by Primario in [3], DT promotes opportunity recognition and innovation confidence among STEM students by enhancing their entrepreneurial self-efficacy through experience-driven pedagogy. DT is playing a relevant role in engineering education, altering the traditional pedagogical practices and opening new pathways for the development of entrepreneurial mindsets among engineering students. Areas, where economic growth and societal progress is high, it cultivates entrepreneurial self-assurance, or entrepreneurial self-efficacy, driven by innovation. This paper examines the relationship between DT experiences and the entrepreneurial self-efficacy of engineering students. This paper focus on how these relationships impact on their ability to identify opportunities, develop new solutions, and manage entrepreneurial challenges.

Entrepreneurial self-efficacy relates to an individual's belief of their capability to successfully perform entrepreneurial tasks. Key competencies underpinning this concept combine market opportunity identification, creative problem-solving, and managing uncertainties typical of entrepreneurial ventures. Individuals showing higher entrepreneurial self-efficacy are more likely to succeed in entrepreneurial activities. While engineering students have strong technical knowledge and rational problem-solving capabilities, these capabilities are not sufficient to navigate entrepreneurial contexts, which also require creativity, adaptability, and confidence. DT, with its foundations in empathy, prototyping, and iteration, proposes a pedagogical approach to develop these necessary entrepreneurial competencies. In [4] Esqueda-Merino confirm that design thinking-based models significantly enhance entrepreneurial self-efficacy in engineering students by immersing them in innovation-focused, real-world problem-solving experiences. By incorporating design thinking into the engineering curricula it can significantly increases students' entrepreneurial self-efficacy, especially in identifying opportunities and building innovation confidence[5].

1.1 Problem Statement

A critical gap in the current literature guides this research. While the benefits of DT in developing creativity and teamwork have been recognised, the specific processes through which DT affects entrepreneurial self-efficacy in engineering students remain underexplored. This paper is addressing this gap by synthesizing qualitative studies to expose how DT interventions is affecting the entrepreneurial self-assurance of engineering students.

The research is grounded by two primary questions:

1. How does engagement in DT develop students' confidence in developing innovative solutions?
2. Which pedagogical strategies amplify design thinking's impact in fostering entrepreneurial self-efficacy among engineering students?

1.2 Significance

The main goal of this research is to provide practical insights for engineering educators aiming to cultivate entrepreneurial mindsets and self-confidence in their students. By synthesizing diverse qualitative studies, the paper develops a comprehensive understanding of how design thinking can empower engineering students for innovative ventures. This work contributes to

the academic dialogue by addressing the incorporation of DT into engineering education and exploring its potential to improve entrepreneurial competencies. Structure

The paper is structured as follows: Section 2 is covering the background on entrepreneurial self-assurance and the role of design thinking in adopting it. Section 3 discuss the methodology used for the meta-synthesis. In section 4 the findings, are discussed in organized key themes and patterns. Section 5 discuss what implications the findings can have on students and offers recommendations for future research. Section 6 concludes the paper.

2 BACKGROUND

2.1 Background: Entrepreneurial Self-Assurance and Design Thinking in Engineering Education

2.1.1 Entrepreneurial Self-Assurance

Entrepreneurial self-assurance, often referred to as entrepreneurial self-efficacy (ESE), is essentially a student's belief in their ability to take a business idea from concept to reality. It links back to Bandura's social cognitive theory and influences how students set goals, take risks, and make decisions[6]. In engineering education, ESE plays a fundamental role in giving students the confidence to turn novel ideas into viable business solutions.

There has been a strong drive in recent studies, showing that entrepreneurship education is key to boosting students' confidence and goals to start a business[7], and[8]. In fact, students who take part in organized entrepreneurship programmes are more likely to consider beginning their own ventures[6].

At DUT, [8]looked into how entrepreneurship education influences the career paths of final-year students. They found that many students became more inspired to follow entrepreneurship. This clearly shows how impactful curriculum design can be in helping students believe in their ability to become entrepreneurs. Looking at the Theory of Planned Behaviour (TPB), we see that apparent behavioural control—basically how much control a student thinks they have—plays a big role in entrepreneurial intentions[6]. On the other hand, [7]connect this to Social Cognitive Theory, indicating how personal beliefs, behaviours, and environments all interact to shape entrepreneurial aspirations. [9]raises the concern that even with institutional support and updated curricula, many engineering students are still not exposed enough to entrepreneurship, and the lack of cross-disciplinary content can hold back their self-belief.

2.1.2 Design Thinking

DT is a hands-on, human-centred method to problem-solving. It promotes creativity, empathy, and continuous improvement through five key steps: empathize, define, ideate, prototype, and test [10], and[11]. In engineering classrooms, DT has become a game-changer, linking the gap between textbook theory and real-world problem-solving[1].

DT forces students to be more innovative and emotionally intelligent. [12]explain that it's not just about coming up with ideas — it's about truly understanding user needs and working with others to solve big, messy problems. This kind of thinking helps students see beyond their technical training.

[9]points out that DT strengthens teamwork, empathy, and leadership — all essential for entrepreneurs. [13]go a step further by showing how DT inspires students through real-world projects that cut across disciplines. With the rise of AI and immersive learning, DT also helps create the kind of future-ready learning spaces we need[14].

At DUT, the IEP department — with support from Finnish partners — hosts DT seminars that prep students with both entrepreneurial skills and a mindset geared toward innovation

(Technology, 2024). These sessions give students real-world exposure and tools for tackling societal problems in creative ways.

2.1.3 Synthesis: Design Thinking as an Incentive for Entrepreneurial Self-Assurance

The link between DT and entrepreneurial self-assurance is a strong one. [15]talk about "imaginative assurance," a type of self-belief tied to innovation, and how DT helps students develop it. Because DT is so iterative and reflective, it helps students embrace uncertainty, learn from failure, and build resilience — all vital for entrepreneurial growth.

At DUT, internal workshops led by the innobiz Centre for Entrepreneurship and Innovation are already using DT as the foundation for teaching entrepreneurship. These efforts show that creativity and confidence can be developed through intentional design. In fact, they're helping shift the entire learning culture toward innovation and self-belief[16].

If we want to prepare our students for today's innovation-driven world, integrating DT into engineering education is not just nice to have — it's necessary.

3 METHODOLGY : META-SYNTHESIS OF QUALITATIVE STUDIES

3.1 Research Design and Approach

This study implements a qualitative meta-synthesis approach to explore how design thinking (DT) experiences foster entrepreneurial self-assurance among engineering students. Grounded in the principles of interpretive synthesis, the study systematically reviews and interprets findings from peer-reviewed qualitative studies published between 2015 and 2025. The methodology uses the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, [17] and incorporates the Enhancing Transparency in Reporting the Synthesis of Qualitative Research (ENTREQ) framework, [18] to ensure transparency and rigor in the synthesis of qualitative research.

3.1.1 Inclusion and Exclusion Criteria

Research papers included in this study were:

1. **Study Type**: Only qualitative studies such as case studies, ethnographic research, phenomenological investigations, narrative inquiries, or mixed-methods studies that report qualitative data.
2. **Focus of Study**: Research examining the relationship between DT interventions and entrepreneurial self-efficacy in engineering disciplines only.
3. **Population**: Participants should be engineering students or undergraduates enrolled in engineering programs.
4. **Intervention/Exposure**: Studies must involve explicit implementation, integration, or investigation of design thinking pedagogies or activities.
5. **Outcomes**: Studies reporting qualitative data related to entrepreneurial self-efficacy, confidence, mindset, opportunities recognition, or similar constructs.
6. **Publication Language**: Studies published in English (or specify other languages if relevant).
7. **Publication Date Range**: Define a specific publication window (e.g., last 10 years) to ensure relevance.

Research papers that were excluded from this study were:

1. **Quantitative-only Studies**: Studies that exclusively employ quantitative methods without qualitative insights.

2. **Non-Engineering Contexts**: Studies focusing on non-engineering student populations unless they explicitly address engineering students.
3. **Lack of Focus on Entrepreneurial Self-Efficacy**: Research not directly examining or discussing entrepreneurial self-efficacy or related constructs.
4. **Theoretical or Literature Reviews**: Studies that are conceptual or review articles without primary qualitative data.
5. **Language**: Studies published in languages other than English (unless translation is feasible and considered).
6. **Interventions Not Involving Design Thinking**: Studies that explore entrepreneurship or innovation without explicit reference or connection to design thinking methodologies.

3.1.2 Search Strategy and Databases

A comprehensive search was conducted across the following databases: Scopus, Taylor and Francis, IEEE Xplore, ERIC, Emarld, and Google Scholar. These databases were selected for their coverage of engineering education, design thinking, and entrepreneurship literature. Boolean search strings were refined iteratively and included terms such as:

"design thinking" AND "entrepreneurial mindset" AND "engineering education"

"entrepreneurship education" AND "self-efficacy" AND "design thinking"

"engineering students" AND "innovation" AND "human-centered design"

Table 1 provides a summary of the number of articles identified in each database with the search terms.

Table 1: Articles from each Data base and search terms used.

Database	Search String Used	Fields Searched	Filters Applied (e.g., Year, Language)	Records Retrieved

3.1.3 Screening process and Data extraction procedure:

All search results were imported into Rayyan for duplicate removal and blinded screening.

The selection process used 4 phases

1. Deletion of duplicate records = 80 initial (endnote)
2. Title screening to remove obvious irrelevant studies

3. Abstract screening based on the inclusion and exclusion criteria.
4. The final phase is the full-text review to confirm suitability of the article.

3.1.4 Prisma Flow Diagram

For the screening process, all search results identified within the 6 databases were imported into Rayyan, an online systematic review software, specifically used to facilitate efficient and blinded screening by multiple reviewers, minimizing biased selection process.

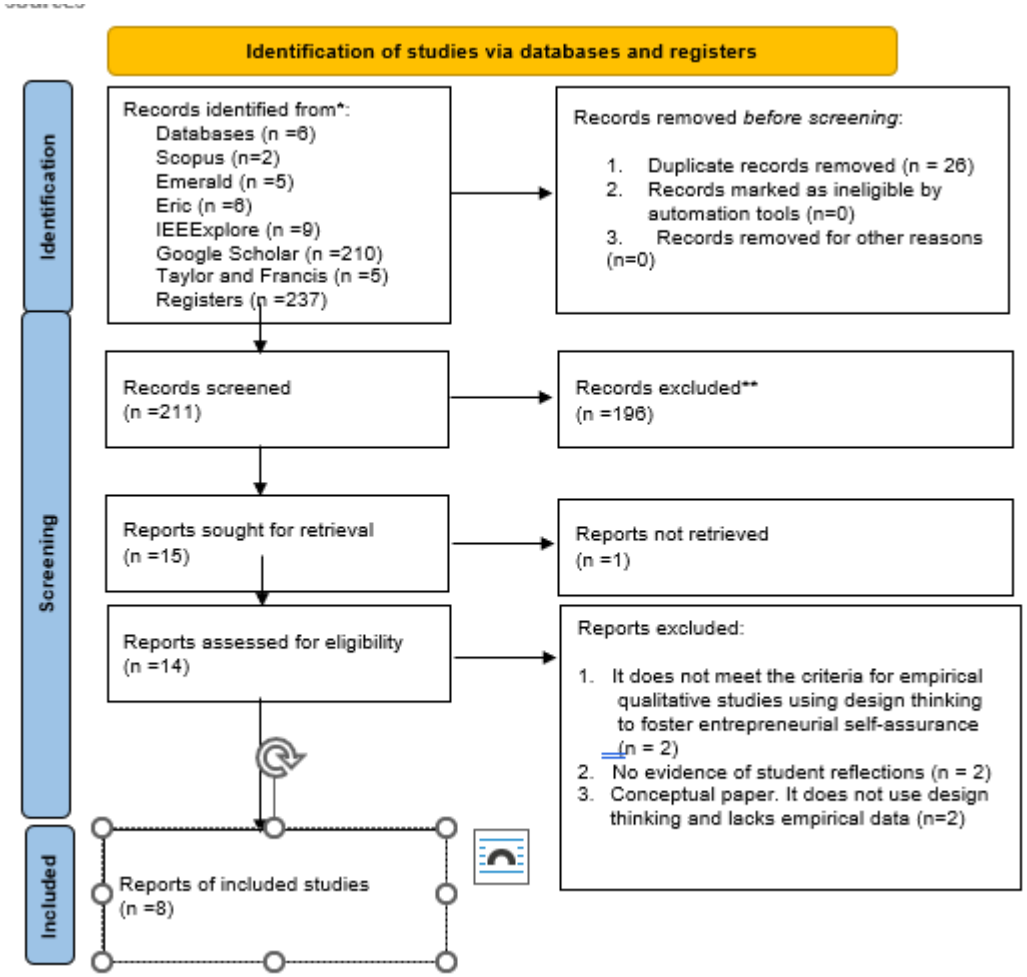

Figure 1: Prisma Flowdiagram

3.1.5 Data Extraction and Coding

Data from the included studies were extracted using a standardized extraction form capturing: Author(s), publication year, and country,

1. Research context and participants,
2. Design thinking frameworks applied
3. Reported outcomes related to entrepreneurial confidence or self-efficacy,
4. Key pedagogical strategies employed.

Themes were identified inductively using thematic analysis, with codes developed iteratively based on emerging patterns across studies.

The methodological quality of each study was evaluated using a combination of the Critical Appraisal Skills Programme (CASP, 2017) checklist. and the Joanna Briggs Institute (JBI) qualitative appraisal tool, (table 2). These tools evaluated each study's research clarity, methodological rigor, data credibility, ethical considerations, and transparency of findings. Only studies rated as moderate to high quality based on these criteria were included in the final synthesis to ensure the reliability and trustworthiness of conclusions.

Table 2: Quality Appraisal Summary Using CASP and JBI Tools

Article Title	Clear Aims	Methodology	Design Fit	Recruitment	Data Rigor	Reflexivity	Ethics/Bias	Findings Clear	Contribution	Score (/10)	Rating
Influence of entrepreneurial mindsets on student design problem framing	Yes	Yes	Yes	Moderate	Yes	Moderate	Yes	Yes	High	9	High
Design thinking in engineering education: Evaluating the impact on student entrepreneurship competencies	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	High	10	High

Using an open-ended socio-technical design challenge	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	High	10	High

Findings were synthesized thematically to construct a narrative summary of how design thinking pedagogies influence entrepreneurial self-assurance among engineering students.

4 FINDINGS

This synthesis drew from the eight studies that passed the CASP quality appraisal, that meet our inclusion criteria, rated from high- to medium-quality qualitative studies. Four primary themes were identified across the studies, each contributing to deeper understanding of how design thinking (DT) interventions impact the entrepreneurial self-assurance of engineering students.

4.1 Developing Entrepreneurial Confidence Through Identity Shifts

It was evident in several studies the DT is playing a crucial role in enabling the students to see themselves differently: not only problem -solvers, but also innovators and entrepreneurs. In modules where the students are engaged in prototyping and solving real-world challenges, a consistent shift of self-perception is evident. [19]observed that students start to see themselves as “solution designers” and “change makers” and not as passive learners. Through repeated exposure to uncertainty, [20]observed that students become more confident in their creative and entrepreneurial capabilities. Gulati [21]

Notably, Gulati et al. (2021) noted that students are more comfortable to tale intellectual risks after being exposed to DT. It’s evident that students started to believe their contribution can have a meaningful impact on society – a key aspect of entrepreneurial self-efficacy.

4.2 Embracing Uncertainty and Ambiguity as a Growth Pathway

Many students originally described they felt anxiety or hesitation when they were faced with the uncertainty that comes with open-ended design challenges. However, as they continued through DT stages their t discomfort often changed into resourcefulness. In the work of [22], several participants expressed a “pivot moment” in which they began to see uncertainty not as a threat, but rather an opportunity to explore multiple valid directions.

This theme was reinforced in the study by[23], where engineering students, who enrolled in a DT-integrated entrepreneurship course, described how ambiguity forced them to think beyond technical feasibility and consider emotional, social, and user-based variables. Over time, this exposure seemed to increase their perceived capability to navigate complicated and uncertain entrepreneurial environments.

4.3 Feedback, Reflection, and Internal Validation

Structured reflections and continued feedback cycles emerged as a significant driver of internal belief formation, and in[21], Gulati cited student-feedback session through reflective journals and guided feedback sessions of key moments of clarity — points where the students recognised their own growth.[20]) also emphasized how visual reflection tools, such as storyboards and progress maps, helped students link their actions with developing self-perceptions.

Interestingly, responses from mentors and peers were not only used to develop design ideas — it also served as a reflection for students in understanding their own potential. The process of external confirmation (through presentations, pitches, or peer reviews) often strengthened internal belief, especially when students received unexpected praise or insight. This dual role of feedback — both developmental and encouraging — was repeatedly noted across several studies.

4.4 Grounding Confidence in Real-World Relevance

The more meaningful or socially relevant the DT project are, the student believed more in their entrepreneurial abilities. [24]and [23] found that if students worked on problems rooted in their community or their environmental requirements, their commitment increased — and so did their confidence.

In one course, students designed technology, that can assist the disabled, and the students later reported that knowing their designs could affect real lives made them feel “capable and responsible”[21]. This connection between empathy, social responsibility, and entrepreneurial assurance suggests the importance of purpose-driven learning environments when fostering mindset shifts.

5 DISCUSSION

The findings of this study stress the idea that DT, when applied meaningfully within engineering education, has the ability to go outside skills development and help model students’ entrepreneurial identities. Across the reviewed studies it is evident that entrepreneurial self-assurance is not something that grows through technical mastery alone — it is refined through emotionally and cognitively rich learning environments, where uncertainty, social connection, and feedback join.

One of the more intriguing experiences was how students began to reframe their self-image through DT practice. The work of [19] and [21] suggests that DT help students move from a narrow view of engineering as technical execution to one of innovation and intervention. What is likewise critical is how students’ acceptance for uncertainty evolved. Across multiple studies, students initially struggled with the open-endedness of DT tasks. However, as in[22], this very anxiety appeared to catalyse personal growth. Within the theory of planned behaviour (TPB), *perceived behavioural control* has been regularly identified as a critical determinant of entrepreneurial intent, [25], particularly when related to confidence in one's ability to act.

In studies like those by [21] and[20], controlled reflection served not only to strengthen learning but also to create internal validation. When students could follow their own growth — particularly in collaborative settings — their self-belief seemed to deepen.

Another important takeaway relates to the role of purpose. Several students reported feeling more positive and connected when the design problem held real-world or social relevance. This is supported in studies by[23]) and[24], where students confronted community challenges or sustainability goals, and students were more likely to demonstrate entrepreneurial persistence. Purpose-driven learning not only stimulates empathy — a known pillar of design

thinking — but anchor inspiration in personal and social meaning, which may in turn contribute to longer-term entrepreneurial orientation.

It is also worth noting that the value of mentoring and institutional platforms, while mentioned in passing, were not always investigated in detail. This signals an area for further research. While student transformation is clearly shaped by curriculum design and DT pedagogy, the relational elements — how instructors position themselves, how feedback is delivered — may also play a critical role in enabling or constraining entrepreneurial self-efficacy.

6 CONCLUSION

This meta-synthesis set out to explore how design thinking (DT) teachings support the development of entrepreneurial self-assurance among engineering students. Across the nine studies included, it became clear that DT does more than teach students how to design — it helps them develop self-confidence in their ability to act, adapt, and create value in uncertain and changing contexts.

Through recurring engagement with real-world problems, reflection, feedback, and collaborative exploration, students began to see themselves not just as learners, but as competent problem-framers and agents of change. The development of entrepreneurial self-efficacy appeared to emerge not from any single element of DT, but from the overall learning ecology it develops — one where uncertainty is welcomed, failure is normalized, and meaningful outcomes are within reach.

The findings highlight key theoretical theories from Bandura's social cognitive theory. Mastery experiences, peer feedback, and perceived control over outcomes are all featuring notably in the change students described. Just as importantly, many students placed their confidence in purpose — in the social or community relevance of the problems they tackled — suggesting that self-assurance is reinforced when students see their ideas as part of a larger human or environmental impact.

From a practical perspective, this synthesis confirms the case for embedding DT meaningfully into undergraduate engineering curricula — and not as a detached module, but rather a pedagogical philosophy that structures the learning process. Activities such as problem scoping, stakeholder engagement, visual prototyping, and reflective storytelling can all be convincing catalysts for confidence-building, provided they are scaffolded intentionally.

Future research should extend beyond immediate classroom outcomes to examine how these shifts in mindset and identity persist over time. Longitudinal studies tracking students' post-graduation, as well as deeper investigation into the role of mentor dynamics and peer networks, would help paint a fuller picture of how DT experiences translate into entrepreneurial action.

In conclusion, fostering entrepreneurial self-assurance through design thinking is not about adding more content to engineering programmes — it is about reshaping the conditions under which students learn, explore, and grow.

TOWARDS DESIGNING A SUSTAINABILITY FUNCTION WITHIN LOGISTICS ENTERPRISES - A SYSTEMATIC REVIEW

D. Chiapperini[1*] and M. de Vries[2]

[1,2]Department of Industrial and Systems Engineering
University of Pretoria, South Africa
[1]chiapperinid@gmail.com, [2]marne.devries@up.ac.za

ABSTRACT

The United Nations offers sustainability development goals (SDG) and guidance in the form of a compass, that companies and governments can use to address the current problems the globe is facing, also linked to global Environment, Governance, and Social (ESG) challenges. The SDGs consist of 17 goals, 169 targets, and 249 indicators that need to be addressed before 2030, saving the planet. Since research remains sparse on how industries, especially the logistics industry, address SDGs and ESG challenges, this study presents a systematic review of literature on existing methods, frameworks and methodologies that focus on bridging the gap between SDGs and the selection, prioritisation, and management of sustainability initiatives to have a notable impact within the context of the logistics industry. As a secondary contribution, we extract how-to knowledge from existing literature in developing guidelines for logistics companies when a company designs and implements a new sustainability function.

Keywords: sustainability development goals, SDG, ESG, sustainability function

1 INTRODUCTION AND RESEARCH QUESTIONS

The United Nations (UN) has been documenting the Sustainable Development Goals (SDGs) for over three decades, receiving support from over 178 countries since sustainable development (SD) was first articulated in Rio de Janeiro, Brazil, during the Earth Summit of 1992 [1, 2]. SDGs have since evolved into a globally recognised framework influencing diverse sectors, including logistics, where sustainability has become both a strategic imperative and a competitive differentiator. In this exploratory study, we use a literature review to show that sustainability adoption in South Africa's logistics industry (SALI) remains inconsistent, with implementation challenges stemming from infrastructure limitations, cost pressures, and a heavy reliance on road freight [3-7]. These contextual realities heighten the importance of industry-specific approaches to SDG integration.

1.1 Background

In September 2000, at the UN Headquarters in New York, the UN launched the Millennium Development Goals (MDGs), better known as Agenda 21 [1]. Initially only measuring seven goals, an eighth goal was added only two years later [8]. Prior to the eighth goal's addition, the UN subtly pointed out that the involvement of Non-Governmental Organisations (NGOs) had already been identified as a critical success factor, and that governments alone would not be able to take on such an enormous task without their support [9, 10]. Agenda 21 now evolved to eight goals to achieve as shown in Figure 1.

Figure 1: 8 Millennium Development Goals [11]

Agenda 21 aimed to alleviate poverty, improve healthcare, and promote environmental sustainability while fostering global collaboration between governments and NGOs [2]. Although Agenda 21 presented the first attempt to unite governments and NGOs to tackle these global challenges, Agenda 21 ultimately fell short of achieving its intended goals [8]. In 2015, the UN decommissioned Agenda 21 and introduced the 2030 Agenda, also known as the SDGs. The SDGs have now expanded to address not only the MDG goals but also broadened the focus on global political and economic challenges resulting in 17 goals, 169 targets, and 249 indicators to address [1, 12, 13]. With the importance of SD increasing globally, governments and NGOs quickly adopted the SDGs [10, 14]. The seventeen SDGs are displayed in Figure 2.

Figure 2: 17 Sustainable Development Goals [15]

The collaboration between the Global Reporting Initiative (GRI), the UN Global Compact (UNGC) and the World Business Council of Sustainable Development (WBCSD), the 2030 Agenda also introduced a blueprint, known as the SDG Compass [12, 13]. The SDG Compass was created to guide stakeholders to achieve the SDGs and to address the lack of guidance that led to the failure of Agenda 21. Figure 3 depicts an overview of the SDG compass that was designed.

Figure 3: The SDG Compass [16]

Despite broad support for the SDGs, the UN [17] in their 2024 annual report, "*The Sustainable Development Goals Report*", indicates that the world is significantly off track. The report shows that from 2015 to 2024, only 17% of the targets are on track, 48% shows moderate or marginal progress, 18% have stagnated, and 17% have regressed [17]. This means that around 35% of the targets are reverting to "ground zero", indicating a need for urgent investigation into the underlying causes of stagnation and regression.

This study used an exploratory approach to investigate the knowledge base for the SALI context, indicating a lag in progress that underscores the need to interpret SDG principles through the lens of the industry's operational and structural realities; ensuring that sustainability integration is not only aligned with global targets but also practical and measurable within South Africa's unique logistics environment.

1.2 Research gap, objectives and discovery questions

The UN's 2024 annual report reveals that the SDGs have significant potential but also some serious analytical and practical challenges that need to be investigated [18]. Furthermore, van Zanten and van Tulder [14] argue that fundamental flaws have been present since the SDGs inception, particularly in their conceptual degree of complexity and symptom-oriented focus, rather than addressing the root causes. Sachs [10], Bennich et al. [19] further noted that the current SDG Compass lacks guidance on its effective use, especially in operationalising goals, governing specific challenges, and managing trade-offs and synergies. Additionally, similarly to Agenda 21, Cuervo-Cazurra et al. [20] stated that there are also no consequences when goals are not met and thus only encouraging stakeholders to use them as a communication tool without contributing towards the goals. Finally, although the indicators also provide a means of measuring progress regarding the targets, Kim [21] believes that the existing indicators are mainly quantitative and inadequate to address the multifaceted aspects of diverse targets they serve, arguing for measuring less quantifiable, often subjective, context specific, indicators.

While these shortcomings apply globally, in the SALI context they are compounded by limited empirical research directly linking SDG implementation to the logistics industry's operational frameworks, supply chain networks, and governance practices. A targeted analysis of SDG Compass application within the SALI is therefore warranted to ensure sector-specific applicability and impact [3-7].

Identifying these discrepancies within the SDG Compass can help the stakeholders to focus on the right goals for their industries [22]. This study therefore defines two main objectives, linked to the discovery questions (DQs) in Table 1. Since the search is still exploratory, the questions are framed as DQs rather than definitive research questions.

Table 1: Discovery questions for the study

Objective 1: Review existing SDG and ESG literature	
DQ1	What SDG related research has already been done in the within South Africa's logistics industry (SALI)?
DQ2	What research has already been conducted on the SDG compass within the logistics industry?
DQ3	What research has already been done on the SDG compass within SALI?
DQ4	How does the ESG framework impact the SDG Compass?
Objective 2: Review knowledge to guide developing a Sustainability function design approach (SUFDA)	
DQ5	How is the SDG compass used within existing literature, to guide SDG implementations?
DQ6	What solutions/frameworks/methodologies exist to guide SDG implementations?

2 RESEARCH METHODOLOGY FOR LITERATURE REVIEW

This chapter uses guidelines from literature on following a systematic process in reviewing existing knowledge to answer this study's DQs. The methodology follows an academic protocol for conducting a systematic literature review (SLR), to gain knowledge that relate to the research questions [23, 24]. According to Al-Zubidy et al. [23] an SLR is used because it is unbiased, repeatable, and comprehensive. Furthermore, Paul et al. [24] did point out that an SLR process should not only provide knowledgeable insights on a research question but also guide researchers when a new field of knowledge is identified.

For this study, a specific emphasis was placed on identifying literature that connects the Sustainable Development Goals (SDGs) and Environmental, Social and Governance (ESG) frameworks to the South Africa Logistics Industry (SALI), thereby aligning directly with the research objectives of the study.

2.1 Research protocol

The research protocol presented in this study followed Okoli's [25] seven steps in his *"A Guide to Conducting a Standalone Systematic Literature Review"*. Following the initial steps, a

search string was developed and applied across selected digital databases for which we had access, indicated in Table 2.

Table 2: Selected databases for the study

Selected Databases for study		
Academic Search Complete	Access Engineering	ACM Digital Library
EBSCO	EI Engineering Village	Emerald
Engineering Database	IEEE Xplore	ProQuest
Sabinet	SAGE	Science Direct
Scopus	Springer Link	Taylor and Francis Journals
Web of Science	Wiley Online Library	

The complete search string used in this study is presented in Appendix A. The search string created for this study indicates 4 parts, where we highlight the AND operators to ensure search specificity. The third part of the string explicitly targeted existing reviews or systematic reviews to build on the existing knowledge base, with particular emphasis on existing literature reviews on frameworks related to SDGs and ESGs within the academic body of knowledge.

Okoli's [25] guidance further requires a *practical screening* process after obtaining and compiling literature into a master data file. This process helps to determine which publications should be considered for answering the DQs by setting up certain criteria that will guide the researcher [25, 26]. For this study, the criteria, indicated in Table 3, were considered to conduct the practical screen on the publications extracted from the digital databases.

Table 3: Selected practical screening criteria for the study

Criteria	**Reason for criteria selected**
Publication year restriction	The use of publications from 2015 will be limited as it marks the start of the SDGs.
Document type	To use only journals, articles, and conference papers with Digital Object Identifiers (DOI) and in certain cases grey literature.
Language	All publications obtained needs to be in English.
Keywords	The study used keyword screening to identify any studies that contain specific terms related to the search string.
Duplication removal	All duplicated publications were removed to ensure that no duplication occurred in the final Primary Publications (PPs) list.

Furthermore, Okoli [25] suggests that a *quality appraisal* is conducted after practical screening. The purpose is to ensure the most relevant and high-quality publications are obtained, reducing the number of publications selected as Primary Publications (PPs) [27]. This study will analyse all publications obtained from the practical screening technique using Okoli's [25] technique, followed by abstract reviewing, full text reviewing, and snowballing to identify relevant publications. No additional quality appraisal techniques were used to assess the quality of the relevant publications.

Okoli [25] suggests that the researcher identifies appropriate techniques to synthesise the data. Hinawi [28] further adds the purpose of data extraction is to create precise extractions that will capture valuable information, that will answer the DQs. Therefore, the data mining technique was used to extract relevant information, used for synthesis as suggested by [25-28]. The specific data extracted to answer the DQs are presented in Table 4.

Table 4: Data mining substance selection for data extraction from the PPs

Data Extraction		
Abstract	Article reference	Country of study
Database	Industry	Journal or publication
Keywords	Publication year	Themes

2.2 Protocol applied

Following the guidelines of Okoli [25] and the flow-diagram guidance of Page et al. [29], which enhance transparency and reproducibility in the search process for an SLR, a systematic and structured approach was adopted. The resulting protocol, as illustrated in Figure 4, provides a transparent overview of the steps taken to ensure methodological rigour and traceability in the review process.

2.2.1 Identification

The first phase of the SLR from Figure 4, involves identifying the search string, databases, and extracting the results to answer the DQs. After applying the search string (See Appendix A) to each database, a total of 218,292 publications were extracted (see Figure 4). These were imported into Microsoft Power Business Intelligence (BI) for further analysis. As shown in Figure 4, 46.47% of the publications were from ProQuest and 35.02% from Sabinet. ProQuest and Sabinet were less sophisticated in interpreting the complexity of the search string and hence extracted a very large result set, but with possible low relevance.

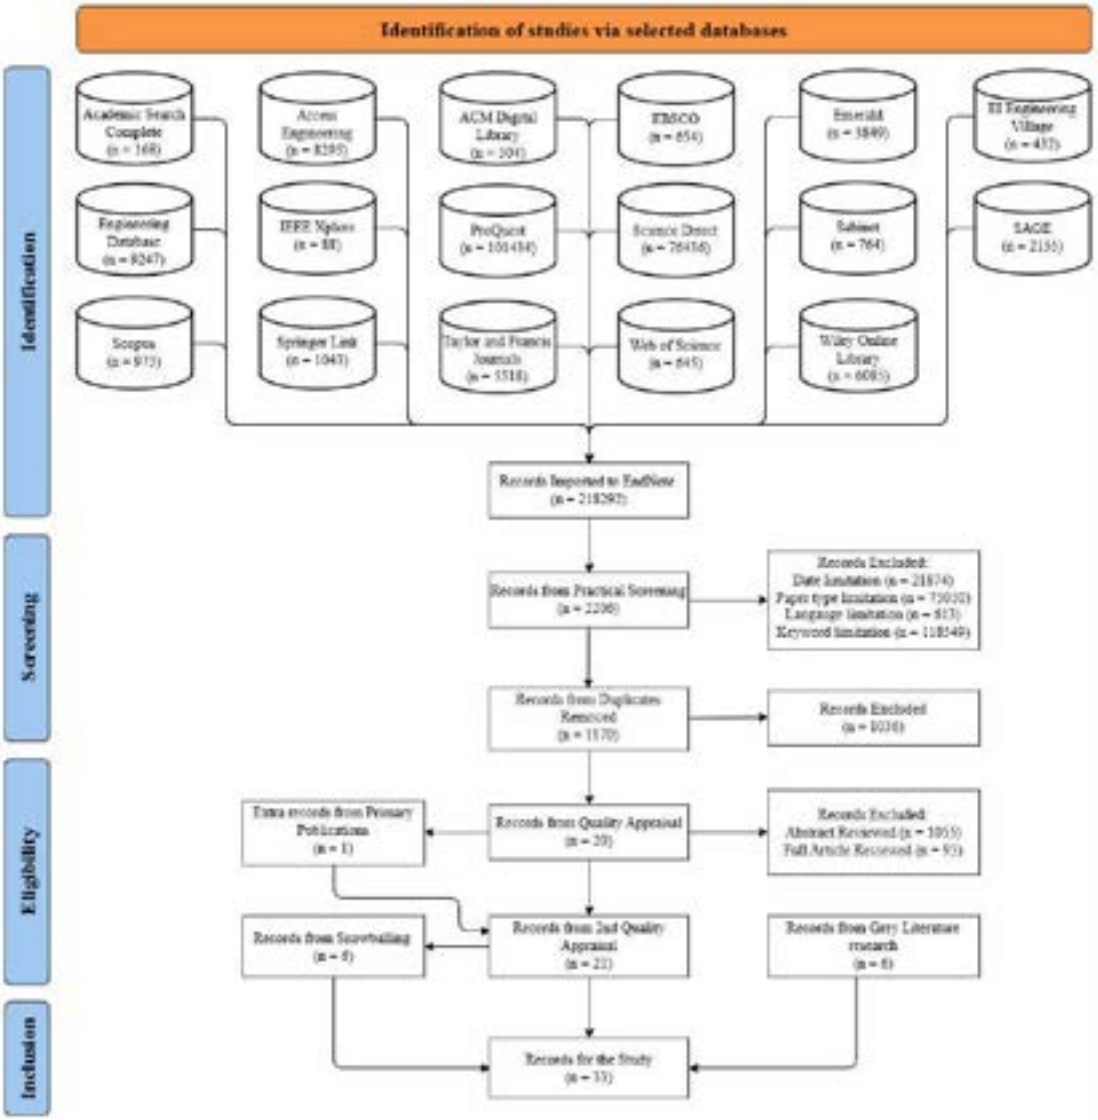

Figure 4: SLR protocol applied

2.2.2 Screening

The second phase of the process is screening (Figure 4). After applying the practical screening criteria from Section 2.1, a total of 2,206 relevant publications were identified out of an initial 218,292, meaning that 99% of the publications were excluded. This steep drop was mainly due to the high number of results from ProQuest and Sabinet. Screening also involved removing duplicates, as noted in Section 2.1. A total of 1,036 were removed, cutting the list by another 65.34% and bringing it down to 1,170 publications of interest.

2.2.3 Eligibility

In the third phase each of the 1,170 publications was subjected to abstract reviewing, full-text analysis, and snowballing to determine the final list of PPs. This process led to the exclusion of 1,150 publications. Publications were excluded primarily due to one or more of the following reasons: (1) Did not include a literature review on an SDG framework; (2) did not link the SDGs to ESGs or a specific industry; (3) Did not address the DQs. Snowballing was then applied to the remaining 20 publications, adding 6 more. To be more comprehensive, the researcher also conducted grey literature research, identifying a further 6 relevant publications.

2.2.4 Inclusion

The final phase presents the final list of PPs to be used for the analysis. These 33 publications, listed in Appendix B, form the empirical foundation for answering the DQs outlined in this study.

2.3 Data extraction and analysis methods

Okoli [25] recommend three synthesis methods namely: Meta-Analysis (MA) for quantitative analysis, Interpretation-Analysis (IA) for qualitative analysis, and Triangulation-Analysis (TA) to consolidate the MA and TA results. In this study, Atlas.ti was used for IA and Microsoft Power BI for MA. The extracted data will be visually presented through these tools and then discussed using TA to synthesise insights from qualitative and quantitative sources. Based on the knowledge embedded in the 33 publications, we present the results in three main sections, also indicating our discoveries regarding the DQs.

3 LITERATURE REVIEW RESULTS FOR MAIN CONCEPTS

Analysis of the reviewed publications in Atlas.ti revealed the most frequent keywords were Sustainable Development Goals (SDGs), Business, Sustainability, Development, Management, Innovation, and Research. However, a notable gap was identified with study relevant keywords (Environmental, Social, and Governance (ESG), framework, logistics, South Africa, and SDG Compass) *being absent*. This absence confirms two key points:

1. There is limited integration between SDG-related research and the logistics-sector application in South Africa, indicating that more sector-specific research is required, also indicated by [3-7].
2. There is insufficient academic discourse linking ESG frameworks to the SDG Compass in a South African context, reinforcing the rationale to address this research gap with future research.

While the keyword analysis revealed these gaps, the systematic literature review also identified a set of main concepts that are most pertinent to understanding how SDGs can be interpreted and operationalised in enterprise contexts; and, where possible, within the logistics sector. These are presented in Table 5 and provided conceptual description towards addressing the DQs.

Table 5: Main concepts for the study

Main concept	Description
Sustainable Development Goals (SDGs)	A global framework aimed at eradicating poverty, protecting the planet, and ensuring inclusive prosperity [30].
Environmental, Social and Governance (ESG)	A strategic framework for measuring and managing an organisation's environmental, social, and governance performance [31].
Circular Economy (CE)	A regenerative system focused on minimising resource input and environmental impact through reuse, recycling, and innovation [32].
Sustainable Supply Chain (SSC)	The integration of sustainability principles across the full supply chain, from sourcing to delivery [33].
Entrepreneurial Ecosystems (EE)	Networks of actors and enabling conditions that foster productive entrepreneurship within specific contexts [34].
Green Human Resource Management (GHRM)	HR practices aligned with environmental objectives to cultivate sustainability-oriented organisational culture [35].
Industry 4.0 (I4)	The integration of advanced digital technologies into manufacturing and supply chain operations, aimed at enhancing flexibility and efficiency [36].
Key Performance Indicators (KPI)	Quantitative metrics used to track organisational performance against predefined sustainability or strategic objectives [37].
Stakeholders and Engagement	Individuals or groups affected by or influencing an organisation's activities, with engagement referring to structured participatory practices [38].
Corporate Social Responsibility (CSR)	A strategic approach where businesses integrate environmental and social concerns in operations and stakeholder interactions [39].

Each concept in Table 5 provides a theoretical anchor that contributes to answering one or more of the Discovery Questions (DQ). For example:

- Sustainability governance frameworks emerged as a dominant theme, but these are often generic and require contextual adaptation to the South African Logistics Industry (SALI) realities.
- Measurement and indicators were predominantly quantitative, echoing Kim's [21] critique and indicating a lack of qualitative, context-specific measures in the logistics sector.
- Innovation in sustainable operations was frequently discussed globally yet rarely grounded in South African freight or warehousing case studies.

In short, the analysis underscores both a knowledge gap and an opportunity: the SDG Compass and ESG frameworks are well-theorised in global literature, but their translation into SALI-specific practice remains underdeveloped. This reinforces the strategic importance of the present study in bridging this gap through the eventual design of the Sustainability Function Design Approach (SUFDA).

4 LITERATURE REVIEW RESULTS REGARDING SDG AND ESG

This section addresses Objective 1 by reviewing the primary themes from the Primary Publications (PPs) in relation to DQs 1 to 4. The analysis consolidates thematic insights with explicit reference to the SALI wherever possible.

4.1.1 SDG Framework in the Context of SALI (answering DQ1 to DQ3)

While all PPs highlights the importance of the SDGs and their integration into core business strategy (CBS), none provide direct evidence of completed SDG-focused research specific to the SALI. However, several insights and research opportunities emerge from the existing literature:

1. Country Relevance: Azmat et al. [40] reported that 64.05% of SDG research has been conducted on developing countries, with 31.7% focused on Africa, indicating regional interest which includes South Africa.

2. Government Role: The South African's government supports and promotes the 2030 Agenda but lacks industry specific standards and guidelines towards the adoption of an SDG Framework [41].
3. Industry Specific: While literature on SDG frameworks is growing, studies rarely focus on specific industries [42, 43]. Several studies highlight the need for industry specific research and performance measurement in SDG implementation [42, 44, 45]. Furthermore, the studies have also revealed that a call for deeper understanding of the SDG framework's challenges, opportunities, and impacts at the industry level is required [40, 46-49].
4. Sustainable Supply Chains (SSC): Although research into SSCs is growing, empirical studies linking to the SDGs remain limited [42].
5. Entrepreneurial Ecosystems (EEs): Audretsch et al. [50] highlight a gap connecting EEs to the ESGs and SDGs.
6. Circular Economics (CE): Vann Yaroson et al. [51] reveal that existing literature only offers context-specific reviews and lacks comprehensive studies exploring the CE–SDG link.
7. Interconnections and Trade-offs: Research on SDG interconnections and trade-offs remain limited, thus highlighting the need for more holistic approaches [40, 42, 43, 46].

Although the SDG Compass is widely recognised across the primary papers (PPs), it is most often referenced simply as the "SDG tool" or "SDG framework." Only Paul et al. [24] explicitly discussed the Compass and its origins within the United Nations Global Compact (UNGC), Global Reporting Initiative (GRI), and World Business Council for Sustainable Development (WBCSD). This limited and fragmented use highlights the absence of a systematic approach to applying the SDG Compass within the South African logistics industry (SALI). The findings from the PPs therefore confirm a clear research gap in the development of industry-specific strategies and metrics that could operationalise the SDGs in SALI. The systematic review further verified that no academic articles directly address the intersection of SALI and the SDGs. While this absence may initially appear as a limitation, it is in fact the central discovery of this study: by revealing this gap, the research directly answers the discovery questions (DQ1–DQ4) and provides a critical foundation for the subsequent design of SUFDA.

4.1.2 Impact of the SDG Compass on the ESG Framework (answering DQ4)

Analysis from the PPs revealed a strong link between the ESG framework and the SDG Compass, suggesting shared synergies that support SDG advancement. While the SDG Compass provides a broad guidance for SDG engagement, the ESG framework offers a more structured approach for measuring and reporting progress. The following themes indicate how ESG and the SDGs are linked:

1. ESG as a measurement tool for SDGs: The ESG framework supports consistent assessment and reporting of CSR performance through scores, ratings, and evaluation system [52, 53]. Furthermore, The ESG framework also complements the SDG Compass which, focusses on goal setting, integration, and high-level reporting.
2. Mapping ESG to SDGs (selected examples): (1) Environmental: ESG emissions indicators align with SDG 13 (Climate Action), focusing on reducing greenhouse gas emissions and enhancing climate resilience [52, 53]. (2) Social: ESG metrics on workforce and human rights correspond with SDG 8 (Decent Work and Economic Growth), emphasising fair labour practices and inclusive employment [52, 53]. (3) Governance: ESG governance practices support SDG 16 (Peace, Justice and Strong Institutions), promoting transparency, accountability, and ethical management [52, 53].
3. Proxy measurement: ESG also serves as a proxy for SDG performances, which allows for monitoring, evaluating, and reporting on SDGs [52, 53].

4. SDG integration: According to Sarkar, et al. [53], ESG-focused companies usually also integrate the SDGs into their operations.
5. Foundational Role: The SDG Compass also reflects the ESG's influence in shaping practical, industry specific SDG implementation [52, 54].

In summary, the ESG framework not only complements the SDG Compass but also enhances its applicability through measurable indicators. A combined ESG-SDG approach offers a promising route to the creation of the SUFDA for the SALI.

5 LITERATURE REVIEW RESULTS ON SOLUTIONS THAT GUIDE DESIGN

This section addresses Objective 2 by identifying solutions, frameworks, and methodologies that can guide the development of a Sustainability Function Design Approach (SUFDA) tailored for enterprises in the South African Logistics Industry (SALI). While the reviewed approaches are not inherently logistics-specific, each offers adaptable principles and processes that can be recalibrated to suit the unique operational, infrastructural, and regulatory realities of the SALI.

5.1.1 Using the SDG compass to guide SDG implementation (answering DQ5)

While no prior studies explicitly define a Sustainable Development Goal (SDG) function tailored for the SALI, multiple studies highlight the SDG Compass as a foundational tool for developing a flexible, context-sensitive sustainability function such as an SUFDA [46, 47, 55].

Although standardised guidance for sustainability function design is lacking, various tools support the mapping, implementation, reporting, assessment, alignment, and monitoring of SDG-related activities within enterprises [49]. For instance, PwC's SDG Selector and ICMA's Mapping to the SDGs provide structured approaches for integrating SDGs into Core Business Strategy (CBS) [49]. Despite their generic nature, these tools offer guiding principles to inform the design of custom SDG functions for SALI.

In developing such a function, the SDG Compass can serve as a foundational framework, with adaptations to address the specific characteristics of the logistics industry [55]. These should consider regional infrastructure limitations, industry-specific sustainability concerns, socioeconomic conditions, regulatory contexts, and potential areas of impact [41, 46, 47, 55]. The literature supports a two-stage approach: (1) Understanding and applying the SDG Compass; and (2) Designing an SDG function based on that foundation:

1. Understanding and applying the SDG compass: Organisations must first familiarise themselves with the SDG Compass and it's five-step process.
2. Developing a context-sensitive SDG function: A function aligned with the SALI's needs should include the following elements:
    a. *Industry specificity:* A successful SDG function must therefore reflect the logistics Industry's operations and contributions to the SDGs [55].
    b. *Geographic relevance:* The SDG function needs to focus on South Africa's priority SDGs, given its socio-economic and infrastructural context [43, 54].
    c. *Stakeholder engagement:* Effective stakeholder engagement is essential for the development of an SDG function. This involves the participation of diverse internal and external actors to support goal selection and function design [40, 41, 43, 48, 49, 55-57].
    d. *Continuous improvement:* The SDG function should allow for continuous iterative updates based on feedback and evolving sustainable challenges or opportunities [58].
    e. *Beyond generic approaches: The SDG function should be able to translate the SDGs into high-level measurable goals for the logistics industry* [54].

f. *Managing trade-offs:* The SDG function must be able to identify and mitigate SDG conflicts and/or trade-offs. The ESG metrics can support this process by enabling transparent reporting [14, 43].

5.1.2 Frameworks guiding SDG implementation (answering DQ6)

From the Primary Publications (PPs), three key frameworks were identified that could offer guidance for constructing the SUFDA for SALI, even if they are not logistics or regional specific.

5.1.2.1 The Gap Frame Methodology

Developed by Muff et al. [12], the Gap Frame Methodology (available at www.gapframe.org) assess regional progress across four domains: Planet, Society, Economy, and Governance (see Figure 5).

Figure 5: The Gap Frame [12]

The Gap Frame Methodology (GFM) uses 68 indicators across 24 issues to assess a region's performance against an ideal state, identifying areas requiring urgent attention to align with specific SDGs [12]. While Muff et al. [12] describe the GFM creation process, the framework is mainly designed for regional analysis, such as for South Africa, and is not directly transferable to other contexts. Although not industry specific, the GFM does offer a structured approach for evaluating SDG performance and identifying regional priorities. Nonetheless, the development of an SDG function must similarly begin with identifying a region's critical sustainability gap.

5.1.2.2 Multi-Criteria Analysis Framework

The Multi-Criteria Analysis (MCA) Framework by Allen et al. [46], is a structured process to prioritise SDG targets based on urgency, impact, and policy gaps. This framework enables a comprehensive assessment to identify relevant SDG targets for a specific industry [46]. Furthermore, the MCA framework also guides resource allocation and action planning to maximise the impact on the SDGs. The six-step process, illustrated in Figure 6 and detailed in Table 6, supports and shows how to prioritise high-impact SDG targets for a specific industry.

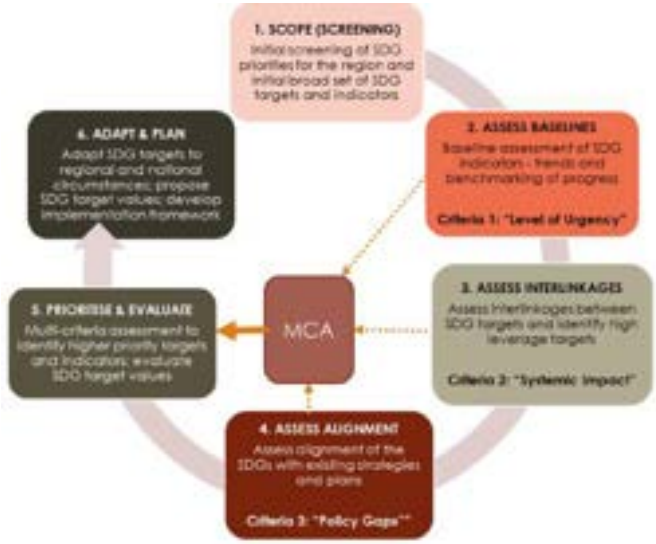

Figure 6: MCA framework [46]

Table 6: MCA framework steps

Steps	Description
Step 1 – Screening	Identify relevant SDGs at both regional and industry levels. After selecting priority SDGs, determine associated targets and indicators through iterative refinement [46].
Step 2 – Assess Baselines	Evaluate urgency by comparing selected targets and indicators against historical trends and global benchmarks to identify areas lagging in progress [46].
Step 3 – Assess Interlinkages	Analyse interconnections among targets using two methods: Cross-Impact Matrix (for direct interactions) and Network Analysis (for indirect links). Targets with the highest systemic impact are prioritised [46].
Step 4 – Assess Alignment	Examine alignment with existing policy frameworks to reveal coverage gaps. Targets with minimal alignment receive higher scores, indicating need for policy focus [46].
Step 5 – Prioritise and Evaluate	Aggregate scores using a weighted linear average informed by stakeholder input, resulting in a ranked list of high-impact targets [46].
Step 6 – Adapt and Plan	Integrate prioritised targets into a context-specific SDG framework tailored to the industry, such as for the SALI [46].

The MCA framework serves as a key tool for identifying high-priority SDGs and will significantly contribute to the development of the SUFDA for SALI.

5.1.2.3 Industry 4.0 and SCOR Model integration

Another model identified from the PPs is the integration of Industry 4.0 (I4) technologies with the Supply Chain Operations Reference (SCOR) Model, as proposed by Srhir et al. [45]. This approach incorporates I4 technologies (e.g., Internet of Things, Artificial Intelligence, Blockchain) with Sustainable Supply Chains (SSC) to improve efficiency, reduce environmental impact, and advance the SDGs within a specific industry [45]. This approach according to Srhir et al. [45] is adaptable to the specific needs and challenges being faced within a specific industry. The approach is illustrated in Figure 7.

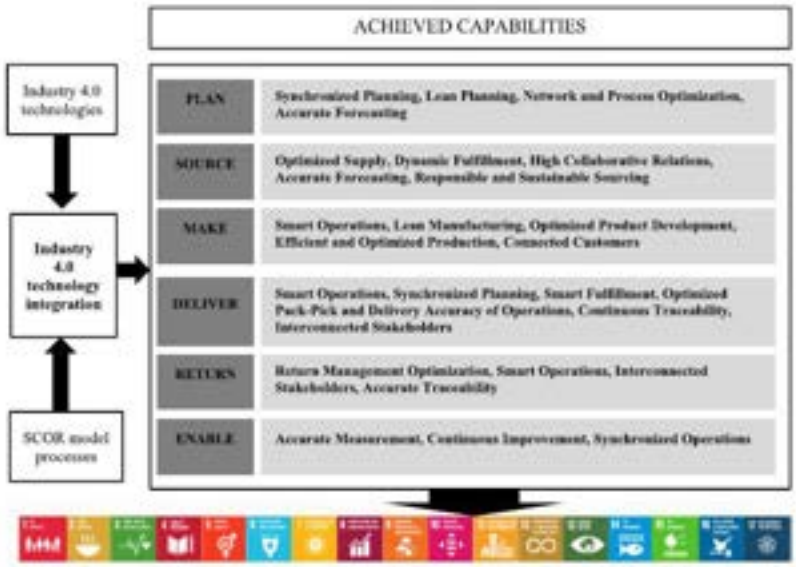

Figure 7: SSC 4.0 integration with the SCOR model impacting 17 SDGs [45]

The Industry 4.0 and SCOR Model (I4-SCOR) approach proposed by Srhir et al. [45], outlines six core processes for developing an SDG function. However, the I4-SCOR approach lacks clarity on how these technologies link to SCOR processes to support the advancement of the SDGs. Srhir et al. [45] did also acknowledge that the steps outlines in the I4-SCOR approach are vague, and they highlight its limited practical application and the absence of an innovation framework.

While none of the reviewed frameworks are fully tailored to SALI, they offer adaptable components. The SDG Compass provides a strategic foundation, the Gap Frame Methodology (GFM) and Multi-Criteria Analysis (MCA) framework guide diagnosis and prioritisation, and the I4-SCOR approach introduces digital transformation potential within the SDGs. Together, they can be used in the development of an SUFDA for the SALI.

6 REQUIREMENTS FOR A SUFDA

The Sustainability Function Design Approach (SUFDA) will be developed by integrating enterprise design and Sustainable Development Goal (SDG) implementation knowledge, as presented in section 5. Designing a new approach artefact requires a foundation in an established body of knowledge. Enterprise Engineering is *"an emerging discipline that takes an engineering perspective on enterprises,"* providing a theory-based methodology for coherent enterprise design [59]. The term *enterprise* includes all kinds of organised human activities, such as companies, agencies, institutions and supply chains [59].

Enterprises comprise concurrent design domains: (1) the organisation domain, consisting of enterprise operations where human beings interact in creating new products and/or services, (2) the information and communication technology (ICT) domain, consisting of hardware and software to support enterprise operations, (3) human skills and know-how domain, consisting of relevant skills to support enterprise operations, and (4) infrastructure domain, including facilities and non-ICT technologies to support enterprise operations [60]. In designing the SUFDA, the enterprise designer should distinguish between three artefacts:

1. The enterprise as an artefact, consisting of multiple design domains.
2. A sustainability function requiring essential tasks to address sustainability concerns.
3. The SUFDA as an approach artefact, guiding the enterprise designer in deploying the sustainability function.

Section 6.1 introduces enterprise design theory to support SDG function development within existing enterprises. Section 6.2 applies this theory and synthesises section 5's sustainability frameworks to derive initial SUFDA requirements tailored to the South African Logistics Industry (SALI).

6.1 Enterprise design knowledge

As demonstrated by Dietz and Mulder [59], the General System Development Process (GSDP) provides a conceptual foundation when designing new functions within an entire enterprise. The enterprise designer begins with the enterprise's environment, referred to as the using system, and proceeds to the design of multiple enterprise functions, considered object system functions [59]. The process concludes with the development of the enterprise constructs, or object system constructs [59]. When designing an SDG function within an existing enterprise, the same logic applies, though only a single enterprise function is created.

The design principles proposed by de Vries [61] are instrumental in guiding the development of a coherent *new approach* such as the SUFDA. The principles help answer three fundamental questions: (1) Why is sustainable development required (i.e. defining the paradigm of SUFDA)? (2) What are the main constructs of SUFDA? (3) How should the SUFDA be deployed?

6.2 Preliminary requirements for a SUFDA

Drawing on the principles from de Vries [61], Table 7 guides the SUFDA development for SALI. Table 8 shows how relevant knowledge from the GFM, MCA, and the I4-SCOR approach, from section 5, can be integrated into the SUFDA artefact.

Table 7: Approach design principles applied to the SUFDA

Approach design principles	Application of principles to SUFDA
1) Enterprise Conceptualisation	The SUFDA artefact must declare a clear enterprise concept, contextualising SALI through theory-based analogies, where the conceptualisation has to reflect the realities of enterprises within the logistical industry.
2) Phenomenon Description and Problem Class	The SUFDA artefact must provide a well-substantiated account of sustainability challenges in SALI, carbon emissions, governance failures, and inefficient resource loops, and show these reflect broader, under-addressed problems needing new design approaches.
3) Paradigm of Value Creation	The SUFDA artefact must include a testable value creation proposition. For instance, when applied to SALI, it should contribute towards SDG 12 and SDG 13 and once implemented, evidence should support the value proposition.
4) Scope Demarcation Methodology	The SUFDA artefact must explicitly define its design scope, domains, and concerns using established theoretical frameworks such as the Design and Engineering Methodology for Organisations (DEMO), ensuring clarity in addressing sustainability across enterprise levels [62].
5) Defend Design Scope	The SUFDA artefact must justify its scope, specifying enterprise layers and external interfaces. It should address internal and external complexities, define boundaries, identify stakeholders, and describe the validation context.
6) Representation and Notation Standardisation	The SUFDA artefact must declare its representational approach for design domains (e.g., BPMN or DEMO to represent the organisation domain). Deviations from standards should be theoretically justified.
7) Structuring and Role Allocation	The SUFDA artefact must specify its architecture, core components, roles and users, mechanisms, and internal interrelations.
8) Justificatory Knowledge Base	The SUFDA artefact must integrate relevant kernel theories to justify component effectiveness and reinforce design integrity.
9) Tailoring and Adaptability	The SUFDA artefact should support tailoring within defined bounds, such as industry-specific SDG weightings or local data. Clear guidelines must specify allowable adjustments and implementation methods.
10) Implementation Advice	Although optional, the SUFDA artefact should ideally offer practical guidance for implementation across logistics contexts, including stakeholder onboarding, system integration, and deployment recommendations.

Approach design principles	Application of principles to SUFDA
11) Real-World Instantiation	A strongly recommended optional requirement is a real-world application or pilot case. A SALI use-case would illustrate the approach and expose design gaps for future refinement.

Table 8: Extracting knowledge from existing sustainability frameworks

Requirement	Extracted from literature
1) Data-Driven Sustainability Gap Assessment	The SUFDA artefact must suggest essential *diagnostic operations*, supported by a diagnostic tool, such as the GFM, to benchmark industry or regional performance across key sustainability indicators. This forms the basis for SDG prioritisation and guides SUFDA actions in SALI. Indicators should be adaptable to global and South African contexts.
2) Depict the essential SUFDA operations	Following the MCA framework, the SUFDA artefact must define essential sustainability operations and roles, currently noted only as composite roles in [46]: • Scope Screener • Baseline Assessor • SDG Interlinkage Assessor • Strategy Alignment Assessor • Priority Assessor • Implementation Developer These roles support structured SDG alignment and efficient enterprise deployment. An operational model should be developed using guidance from [46].
3) Supply Chain Transaction Integration	The approach must map SDG objectives to supply chain phases, Plan, Source, Make, Deliver, Return, and Enable, as indicated in [45]. Each phase should describe relevant transaction types, ensuring that sustainability logic is operationally embedded in the SUFDA artefact for the SALI.

While Table 8 draws from existing theory to inform the SUFDA's structure, its development should follow a systematic design heuristic. This includes creating an integrated architecture across organisation, ICT, skills and know-how, and infrastructure domains, ensuring that the SUFDA is both theoretically sound and practically deployable in the SALI.

7 CONCLUSION, LIMITATIONS AND FUTURE WORK

This study reviewed existing sustainability approaches to determine whether an established model could guide enterprises in the South African logistics industry (SALI) to embed sustainability into their operations. The findings confirm the absence of a comprehensive, industry-specific approach, thereby underscoring the need for a tailored Sustainability Function Design Approach (SUFDA).

At the same time, the review highlighted literature that can inform the requirements for SUFDA as a theoretically grounded artefact capable of guiding sustainability transformation in SALI. By integrating enterprise engineering principles (Dietz and Mulder [59], de Vries [61]) with sustainability frameworks such as the Gap Frame Methodology (GFM), Multi-Criteria Analysis (MCA), and the Industry 4.0–SCOR model (I4-SCOR), the study directly addresses its research objective: to conceptualise a coherent approach that enables the deployment of an SDG-aligned sustainability function within existing enterprises.

Finally, this paper constitutes the first phase of a broader design science research program. By empirically demonstrating the absence of SDG-focused research on SALI, it positions this discovery as a rigorously identified research gap. This foundation provides the basis upon which the SUFDA artefact will be developed in subsequent studies, ensuring that later applied contributions are both theoretically robust and practically relevant.

7.1 Limitations of this study

While this study lays a conceptual foundation for designing an SUFDA within the SALI, several limitations warrant consideration:

1. The Search String: The study only included literature reviews, with the assumption that literature reviews would represent the existing body of knowledge. The limitation was mitigated, using snowballing and also including grey literature.
2. Conceptual Emphasis: The work is theoretical, grounded in literature and existing frameworks, without empirical validation. This constrains immediate applicability in real-world SALI contexts.
3. Contextual Generality: Though the SALI is central, integrated frameworks (e.g., SDG Compass, GFM, MCA, I4-SCOR) are not logistics- or region-specific, necessitating further localisation to address South African and industry-specific dynamics.
4. Evolving Sustainability Landscape: The dynamic nature of sustainability and SDG frameworks demands adaptability. While conceptually considered, operational mechanisms remain undeveloped.

These limitations underscore the need for empirical research, pilot studies, and iterative refinement to improve the SUFDA's practical relevance and effectiveness in SALI.

7.2 Future work

Building on the SUFDA's conceptual foundations and initial requirements, the study forms part of a larger research initiative, where design science research (DSR) will be used to develop SUFDA as an *approach* artefact. Applying the DSR cycle of Peffers et al. [63], future work is required to extend and validate the initial requirements, followed by constructing, demonstrating and evaluating the SUFDA.

Other research directions are also proposed when developing and evaluating the SUFDA:

1. Component Refinement: Detailed development of the SUFDA's roles and operational models, incorporating Industry 4.0 (I4) technologies for improved sustainability monitoring and decision-making.
2. Sector-Specific Adaptation: Tailoring the SUFDA for logistics sub-sectors (e.g. freight, warehousing, last-mile delivery) to address distinct sustainability needs and opportunities.
3. Stakeholder Engagement: Developing methods for sustained stakeholder engagement to align SDG targets dynamically and manage trade-offs.
4. Policy Integration: Aligning the SUFDA with South Africa's sustainability regulations and global logistics standards to enhance compliance and reporting.
5. Digital Infrastructure: Leveraging from the Internet of Things (IoT) and data analytics for real-time sustainability assessments and continuous improvement.
6. Empirical Validation: Pilot multiple implementations in the SALI enterprises to assess the SUFDA's practicality, adaptability, and performance.

By addressing these areas, future research will not only validate the SUFDA's conceptual robustness but also enhance its capacity for scalable, evidence-based sustainability transformation in the SALI.

ABSTRACT

This paper investigates the evolution, problems, and future directions of Enterprise Resource Planning (ERP) deployment in Africa, situated within recognised theoretical models such as the Technology-Organisation-Environment (TOE) framework and Diffusion of Innovation (DOI) theory [1, 2]. It covers significant factors like globalisation, government regulations, and technological improvements while identifying problems such as infrastructural gaps, high costs, and organisational resistance [3, 4]. The integration of Artificial Intelligence (AI) into ERP systems is analysed using the lens of the socio-technical systems theory, proving AI's ability to optimise decision-making, automate processes, and increase data analytics [5, 6]. Industry-specific case studies illustrate how AI-enhanced ERP may overcome existing constraints and enable sustainable growth [7, 8]. This analysis offers practical insights for enterprises, governments, and researchers aiming to utilise ERP and AI for competitive advantage and sustainable economic growth in Africa, while enhancing the theoretical discussion on technology adoption in emerging economies [9, 10].

Keywords: Enterprise Resource Planning (ERP), Artificial Intelligence (AI), Technology Adoption, Industrial Engineering, Process Automation, Supply Chain Management, Data Analytics, Systems Integration, Innovation Diffusion, Socio-Technical Systems

1 INTRODUCTION

1.1 Background and Context of ERP Implementation in Africa

Enterprise Resource Planning (ERP) systems have emerged as a fundamental element in organisations' digital transformation journeys. ERP systems provide integrated platforms for managing financial, human resource, procurement, and supply chain functions [11]. In Africa, the usage/adoption of ERP has increased consistently as organisations seek operational efficiency, compliance, and competitiveness. This advancement is not consistent, frequently hindered by infrastructural limitations, elevated expenses, and resistance to organisational change [4, 12]. Notwithstanding these obstacles, governments and the commercial sector increasingly regard ERP systems as essential for digital maturity.

The continent's digital landscape has been evolving. This has been seen with many parts having improved internet connectivity, cloud computing, and mobile penetration—creating new opportunities for ERP implementations [2]. With recent advancements, integrating ERPs with Artificial Intelligence (AI) has introduced new capabilities in the areas of predictive analytics, fraud detection, and intelligent automation [5]. These AI-enhanced systems provide more agile, data-informed decision-making, which is especially advantageous for industries like mining, agriculture, and finance that are characterised by significant operational complexity and regulatory requirements.

1.2 Statement of the Research Problem

The strategic potential of ERP systems is highly respected; however, their adoption in African organisations is often plagued by high failure rates, poor system utilisation, and a disconnect between technology and organisational culture [12]. The challenges encountered in most adoptions are a result of vendor models that are not flexible, a low number of skilled users, and an inability to align ERP capabilities with sector-specific processes [11]. Furthermore, although AI has become a pivotal element for ERP transformation worldwide, its significance within the African context is still inadequately examined, particularly across various industries.

1.3 Significance and Rationale for the Study

This study addresses two research gaps: the under-documented contribution of artificial intelligence to improve ERP performance in Africa and the limited contextual knowledge of ERP challenges in Africa. By focusing on specific industries—mining, retail, finance, agriculture, and manufacturing—analysing AI-enhanced ERP adoption helps to provide a holistic picture of the drivers, obstacles, and effects of these technologies in Africa. It also contributes to theoretical advancement by applying socio-technical and innovation diffusion perspectives to ERP adoption in resource-constrained environments.

The findings aim to inform policymakers, technology vendors, and enterprise leaders about the enablers of successful ERP-AI integration, offering recommendations that are both scalable and context-specific.

1.4 Research Objectives and Key Questions

The main aim of this research is to assess the impact of AI integration in ERP systems on business transformation within African firms. The research intends to:

- Identify the principal challenges and determinants of success in ERP implementations within African industries.
- Examine how AI has improved ERP performance in terms of efficiency, compliance, and decision-making support.

- Investigate the influence of industry-specific characteristics on the outcome of ERP-AI integration.
- Formulate policy and practice suggestions that facilitate sustainable digital transformation.

This study is directed by the following research questions:

- What are the primary contextual obstacles impeding successful ERP implementation in Africa?
- In what ways does AI augment the capabilities and strategic significance of ERP systems?
- What sector-specific insights may be derived from the implementation of ERP-AI in African industries?
- What insights can Africa glean from global best practices to inform its ERP transformation journey?

2 METHODOLOGY

A systematic literature review (SLR) approach is utilised to explore the adoption, challenges, and transformative impact of AI-enhanced ERP systems across African industries. ERP research is dynamic and multidisciplinary—an SLR was chosen to ensure methodological rigour and thematic depth.

2.1 Systematic Literature Review Approach

The SLR approach is well-suited for synthesising diverse empirical and theoretical contributions on a complex topic such as ERP implementation in Africa. Following guidelines from Tranfield, et al. [13], the review was conducted in three phases: planning, conducting, and reporting, ensuring transparency and replicability. The study aimed to identify how AI integration modifies ERP outcomes, particularly in light of the infrastructural, financial, and organisational challenges prevalent in African enterprises.

The review was limited to peer-reviewed journal articles, conference papers, and high-quality grey literature published between 2015 and 2024. A few seminal studies before 2015 were also included for theoretical anchoring.

2.2 Specific Databases and Search Criteria

The databases examined comprise Google Scholar, Scopus, ScienceDirect, and SpringerLink, in addition to pertinent open-access journals. The keywords used were organised into various boolean combinations, as follows:

- "ERP implementation" AND Africa
- "AI in ERP systems" AND performance
- "enterprise systems" AND agriculture/finance/mining in Africa
- "ERP challenges" AND developing countries

The search also included pan-African ERP experiences, including Kenya, Nigeria and South Africa, to ensure contextual relevance.

2.3 Inclusion and Exclusion Criteria

Articles were considered if they:

- Focus on ERP implementation in Africa.
- Discuss AI-ERP integration.
- Delivered case-specific, sectoral, or theoretical insights relevant to Africa.
- Were published in English between 2015 and 2024.

Articles were excluded if they were purely technical, in non-African contexts, or repetitive reviews without original analysis.

2.4 Explanation of Thematic Analysis Technique

A preliminary selection of 54 publications was evaluated, resulting in 15 that fulfilled the final inclusion criteria for theme analysis, including contextual depth, methodological rigour, and relevance to ERP-AI adoption in African industries. The process was directed by Braun and Clarke [14] six-phase framework, which includes familiarisation with data, coding, theme development, reviewing themes, defining/naming themes, and writing up. The coding process was both deductive—guided by theoretical frameworks (TOE, DOI, STS)—and inductive, allowing themes to emerge directly from the data. This hybrid approach helped identify the dominant themes under each core research objective.

2.4.1 Application of Theoretical Frameworks in the Analysis

The coding and synthesis were explicitly guided by three frameworks: Technology–Organisation–Environment (TOE), Diffusion of Innovation (DOI), and Socio-Technical Systems (STS). We operationalised these frameworks into the code families used during Braun & Clarke's thematic analysis [14].

We used a hybrid approach: deductive codes (seeded from TOE/DOI/STS) plus inductive codes emerging from the data. Codes were grouped into themes (challenges, enablers, outcomes, AI-specific transformations), then matrix-mapped by sector (mining, retail, finance, agriculture, manufacturing) to support the case studies. A second-pass review checked that each reported theme had at least one supporting code from a framework dimension; disagreements were resolved via memoing and codebook refinement.

Themes were categorised into:

- Challenges (e.g., infrastructural, financial, organisational resistance)
- Enablers (e.g., executive support, change management, cloud flexibility)
- Outcomes (e.g., efficiency, compliance, data visibility)
- AI-specific transformations (e.g., risk prediction, fraud detection)

These were later mapped to sector-specific contexts such as mining, finance, and agriculture to deepen insights in the case study sections.

2.4.2 Thematic Saturation

Thematic saturation was reached when no new codes, sub-themes, or theoretical insights emerged from reviewing additional studies. The initial pool of 54 eligible publications was progressively reduced as coding revealed recurring patterns, with later papers contributing only confirmatory evidence. After coding the first 35 papers, the codebook had stabilised, and no new categories were generated in subsequent analyses.

A quality appraisal step was then applied, resulting in the retention of 15 high-quality articles that met all methodological and relevance criteria. These studies covered multiple African regions and sectors (mining, retail, finance, agriculture, and manufacturing) and varied in research design, ensuring both breadth and depth.

The decision to limit synthesis to these 15 articles was supported by:

1. **Content redundancy** – later studies reiterated existing themes without adding distinct perspectives.
2. **Diversity assurance** – the final set encompassed all sectors and contexts within the study's scope, offering a representative yet analytically manageable corpus.

This process aligns with SLR best practice, ensuring that the thematic framework is comprehensive, stable, and supported by sufficiently diverse evidence.

2.4.3 Critical Appraisal of Sources

Each article retained for thematic analysis was evaluated for methodological quality and risk of bias using adapted appraisal criteria for information systems research. The following factors were considered:

- **Research design robustness** – preference was given to empirical studies with clear methodological descriptions (e.g., case study protocols, survey designs, sampling strategies).
- **Data triangulation** – inclusion of multiple data sources (e.g., interviews, system usage data, archival records) to strengthen validity.
- **Sample diversity and adequacy** – representation across organisational sizes, sectors, and African regions.
- **Transparency of reporting** – clarity in data collection and analysis processes, including ethical considerations.
- **Analytical rigour** – evidence of systematic coding, theoretical framing, and clear linkage between data and conclusions.

Studies that lacked sufficient methodological detail, relied solely on anecdotal accounts, or presented findings without clear data provenance were excluded. This ensured that the final synthesis was built on evidence of acceptable empirical rigour.

While this process reduced the total number of eligible studies, it enhanced the reliability of the thematic framework by minimising the influence of low-quality or biased sources.

This process aligns with SLR best practice, ensuring that the thematic framework is comprehensive, stable, and supported by sufficiently diverse evidence.

2.4.4 Language Scope Justification

Only English-language publications were included in the review. This decision was guided by two practical considerations:

1. Resource constraints – Accurate interpretation of ERP–AI adoption literature requires not only linguistic fluency but also familiarity with technical and theoretical terminology. The research team did not have access to professional translation resources within the project timeline.
2. Consistency of conceptual analysis – Limiting the corpus to English ensured that coding and framework mapping (TOE, DOI, STS) could be applied consistently without the risk of meaning shifts introduced through translation.

This approach is common in SLR practice but introduces a limitation in the African context, where significant ERP implementation and AI adoption may be documented in French, Portuguese, Arabic, and other local languages. Such exclusion may narrow the scope of cultural and regional diversity in the findings. Future research should address this gap by incorporating multilingual search strategies and translation support to capture a more comprehensive continental perspective.

2.5 Justification for Chosen Methodology and Potential Limitations

The SLR technique was chosen to deliver a thorough yet targeted synthesis of disparate literature across several fields and sectors. It facilitates both generalisation (trends across Africa) and contextualisation (sectoral and national insights). Furthermore, utilising recognised theoretical frameworks during coding ensures conceptual consistency in the study.

However, the approach has limitations:

- It relies on the availability of published materials and may exclude valuable insights from unpublished organisational reports.
- Bias in keyword selection and language (English-only) may limit scope.
- While sector-specific, the study does not provide in-depth ethnographic or field-based validation.

Despite these limitations, the methodology provides a robust foundation for understanding ERP-AI adoption in Africa and supports the analytical depth required for theoretical, practical, and policy contributions.

3 LITERATURE REVIEW

3.1 ERP Systems Overview

Enterprise Resource Planning (ERP) systems are well-integrated software platforms designed to facilitate business processes across multiple departments by streamlining data entry and usage. They facilitate real-time data access, standardised workflows, and improved operational control [4]. In the 1990s ERP solutions were just manufacturing resource planning tools, but they have now evolved to full-suite, cloud-based enterprise platforms supporting AI-driven decision-making and business intelligence [2].

3.2 Definition and Historical Evolution of ERP

Historically, ERP systems emerged to resolve the inefficiencies and fragmentation of legacy systems. From MRP II systems in the 1980s, ERP transitioned into monolithic, on-premises platforms in the early 2000s and has since evolved into modular, cloud-native, and AI-enhanced solutions. The evolution also reflects a shift from transaction processing to strategic enablers of competitiveness, compliance, and innovation [8]. More recently, cloud ERP and Software-as-a-Service (SaaS) models have expanded access, especially for SMEs in developing economies [3].

3.3 Global Trends and Significance

Due to compliance requirements, data complexity and competitive pressures, ERP systems are being adopted as part of global digital transformation strategies. Developed economies have led this movement, with organisations increasingly integrating AI capabilities, such as predictive analytics, robotic process automation (RPA), and intelligent workflow orchestration [5]. These developments have also impacted how ERP systems are designed—emphasising modularity, API-based architecture, and sector-specific customisation [15].

In developing regions, ERP adoption is seen as a pathway to global competitiveness and supply chain integration. As Bag, et al. [8] highlight, ERP systems in healthcare and manufacturing are increasingly used to enhance resilience, quality assurance, and regulatory alignment.

3.4 ERP Adoption in Africa

3.4.1 General Overview and Key Adoption Trends

In the African context, ERP systems are gradually gaining traction, particularly in sectors like mining, telecommunications, banking, and public administration. Countries such as South Africa, Nigeria, and Kenya are leading adoption due to relatively mature digital infrastructure and policy support for digital transformation [4]. Moreover, the increasing affordability of cloud-based platforms is helping small and medium enterprises access ERP tools previously available only to large corporations [2].

Nevertheless, adoption remains uneven. Many implementations are donor- or consultant-driven, with limited internal capacity-building or contextual customisation. For example,

systems procured using foreign aid often reflect the architecture of the donor's business culture, rather than the operational realities of the African enterprise [12].

3.4.2 Factors Influencing Adoption (Economic, Infrastructural, Organisational)

Key economic factors influencing ERP adoption include affordability, access to capital, and exchange rate volatility. Organisations often face foreign currency costs for licensing and upgrades, which increase financial risk [12]. Infrastructure is another constraint, particularly in rural or peri-urban areas with unreliable internet connectivity or electricity [4].

Organisational factors include leadership commitment, digital readiness, employee digital literacy, and internal change management capacity. In environments where informal practices and manual workarounds dominate, structured ERP processes can meet resistance or fail to integrate with legacy operations [11].

3.5 ERP Implementation Challenges in Africa

3.5.1 Infrastructural Challenges

Africa's digital infrastructure gap has a direct impact on ERP performance. Inconsistent electricity supply, slow internet speeds, and limited data centres hinder deployment, maintenance, and cloud integration. As a result, organisations are often forced to settle for less robust, outdated systems or underutilise available functionality [2].

3.5.2 Cost-related Challenges

ERP systems—especially those developed by global vendors—are often priced in USD or EUR, making them prohibitively expensive for many African firms. High upfront licensing fees, implementation costs, customisation, training, and ongoing maintenance often exceed budget forecasts [12]. Cloud-based models reduce capital expenditure but can accumulate significant operating expenses over time.

3.5.3 Organisational and Cultural Resistance

ERP success relies on user buy-in and behavioural changes. Resistance can stem from fear of redundancy, distrust of external systems, or lack of understanding about the system's value. In addition, hierarchical decision-making, weak change management structures, and insufficient training contribute to poor adoption and underuse [11].

3.6 Theoretical Frameworks

To understand ERP adoption in Africa, this study applies three interrelated frameworks:

3.6.1 Technology-Organisation-Environment (TOE)

The TOE framework emphasises that technology adoption is influenced by technological readiness, organisational capabilities, and environmental pressures [15]. In Africa, environmental factors—such as government digital strategies, donor support, and economic constraints—heavily influence ERP decisions.

3.6.2 Diffusion of Innovation (DOI)

Rogers' DOI theory explains how innovation adoption occurs through five stages: knowledge, persuasion, decision, implementation, and confirmation. African ERP adopters often stall at the persuasion or decision stages due to risk aversion or lack of demonstrable return on investment (ROI) [12].

3.6.3 Socio-Technical Systems (STS)

STS theory focuses on the alignment between technological systems and social structures. In Africa, misalignment between rigid ERP modules and informal practices leads to

underperformance or resistance. Effective implementation thus requires co-evolution of systems and structures, not just technical deployment [11].

4 AI INTEGRATION INTO ERP SYSTEMS

4.1 Overview of AI Capabilities in ERP

Artificial Intelligence (AI) is rapidly reshaping the value proposition of Enterprise Resource Planning (ERP) systems, especially in emerging economies like those in Africa. Beyond process automation, transactional control, and data storage, the incorporation of AI technologies—such as machine learning (ML), natural language processing (NLP), robotic process automation (RPA), and predictive analytics—has enabled ERP systems to evolve into intelligent decision-making engines [2].

AI-enhanced ERP systems can autonomously detect anomalies, suggest optimal actions, and learn from historical data to continuously improve business processes. These capabilities are particularly valuable in dynamic sectors such as mining, finance, and agriculture, where volatility, data overload, and compliance demands are high [5]. AI also empowers ERP with conversational interfaces, allowing users to interact with systems via voice or chat, improving accessibility and user experience.

4.2 Strategic Benefits of AI in ERP

4.2.1 Enhanced Risk Management and Fraud Detection Outcomes

Risk management is a central concern for enterprises operating in unpredictable regulatory and economic environments. AI-enhanced ERP systems enable organisations to proactively monitor and flag inconsistencies in financial reporting, procurement, and human resources transactions. According to Bag, et al. [8], the integration of AI in ERP systems supports the early identification of fraud patterns and reduces the risk of financial leakage, especially in complex supply chains.

For example, AI tools embedded in ERP platforms can use historical transactional data to detect outliers that deviate from established behavioural norms. These patterns could indicate procurement collusion, over-invoicing, or ghost vendors—issues that plague many African public and private institutions. Moreover, AI-enhanced audit trails ensure regulatory compliance by automatically documenting decision points and justifications.

4.2.2 Operational Cost Reductions and Regulatory Compliance

The automation capabilities introduced by AI substantially reduce manual workloads, streamline data entry, and enhance process accuracy. In a study focused on digital transformation among African SMEs, Eboigbe, et al. [2] noted that AI-enhanced ERP solutions reduced administrative costs and decision cycle times, contributing to overall productivity.

In industries like manufacturing and agriculture, AI algorithms integrated into ERP systems forecast demand, track equipment conditions, and optimise inventory levels, reducing wastage and enhancing supply chain reliability [10]. These optimisations lower operational costs and enhance an organisation’s ability to respond to changing market conditions.

Furthermore, AI capabilities within ERP systems assist with compliance by continuously monitoring legislation, updating internal policy workflows, and sending real-time alerts for non-compliance risks. This is especially important in Africa, where multinational enterprises must navigate both local regulations and international compliance standards such as the International Financial Reporting Standards (IFRS) or Basel III.

4.3 Specific Cases from South Africa and Africa-Wide Examples

Evidence of AI-ERP integration is emerging across several African nations. In South Africa's telecommunications and financial sectors, ERP systems powered by AI have demonstrated measurable improvements in both efficiency and governance. For example, Walker and Brown [7] describe a case study of a South African telecom firm that used AI-enhanced ERP to improve strategic procurement and reporting efficiency, leading to better budget control and vendor transparency.

Similarly, Eboigbe, et al. [2] highlight how Nigerian and Kenyan SMEs leveraged AI-enhanced ERP tools to simplify inventory planning and customer relationship management. These solutions, offered on cloud-based platforms, allowed smaller firms to access enterprise-level decision intelligence without investing in expensive on-premise infrastructure.

Furthermore, case studies in agriculture reveal that AI-enhanced ERP platforms are being used to monitor crop cycles, predict yield outcomes, and automate financial reporting for cooperative farming groups [3]. These tools provide a crucial link between farmers, financiers, and markets, creating digital ecosystems that drive inclusive growth.

AI has significantly expanded the scope and strategic value of ERP systems across Africa. By enhancing risk controls, lowering operational costs, and improving compliance, AI-enhanced ERP platforms support enterprise resilience in volatile and resource-constrained environments. Additionally, the scalability offered by cloud-AI ERP combinations is particularly well-suited to the continent's SME-driven economies. As case evidence continues to emerge from countries such as South Africa, Nigeria, and Kenya, AI-enhanced ERP is proving to be not just a technological upgrade but a transformative business enabler.

Table 1: Mapping of Themes to Framework Dimensions, Sector Examples, and AI-Enhanced ERP Impacts

Theme	Framework Dimension	Sector Example	AI-Enhanced ERP Impact
Infrastructural challenges (e.g., connectivity, power supply)	TOE – Technological	Agriculture (Kenya, Ghana)	AI-enhanced offline data capture and predictive maintenance reduce downtime and improve service continuity
Leadership support & change management	TOE – Organisational	Mining (South Africa, Tanzania)	AI dashboards provide real-time KPIs to leadership, improving agility during transformation
Regulatory and market environment	TOE – Environmental	Finance (Nigeria, Mauritius)	AI compliance modules automate reporting and adapt to changing regulatory frameworks
Relative advantage & compatibility	DOI – Innovation Attributes	Retail (South Africa)	AI-enhanced demand forecasting and personalised promotions enhance market responsiveness
Trialability & observability	DOI – Innovation Attributes	Manufacturing (Egypt, Morocco)	AI simulation tools enable safe, low-cost ERP testing before full rollout
Joint optimisation of technology & human factors	STS – Socio-Technical Alignment	Agriculture (Rwanda)	AI-enhanced training customises learning paths, increasing adoption and reducing resistance
Data-driven decision-making culture	STS – Organisational Process Alignment	Mining & Finance	AI analytics integrate multi-source data for scenario planning, enabling proactive strategies

As summarised in Table 2, the emergent themes from the literature are closely tied to the TOE, DOI, and STS frameworks and manifest differently across industries. The next section builds on this mapping to explore sector-specific adoption narratives in detail.

4.4 Transition to Industry-Specific Case Studies

The literature review and analysis of AI integration into ERP systems have identified cross-cutting themes—challenges, enablers, outcomes, and AI-specific transformations—mapped through the TOE, DOI, and STS frameworks. While these findings present a continental view of ERP–AI adoption, the literature also reveals substantial sectoral differences. Industry context influences the weight of each driver and barrier, as well as the perceived benefits of AI-enhanced ERP.

The following section presents five industry-specific case studies—mining, retail, finance, agriculture, and manufacturing—each synthesised from the reviewed literature. For each sector, the analysis:

- Identifies unique adoption drivers and challenges.
- Aligns these with TOE, DOI, and STS dimensions.
- Evaluates the impact of AI-enhanced ERP on operational and strategic performance.

This transition ensures a clear link between the generalised findings of the review and the practical, context-specific narratives that follow.

5 INDUSTRY-SPECIFIC CASE STUDIES

5.1 Mining

The mining sector in Africa faces unique operational, environmental, and regulatory challenges that demand robust digital systems. Unlike traditional ERP systems that simply log transactions and track inventory, AI-enhanced ERP platforms analyse sensor data, anticipate equipment failures, and optimise resource scheduling [8].

One of the most valuable applications of AI in mining ERP is predictive maintenance. Downtime in mining operations can result in significant revenue loss. AI models trained on historical equipment data can forecast machinery breakdowns, triggering proactive servicing. This reduces unexpected halts and enhances operational safety—critical concerns in hazardous mining environments [5].

AI also supports regulatory compliance by automating the monitoring and reporting of safety inspections, environmental impact metrics, and labour hours. These capabilities are especially important in Africa, where regulatory oversight varies and manual recordkeeping often leads to inconsistencies.

In South Africa, a leading telecom company with mining infrastructure dependencies used AI-enhanced ERP tools to streamline procurement and asset tracking. The integration of AI led to improved vendor transparency and budget control, demonstrating measurable operational efficiency [7].

Compared to traditional ERP systems that are mostly reactive, AI-ERP platforms in mining deliver predictive insights and real-time decision support. They enable companies to transition from basic record-keeping to intelligent, agile operations. As African nations seek to increase local beneficiation and enforce ESG standards in mining, AI-enhanced ERP systems can serve as strategic tools that enhance both performance and accountability.

5.2 Retail

The retail sector in Africa is experiencing rapid digitalisation, driven by consumer expectations for personalisation, efficient inventory management, and seamless service delivery. AI-enhanced ERP solutions support personalised customer experiences by leveraging historical purchasing data, browsing patterns, and regional demand signals to drive targeted promotions and dynamic pricing strategies [5].

Traditional ERP systems primarily manage transactional processes, such as inventory tracking and point-of-sale data capture. However, AI-driven ERP platforms extend these capabilities by forecasting customer demand, detecting purchasing trends, and recommending stock rebalancing across retail branches. This transition enhances both customer satisfaction and inventory efficiency—critical issues for African retailers managing fluctuating demand and constrained storage infrastructure [2].

A notable South African example involves a retail chain that integrated AI with its cloud-based ERP system to enhance customer relationship management (CRM). By analysing real-time sales data and customer feedback through machine learning models, the company improved customer retention and reduced stockouts by 25% within six months [3].

While adoption remains concentrated among larger retailers, the declining cost of cloud ERP platforms is opening doors for small and medium-sized enterprises (SMEs) to adopt similar tools. As consumer expectations continue to evolve, the ability of AI-enhanced ERP systems to deliver personalisation, optimise inventory, and automate key workflows is becoming a competitive necessity in Africa's emerging retail ecosystems.

5.3 Finance

In Africa's finance sector, the integration of Artificial Intelligence (AI) into Enterprise Resource Planning (ERP) systems is transforming how financial institutions manage risk, ensure compliance, and optimise operations. Traditional ERP systems offer standardised modules for accounting, reporting, and procurement; however, these are increasingly being enhanced by AI capabilities, such as anomaly detection, fraud prediction, and real-time financial forecasting [8].

AI-enhanced ERP platforms assist banks, insurance firms, and fintech startups with identifying suspicious transactions through continuous behavioural analysis. Machine learning models embedded in ERP systems can monitor payment flows, flag outliers, and prevent internal fraud, thereby strengthening governance frameworks [5]. These features are especially critical in regions where financial fraud remains a major concern and where institutions are subject to both local and international regulatory scrutiny.

Operationally, AI-enhanced ERP systems reduce manual data processing, accelerate financial close cycles, and support automated compliance reporting aligned with frameworks such as IFRS and Basel III. In Nigeria and Kenya, digital banks have reported improved reconciliation accuracy and faster loan approval times after integrating AI-enhanced ERP workflows [2].

A notable example is a South African investment management firm that deployed AI tools within its ERP system to monitor market conditions and automate portfolio rebalancing. This led to improved client reporting and reduced portfolio drift, showcasing the potential for ERP-AI convergence to enhance both back-office and client-facing functions.

As Africa's financial institutions face growing pressure to scale digitally while minimising risk, AI-enhanced ERP systems offer a dual advantage: regulatory assurance and operational agility. Their adoption is likely to expand, particularly among firms seeking to balance cost efficiency with competitive differentiation.

5.4 Agriculture

ERP systems, when integrated with Artificial Intelligence (AI), are transforming agricultural operations in Africa by enabling precision farming, financial transparency, and digital traceability. AI-enhanced ERP platforms address this by providing real-time insights into crop performance, weather patterns, pest risks, and input management [3].

AI-enhanced ERP systems support smallholder farmers, cooperatives, and agribusinesses in optimising resource use—water, fertiliser, and seed—and forecasting yields with higher

accuracy. These systems improve visibility across supply chains, enabling alignment between production schedules, logistics, and market demand. For instance, AI models integrated into ERP platforms can analyse soil data and recommend planting times or irrigation cycles, boosting productivity and sustainability [10].

A practical example is the use of ERP-AI platforms in East African agribusiness cooperatives. These systems track farmer inputs, automate payment settlements, and generate reports used to secure microfinance or government subsidies. In Kenya, a cooperative using AI-enhanced ERP improved loan recoveries and increased yield forecasting accuracy by over 20% in one season [2].

Compared to traditional ERP systems that only document transactions, AI-enhanced platforms actively guide agricultural decision-making and enable early warning systems. They also facilitate data sharing with banks, insurers, and supply chain partners, promoting ecosystem-level integration and financial inclusion.

With agriculture employing a large share of Africa's workforce, the adoption of AI-enhanced ERP in this sector holds significant promise. These tools are not only modernising how farms are managed but are also helping bridge the rural digital divide, improving productivity, accountability, and access to markets across the continent.

5.5 Manufacturing

Africa's manufacturing sector is increasingly adopting AI-enhanced ERP systems to boost efficiency, improve product traceability, and strengthen supply chain resilience. Traditional ERP systems in manufacturing help manage core functions such as procurement, production planning, and inventory control. However, the integration of Artificial Intelligence (AI) introduces predictive maintenance, demand forecasting, and dynamic scheduling—capabilities critical to the continent's industrial growth [5].

AI-enhanced ERP platforms enable manufacturers to predict equipment failure before it happens, reducing unplanned downtime and extending machine life. These predictive insights are driven by sensor data and machine learning models that detect anomalies in real time. In African factories where maintenance resources are often limited, this shift from reactive to predictive maintenance significantly improves operational continuity [8].

Additionally, AI algorithms support supply chain visibility by tracking raw materials, production timelines, and delivery schedules across decentralised facilities. This helps manufacturers respond more flexibly to market fluctuations and resource constraints. In South Africa, a mid-sized food processing company used an AI-enhanced ERP solution to improve its batch production forecasts and reduce waste by 18% in under six months [2].

As African governments push for local industrialisation under initiatives like the African Continental Free Trade Area (AfCFTA), smart ERP systems can serve as key enablers. They support better quality control, traceability, and lean operations—factors that are essential for competitiveness in both domestic and export markets.

6 COMPARATIVE ANALYSIS WITH ERP IMPLEMENTATIONS IN OTHER REGIONS

6.1 ERP Adoption Examples from Asia and Europe

In both Asia and Europe, ERP adoption has matured considerably, with widespread integration of cloud computing, real-time analytics, and AI capabilities. Countries such as Germany, Sweden, and the Netherlands have adopted advanced ERP systems to support Industry 4.0, characterised by automation, cyber-physical systems, and IoT integration [10]. Similarly, in Asia—particularly in China and India—ERP systems have been scaled across large industrial and government sectors, often supported by strong ICT infrastructure and policy-driven digitalisation [15].

These regions have also focused on sector-specific ERP solutions tailored to industries like automotive, pharmaceuticals, and electronics. Furthermore, vendor ecosystems in Europe and Asia often offer local support, extensive documentation, and flexible deployment models, factors that reduce the total cost of ownership and improve system sustainability.

6.2 Identifying Unique Challenges and Similarities with Africa

While Africa shares some ERP adoption drivers with Asia and Europe—such as the need for integration, efficiency, and compliance—the continent faces distinct challenges. These include inconsistent power supply, weak broadband infrastructure, limited local vendor presence, and constrained digital skills [4, 12]. In contrast to mature markets, many African ERP implementations rely heavily on donor funding or top-down public sector procurement, often without adequate change management or local capacity-building [3].

However, similarities do exist: SMEs in all regions cite affordability and implementation complexity as key concerns. The adoption of cloud ERP has helped address this in Europe and Asia—and now in Africa, cloud-based AI-enhanced ERP tools are also enabling lean deployments, especially for SMEs [2].

6.3 Best Practices from Global Examples Relevant to the African Context

African ERP implementers can draw on several global best practices:

- Use of **modular ERP** to allow phased implementation.
- Strong focus on **user training and change management**.
- Emphasis on **local customisation** and language adaptation.
- Leveraging **AI** for continuous system learning and predictive performance.

Applying these practices—alongside African-centric innovation—can accelerate successful ERP transformation, ensuring that systems are both technologically robust and contextually relevant.

7 DISCUSSION

7.1 Interpretation of the Findings in Light of Theoretical Frameworks

This study employed the Technology-Organisation-Environment (TOE), Diffusion of Innovation (DOI), and Socio-Technical Systems (STS) frameworks to interpret ERP and AI adoption in African contexts. Findings from the industry case studies affirm that ERP-AI integration is not solely a technological upgrade but a systemic transformation influenced by the external environment, organisational dynamics, and user adaptability.

From the **TOE perspective**, technological readiness (e.g., cloud infrastructure, AI capabilities), organisational factors (e.g., leadership, user skills), and environmental forces (e.g., regulatory mandates, market volatility) jointly influence ERP adoption. In all five sectors studied, success hinged on the intersection of these dimensions, particularly when external pressures—such as compliance in finance or traceability in agriculture—drove innovation.

Through the **DOI lens**, the variance in AI-ERP adoption reflects differences in organisations' innovation maturity. Early adopters in South African finance and retail sectors illustrate higher AI integration due to visible benefits like fraud detection and customer personalisation (Bag, Gupta and Kumar, 2021). Conversely, in sectors like agriculture and manufacturing, diffusion remains uneven, slowed by infrastructural and skills-related barriers.

The **STS framework** further explains challenges such as cultural resistance, misalignment between ERP logic and informal workflows, and the need for human-centric system design.

Across case studies, it became evident that AI-ERP success depended not just on technical capacity but also on training, usability, and inclusive stakeholder engagement [11].

7.2 Analysis of Implications for Policymakers, Industry Leaders, and Academia

For policymakers, the findings suggest a need for enabling environments—support for data infrastructure, AI innovation hubs, and cross-sectoral digital literacy programmes. Investment incentives and public-private partnerships can help localise ERP solutions and build domestic capabilities.

For industry leaders, AI-enhanced ERP systems offer clear benefits: better resource planning, risk mitigation, and compliance. However, success requires long-term strategic commitment, phased rollouts, and cross-functional change management teams. SMEs, in particular, benefit from scalable cloud platforms that match their operational agility.

For academia, the ERP-AI interface presents rich opportunities for future research—especially in local customisation, user behaviour, and sector-specific adoption models. There is also a gap in African-origin case studies and methodologies that reflect the continent's heterogeneity.

7.3 Critical Evaluation of Strengths and Limitations of AI Integration

While AI significantly strengthens ERP systems, the review reveals notable limitations. AI tools depend heavily on structured, clean data—something many African enterprises lack due to fragmented systems or paper-based processes. Moreover, algorithmic bias and lack of local language processing capabilities can restrict inclusiveness and usability, particularly in rural areas [2].

There is also a risk of overreliance on vendor-driven solutions that may not align with local operational realities or long-term development goals. Without strong institutional capacity, AI-enhanced ERP may entrench dependency rather than build local digital resilience.

8 CONCLUSION AND RECOMMENDATIONS

8.1 Summary of Key Findings and Insights

This study explored how AI-enhanced ERP systems are reshaping enterprise performance across five major African sectors: mining, retail, finance, agriculture, and manufacturing. Through a systematic literature review grounded in the TOE, DOI, and STS frameworks, it identified that successful ERP adoption in Africa depends on more than technology—it requires supportive infrastructure, contextual alignment, and human-centric change management.

AI adds significant value by enabling predictive analytics, automating compliance, improving operational visibility, and enhancing customer experiences. However, this transformative potential is not uniformly realised due to infrastructural limitations, affordability challenges, and skills shortages. Sectoral case studies revealed that while early adopters are gaining tangible benefits, widespread diffusion remains limited by ecosystem maturity.

8.2 Concrete and Actionable Recommendations

8.2.1 For Policymakers:

Promote localised ERP solutions through public-private innovation hubs that develop modules tailored to African languages, regulatory environments, and informal business processes.

Subsidise cloud infrastructure and digital literacy programmes, particularly targeting SMEs and rural cooperatives.

Implement cross-sector AI governance frameworks to ensure ethical, transparent, and inclusive deployment of intelligent enterprise systems.

8.2.2 For Business Leaders:

Prioritise incremental ERP rollouts that focus on high-impact areas first—such as procurement or inventory management—before scaling AI features.

Invest in staff training and internal champions, ensuring users are involved early in implementation and workflow redesign.

Use AI strategically, not just for automation but for decision support in areas like demand forecasting, fraud prevention, and scenario analysis.

8.2.3 For ERP Vendors and Consultants:

Offer modular, scalable solutions to reduce upfront costs and encourage gradual adoption.

Develop industry-specific packages for key African sectors like agriculture and public services.

Strengthen post-implementation support through local partnerships and user communities.

8.3 Recommendations for Future Research Directions

Further empirical research is needed to:

- Examine longitudinal impacts of ERP-AI adoption in Africa's informal and micro-enterprise sectors.
- Investigate AI biases in ERP applications and their implications for equitable outcomes.
- Explore hybrid implementation models that integrate local legacy systems with global ERP platforms.
- Cross-country comparative studies and participatory action research could yield deeper insights into how culture, governance, and organisational maturity shape ERP-AI success across African regions.

8.4 Implications for ERP Implementation in Africa

AI-enhanced ERP systems are not simply digital upgrades—they represent foundational shifts in how African organisations manage resources, deliver services, and interact with global markets. If scaled responsibly, these systems can help bridge operational gaps, foster transparency, and support inclusive economic transformation. However, achieving this potential requires deliberate effort to contextualise implementation, build local capability, and embed ethical AI practices within ERP ecosystems.

ABSTRACT

This paper examines the differences between Model-Based Systems Engineering (MBSE)and traditional documentation-based approaches in the development of radar systems. MBSE leverages digital models to enhance system design, integration, and verification, promoting greater consistency, automation, and traceability. In contrast, documentation-based methods rely on static documents, which can lead to inefficiencies and inconsistencies, particularly in complex systems. The study evaluates both approaches based on key factors such as requirements management, system complexity, verification processes, and overall lifecycle costs. Case studies and industry practices are analysed to assess the practical implications of each methodology. The findings suggest that MBSE improves collaboration, reduces errors, and increases design flexibility, though documentation-based methods remain relevant in certain regulatory and legacy contexts. The paper concludes by offering guidance on selecting the most suitable approach based on project-specific needs, balancing innovation with compliance and operational constraints.

Keywords: Model-Based Systems Engineering (MBSE), RADAR, Systems Engineering

1 INTRODUCTION

The development of radar systems is inherently complex, requiring rigorous engineering methodologies to ensure reliability, efficiency, and adaptability. Traditionally, documentation-based approaches have been employed, relying on extensive textual descriptions, spreadsheets, and static diagrams to capture system requirements, design, and validation processes. However, as radar systems grow increasingly sophisticated, driven by advancements in signal processing, sensor integration, and real-time data analytics, these traditional approaches exhibit significant limitations [1]. The fragmented nature of documentation-based engineering leads to inefficiencies, inconsistencies, and difficulties in traceability, which can compromise system performance, increase development costs, and prolong project timelines [2]. In response to these challenges, Model-Based Systems Engineering (MBSE) has emerged as a transformative approach, leveraging digital models to represent, simulate, and manage complex system architectures. MBSE offers several advantages over documentation-based methods, including improved consistency, automated validation, enhanced collaboration, and real-time system analysis [3]. Despite its potential, the adoption of MBSE in radar system development remains limited due to organisational inertia, the steep learning curve associated with MBSE tools, and a lack of empirical studies comparing its effectiveness against traditional documentation-driven methods [4].

This research aims to conduct a comparative analysis of Model-Based Systems Engineering (MBSE) and documentation-based approaches in radar system development, evaluating their impact on system design efficiency, accuracy, and maintainability. By addressing this knowledge gap, the study seeks to provide actionable insights into the strengths and limitations of each methodology, offering guidance for radar system engineers and decision-makers in selecting the most effective approach for modern radar system projects. Understanding the trade-offs between Model-Based Systems Engineering (MBSE) and documentation-based approaches is crucial for ensuring that radar systems meet the demanding performance and reliability requirements of defense, aerospace, and commercial applications. If these issues are not adequately addressed, engineering teams risk relying on outdated and inefficient development methodologies, ultimately hindering innovation and operational effectiveness in radar technology. Conversely, if MBSE proves to be a superior methodology, its broader adoption could streamline development cycles, reduce errors, and enhance the agility of radar system engineering. By systematically analysing these methodologies, this research contributes to a more comprehensive understanding of best practices in radar system development, bridging the gap between traditional engineering paradigms and emerging digital transformation strategies in systems engineering [5], [6].

The structure of this paper is organised as follows. Section II presents the research problem, outlining the core challenge associated with traditional documentation-based approaches in radar system development. Section III introduces the research question, which guides the comparative evaluation of Model-Based Systems Engineering (MBSE) and documentation-based methods. Section IV articulates the research objectives, detailing the study's aims and specific areas of analysis. Section V describes the research methodology, including the desktop-based qualitative design, systematic literature review, expert reflection, and comparative benchmarking framework. Section VI provides the literature review, exploring key MBSE frameworks, critiques, and radar-related applications. Section VII examines the application of MBSE in radar development, drawing comparisons with documentation-centric approaches across dimensions such as traceability, adaptability, and system integration. Section VIII presents the case studies, with particular focus on a professional project involving a land-based X-band radar system developed using traditional systems engineering methods. Section IX offers the conclusion, summarising key findings and proposing recommendations for future adoption of MBSE in complex radar development environments.

2 PROBLEM STATEMENT

The increasing complexity of modern radar systems has exposed the limitations of traditional documentation-based engineering, including poor traceability, inefficiencies, and inconsistencies. While Model-Based Systems Engineering (MBSE) offers a more integrated and automated approach, its adoption remains limited due to implementation challenges and a lack of comparative evidence. A clear evaluation of both approaches is needed to inform methodology selection and optimise radar system development.

3 RESEARCH QUESTIONS

The critical research question for the study is:

- How does MBSE compare to traditional document-based approaches in the development of radar systems, particularly in terms of efficiency, accuracy, and adaptability to complex system requirements?

4 RESEARCH OBJECTIVES

- The objective of this research is to conduct a comparative analysis of Model-Based Systems Engineering (MBSE) and documentation-based approaches in the development of radar systems. The study aims to assess their effectiveness, efficiency, and suitability for complex system engineering. The specific research objectives are:
- To evaluate the effectiveness of MBSE and documentation-based approaches in radar system development – Examining their impact on system design, integration, qualification, and verification processes.
- To compare the efficiency of MBSE and documentation-based approaches in managing system complexity – Assessing how each approach handles the increasing complexity of radar systems, particularly in multi-disciplinary engineering environments.
- To investigate the accuracy and consistency of system requirements, design, integration, qualification, and validation processes in both approaches – Analysing how MBSE and traditional documentation methods ensure traceability, compliance, and reduced errors.
- To determine the challenges and limitations of MBSE and documentation-based approaches in radar system development – Identifying constraints related to implementation, resource allocation, and industry adoption.
- To propose a framework for optimizing radar system development through MBSE and/or documentation-based best practices, recommending strategies for improving efficiency, accuracy, and reliability in radar engineering projects.

5 RESEARCH METHODOLOGY

This study adopted a desktop-based, qualitative research design to evaluate the comparative effectiveness of Model-Based Systems Engineering (MBSE) and traditional documentation-based approaches in the development of radar systems. The aim was to synthesise current practices, derive analytical insights, and assess methodological strengths and weaknesses within the systems engineering domain, particularly in the context of complex defence-related projects. The approach is exploratory in nature and interpretive in application, offering a grounded assessment rooted in both published literature and professional engineering experience. To ensure methodological rigour, the study employed three core techniques: a systematic literature review (SLR), a technical artefact and process analysis, and a comparative benchmarking framework. These elements were selected to facilitate

triangulation between theoretical insights, documented engineering practices, and expert testimony.

5.1 SYSTEMATIC LITERATURE REVIEW (SLR)

The SLR was conducted on 3 March 2025 using a modified PRISMA-style screening protocol to ensure transparency and reproducibility. Literature searches were performed across multiple scholarly and defence-focused databases, including IEEE Xplore, Scopus, and Google Scholar. Boolean operators and targeted keyword strings were used to refine the search scope, including:

- “Model-Based Systems Engineering” AND “Radar System Development”
- “MBSE” AND “Defence Systems” OR “Systems Engineering”
- “Documentation-based engineering” AND “Complex Systems Development
- “Radar system integration” AND “MBSE vs traditional approaches”

The search was restricted to English-language publications from 2020 to 2025 to prioritise contemporary technologies and engineering practices. Grey literature such as technical white papers, case documentation, and policy guidelines was also consulted, with material sourced from Armscor, Denel, and other defence-related academic sources. Reference mining and manual screening were used to identify supplementary sources not indexed in academic databases.

5.2 CASE-BASED EXPERT REFLECTION

To ground the literature in a practical context, a detailed professional case study was incorporated based on the author’s direct involvement in the development and deployment of a land-based X-band surveillance radar system. This case study provides insight into the traditional documentation-centric engineering lifecycle, covering phases from requirements specification to system integration, field testing, and sustainment planning. This experiential reflection enabled a qualitative comparison between actual project constraints, engineering artefacts, and best-practice principles derived from MBSE literature. The case study was not presented as empirical proof but rather as a context-rich platform to interrogate assumptions and evaluate methodological efficacy.

5.3 COMPARATIVE FRAMEWORK

A benchmarking framework was constructed to facilitate a structured comparison between the two engineering approaches. Key evaluation criteria were derived from the literature and included:

- Requirements traceability
- Change management
- Verification and validation efficiency
- Cross-disciplinary collaboration
- Error reduction and quality assurance
- Adaptability to complexity and scalability
- Regulatory compliance support

Each criterion was assessed through the synthesis of documented literature claims, professional experience, and inferred project dynamics. While the analysis remains largely

qualitative, the structured framework serves to standardise evaluation and enhance transparency.

6 LITERATURE REVIEW

She et al. proposed a Model-Based Systems Engineering (MBSE) framework to support the integrated modelling and optimisation of UAV radar cabin layouts. The approach employs the KARMA semantic modelling language to formalise system design using the RFLP structure, capturing Requirements, Functional, Logical, and Physical aspects through nine SysML-compliant diagrams. These include use case, activity, state machine, block definition, and parameter diagrams, offering a comprehensive digital representation of the radar cabin system. The framework integrates automatic code generation that converts KARMA models into input files for a Genetic Algorithm (GA) in MATLAB, which performs layout optimisation by minimising cable length and improving the spatial configuration of radar equipment. A model synchronisation toolkit enables bi-directional data flow, ensuring that the optimised spatial coordinates of devices are accurately updated in the original KARMA models. This bidirectional linkage supports consistency between system design and simulation models, addressing issues commonly seen in document-centric radar cabin designs.

In a UAV case study, the proposed approach significantly improved layout efficiency and design traceability. The semantic modelling facilitated structured configuration management, while the GA-driven optimisation yielded spatial layouts with reduced inter-device distances and streamlined cable routing. The results demonstrate that MBSE, when supported by domain-specific languages like KARMA, enhances automation, accuracy, and design quality in complex aerospace systems [7].

Keysight Technologies developed a model-based engineering (MBE) framework to streamline and de-risk radar system development through integrated simulation and design analysis. Implemented primarily in SystemVue and co-simulated with MATLAB, ADS, STK, and Google Maps, the framework enables comprehensive modelling across the radar lifecycle from requirement definition to validation. It formalises system behaviour through a layered architecture comprising trajectory, antenna, and signal domains, capturing platform dynamics, waveform synthesis, phased array beamforming, and environmental effects such as clutter, jamming, and interference.

The main system model allows scalable fidelity, supporting both high-level performance estimation and detailed subsystem verification. Subsystems such as transmit-receive modules and power amplifiers are co-simulated using ADS and can incorporate measured or circuit-level data. Signal processing elements, including pulse compression, MTI, and MTD, are modelled to support Doppler estimation and target tracking. External control via C++, LabVIEW, or MATLAB enables automated scenario testing and parameter sweeping, promoting rapid iteration and top-down design convergence. This MBE approach enhances traceability, system validation, and architectural optimisation while reducing physical prototyping dependency. It is particularly effective for complex radar configurations such as multi-static systems, dynamic environments, and adaptive waveform operations, ensuring performance assurance before hardware realisation [8].

Lerat conducted a critical analysis of Model-Based Systems Engineering (MBSE), contending that traditional document-based systems engineering (SE) often proves more effective in practice than poorly implemented MBSE initiatives. Framed provocatively, his paper outlines three fundamental reasons why most MBSE applications fail to deliver their promised benefits: misalignment with core SE principles, self-generated complexity, and limited capability for cross-disciplinary information sharing. Built from extensive industry experience, the paper argues that MBSE efforts frequently substitute modelling activity for genuine systems engineering, focusing on product-level details rather than system-level architectural

reasoning. Lerat distinguishes between true systems engineering, defined by a deep understanding of mission objectives, environmental constraints, and technical consequences, and superficial modelling efforts that fail to anchor architectural integrity. He notes that in many organisations, MBSE tools are used to generate disconnected diagrams with little relevance to system behaviour, often bypassing the rigorous validation loops essential to SE.

The second concern raised is that MBSE can exacerbate complexity when it fails to account for varying control-command (C2) structures across system hierarchies. Lerat explains how systems composed of heterogeneous subsystems, each with distinct C2 strategies (e.g., Boolean, probabilistic, analog), require thoughtful architectural coordination, something document-based SE, with its forced discipline, often handles better. In contrast, MBSE platforms, when misused, allow these differences to go unchecked, leading to misaligned models, inconsistent interfaces, and degraded system performance.

Thirdly, the paper critiques MBSE's claim to improve information sharing. Lerat observes that many MBSE implementations simply digitise siloed practices, embedding domain-specific models within incompatible tools and profiles. Far from enhancing collaboration, this often results in bloated, opaque models that obscure rather than clarify system intent. He argues that genuine architecture, the backbone of any system, is frequently lost amid excessive tool-driven modelling. While not rejecting MBSE as a concept, Lerat insists that successful MBSE adoption must be rooted in sound systems engineering culture. Tools must serve engineering thought, not replace it. The paper concludes by asserting that MBSE, when introduced into organisations lacking architectural discipline and cross-functional readiness, can fail spectacularly. Conversely, when layered onto an already robust document-based process, MBSE can enhance efficiency, traceability, and analytical power, provided the architectural foundations are firm [9].

Banik and Sengupta conducted a comparative study evaluating the performance of a document-centric systems engineering approach by modelling a serial transfer line with three machines and two buffers. The system was modelled using discrete event simulation (DES), and performance was evaluated through key performance indicators (KPIs) such as system throughput, machine utilisation, and cycle time. The study adopted a document-based technique where system requirements and process logic were captured using textual documentation, flowcharts, and manual calculations, reflecting the characteristics of traditional systems engineering. The model captured the stochastic behaviour of machine failures and repairs through exponential distributions and was implemented in a DES environment. Performance metrics were derived through simulations, including state time distribution, average time in system, and throughput flexibility. These KPIs were used to analyse system efficiency and inform improvement recommendations, such as adjustments to buffer capacities or maintenance schedules.

Findings from the study indicate that the document-centric method resulted in a significantly higher development cost and longer delivery timeline when compared to a previously published MBSE implementation on the same case. The document-centric approach required 240 hours and cost USD 14,400, whereas the MBSE method completed the same scope in 120 hours for USD 7,200. This indicates that the traditional document-based approach nearly doubles resource expenditure without proportional performance gain. The authors concluded that while the document-centric methodology may offer flexibility and be simpler to implement in smaller or informal projects, it is inherently inefficient and difficult to scale for complex systems. The lack of traceability, modularity, and simulation support presents major challenges, especially in change management and decision-making. Banik and Sengupta argue for the superiority of MBSE in such contexts, suggesting that model-based methods enhance consistency, reusability, and cost-effectiveness [10].

7 APPLICATION OF MBSE IN RADAR DEVELOPMENT

7.1 Comparative Analysis Between MBSE and Document-Centric Approach in Radar Development

In radar system development, both Model-Based Systems Engineering (MBSE) and traditional documentation-based approaches serve distinct purposes, yet the comparative analysis in this study demonstrates MBSE as the superior methodology for modern, complex projects. MBSE offers significant advantages across critical dimensions such as traceability, efficiency, error reduction, adaptability, and scalability. By embedding requirements, design logic, test cases, and simulation outputs within a single coherent model, MBSE ensures real-time verification and transparent audit trails that support regulatory compliance, whereas traditional documentation often struggles to maintain consistency in large, complex systems. The use of automated simulation tools and report generation within MBSE reduces redundant review cycles, accelerates certification timelines, and minimizes human error, in contrast to document-centric methods, which rely on manual, repetitive processes.

Furthermore, MBSE's structured, model-driven approach reduces inconsistencies and promotes higher data integrity through automatic synchronisation between system models. Its frameworks also demonstrate strong adaptability to design changes and emerging technologies, which is particularly critical in radar systems that must respond rapidly to evolving operational demands. Moreover, MBSE scales effectively by supporting multidisciplinary integration and iterative assessments, an area where document-centric approaches fall short. Nonetheless, documentation-based systems engineering remains a viable option for smaller or less complex projects, or where regulatory and legacy system environments demand it. However, its limitations are clear: poor traceability across documents, a higher incidence of errors from manual updates, inefficient verification and validation cycles, and a lack of flexibility in managing dynamic design iterations, all of which reinforce MBSE as the more robust and future-ready approach.

In support of the foregoing comparison, the reviewed literature highlights several pertinent findings. [7] demonstrated that, within the context of UAV radar cabin layouts, Model-Based Systems Engineering (MBSE) significantly enhances layout efficiency, traceability, and structured configuration management. Similarly, Keysight Technologies [8] illustrated that model-based frameworks enable comprehensive simulation across the radar system lifecycle, thereby reinforcing performance assurance before hardware realisation. Table 1 below shows a comparison of MBSE vs the Traditional document-centric approach to systems engineering in a complex project.

Table 1 Comparing MBSE vs Traditional Documentation-Centric Approach

Aspect	Model-Based Systems Engineering (MBSE)	Traditional Documentation-Centric Approach
Traceability	Requirements, design, verification, and validation are integrated within a coherent model. [2] , [7]	Traceability relies on manual cross-referencing across multiple static documents. [9]
Change Management	Dynamic updates propagate automatically across models, maintaining consistency. [8]	Changes require manual updates across various documents, risking inconsistencies. [Author's Case Study]
Error Reduction	Automated validation and synchronisation reduce human error. [3] [9]	High potential for errors due to manual editing and document version control issues. [Author's Case Study]
Collaboration	Enhanced real-time collaboration across disciplines through shared digital models. [8]	Collaboration is often hindered by document silos and inconsistent

		information sharing. [1], [Author's Case Study]
Verification and Validation	Supports simulation-based verification early in the lifecycle, reducing physical prototyping [8]	Relies heavily on physical testing and retrospective validation activities. [1]
Adaptability to Complexity	Scales effectively for highly complex, multidisciplinary systems [2], [6]	Struggles with scaling; complexity leads to fragmented and inefficient [9] documentation [Authors Case Study]
Efficiency	Streamlines design cycles with model reuse, automated reporting, and system simulations [3], [9]	Labour-intensive processes with redundant document updates and reviews documentation [10], [Authors Case Study]
Learning Curve	Requires significant initial investment in training and tool adoption [9]	Familiarity with traditional tools; lower initial training requirements [1], [Authors' Case Study]
Regulatory Compliance	Facilitates real-time audit trails and compliance documentation generation [8]	Compliance management is manual, often leading to increased audit preparation time [9], [Authors Case Study]
Risk Management	Enables proactive identification and mitigation of design risks through model-based analysis [2]	Risk identification is often reactive, discovered during integration or testing stages [1],[Author's Case Study]

8 CASE STUDY 2: MY ROLE IN THE DEVELOPMENT AND DEPLOYMENT OF A LAND-BASED X-BAND SURVEILLANCE RADAR SYSTEM USING A DOCUMENT-CENTRIC APPROACH – A SYSTEMS ENGINEERING PERSPECTIVE

This case study outlines my experience as a system engineer leading the development and deployment of a land-based X-band radar system for low-flying target detection in contested airspace. Using a documentation-centric systems engineering (SE) approach, I managed over 230 requirements, but manual traceability led to 17 documented inconsistencies, costing approximately 11 engineer-days per update cycle issues similar to those identified by [7] Across 68 module and 14 system-level tests, nine rework incidents occurred due to misaligned verification records, each requiring around 18 hours to rectify, reflecting inefficiencies compared to MBSE-based automation [8]. Field trials incurred 5–7 day validation delays per iteration due to manual correlation, echoing findings in Qin et al. [2]. During deployment, over 500 pages of documentation revealed 12 configuration control issues, which MBSE could have resolved through synchronised modelling [9]. Sustainment planning also experienced a 3-week delay from document version mismatches, an area where MBSE, as demonstrated by Banik and Sengupta [10], improves lifecycle integration. Post-project literature review confirmed MBSE's advantages in enhancing responsiveness, simulation fidelity, and cross-domain coherence [7], [8], [10]. While the documentation-based process enabled delivery, the project revealed costly limitations in traceability, validation, and adaptability. MBSE would have mitigated these challenges and, when implemented with architectural discipline and collaboration, provides a more efficient, coherent, and future-ready alternative. In conclusion, my experience confirms that a documentation-centric approach, while compliant and feasible, is inefficient in high-complexity environments. MBSE provides a demonstrable improvement in traceability, system validation, and lifecycle integration, particularly when deployed with architectural discipline and cross-functional collaboration, as advised by [9]. For future radar projects, especially those involving rapid iteration or modular upgrades, MBSE should be adopted strategically to reduce errors, compress timelines, and improve engineering agility.

8.1 Proposed Decision-Support Framework for Approach Selection

While Table 1 presents a structured comparison between MBSE and documentation-based systems engineering, practitioners often require prescriptive guidance on when to adopt one approach over the other. To address this, a decision-support framework is proposed to support project managers and system engineers in approach selection.

8.1.1 Step 1: Define Project Context

Projects should first be characterised in terms of complexity, scale, regulatory requirements, team structure, and resource availability.

8.1.2 Step 2: Apply the Decision Matrix

The matrix in Table X provides a quick diagnostic for approach selection. High complexity, regulatory pressure, multidisciplinary collaboration, and short time-to-market all strongly favour MBSE adoption, while resource constraints and low tool familiarity may justify documentation-based methods in smaller projects. Table 2 Decision-Support Matrix for Selecting Between Model-Based Systems Engineering (MBSE) and Documentation-Centric Approaches in Complex System Development.

Table 2*:* Decision-Support Matrix for Selecting Between Model-Based Systems Engineering (MBSE) and Documentation-Centric Approaches in Complex System Development

Criterion	IF HIGH	Preferred Approach
System Complexity	X	MBSE
Regulatory/Compliance Needs	X	MBSE
Multidisciplinary Team Size	X	MBSE
Urgency/Time-to-Market	X	MBSE
Budget/resource Constraints	X	Document-Centric
Familiarity with Tools	X	Document-Centric

Figure 1 below shows a decision path in selecting either the MBSE or the Document-centric approach.

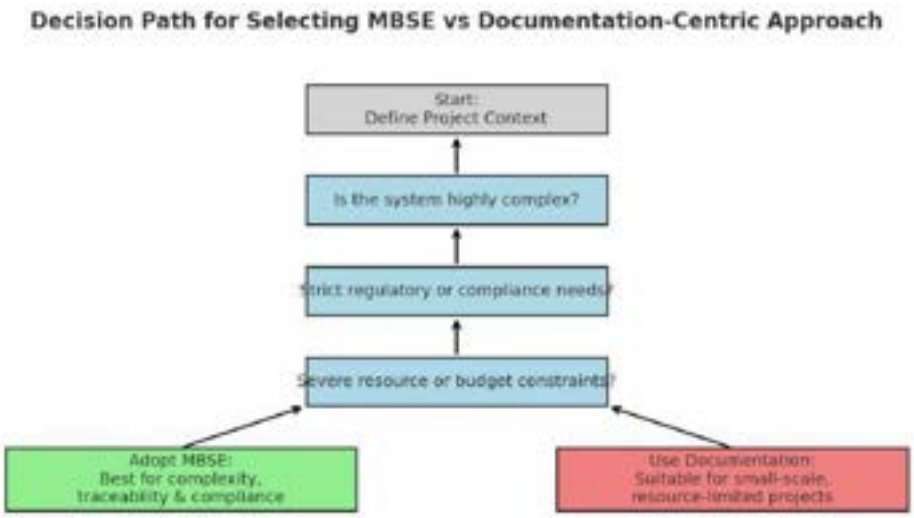

Figure 1: Decision Path for Selecting MBSE vs Document-Centric Approach

Step 3: Prescriptive Guidance

- Adopt MBSE where complexity, traceability, and compliance are central, e.g., radar, aerospace, and defence.
- Use documentation-based approaches for small, low-risk, or early feasibility projects.

- Apply a hybrid method where conceptual design begins in documents and later transitions to MBSE models.

Step 4: Implementation Checklist (MBSE Adoption)

- Secure management buy-in and allocate upfront resources.
- Train cross-disciplinary teams in MBSE tools and workflows.
- Establish traceability between requirements, models, and verification artefacts.
- Pilot MBSE at the subsystem level before scaling across the full project.

This prescriptive framework strengthens the practical transferability of the study, enabling engineers to move from comparative insight to actionable decision-making in their project environments.

9 CONCLUSION

This study critically explored the comparative merits of MBSE and traditional documentation-based approaches in the context of complex radar system development. Drawing from a combination of scholarly literature and practitioner insights, it is evident that MBSE provides compelling advantages in areas such as requirements traceability, verification efficiency, error minimisation, and adaptability to complexity. The inclusion of digital modelling tools facilitates tighter integration across engineering phases, enabling real-time validation, design consistency, and more agile responses to system modifications capabilities, which are particularly crucial in high-stakes sectors such as defence and aerospace. While MBSE is increasingly recognised as a forward-looking methodology, it is not without limitations. Its successful adoption hinges on organisational readiness, disciplined implementation, and a strong foundation in sound systems engineering principles. The literature and professional experience reviewed both caution against the uncritical or superficial application of MBSE, noting that poor tool usage can introduce avoidable complexity and hinder cross-disciplinary collaboration. Moreover, empirical evidence supporting MBSE's benefits remains somewhat limited, underscoring the need for continued research involving real-world project data, such as defect tracking, rework costs, or verification timelines.

Traditional documentation-based methods, although increasingly strained under modern system complexity, still hold value in legacy programmes and highly regulated environments where change management processes are constrained. As such, these approaches should not be dismissed outright but rather integrated strategically where appropriate. Importantly, this paper contributes to the growing discourse on digital transformation in systems engineering by proposing a structured comparison framework, supported by both literature and practice. The case study provided adds grounded insight into the lived realities of documentation-centric project execution, while the broader comparative analysis promotes informed decision-making for engineering leaders facing methodological choices.

In conclusion, MBSE is not a silver bullet, but when implemented thoughtfully with clear architectural rigour, multidisciplinary engagement, and proper validation protocols, it can significantly enhance the engineering of complex radar systems. South African industries, particularly in defence and aerospace, stand to benefit from this transition, provided that it is accompanied by investment in skills development, tool integration, and empirical performance tracking. Future research should focus on quantifying MBSE's real-world impacts across diverse project environments, thereby enabling more robust benchmarking and advancing the maturity of systems engineering practice both locally and globally.

ABSTRACT

Integrating circular economy concepts into small and medium enterprises (SMEs) in South Africa is necessary for sustainability, improving resource efficiency, and reducing waste. This study offers a comprehensive framework for incorporating the circular economy (CE) into South African manufacturing SMEs to encourage waste reduction and sustainable resource use. This study discusses CE adoption challenges in SMEs such as restricted access to funding, technical know-how, and regulatory assistance. The findings indicate that CE adoption faces challenges like high costs and inadequate skills; the benefits, such as reduced material costs, new revenue streams, environmental compliance, and competitive resilience, are significant. Government incentives, capacity-building programs, and advanced digital tools can support SMEs' transition from linear to CE. The framework emphasises the importance of a collaborative approach that involves industry stakeholders, policymakers, and consumers to promote sustainable industrial development and align South African SMEs with global sustainability standards.

Keywords: Circular economy, industrial symbiosis, manufacturing SMEs, sustainable resource utilisation, waste reduction

1 INTRODUCTION

The goal of a circular economy (CE) is to maximise resource use and minimise waste. It maximises the value of materials while in use, extending their useful lives, and recovering and regenerating materials and products at the end of each service life [1]. This is contrary to the 'take-make-dispose' model of the conventional linear economy. The CE encompasses the design of systems and products with the objectives of regenerating nature, circulating materials and products, and mitigating waste and pollution. The need for sustainable development strategies in all sectors has grown globally due to the acceleration of resource scarcity, climate change, and environmental degradation [2]. The CE is becoming more well-known as a revolutionary method of production and consumption. CE challenges the conventional linear "take-make-dispose" economic model and encourages a restorative and regenerative system by placing significance on resource efficiency, waste minimisation, and continuous material use. Governments, businesses, and civil society organisations are realising that CE is an essential framework for attaining long-term sustainability. But putting it into practice is still a difficult task, especially for small and medium-sized businesses (SMEs) and in developing nations [3].

An SME is defined as a business that has the following attributes: fewer than 250 employees, less than R64 million in annual turnover, less than R10 million in capital assets, and direct managerial engagement by the owners. Small firms need 10 to 50 employees, medium-sized organisations can have up to 250 employees, and micro enterprises can have no more than 10 [4]. SMEs are an essential part of the South African economy; they have a major impact on GDP, innovation, and employment. However, these businesses also have to deal with systemic issues, such as restricted access to capital, lack of skilled workers, inadequate infrastructure, and a frequently lax regulatory framework [5]. Embracing and incorporating CE principles into SME operations is hindered by a lack of skilled workers, inadequate infrastructure and finance [6]. Because of a lack of specialised frameworks that connect sustainability ideals with practical realities and a lack of institutional support, many South African SMEs continue to operate within resource-intensive and waste-generating models despite growing awareness of sustainability issues [7].

In addition, South Africa has urgent environmental problems like excessive landfill usage, water scarcity, high carbon emissions, and wasteful energy use, many of which are made worse by unsustainable industrial practices. Enabling SMEs to implement CE practices is both necessary and advantageous in light of these obstacles. By lowering material costs, creating new markets, and conforming to global sustainability standards and laws, the shift to a circular economy can improve SMEs' resilience and competitiveness. This study offers a framework for integrating the CE into South African manufacturing SMEs. The framework seeks to promote efficient waste reduction and sustainable resource use.

South African manufacturers can simultaneously reduce the effects on the environment, increase their ability to withstand resource shortages, and open up new business prospects in a global marketplace that is more competitive by embracing these changes. The focus and gaps in a few recent studies on CE in SMEs are compiled in Table 1.

Table 1: Previous studies on CE in SMEs

Research focus	Research Gap	Limitation	Ref
The paper suggests developing a CE framework in South African manufacturing SMEs by enhancing resource productivity and implementing waste minimisation projects.	Waste minimisation initiatives have little effect.	Low impact of waste minimisation projects in municipalities.	[8]
The paper highlights the need for identifying CE opportunities in manufacturing, emphasising early-stage product design and resource demand to promote sustainable resource utilisation and waste reduction in SMEs.	Identify CE opportunities in resource-intensive divisions.	More needs to be done at the early stage of product design	[3]
Developing a framework for sustainable resource utilisation in South African manufacturing SMEs involves integrating CE principles like eco-design, advanced technologies, and consumer engagement.	Challenges and barriers to circular manufacturing implementation are evaluated. Prospects and opportunities within the CE landscape have been identified.	Challenges and barriers to circular manufacturing implementation. Limitations of the traditional linear economic model.	[9]
Implementation involves integrating resource efficiency practices, waste minimisation techniques, and sustainability in South African manufacturing SMEs.	Lack of technical competence and funds	Need for strategies to enable successful integration.	[10]
A framework for sustainable resource utilisation in South African manufacturing SMEs can be developed by integrating supply chain management and smart production techniques.	Linkages between theoretical vision and practical ideas need clarification.	Insufficient detail on theoretical and practical linkages. Lack of a metrics-oriented approach for social sustainability.	[11]
Sustainable resource utilisation in South African manufacturing SMEs involves adopting CE principles.	Barriers to implementing CE principles	Challenges of implementing CE principles	[12]
The paper suggests a phased transition framework for SMEs, utilising management tools like value mapping and life cycle assessment, to enhance circular economy integration.	Transition framework for circular economy tool deployment Integration	Limited adaptation of current management tools for SMEs Need for phased transition in CE tool deployment for SMEs	[13]
Determine models for implementing the CE, in particular, the Sub-Saharan African and South Asian economic sectors, using data from the Sustainable Manufacturing and Environmental Pollution (SMEP) program.	Ambiguity around pathways to implement the circular economy.	The fragmented and highly granular nature of circular economy research Lack of practical examples and pathways for implementation	[14]

Despite previous innovations in CE studies in Table 1, it is clear that new research in CE is needed to address the need for improvement, flexibility, affordability, sustainability, and best practices. This serves as the driving force behind this current study. This study contributes to the literature on SME sustainable manufacturing in South Africa by providing useful information to business owners and policymakers. This study employs, synthesising of existing literature on Circular Economy, SME development, and the South African industrial context to develop a practical framework for CE integration. The proposed framework serves as a tactical instrument to encourage the shift to a resilient and circular manufacturing industry.

2 THE CONCEPT OF CE IN SOUTH AFRICA

CE has developed from a fringe environmental concept to a workable strategy for increasing manufacturing efficiency throughout South Africa's industrial landscape [15]. Understanding circularity becomes crucial for business survival and expansion as the pressures on our resource-intensive economy increase [16]. Through practices like upkeep, reuse, refurbishment, remanufacturing, recycling, and composting, the CE symbolises a system in which materials never end up as waste and nature is restored. Circularity is different from the linear economy that involves a "take-make-dispose" approach, and is based on three fundamental ideas: regenerating natural systems, circulating goods and materials at their maximum value, and removing waste and pollution. This entails changing production procedures for South African manufacturers so that resources are used continuously rather than being thrown away. The 4Rs, reducing material inputs, reusing components, recycling materials, and recovering energy and resources, are how manufacturing companies can implement circular strategies. SDG 12 (responsible production and consumption), in particular, calls for waste reduction through prevention, recycling, and reuse, and is directly supported by these practices. The comparison between the linear and CE is shown in Figure 1 [17].

Figure 1: Comparison of Linear and Circular Economy [17]

2.1 Linear versus circular models in South African SMEs

The current linear models used by South Africa's manufacturing sector are characterised by high resource throughput and substantial waste generation [18]. Due to some difficulties, the industry's share of the GDP has decreased from about 22% in the 1990s to about 12% in 2024 [19]. This decline offers a chance for reinvention using circular principles as a challenge. According to CSIR research, resource efficiency, cleaner production, material looping, and application of renewable energy technologies are examples of circular interventions that are already present in South African manufacturing [20]. However, the scale required for a significant economic and environmental impact has not been attained by these practices. Additionally, more sophisticated circular strategies are still lacking, such as:

- Circular product design and business models
- Green steel manufacturing
- Biobased fuels and materials
- Industrial symbiosis partnerships

The transition of SMEs from linear to CE faces certain challenges, such as the equipment costs, data measurement capabilities, and perceived regulatory complexity.

3 CURRENT PRACTICES, CHALLENGES, AND OPPORTUNITIES OF CE IMPLEMENTATION IN SME

There are many advantages to a circular economy, such as resource conservation, decreased waste, and decreased pollution. Additionally, it generates new economic opportunities and encourages innovation. Nevertheless, there are obstacles to overcome, including the requirement for substantial infrastructure modifications, changes in consumer behaviour, and getting past opposition from conventional linear economic models. Consumers, governments, and industries must work together to implement the principles of the circular economy. A sustainable culture, technological advancements, and effective policy are all necessary for a successful transition. Table 2 displays the CE benefits.

Table 2: Circular economy benefits

Term	Explanation	Ref
Resources conservation	The CE reduces the demand for new resources, such as water, metals, and electricity. This helps the conservation of natural resources.	[2]
Environmental sustainability	Eliminates waste and minimises the necessity for new resources	[21]
Resource efficiency	Extends the lifecycle of products and materials	[22]
Job creation	Stimulates innovation and creates employment opportunities	[23]
Waste reduction	Managing materials and products will reduce waste that goes into landfills and pollutes oceans.	[2]
Lower Carbon Footprint	Circular practices reduce the need for new raw materials, production, and transportation. It helps with climate change.	[24]
Market Innovation	The CE boosts innovative product design, business models, and services. Companies that embrace this model can differentiate themselves and capture new market opportunities.	[25]
Cost Savings	A circular model achieves substantial savings on material costs. Companies can use fewer resources, cut waste management expenses, and create new revenue streams by selling recycled products.	[26]
Enhanced Resilience	Businesses that rely less on a few resources can become resilient to supply chain disruptions.	[27]
Healthy society	Reducing pollution and waste can lead to cleaner water, improve the quality of air and soil, and promote healthier living conditions.	[28]

The significant prospects for sustainability and economic expansion can be achieved by implementing the CE framework in SMEs; however, obstacles like high implementation costs and constrained industry capacity still exist. To achieve the potential of a circular economy in South Africa, these issues must be resolved, as indicated in Table 3.

Table 3: Circular economy challenges

Term	Explanation	Ref
Technological dependency	Requires advanced technology and infrastructure	[29]
Cultural and behavioural change	Requires a shift in consumer behaviour and mindset. Changing Mindsets by shifting from a linear to a circular mindset requires significant changes in consumer behaviour, business practices, and policy frameworks.	[30]
Market disruptions	Challenges in transitioning from traditional business to circular models may occur.	[31]
Regulatory complexities	Needs government policies and regulations to support circular practices	[32]
Finance	Inadequate financial support	[33]

4 SOUTH AFRICA'S CE FRAMEWORK

As global trade becomes more focused on sustainability, South Africa has exceptional opportunities to use circularity for a competitive advantage. The CE framework tailored for SME implementation is shown in Figure 2.

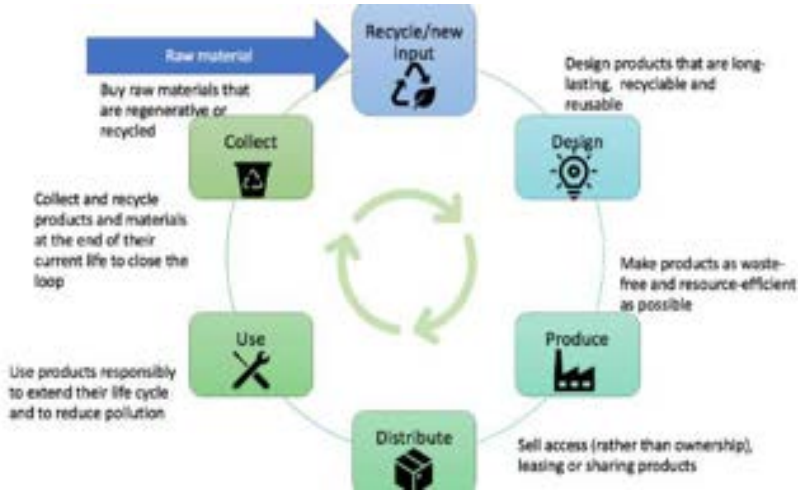

Figure 2: CE framework tailored for SME adoption [34]

Framework mechanisms that promote increased resource productivity, innovation, producer responsibility, consumer education and awareness are depicted in Figure 2 by following the six-step method:

i. Design: Products and packaging are made with more sustainable materials that are easily recyclable at the end of their useful lives, utilising fewer raw materials, and lasting longer.

ii. Produce: Companies work together and coordinate across industries to cut back on the use of fossil fuels and greenhouse gas emissions.

iii. Distribute: Retailers provide end-of-life take-back or maintenance and repair services, products that are easily refurbished and reused, and assistance to producers in educating and raising consumer awareness.

iv. Consumer Use: Choosing more environmentally friendly products, sharing resources (such as vehicles and tools), and fixing or donating them to others for repair and reuse

v. Reuse and Repair: Throughout the life cycle of products and packaging, manufacturers devise a method to recover materials and provide service for repairs.

vi. Recycle: Increasing the efficiency of collection and treatment systems will reduce the amount of waste ending up in landfills and promote the circular design's economics.

Previous studies indicate that circular economy practices are readily accessible for approximately 95% of SMEs and typically result in immediate new revenue streams [35-37]. With manufacturing strategically positioned to influence both upstream and downstream processes across value chains, the sector is uniquely placed to lead South Africa's broader economic transformation toward circularity.

4.1 Waste Cost Breakdown in South African SMEs

South Africa generates nearly 55 million tons of total waste annually, with only 11% being diverted from landfill. In the manufacturing sector, waste streams primarily consist of biomass and organic materials (the largest single waste type), followed by construction and demolition

waste at 13%. Additional significant streams include paper, plastics, glass, metals, and various types of hazardous waste [38].

4.2 Circular Economy Saving Strategies

Waste generated in SMES can be converted into useful resources through creative circular strategies. Innovative manufacturers are cutting costs and their environmental impact by abandoning conventional production models. The five strategies on how SMEs can use circular economy techniques to make a significant amount of money are as follows:

4.2.1 Material reuse in packaging and production

By extending the life span of materials in circulation, the circular economy minimises waste and resource extraction. Reusing materials that would otherwise be thrown away has allowed South African small manufacturers to save a significant amount of money. Reusing packaging materials is one strategy, for example. An online retailer encourages consumers to return items in their original packaging so that the business can fix and reship the items without incurring extra packaging expenses.

4.2.2. Process redesign to reduce offcuts and defects

SMEs wishing to cut waste often use the Lean Six Sigma methodology. Lean thinking, which emphasises speed, flow, and cost, and Six Sigma, which emphasises quality consistency, are combined in this integrated approach. SME Manufacturers find inefficiencies and make targeted improvements by using the methodical DMAIC (Define, Measure, Analyse, Improve, Control) process. In actuality, this takes the form of redesigned production procedures that maximise resource utilisation, minimise material offcuts, and minimise defects. Businesses that use these guidelines usually see a reduction in production waste and a quality improvement, which directly lowers costs.

4.2.3 Energy recovery from biomass and waste heat

Approximately 50% of South Africa's renewable energy consumption comes from bioenergy, which is mostly utilised in the industrial and residential sectors to produce heat [39]. Waste-to-energy technologies are helping manufacturing companies realise their potential. Technologies for thermal destruction, such as pyrolysis and gasification, recover energy from tires, rubber, biomass, municipal waste, and some types of plastic. Biogas and anaerobic digestion are two examples of biological waste-to-energy systems that use organic waste, such as food scraps and agricultural residues, to produce energy. By capturing and redistributing otherwise wasted heat energy back into production systems, waste heat recovery systems provide extra energy sources for producing steam, hot water, or electricity.

4.2.4 Supplier take-back and reverse logistics

The management of goods flowing in the opposite direction from the main logistics chain, or reverse logistics, has become a significant untapped source of profitability. Under this model, suppliers retrieve used goods from clients for recycling, remanufacturing, or refurbishment. Effective reverse logistics initiatives set businesses apart from rivals and foster greater client loyalty. Companies using reverse logistics systems now report significant waste reduction and cost savings from extending product lifecycles, even though only 3% of the South African supply chain practices reverse logistics [40].

4.2.5 Local industrial symbiosis partnerships in South Africa

The practice of turning one company's waste into another's resource, known as industrial symbiosis, has grown significantly in South Africa in recent years. The provinces of KwaZulu-Natal, Western Cape, and Gauteng currently have three regionally facilitated industrial symbiosis programs in place.

Just the Western Cape Industrial Symbiosis Program (WISP) has produced impressive outcomes, diverting 36,600 tons of waste from landfills, reducing greenhouse gas emissions by 147,700 tons, and generating R67.9 million in financial benefits, including cost savings, private investments, and additional revenue. Initiatives promoting industrial symbiosis have saved 431,000 tons of virgin resources, diverted 518,000 tons of waste from landfills, and decreased CO_2 emissions by 1.7 million tons nationwide between 2015 and 2022. The percentage of urban households that sort their waste for recycling is shown by province in Figure 3 [41]. This highlights the benefits of industrial symbiosis partnerships in South Africa.

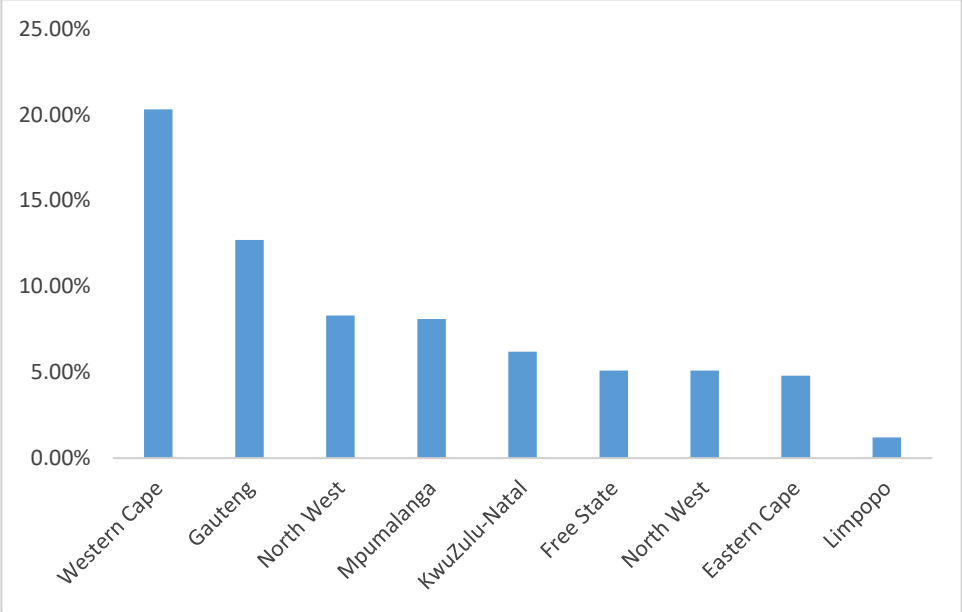

Figure 3: Percentage of Urban Households that Sorted Refuse for Recycling Purposes by Province [41]

5 POLICY AND REGULATION FOR PROMOTING CIRCULAR MANUFACTURING

Circular manufacturing principles are becoming more and more important in South Africa's policy framework, which makes it easier for small manufacturers to gain the financial and environmental rewards.

5.1 Incentives and funding for green manufacturing

Circular manufacturing receives funding through many sources. Over three years, the Manufacturing Competitiveness Enhancement Program provides incentives to manufacturing companies, including grants for resource efficiency improvements and green technology. Supported by the Department of Science and Innovation (DSI) and carried out by the Council for Scientific and Industrial Research (CSIR), the recently created Circular Economy Demonstration Fund seeks to showcase successful circular economy initiatives that haven't yet reached scale in South Africa [20]. There are additional tax breaks available for assets related to environmental treatment and recycling, renewable electricity production, and energy efficiency improvements.

5.2 Role of CSIR, NCPC-SA, and DSI in SME support

Adoption of circular manufacturing is greatly aided by the National Cleaner Production Centre South Africa (NCPC-SA), which is run by CSIR and supported by the Department of Trade, Industry, and Competition. Among its extensive offerings are:

- The Eco-Industrial Parks Program, the Industrial Water Efficiency Project, the Industrial Symbiosis Program, and the Industrial Energy Efficiency Project
- The NCPC-SA hosted the launch of the South African Circular Manufacturing Initiative (SACMI) in 2024. In order to direct future interventions, this initiative will create a Circularity in Manufacturing STI strategy. To strengthen the government's commitment to this shift, the DSI is creating a more comprehensive circular economy STI strategy to direct investment from the public and private sectors.

5.3 Scaling Circular Practices Across the Sector

Expanding CE practices across South African manufacturing requires overcoming multiple barriers before businesses can fully realise the savings potential. While pioneering companies demonstrate impressive results, widespread adoption faces practical challenges.

5.4 Training and capacity building for SME owners

The need to provide workers with skills related to the CE is becoming more apparent in educational programs. Nowadays, most training programs still ignore crucial soft and digital skills in favour of concentrating primarily on technical topics like remanufacturing procedures and circular product design.

The vocational education and training (VET) programs must provide curricula tailored to the particular constraints of SMEs to engage them. Crucially, as companies face implementation obstacles, follow-up mentoring, assessment tools, and ongoing advice assist them in honing their strategies.

5.5 Digital tools and 4IR technologies for waste tracking

The adoption of the CE could be faster with Industry 4.0 technologies [42]. In essence, these digital tools facilitate effective resource management and waste tracking across product lifecycles.

Throughout production cycles, smart manufacturing tools maximise the use of materials and energy. Predictive maintenance also reduces energy waste and replacements while increasing machine lifespans.

In order to facilitate reporting requirements and discourage waste crimes, South Africa intends to implement a mandatory digital waste tracking service starting in 2025. In order to use this service, waste producers will need to replace the current paper-based systems with detailed records of waste movements.

Recycling is already being formalised and encouraged through the use of mobile applications. For example, Urban Surfer tracks waste management activities using GPS on collection trolleys, locating collection hotspots and extracting useful information on brand penetration.

6 CONCLUSION

A revolutionary way to achieve resource efficiency, economic resilience, and sustainable industrial development is through the incorporation of CE principles into SMEs. A thorough framework that is adapted to the particular opportunities and difficulties faced by SMEs in the South African context has been developed by this study. The proposed framework enables small manufacturers to shift from the conventional linear economic model to a more regenerative approach by emphasising strategic areas like waste valorisation, process redesign, industrial symbiosis, and digital innovation.

The results highlight that while SMEs encounter numerous obstacles, such as a lack of technical know-how, high implementation costs, and insufficient policy support, the financial and ecological advantages of adopting CE are substantial. These include reduced operational costs, enhanced competitiveness, new revenue streams, and improved environmental compliance.

Furthermore, digital waste tracking systems, government incentives, and capacity-building programs can greatly facilitate the transition for SMEs. Importantly, stakeholders must work together for CE practices to spread throughout the manufacturing industry. This entails improved vocational training, targeted financial mechanisms, stronger government leadership, and ongoing public-private cooperation. SMEs in South Africa that adopt circularity will be better positioned to prosper in a low-carbon, resource-conscious economy as global markets place an increasing emphasis on sustainable production standards. Finally, the suggested framework ensures a future in which economic growth is not accompanied by environmental degradation by addressing present constraints and bringing SMEs into line with long-term national and international sustainability goals.

ABSTRACT

South Africa is transitioning towards renewable energy technologies after decades of reliance on coal and fossil fuels for power generation, as outlined in national energy policy. This policy emphasizes the need for long-duration storage to ensure grid stability. As the energy sector moves towards more sustainable solutions, the need for large-scale, reliable energy storage has grown due to the intermittency of renewable sources such as solar and wind. Redox flow batteries (RFBs) have emerged as a promising electrochemical storage solution, offering modular scalability, using non-flammable aqueous electrolytes, enabling long cycle life, and providing operational flexibility. This study conducts a systematic literature review (SLR) of peer-reviewed journal articles, conference proceedings, and industry reports published between 2016 and 2024, sourced from five major databases, to assess the technological maturity of RFBs and their potential applications. The findings reveal that while some RFB applications have reached commercial viability, broader adoption remains limited due to high capital costs, low energy density, and limited local manufacturing capacity. With advancements in design, chemistry, and efficiency, RFBs could play a crucial role in grid stabilisation, renewable energy integration, and rural electrification in South Africa. Further industry collaboration and policy support are essential to accelerate widespread implementation.

Keywords: Systematic literature review, Redox flow batteries, energy storage, technological maturity.

1 INTRODUCTION

The global energy landscape is experiencing a significant shift from traditional fossil fuels towards renewable energy sources. This transition, driven by the urgent need to mitigate climate change and ensure sustainable development, necessitates effective and scalable energy storage solutions [1], [2]. In South Africa, this shift is framed by the Integrated Resource Plan (IRP 2019), which outline targets for renewable energy integration and emphasizes long-duration storage to support grid stability and mitigate load shedding [39]. Among various energy storage technologies, Redox Flow Batteries (RFBs) have emerged as a promising option due to their inherent advantages, including modular scalability, non-flammable aqueous electrolytes, long cycle life, and flexible operational profiles [3], [4].These characteristics are particularly relevant to South African's renewable integration targets, where long-duration storage can mitigate load shedding and facility higher renewable penetration in both urban and rural grids.

RFBs function through electrochemical reactions between two liquid electrolytes stored in external tanks. These electrolytes flow through an electro-chemical cell stack where ion exchange across a membrane, generating electrical energy. This design allows independent scaling of power capacity, determined by the cell stack, and energy capacity, dictated by the volume of electrolyte stored, making RFBs suitable for large-scale, stationary energy storage applications [5]. Unlike lithium-ion batteries, RFBs offer enhanced safety due to their aqueous electrolytes, reduced risk of thermal runaway, and improved recyclability, making them highly attractive for sustainable energy storage [6].

Figure 1 illustrates the fundamental operating principle of Redox Flow Batteries (RFBs) compared with three widely deployed battery technologies: lithium iron phosphate ($LiFePO_4$), lithium-ion (Li-ion), and lead-acid batteries. While Li-ion and $LiFePO_4$ batteries store energy within solid electrodes, RFBs store energy in external liquid electrolyte tanks, enabling independent scaling of power and energy capacity. This distinction underpins the superior scalability and operational flexibility of RFBs. Lead-acid batteries, though cost-effective and established, suffer from lower cycle life and reduced efficiency compared to modern chemistries. The figure also highlights safety, environmental impact, and application flexibility differences, providing a contextual foundation for understanding RFB advantages and trade-offs in subsequent sections.

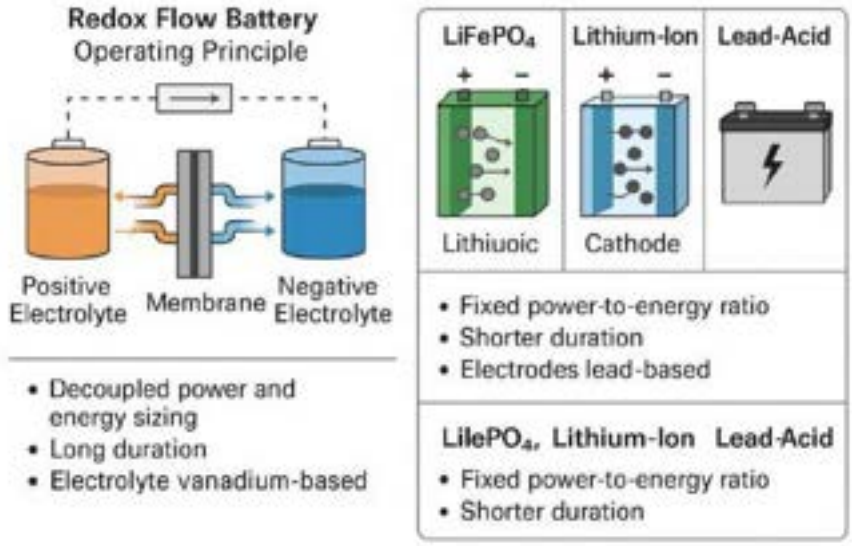

Figure 1: Comparative operating Principle of RFBS vs $LiFePO_4$, Li-ion and lead-acid battery technologies

For policymakers, such distinctions influence regulatory priorities, incentive structures, and national energy planning, particularly when balancing cost, sustainability, and reliability objectives. Investors require clear performance benchmarks, long-term operational data, and market maturity assessments to guide capital allocation. For grid operators and energy suppliers, understanding the operational flexibility, cycle life, and integration requirements of different battery technologies is critical to designing systems that maintain stability, enable renewable energy penetration, and reduce reliance on fossil-based peaking plants. The comparative perspective provided in Figure 1 therefore serves as a foundation for strategic decisions across the energy value chain.

However, despite their advantages and growing interest, the technology maturity and practical applications of RFBs across different contexts remain varied and inadequately documented in academic literature [7]. This inconsistency poses challenges for policymakers, investors, and grid operators who must make informed decisions about large-scale deployment. Understanding the current state of technological maturity, identifying the diverse storage applications, and examining the commercial readiness of RFBs is thus crucial for facilitating their broader adoption and integration into renewable energy infrastructures [8], [9].

This systematic literature review (SLR) aims to address the gap by critically assessing the technological maturity status of Redox Flow Batteries and exploring their various storage use cases. Specifically, the review synthesizes recent literature to address the following Research Questions (RQ):

- RQ1: What is the technology maturity status of Redox Flow Batteries (RFBs)?
- RQ2: What are the current advancements and challenges of RFB development?
- RQ3: What are the main uses of RFBs?

These research questions guide the synthesis of technological advancements, evaluation of commercialization status, and identification of potential application scenarios [10], [11].

2 RESEARCH METHOD

This systematic literature review adopts a structured and comprehensive approach based on widely accepted methodologies for systematic reviews. The method consists of three main

phases: (i) planning, (ii) conducting, and (iii) documenting, as proposed by Albliwi *et al*. [12]. The review process involves several clearly defined steps within these phases:

A. Planning the review

- *Step 1* – Research purpose and objectives: Clearly establish the aims and objectives of the review.
- *Step 2* – Development of research protocol: Formulate inclusion and exclusion criteria, databases to be searched, and specific keywords.

B. Conducting the review

- *Step 3* – Establishing relevance criteria: Define explicit criteria for screening literature based on relevance.
- *Step 4* – Literature search and retrieval: Search the selected electronic databases for literature using predefined keywords.
- *Step 5* – Selection of studies: Screen retrieved literature based on established inclusion and exclusion criteria.
- *Step 6* – Quality assessment: Evaluate the methodological rigor and relevance of selected studies.
- *Step 7* – Data extraction: Extract relevant data systematically from selected literature.
- *Step 8* – Synthesis of studies (analysis): Analyse and synthesize extracted data to draw meaningful conclusions regarding the technology maturity and storage applications of Redox Flow Batteries.

C. Documenting the review

- *Step 9* – Reporting: Report on the SLR in detail.
- *Step 10* – Dissemination: Publish the SLR findings in an academic source.

This structured approach ensures comprehensive coverage of objective assessment of existing literature, enhancing the reliability and validity of the findings. The outcomes of step 1-6 are discussed in the sub-sections that follow (Section 2.1 – 2.6), while the findings of this study (step 7 & 8) are documented in section 3. Documenting the review (step 9 & 10) are addressed by publishing this research paper.

2.1 Step 1: Research purpose and objectives

The purpose of this SLR is to assess the technology maturity status of redox flow batteries (RFBs) and their various storage use cases. The focus is on studying the advancements and maturity of redox flow battery technology over time. The objective is to provide insight into the current state of redox flow batteries, their applications for energy storage as well as potential future directions identified from the synthesized body of evidence.

2.2 Step 2: Develop research protocol

The review protocol followed while conducting the SLR is depicted in Table 1.

Table 1: Research protocol

Purpose of study	To conduct an evaluation of the current state of development and maturity of redox flow batteries and to identify various use cases.
Inclusion criteria	• Literature including "Redox Flow Batteries", "Energy Storage", "Technology" in their title, abstract or keywords. • The literature should either cover (discuss) the recent technological advancements or developments in terms of efficiency, reliability, and commercial readiness. • Peer-reviewed journal articles, conference proceedings, industry reports, patents, and publicly available technical documentation are included. • Include studies from 2016 – 2024.
Exclusion criteria	• Non-English Articles. • Opinion pieces and non-peer-reviewed sources were excluded to maintain dataset quality.
Search databases	Searches were conducted using the following databases: • ScienceDirect, • Scopus, • IEEE Xplore, • Web of Science, • Emerald Insight Journals.
Keywords	The databases were searched using the following key words: "Redox Flow Batteries", "Energy Storage", "Technology"
Quality Assessment Criteria	• All duplicate literature was excluded. • Recovered literature will be checked for relevance. • Ensure the aims and objectives align with the study. • Ensure that clear links between data, interpretations and conclusions exist. • Papers with unclear scope and context to be excluded. • Papers with unanswered research question to be excluded. • Papers with lack of credibility, reliability, and validity to be excluded.

The 2016-2024 window was selected to capture the most recent decade of RFB innovation, coinciding with intensified research into non-vanadium chemistries, increasing pilot deployments, and clearer commercialization signals. ScienceDirect, Scopus, IEEE Xplore, Web of Science, and Emerald Insight were chosen for their complementary coverage of electrochemistry, industrial/energy systems engineering, and applied technology, minimizing retrieval bias across disciplines.

2.3 Step 3: Establish relevance criteria

Using the specific keywords listed in Table 1, the five different databases were searched. This search resulted in 73 studies being screened for inclusion based on the inclusion and exclusion criteria, as per their published title, abstract and keywords. Studies that included "Redox Flow Batteries", "Energy Storage", and "Technology" in the title, abstract or keywords were included in the study. Literature that covered or addressed recent technological advancements or developments in terms of efficiency, reliability, and commercial readiness and the various storage use cases were also included. This resulted in 41 studies being eligible for full-text assessment.

2.4 Step 4: Search and retrieve from literature

Using the research search protocol depicted in Table 1; ScienceDirect, Scopus, Web of Science, IEEE Xplore, and Emerald Insight Journals were subjected to the search strategy. Figure 2 2 illustrates a graphical overview of the retrieval process. The five databases were searched using the keywords and resulted in a 73 research papers/studies being identified.

2.5 Step 5: Selection of studies

The identified research papers/studies were screened based on the protocol stipulated in *Step 1*. These studies were evaluated by removing all duplicates. This resulted in 41 articles being eligible for inclusion as can be seen in Figure 2. The review results of the systematic literature review are tabulated in Table 4 and contains the title, type of paper, overview, journal paper and year as well as the authors of the studies.

2.6 Step 6: Quality assessment

In order to assess the quality of each of the selected studies, the following criteria were utilized as a guide for final inclusion, this resulted in 34 full-text assessments as can be seen in Figure 2.

a) All duplicate literature was excluded from assessment.
b) Recovered literature is checked for relevance.
c) Ensure the aims and objectives align with the research purpose and objectives.
d) Ensure clear links between data, interpretations and conclusions.
e) Papers with unclear scope and context were excluded.
f) Papers with unanswered research question were excluded.
g) Papers with lack of credibility, reliability, and validity were excluded.

The database search identified 73 records. After title/abstract screening against inclusion/exclusion criteria, 41 articles were selected for full-text assessment. Following quality appraisal, 34 studies met the criteria and were included in the synthesis. Figure 2 provides the PRISMA flow of records through identification, screening, eligibility and inclusion.

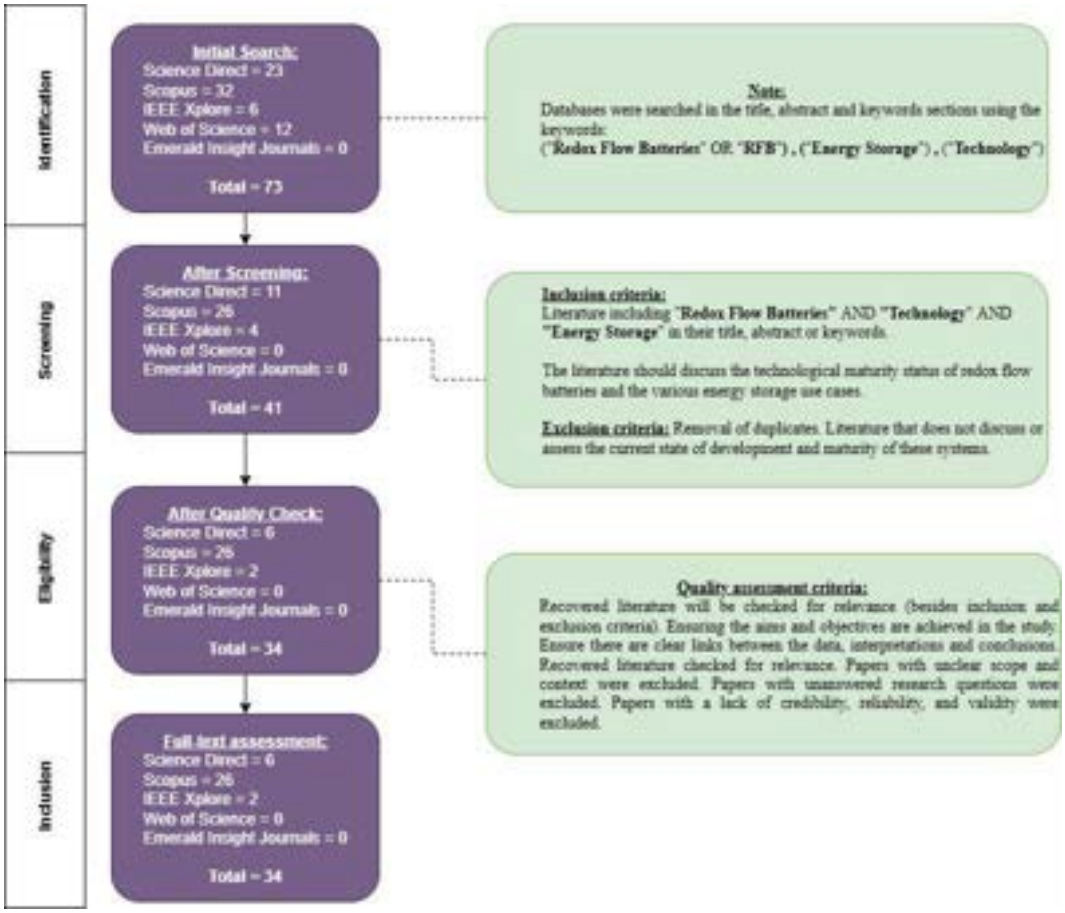

Figure 2: PRISMA flow diagram of study selection (keywords: "Redox Flow Batteries", "Energy Storage", "Technology")

3 FINDINGS

The findings (step 7 & 8) from the systematic literature review methodology are discussed in the following sub-sections.

3.1 Step 7: Data extraction

After finalizing the list of studies to be included, their full texts were reviewed, and relevant data were extracted. Data were extracted on battery chemistry and configuration, performance metrics, systems design, application domains/use case, cost/techno-economics, environmental aspects, and indicators of maturity. Appendix A contains a table summarizing the studies and the key data from each paper.

Several common themes emerged relating to technological advancements (efficiency, reliability), commercial readiness, and various storage use cases. Appendix B illustrates a Sankey diagram revealing the key research themes identified. Analysis of the diagram highlights the multifaceted nature of assessing the technology maturity status of Redox Flow Batteries and their various storage applications.

The themes identified can be categorized as follows:

- Advancement & Development: Characterizing the trajectory of growth (maturity) in battery technology, battery storage and Redox Flow Batteries.
- Cost Effectiveness: Analysing the cost factors influencing the development, scalability, and commercialization of RFBs.

- Energy Storage Applications: Use cases and technological advancements in energy storage.

The review covers a broad range of sectors; most selected studies focus predominantly on grid-scale and renewable energy integration contexts. This reflects current research priorities, especially the global demand for long-duration energy storage solutions to support renewable energy deployment. However, a noticeable gap remains in the literature concerning the applications of Redox Flow Batteries in niche or emerging domains such as remote mining operations, rural electrification, and hybrid storage systems. Future research should therefore explore these underrepresented areas to broaden the applicability and impact of Redox Flow Battery technologies.

3.2 Step 8: Synthesis of studies (analysis)

The synthesis involved organizing the extracted data (Appendix A) to identify patterns, similarities, and differences across the selected literature. Thematic coding grouped findings into categories such as technological advancement, commercialization potential and application domains. These categories were analyzed to produce aggregated insights that reflect the collective state of knowledge on Redox Flow Batteries. This approach enables a holistic understanding of the maturity and use cases of RFBs and helps identify the gaps that warrant future research.

As part of the evaluation, the journals in which each study was published were also analyzed as shown in Appendix A. The appendix provides an overview of the relevant journals publishing studies on Redox Flow Batteries and can assist researchers, policy makers, and industry stakeholders in identifying useful sources for future research or practical queries.

The years of publication were analyzed, as shown in Figure 3. Notably, there has been an increase in publication from 2019 onwards, indicating rising interest in redox flow battery technologies.

Most studies highlight the factors influencing cost-effectiveness and feasibility of implementing redox flow battery storage systems, as well as technological advancement that may enable their sustainable commercialization.

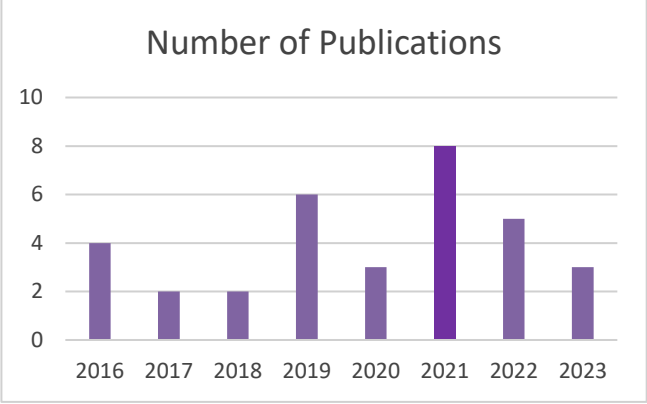

Figure 3: Number of publications per year

Figure 4 illustrates the word cloud that was created from analyzing the 34 articles. The word cloud was generated to showcase the types of words most frequently found in the literature pertaining to full-text assessment of these studies. The word cloud shows good relation to the keywords and search terms used to conduct the systematic literature review, therefore highlighting the relevance of these studies.

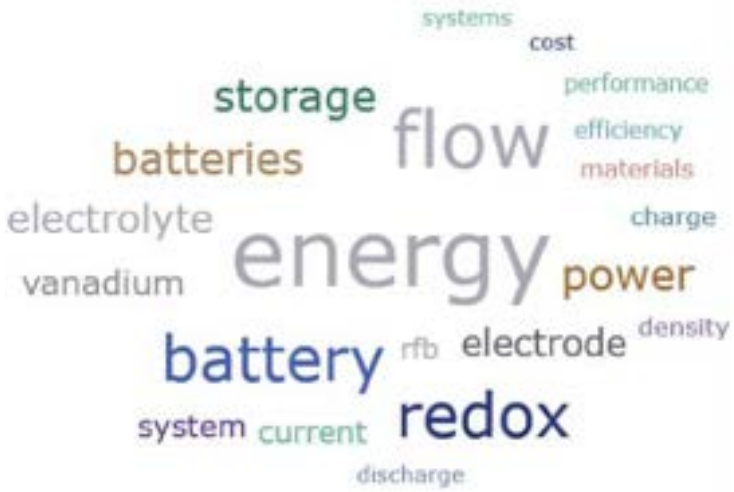

Figure 4: Word cloud of the keywords

4 TECHNOLOGICAL MATURITY AND USE CASES OF REDOX FLOW BATTERIES

Although this review is internationally in scope, several aspects are uniquely relevant to the South African context. The country's high solar resource, ongoing grid challenges, and need for decentralized rural electrification make RFBs particularly attractive. However, barriers such as high initial costs, limited local manufacturing capacity, and the absence of large-scale demonstration projects remain. Targeted policy support and industry collaboration are essential to address these barriers and unlock the full potential of RFBs for South Africa's energy transition.

4.1 Research Question 1: Technology maturity status of redox flow batteries

Redox Flow Batteries (RFBs) are increasingly recognized as a pivotal technology for integrating renewable energy into modern power systems. Their ability to store large volumes of energy over extended durations makes them well-suited for mitigating the variability of intermittent sources such as solar and wind [14]. By absorbing surplus energy during periods of high generation and dispatching it during periods of high demand, RFBs enhance grid reliability and support load levelling. A key advantage over lithium-ion or lead-based batteries is the decoupling of power and energy scaling, with power capacity determined by the cell stack size and energy capacity by the electrolyte volume [15]. This flexibility, coupled with a robust safety profile, low environmental impact, and long cycle life, positions RFBs as an attractive option for stationary storage scenarios.

Among RFB chemistries, the Vanadium Redox Flow Battery (VRFB) is the most technologically mature, with proven scalability and commercial deployment [16]. VRFBs are widely explored for grid services such as frequency regulation, peak shaving, and backup power. However, they require electrolyte temperature to remain within a narrow operating window (10°C-40°C) to avoid vanadium precipitation and performance losses [17]. Real-world performance assessments have revealed notable discrepancy between laboratory specifications and field results; for example, one study measured an efficiency of around 50%, compared to the 70-90% commonly reported in manufacturer datasheets [17]. This highlights the need for standardized, real-world performance testing.

Other RFB chemistries are at varying stages of maturity. Alkaline Redox Flow Batteries (AORFBs) offer superior thermal stability but remain in early commercial development. Organic RFBs (ORFBs) present environmentally friendly designs using biodegradable compounds, though they face challenges in scaling and long-term stability.

Zinc-Bromine, Zinc-Cerium, Iron-Chloride, Hybrid and Copper Hexacyanoferrate RFBS each have niche advantages, such as material abundance, higher energy densities or cost reduction potential, but generally remain at experimental or pilot-project stages.

Despite technical progress, gaps persist in long-term operational data, large-scale demonstration projects, and cost-benefit analyses under practical operating conditions [16], [19]. System-level inefficiencies, including pump energy consumption, must also be incorporated into techno-economic models for realistic viability assessments. The comparative analysis in Table 2 summarizes the maturity status, scalability, and key characteristics of the seven main RFB types. Table 3 outlines their typical applications, environmental benefits, and key challenges. These insights form the basis for assessing how current technological maturity influences both the strategic relevance of RFBs and their potential use cases, which are examined in subsequent sections.

Table 2: Technological Maturity of RFBs

Type of RFB	Maturity Status	Scalability	Key Characteristics
VRFBs (Vanadium Redox Flow Batteries)	Highly Mature	Highly Scalable	§ Long life cycles § Fast response times
AORFBs (Alkaline Redox Flow Batteries)	Emerging/Developing	Moderate to High	§ Superior thermal stability § Good capacity retention
ORFBs (Organic Redox Flow Batteries)	Early Development	Moderate	§ Uses organic compounds § Eco-friendly
Iron-Chloride RFBs	Developing	Moderate	§ Utilizes abundant materials § High charging efficiencies
Zinc-Bromine and Zinc-Cerium RFBs	Moderate Maturity	Moderate	§ Research in materials and design § Efficiency and stability challenges
Hybrid RFBs	Early to Moderate	Moderate to High	§ Combines different RFB features § Focus on energy density and efficiency
Copper Hexacyanoferrate RFBs	Early Research	Moderate	§ Stable performance § High efficiency

These tables provide a comprehensive overview of Redox Flow Battery technologies, offering valuable insights into their different stages of development, prospective and typical use cases, environmental impact as well as ongoing research and problems that influence the commercialization and adoption of these battery technologies.

Table 3: RFBs applications, benefits & Challenges

Type of RFB	Typical Applications	Additional Use Cases	Implementation in Grid Applications	Environmental Benefits	Challenges and Ongoing Research
VRFBs (Vanadium Redox Flow Batteries)	§ Grid energy storage § Integration with renewable energy	§Uninterruptible power supplies (UPS) § Electric vehicle charging stations	§ Widely implemented in grid storage § Stabilization of renewable sources	§ Reusable and recyclable electrolyte § Non-flammable	§ Cost reduction § Improving energy density
AORFBs (Alkaline Redox Flow Batteries)	§ Commercial and industrial	§ Backup power systems § Remote	§ Limited grid implementation § Suitable for temperature-	§ Uses less harmful materials § Potential	§ Commercialization § Voltage efficiency and

	energy storage § Renewable energy integration	area power supply	sensitive applications	for less environmental impact	energy density improvement
ORFBs (Organic Redox Flow Batteries)	§ Sustainable energy systems § Small-scale renewable energy storage	§ Experimental grid applications § Research facilities	§ Limited grid implementation § Suitable for niche applications	§ Lower environmental impact § Uses organic, biodegradable materials	§ Efficiency and stability improvements § Scale-up challenges
Iron-Chloride RFBs	§ Industrial-scale storage solutions § Eco-friendly applications	§ Backup power for critical systems § Off-grid power solutions	§ Emerging in industrial applications § Limited grid use	§ Abundant, eco-friendly materials § Less environmental impact	§ Electrode optimization § Achieving higher current densities
Zinc-Bromine and Zinc-Cerium RFBs	§ Future energy storage applications § Specific design applications	§ Experimental grid and off-grid storage § Industrial power backup	§ Limited grid implementation § Specialized applications	§ Varies with materials used § Potential for lower impact	§ Efficiency and stability improvement §Material and design optimization
Hybrid RFBs	§ Research and pilot projects § Specialized energy storage	§ Experimental small-scale applications § Integration with other storage technologies	§ Limited to experimental setups § Versatile storage solutions	§ Potential reduced impact § Depends on materials used	§ Integrating different technologies § Balancing cost and performance
Copper Hexacyanoferrate RFBs	§ Solid energy storage research § Low-cost storage solutions	§ Potential in residential storage § Small-scale commercial applications	§ Not yet implemented in grids § Cost-effective storage potential	§ Less expensive materials § Lower environmental footprint	§ Scaling up for practical use § Long-term stability and performance tests

4.2 Research Question 2: Current advancements and challenges

Recent literature highlights significant advancements in Redox Flow Battery (RFB) technology alongside persistent barriers that influence their industry relevance, strategic decision-making, and commercial readiness.

On the innovation front, material research has progressed with organic redox-active compounds offering lower cost, improved sustainability, and molecular flexibility suitable for large-scale deployment [2]. Hybrid configurations, such as VRFB–supercapacitor systems, have

demonstrated improved stability for wind and solar integration by mitigating output fluctuations [20]. Comparative studies of chemistries—including vanadium, zinc-bromine, and iron-chromium—show trade-offs between stability, cycle life, and energy density [22]. Emerging systems, such as hydrogen–bromine and alkaline organic RFBs, have achieved efficiencies exceeding 76% in elevated-temperature environments, making them suitable for hot climates and industrial applications [23], [24]. Data-driven frameworks are increasingly used to identify electrolyte candidates and improve scalability, while engineering-focused studies emphasize full-scale validation, robust transducer and electrode design, and physics-based modelling to guide scale-up [3], [25], [26].

Integration strategies are also advancing. Solar–RFB hybrid systems using CdS photoanodes enable direct solar-to-chemical energy conversion with improved efficiency [27], and modular active balancing circuits have been developed to minimize pump energy losses while managing state-of-charge effectively [30]. Thermal regulation innovations, including infrared imaging and optimized hydraulic designs, address electrolyte degradation and membrane efficiency losses outside optimal operating ranges [13], [28]. Life Cycle Assessments (LCAs) consistently show lower environmental impact for VRFBs compared to lithium-ion batteries due to reduced rare material usage and extended service life [31], [32], [33], [34], [35].

Despite these advancements, several challenges persist. High-purity vanadium costs, expensive stack and membrane manufacturing, and limited large-scale demonstration projects constrain commercial rollout [33]. Discrepancies between laboratory-reported efficiencies (up to 90%) and real-world performance (often lower due to integration losses) point to the need for standardized, real-world testing protocols. The scarcity of long-term operational and degradation data further limits confidence among utilities, policymakers, and investors. Techno-economic studies stress that while VRFBs outperform lithium-ion batteries in cost-effectiveness for discharge durations beyond four hours, sustained adoption will require addressing cost reduction, improving system integration, enhancing thermal management, and developing universally accepted performance benchmarks [34],[35],[36]. For South Africa, these challenges are amplified by import dependency, currency volatility affecting vanadium prices, and the lack of policy-driven pilot programmes to demonstrate commercial readiness.

4.3 Research Question 3: Use cases of redox flow batteries

RFBs are increasingly recognized for their versatility across multiple energy storage applications, with their modular scalability and long-duration capability making them adaptable to diverse operational contexts. At the utility scale, RFBs are deployed for grid services such as peak shaving, load levelling, and frequency regulation, where their ability to deliver consistent power over extended durations provides a strategic advantage over conventional lithium-ion systems [14], [15]. Microgrid integration is another growing application, particularly in remote communities, critical infrastructure, and disaster recovery zones, where RFBs enhance resilience and support decentralized energy architectures [20]. Their robust safety profile and non-flammable electrolytes also make them suitable for deployment in densely populated areas or sensitive industrial environments.

In commercial and industrial sectors, RFBs serve as backup systems and support high-demand processes that require stable energy output. With proper sizing and integration, they can complement intermittent renewable sources such as solar photovoltaics and wind turbines, enable greater self-consumption and reduce reliance on fossil fuel-based backup generation. Additionally, hybrid systems that pair RFBs with high-power storage technologies—such as supercapacitors or lithium-ion batteries—are being explored to meet applications that demand both high power density and long-duration energy delivery [20], [37], [38].

Emerging niche applications include coupling RFBs with electric vehicle charging infrastructure, particularly for fleet charging depots, where they can buffer grid demand

peaks and optimize energy costs. Research also indicates potential for integrating RFBs into combined heat and power (CHP) systems and renewable-to-hydrogen energy pathways, expanding their role beyond purely electrical storage into broader energy sector coupling [27], [38].

However, the commercial penetration of these use cases remains limited by cost, supply chain constraints, and the absence of widespread demonstration projects. While modelling and pilot studies consistently validate the technical feasibility of RFB integration in various contexts, large-scale deployments are still relatively rare. In South-Africa, short-term opportunities include rural microgrids, renewables mining operations, and industrial peak shaving, sectors where energy security and long-duration storage have high strategic value. Future growth will depend on targeted investment in use case-specific pilot programmed, supportive regulatory frameworks, and continued advancements in cost reduction and performance optimization to improve competitiveness across market segments.

5 CONCLUSIONS AND RECOMMENDATIONS

This study presents a systematic review of literature on the technological maturity, industry relevance, and energy storage applications of Redox Flow Batteries (RFBs). The review synthesizes developments in performance optimization, materials innovation, commercial readiness, and environmental impact from publications between 2016 and 2024.

The findings indicate that RFB development has reached a pivotal stage, as evidenced by increasing research activity and a growing diversity of use cases. Vanadium Redox Flow Batteries (VRFBs) remain the primary focus due to their proven stability and scalability. However, emerging technologies, including organic, hybrid, and aqueous systems, suggest an industry shift toward broader material exploration. Notably, machine learning and data-driven approaches are increasingly employed to identify promising electrolyte candidates and optimize battery architecture.

The literature also shows significant progress in real-world applications, particularly for grid-scale storage and renewable energy integration. These systems have demonstrated potential for enhancing grid reliability, load levelling, and peak shaving. Nonetheless, challenges related to cost, energy density, operational complexity, and environmental footprint persist. While early-stage solutions, such as modular designs, active balancing circuits, and low-cost materials, show promise, further research and validation are required.

Considering the current technological maturity of RFBs and their various storage use cases, future research and implementation strategies should priorities the following areas:

Advanced materials research: Identify new electrolytes with higher energy densities, including hybrid, organic, and inorganic options. Develop more efficient, low-cost membranes with high ion selectivity and low resistance, and optimize electrode materials and designs to enhance reaction kinetics, improve system efficiency, and reduce degradation.

System design and integration: Advance modular designs for greater flexibility and scalability, enabling deployment from small-scale residential to large-scale industrial and grid applications. Promote integration with complementary storage technologies, such as lithium-ion batteries, to meet requirements for both high power and long-duration energy delivery.

Cost reduction and sustainable manufacturing: Lower the material cost of vanadium, improve material utilization efficiency, and assess environmental impacts across the full lifecycle—from production to disposal—to promote sustainable practices.

Use case-specific optimization: Tailor RFB design and operation for peak shaving, load levelling, and integration with intermittent renewable sources such as solar and wind.

Technology innovation and emerging applications: Explore integration with IoT devices and smart-grid technologies to enhance energy management capabilities. Conduct pilot plant studies to validate mathematical models and refine performance predictions.

These recommendations directly address the study's three research questions. Research Question 1 is answered by mapping the current technological maturity across multiple RFB chemistries and identifying the most commercially advanced options. Research Question 2 is addressed through the synthesis of recent advancements in materials, system design, and integration strategies, alongside the identification of key techno-economic and operational barriers. Research Question 3 is fulfilled by outlining current and emerging use cases, highlighting their technical feasibility and commercial potential. Together, these findings provide a structured framework for guiding both future research and strategic decision-making in the deployment of RFB technologies.

7 APPENDIX A

Table 4: The 34 studies selected for this review

#	Title	Type of paper, overview and the technological advancements and/or maturity status of redox flow battery energy storage systems and the various storage use cases.	Publication Title	Publication Year	Reference
1	Comprehensive study of the performance of alkaline organic redox flow batteries as large-scale energy storage systems	Journal Article – This research paper explores the viability of alkaline redox flow batteries (AORFBs) as large-scale energy storage solutions. The cost effectiveness of AORFBs is explored and its advantages compared to vanadium-based battery technologies are emphasized due to the use of organic compounds. The study proves that AORFBs have superior thermal stability and capacity retention when comparing to vanadium redox flow batteries (VRFBs). Although AORFBs have a slightly lower voltage efficiency and energy density, the study concludes that AORFBs show great promise to be commercialized.	International Journal of Energy Research	2019	(Chang, Kim and Jung, 2019)
2	Research and analysis of performance improvement of vanadium redox flow battery in microgrid: A technology review	Journal Article – The article analyses the development status of renewable energy and states that a strong possibility exists that renewable energy power generation will become the dominant energy source in the world. This research paper reviews the advantages and performance improvement of vanadium redox flow batteries (VRFBs) when implemented within microgrids. When generating power with renewable energy sources, there are numerous challenges to be addressed, and this paper explores how VRFBs can be used with microgrids and photovoltaic energy (PV) sources to overcome these challenges.	International Journal of Energy Research	2021	(Huang and Mu, 2021)
3	Optimal allocation of vanadium redox flow battery energy storage systems in active distribution networks considering multiple operation strategies	Journal Article - This research article explores the optimal allocation of vanadium redox flow battery (VRFB) energy storage systems (ESS) within active distribution networks (ADNs). Numerous operation strategies were derived as well as other characteristics such as the optimal power and capacity for VRFB ESS deployment. The paper uses quantitative data to describe the total operational benefits associated with VRFBs.	International Journal of Energy Research	2022	(Sun, Lei and Liu, 2022)
4	Status and Prospects of Organic Redox Flow Batteries toward Sustainable Energy Storage	Journal Article – This article discusses the development status and challenges of organic redox flow batteries (ORFBs) when in sustainable energy systems. A lot of emphasis is placed on the design aspects of using organic compounds in ORFBs and the respective advantages and disadvantages. This article concludes that ORFBs can be utilized as practical energy storage solutions.	ACS Energy Letters	2019	(Luo *et al.*, 2019)
5	Data-driven discovery of small electroactive molecules for energy storage in aqueous redox flow batteries	Journal Article – This paper focuses on machine learning techniques to identify new electroactive molecules to be used in aqueous redox flow batteries (ARFBs). A virtual chemical library was constructed and molecules with higher solubility and lower redox potentials were identified. The article states that commercially available indigo trisulfonate exhibits superior characteristics such as better capacity retention, solubility and coulombic efficiency when comparing it to current ARFB anolytes. This study shows that data-driven solutions exist to improve the efficiency of ARFBs.	Energy Storage Materials	2022	(Zhang *et al.*, 2022)
6	Redox flow batteries: Status and perspective towards sustainable stationary energy storage	Journal Article – This article focuses on different redox flow battery (RFB) topologies such as vanadium redox flow batteries (VRFBs) and alternative technologies such as zinc-bromine flow batteries and hydrogen-bromine flow batteries. This article focuses on possible methods to improve certain characteristics of RFBs such as improving proton conductivity in membranes and enhancing performance of electrodes used. However, numerous challenges remain such as the low energy density when comparing to lithium-ion batteries and the lack of availability of key components. Alternative approaches are also explored such as the use of aqueous organic redox flow batteries (AORFBs) using organic molecules as active materials. Commercialization aspects are discussed (particularly for VRFBs) as well as the potential for large scale energy storage. This paper provides a comprehensive overview of the status of RFBs and its future prospects for sustainable energy storage.	Journal of Power Sources	2021	(Sánchez-Díez *et al.*, 2021)
7	A High Efficiency Iron-Chloride Redox Flow Battery for Large-Scale Energy Storage	Journal Article – This article discusses development of efficient iron-chloride redox flow batteries for industrial-scale storage solutions. This battery utilises abundant, inexpensive and eco-friendly materials to make it more viable as a sustainable energy storage solution. Numerous optimisations were done on this battery topology, such as maintaining high charging efficiencies and achieving higher current densities. Thus, this paper provides insight into the optimization of iron-containing batteries and the optimization of electrodes.	Journal of The Electrochemical Society	2016	(Manohar *et al.*, 2016)
8	Progress and directions in low-cost redox-flow batteries for large-scale energy storage	Journal Article – This article reviews the status and future prospects of low-cost redox flow batteries (RFBs) for large-scale energy storage. The challenges and potential solutions for the development of aqueous systems are discussed. Furthermore, potential designs for redox molecules and breakthroughs regarding new membranes and separators are discussed. This article discusses the advantages of RFBs over lithium batteries, cost reduction of RFBs, and the need for new innovations in electrode surfaces of RFBs. Further applications of RFBs are also explored, such as electric vehicles batteries and grid-scale storage solutions.	National Science Review	2017	(Li and Liu, 2017)
9	Redox flow batteries—Concepts and chemistries for cost-effective energy storage	Journal Article – This article consists of a collection of research papers related to redox flow batteries (RFBs) and their respective components, design, performance and potential applications. Some discussed topics include electrolyte selection, electrode materials, membrane properties and	Frontiers in Energy	2018	(Holland-Cunz

		advancements in RFB technology. The content of this article aims to improve the energy density, power-density, and cost-effectiveness of large-scale energy storage solutions.			*et al.*, 2018)
10	Solar vanadium redox-flow battery powered by thin-film silicon photovoltaics for efficient photoelectrochemical energy storage	Journal Article – This article explored the development of a solar-driven vanadium redox-flow battery (VRFB) using thin-film photovoltaics for efficient energy storage and conversion. With further optimisations to the membrane, current density and electrolyte and overall electricity efficiency of 10.46% was achieved, demonstrating the viability of this concept as an alternative for photoelectrochemical energy storage and conversion.	Journal of Physics D: Applied Physics	2019	(Urbain *et al.*, 2019)
11	Vanadium Redox Flow Batteries: Potentials and Challenges of an Emerging Storage Technology	Journal Article – This article discusses the potential of vanadium redox-flow batteries (VRFBs) as promising energy storage solution for smart grids. VRFBs have highly desirable characteristics such as their ability to scale, long life cycles and fast response times. VRFBs are compared to other battery storage technologies and cost figures are presented to demonstrate their competitiveness, however the respective challenges surrounding the use of VRFBs are also discussed. This article concludes that VRFBs have potential to be widely used in the future and significant investments are currently being made into VRFBs.	IEEE Industrial Electronics Magazine	2016	(Guarnieri *et al.*, 2016)
12	Research on All-Vanadium Redox Flow Battery Energy Storage Device Based on Energy-Saving and Environmentally Friendly New Energy Power Station Interface Technology	Journal Article – This article discusses research on using an all-vanadium redox flow battery (VRFB) energy storage system (ESS) for new power stations. This article focuses on the introduction of vanadium ion diffusion and proposes a simulation model which considers ion diffusion. The result of the model shows that VRB operating characteristics can accurately be simulated, and real time prediction results can also be provided.	IOP Conference Series: Earth and Environmental Science	2021	(Wang, 2021)
13	Engineering aspects of the design, construction and performance of modular redox flow batteries for energy storage	Journal Article – This article discusses engineering design considerations for redox flow batteries (RFBs) used for energy storage. Characteristics such as electrode configuration, membrane characteristics and cell design are discussed and elaborated upon. A lot of emphasis is placed on engineering design principles and the need for future research and development. The use of mathematical modelling to optimize RFB performance is discussed as well as challenges around commercialization.	Journal of Energy Storage	2017	(Arenas, Ponce De León and Walsh, 2017)
14	Solid electrochemical energy storage for aqueous redox flow batteries: The case of copper hexacyanoferrate	Journal Article – This article focuses on the use of copper hexacyanoferrate (CuHCF) as a solid energy storage material in aqueous redox flow batteries (ARFBs). The use of CuHCF in ARFBs shows promise due to it its stable performance paired with high efficiency and capacity. This article concludes that redox materials play an important role in improving performance characteristics of solid energy storage materials and that inexpensive raw materials can greatly reduce the cost of redox flow batteries (RFBs).	Electrochimica Acta	2019	(Zanzola *et al.*, 2019)
15	Unbiased solar energy storage: Photoelectrochemical redox flow battery	Journal Article – This article discusses the use of photoelectrical redox flow batteries to store solar energy directly. This article demonstrates that a CdS photoanode can be used successfully for direct solar charging and performance can be increased by adding a CdSe overlayer.	Nano Energy	2016	(Azevedo *et al.*, 2016)
16	Techno-economic analyses of several redox flow batteries using levelized cost of energy storage	Journal Article – This article contains a techno-economic analyses of redox flow batteries (RFBs) for long-term energy storage. Different battery technologies are compared and concludes that batteries using inexpensive active materials are favoured for long-term energy storage, however more expensive lithium-based technologies are favoured for short term energy storage, due to higher efficiencies.	Current Opinion in Chemical Engineering	2022	(Darling, 2022)
17	Advancing chemical hazard assessment with decision analysis: A case study on lithium-ion and redox flow batteries used for energy storage	Journal Article – This article evaluates chemical hazards of redox flow batteries (RFBs) and lithium-ion batteries using the Greenscreen framework. The results show that vanadium redox flow batteries (VRFBs) had consistent lower hazard ratings when compared to other batteries. The study concludes that hazard evaluation is a critical component when it comes to battery selection and that safer alternatives should be chosen with lower toxicities and hazards. This article also discusses various assessment methods, certifications and studies related to battery safety.	Journal of Hazardous Materials	2022	(He *et al.*, 2022)
18	The characteristics and performance of hybrid redox flow batteries with zinc negative electrodes for energy storage	Journal Article – This article reviews different types of zinc-based redox flow batteries and discusses their respective performance characteristics and challenges. This article emphasizes the importance of the selection of electrode materials, electrolyte additives and cell design. This selection is crucial to achieving better efficiency and ensuring stability in the system. The article states that potential use of zinc-based batteries in the future is possible, however further research and development will be required.	Renewable and Sustainable Energy Reviews	2018	(Arenas *et al.*, 2018)
19	Life cycle assessment of lithium-ion batteries and vanadium redox flow batteries-based renewable energy storage systems	Journal Article – This article compares the environmental impact of vanadium redox flow batteries (VRFBs) and lithium-ion batteries. VRFBs can use recycled electrolytes leading to a smaller environmental impact, when comparing to lithium-ion batteries. This study emphasizes the importance of considering the environmental impacts when choosing a battery technology. A sensitivity analysis was conducted, showing that by using alternative battery compositions the impact on the environment can be reduced. The study concludes that VRFBs have a lower impact on the environment than VRFBs.	Sustainable Energy Technologies and Assessments	2021	(Da Silva Lima *et al.*, 2021)
20	Life cycle assessment of compressed air, vanadium redox flow battery, and molten salt systems for renewable energy storage	Journal Article – This article compares the environmental impact of three energy storage techniques. The techniques compared are compressed air storage, vanadium redox reflow batteries and molten salt thermal storage. Of the three storage techniques, VRFBs have the highest environmental impact, while molten salt has the lowest. It was found that the manufacturing stage of these storage systems has the highest carbon footprint. The study further emphasizes the	Energy Reports	2021	(AlShafi and Bicer, 2021)

		importance of using solar energy to minimize damage caused to the environment.			
21	Redox flow batteries for energy storage: their promise, achievements and challenges	Journal Article – This article summarizes research conducted on vanadium redox flow batteries VRFBs and covers the following topics: • Electrolyte Balancing • Flow Patterns and Behaviour • Electrolyte Additives • Low Potential Electrolytes • Organic Redox Flow Batteries • Monitoring of RFBs • Long-cycling Aqueous Batteries • Organic Electroactive Materials This article covers a wide spectrum of RFBs and can provide valuable insights for researchers and engineers in the field of energy storage.	Current Opinion in Electrochemistry	2019	(Arenas, Ponce De León and Walsh, 2019)
22	A Modular Active Balancing Circuit for Redox Flow Battery Applied in Energy Storage System	Journal Article - This study proposes a modular active balancing circuit that is intended to be used with redox flow batteries (RFBs) within an energy storage system. The circuit's goal is to guarantee high efficiency, scalability, and reliability while reducing the complexity of the RFB's battery management system. The exact operation principle and control approach including the dynamics of MOSFET current and capacitors are supported by simulations and tests that verify their viability and efficacy. By optimizing the SOC balance, the suggested approach raises the RFB's overall performance and energy conversion efficiency. In summary, it appears that the modular balancing circuit can improve RFB performance in energy storage systems.	IEEE Access	2021	(Guan and Huang, 2021)
23	Assessing Suitability of Various Battery Technologies for Energy Storages: Lithium-ion, Sodium-sulphur and Vanadium Redox Flow Batteries	Conference Article - This study examines and compares different battery technologies, such as lithium-ion, sodium-sulphur, and vanadium redox flow batteries for use in large-scale energy storage systems. To determine the advantages and disadvantages of each battery technology, case studies were evaluated to assess the strengths and weaknesses of each technology. This paper presents calculations for the best battery size for each technology, and accounts for certain variables such as power, capacity, depth of discharge, and number of working cycles. The case studies show how various battery technologies are suitable for different applications depending on the power and capacity needs.	2020 International Conference on Applied Electronics (AE)	2020	(Vins and Sirovy, 2020)
24	Hybrid Energy Storage Systems Based on Redox-Flow Batteries: Recent Developments, Challenges, and Future Perspectives	Journal Article – This article focuses on hybrid energy storage systems (HESS) based on redox-flow batteries (RFBs). Key performance indicators (KPIs) are discussed for different storage systems ready for use in hybrid storage systems. The article suggests and uses numerical simulation to assess the best coupling design between an RFB and a Supercapacitor (SC). Furthermore, this article examines different optimization strategies for energy management systems (EMSs) and discuss EMSs for HESSs and concludes with future perspectives on optimization and control algorithms for management systems.	Batteries	2023	(Schubert *et al.*, 2023)
25	Redox Flow Batteries: Recent Development in Main Components, Emerging Technologies, Diagnostic Techniques, Large-Scale Applications, and Challenges and Barriers	Journal Article – This article provides and overview of redox flow batteries and (RFBs) and the benefits of using RFBs in large-scale energy systems. The main components of RFBs are discussed, as well as the challenges associated with their implementation and new developments in the field of RFBs. The development of membranes for Vanadium Redox Flow Batteries (VRFBs) and various RFB diagnostic methods are examined in this article. Additionally, this article covers the use cases of RFBs and provides a summary of recent developments in this research area. This article concludes by addressing the commercialization barriers and challenges associated with RFBs and emphasize the need to conduct further research and development to unlock RFBs' full potential as a sustainable energy storage solution.	Batteries	2023	(Olabi *et al.*, 2023)
26	Economic Analysis of a Redox Flow Batteries-Based Energy Storage System for Energy Savings in Factory Energy Management System	Journal Article – This article discusses an economic analysis of using redox flow batteries in a factory's energy management system. This article analyses the cost estimation and economic feasibility of using solar power and redox flow cells to save energy in a factory. The advantages of using redox batteries are also discussed and the importance of energy storage systems is explained to reduce carbon emissions. Furthermore, this article explores the economics of implementing a hybrid energy system in a factory and a sensitivity analysis was also conducted. The results can provide insights into the economic feasibility and applicability of the proposed energy storage system in industrial facilities.	Batteries	2023	(Kim *et al.*, 2023)
27	Energy storage inspired by nature – ionic liquid iron–sulfur clusters as electrolytes for redox flow batteries	Journal Article – This paper proposes a novel approach to redox flow batteries (RFBs) that makes use of iron-sulphur clusters and ionic liquid electrolytes. The results demonstrate that the both the coulombic and energy efficiency is high as well as the predicted energy density. The study also examines the limits of current RFBs based on acidic vanadium electrolyte solutions, as well as how iron-sulphur clusters and imidazolium cations interact to form the novel ionic liquid electrolyte materials.	Dalton Transactions	2019	(Modrzynski and Burger, 2019)
28	The Development of Zn–Ce Hybrid Redox Flow Batteries for Energy Storage and Their Continuing Challenges	Journal Article – This article highlights the development and problems of zinc-cerium hybrid redox flow batteries (RFBs) for energy storage. It explores subjects like the thermodynamics and kinetics of electrode reactions, operating factors, cell component materials, and cell design. The article also explores the elements that influence zinc deposition on the negative electrode, as well as other research that have been undertaken to improve its performance. The utilization of carbon-polymer composite electrodes in zinc-cerium RFBs is investigated, as well as electrode behaviour under various conditions and cell designs. The importance of electrolyte composition and electrode stability in the overall performance of zinc-cerium RFBs is also emphasized. The usage of polyvinyl ester plates as negative electrodes and the optimization of charge/discharge performance are discussed in the article. The article concludes	ChemPlusChem	2015	(Walsh *et al.*, 2015)

		by emphasizing the importance of additional research and developments in scaling up zinc-cerium battery technology.			
29	Design of A Two-Stage Control Strategy of Vanadium Redox Flow Battery Energy Storage Systems for Grid Application	Journal Article – The study presents a two-stage control technique aimed at enhancing the operational efficiency of vanadium redox flow battery (VRB) systems when utilized in grid applications. The suggested strategy entails the optimization of the flow rate of the Vanadium Redox Battery (VRB) in order to minimize parasitic losses and improve overall efficiency. In addition, a feedback flow rate controller is used in the second stage to swiftly react to fluctuating power requirements. The efficacy of the proposed strategy is demonstrated to be superior in comparison to existing approaches. A multi-physics model of the Vanadium Redox Flow Battery (VRB) system is also formulated and verified by the utilization of experimental data. The paper includes an analysis of the control strategy's architecture and offers more resources for exploring energy storage systems and VRB technology.	IEEE Transactions on Sustainable Energy	2022	(Xiong *et al.*, 2022)
30	Real-Time Monitoring of the Thermal Effect for the Redox Flow Battery by an Infrared Thermal Imaging Technology	Journal Article – This article discusses the use of infrared thermal imaging technology for the purpose of monitoring the thermal effects resulting from charge-discharge experiments conducted on a vanadium/iodine redox flow battery. This study presents a comparative analysis of the thermal effects exhibited by an all-vanadium redox flow battery and a vanadium/iodine redox flow battery. The investigation further investigates the influence of charge-discharge parameters, flow rate, and current density on the thermal effect. The article examines the utilization of a novel membrane and a composite electrode to enhance the efficacy of the vanadium/iodine redox flow battery. The authors present evidence to support the effectiveness of infrared thermal imaging technology in monitoring the thermal effects within batteries, hence offering valuable insights for enhancing the design of redox flow battery systems.	Energies	2020	(Huang *et al.*, 2020)
31	Environmental and Preliminary Cost Assessments of Redox Flow Batteries for Renewable Energy Storage	Journal Article – This article discusses different methodologies used for the evaluation of environmental impacts associated with batteries, with a particular focus on the evaluation of the water footprint, abiotic resource depletion, climate change, stratospheric ozone depletion, and human toxicity. The implementation of the AWARE method is recommended for conducting water scarcity footprint evaluations, whilst the CML baseline methodology is used for the quantification of environmental burden. The article also presents a comparative analysis of the environmental effects associated with different battery technologies, including lead-based, Li-ion, Na-based, and redox flow batteries.	Energy Technology	2020	(Fernandez-Marchante *et al.*, 2020)
32	Energy Storage Analysis and Flow Rate Optimization Research of Vanadium Redox Flow Battery	Journal Article – This article investigates the optimization of a Vanadium Redox Flow Battery (VRFB) for enhanced energy storage, with a focus on current renewable energy requirements, VRFB operating principles, and technical challenges. This article further emphasizes the importance of flow field structure design in improving electrolyte distribution and battery performance, and it proposes a method for performance prediction which incorporates modelling and simulation. The article also examines the effect of flow rate on battery voltage, polarization, pressure drop, and pump power loss, emphasizing the relationship between flow rate and key performance measures. The article concludes that enhancing VRFB flow field design can greatly improve battery efficiency and compensate for its poor energy density.	Journal of Physics: Conference Series	2021	(Huang *et al.*, 2021)
33	Redox Flow Batteries for small scale energy storage	Conference Article – The paper investigates the potential of redox flow batteries (RFBs) for small-scale energy storage, showing their advantages in storing renewable energy over standard solid electrode batteries. It explores many forms of RFBs, highlighting their benefits and current prevalence in large-scale applications, particularly in Asia, while acknowledging the slower pace of development for commercial and residential uses. The article emphasizes the importance of research in overcoming commercialization barriers for residential applications, anticipating that redox flow batteries will become commercially viable over the next five years. It emphasizes the importance of conducting more research in scaling, monitoring, and modelling for various renewable sources, as well as policy and economic simulation modelling. The article suggests that redox flow batteries can be used as a potential technology for supporting renewable energy in smart grid systems.	2016 IEEE Conference on Technologies for Sustainability (SusTech)	2016	(Hiksas and Anindi tio, 2016)
34	Redox-flow batteries for high energy-to-power ratio storage: a preliminary experimental study	Conference Article - This article presents a comprehensive overview of the development, challenges, and possibilities of redox flow batteries (RFBs) for large-scale energy storage. It emphasizes the growing usage of RFBs due to desirable characteristics such as safety, adaptability, and suitability for grid-level storage. However high costs restrict the usage of these batteries in grid-scale energy storage required.	2021 IEEE International Conference on Environment and Electrical Engineering a	2021	(Ceraolo *et al.*, 2021)

ABSTRACT

Magnesium-based energy storage systems are emerging as promising alternatives to lithium-ion batteries, offering enhanced safety, higher energy density, and abundant resources. This Systematic Literature Review (SLR) systematically assesses the technological readiness of these systems using a Technology Readiness Level (TRL) framework, focusing on cost factors influencing research, scalability, and market adoption. Following PRISMA guidelines, five databases were searched for 2016-2023; 69 records were identified, 31 remained after duplication removal, and 25 studies were included. Readiness mapped using a TRL lens indicates most pure magnesium systems at TRL 2-4, while Mg/Li architectures are approaching TRL 4-5. Field validation prototypes remain scarce. Findings highlight dendrite-free cycling and favourable safety, and Coulombic efficiencies exceeding 97% in laboratory-scale prototypes, while challenges such as material costs, manufacturing complexity, and cathode-electrolyte compatibility continue to hinder progress. Innovations such as nanostructured cathodes and polymer-based electrolytes show promise for enhancing performance and reducing costs. The review underscores the critical role of cost optimisation, standardised full-cell reporting, and prototypes and field trials in progressing from laboratory prototypes to commercially viable solutions. This paper makes an applied contribution by synthesising established concepts through a TRL lens to inform practitioners, policymakers, and industry stakeholders, highlighting targeted R&D in magnesium-sulphur cathodes and scalable solid-state electrolytes to accelerate readiness.

Keywords: Systematic literature review, Magnesium-ion batteries, technology readiness level (TRL), electrochemical energy storage, cost-performance analysis.

1 INTRODUCTION

The accelerating shift from fossil-based fuels to renewable energy sources marks a defining moment in the global energy landscape. As countries strive to reduce carbon emissions and enhance energy sustainability, integrating increasing amounts of renewable energy sources such as solar and wind has become a central priority [1], [2].

However, the variable and intermittent nature of these renewable resources presents a critical challenge for grid reliability and energy security. As a result, the demand for advanced energy storage solutions that can smooth fluctuations, store excess generated electricity, and provide power on demand is greater than ever [3].

Traditional energy storage technologies, particularly rechargeable lithium-ion batteries (LIBs), have been instrumental in enabling this transition. Since their introduction in 1991, LIBs have revolutionised not only portable electronics and smart infrastructure, but also the rapidly expanding market for electric and hybrid vehicles [4]. Their widespread adoption is largely attributed to their high energy density, long cycle life, and proven reliability. Nevertheless, as the deployment of energy storage systems continues to expand, LIBs face growing scrutiny over several critical issues. These include the rising costs and limited geographical availability of lithium resources, the safety hazards associated with dendrite formation and thermal runaway (noted to occur at cell temperatures above 200 °C without proper management), and persistent concerns over the environmental and geopolitical impacts of lithium extraction and processing, with global demand projected to more than double by 2030 [5-6]. Although advances in electrolyte chemistry and cell engineering have addressed some of these concerns at the laboratory scale, many solutions have yet to achieve widespread industrial applications [7]. These limitations highlight an urgent need for alternative battery chemistries that are safer, more sustainable, and economically viable for large-scale deployment.

This review applies established systematic review and TRL evaluation frameworks to the magnesium context, providing structured insights for industrial engineering and energy policy rather than introducing new theoretical constructs.

Against this backdrop, magnesium-based energy storage systems, particularly magnesium-ion batteries (MIBs), have emerged as a promising candidate for next-generation energy storage technologies. Magnesium offers several inherent advantages over lithium: it is the eighth most abundant element in the Earth's crust, inexpensive, and less prone to supply chain constraints [8]. From a technical perspective, magnesium's divalent nature affords high theoretical volumetric capacity, and its high melting point, low toxicity, and resistance to dendrite formation contribute to enhanced safety and stability during operation [9-10]. These features position MIBs as an attractive solution for stationary energy storage and other applications where cost, scalability, and safety are paramount.

Despite these promising attributes, the commercial development and deployment of magnesium-based batteries have lagged their lithium counterparts. Most prototypes remain relatively low Technology Readiness Levels (TRL 2-4), with very few demonstrations beyond TRL 5, highlighting a clear gap between laboratory feasibility and practical deployment. Several formidable scientific and engineering challenges remain. Progress in the field is limited primarily by the difficulty of identifying suitable cathode materials that allow for efficient magnesium-ion intercalation, the development of electrolytes with sufficient ionic conductivity and electrochemical stability, and the engineering of compatible current collectors and cell components [11-13]. Pioneering research in the early 2000s demonstrated the technical feasibility of rechargeable magnesium batteries with encouraging capacity retention and cycling stability, yet translating these results into practical market-ready products has proven complex [14]. Recent years have seen a surge in research activity targeting these barriers. Advances in material chemistry, including the exploration of two-

dimensional materials such as MoS_2 (demonstrating reversible Mg intercalation at around 110 mAh/g), nanostructured electrodes, and polymer-based electrolytes for improved interfacial stability, alongside hybrid ion batteries that integrate lithium or sodium ions, have expanded the design space and improved performance metrics for magnesium-based systems [15]. This approach aligns with established practices for systematic reviews in engineering and technology [21].

To aid objective comparison and decision-making, this review evaluates magnesium-based systems through a TRL lens. It synthesises recent scientific and engineering developments, identifies principal barriers and cost drivers affecting research and scale-up, and clarifies current readiness in the context of grid-relevant applications.

2 RESEARCH METHOD

This systematic literature review adopts a structured and comprehensive approach based on widely accepted methodologies for systematic reviews. The method consists of three main phases: (i) planning, (ii) conducting, and (iii) documenting. The review process involves several clearly defined steps within these phases:

A. Planning the review
- *Step 1* – Research purpose and objective: Clearly establish the aims and objectives of the review.
- *Step 2* – Development of research protocol: Formulate inclusion and exclusion criteria, databases to be searched, and specific keywords.

B. Conducting the review
- *Step 3* – Establishing relevance criteria: Define explicit criteria for screening literature based on relevance.
- *Step 4* – Literature search and retrieval: Search the selected electronic databases for literature using predefined keywords.
- *Step 5* – Selection of studies: Screen retrieved literature based on established inclusion and exclusion criteria.
- *Step 6* – Quality assessment: Evaluate the methodological rigour and relevance of selected studies.
- *Step 7* – Data extraction: Extract relevant data systematically from selected literature.
- *Step 8* – Synthesis of studies (analysis): Analyse and synthesise extracted data to draw meaningful conclusions regarding the technology maturity and storage applications of magnesium-based systems.

C. Documenting the review
- *Step 9* – Reporting: Report on the SLR in detail.
- *Step 10* – Dissemination: Publish the SLR findings in an academic source.

This structured approach ensures comprehensive coverage of objective assessment of existing literature, enhancing the reliability and validity of the findings. The outcomes of steps 1-6 are discussed in the sub-sections that follow (Section 2.1 – 2.6), while the findings of this study (steps 7 & 8) are documented in Section 3. Documenting the review (steps 9 & 10) is addressed by publishing this research paper.

2.1 Step 1: Research purpose and objectives

The purpose of this SLR is to assess the current state of technological development and maturity of magnesium-based energy storage systems. The focus is on evaluating the advancements in terms of reliability, safety, efficiency, and commercial readiness. The objective is to identify and analyse the principal cost factors that influence research, development, and the commercialisation of these systems.

2.2 Step 2: Develop research protocol

The review protocol that was followed while conducting the SLR is depicted in **Table 1.** The 2016-2023 window was chosen to capture the most recent decade of magnesium-based electrochemical storage research. Searches in ScienceDirect, Scopus, IEEE Xplore, Web of Science, and Emerald Insight used Boolean string ("magnesium" AND "energy storage" AND "technology"), restricted to English, peer-reviewed journal and conference publications, with keywords chosen to balance scope and specific while ensuring coverage across materials, electrochemistry, and industrial engineering.

Table 1: Research protocol

Purpose of the study	To conduct an evaluation of the current state of development and maturity of magnesium-based energy storage systems and to identify any key cost elements/factors that influence research and development in this area.
Inclusion criteria	• Literature including "Magnesium", "Energy Storage", "Technology" in their title, abstract or keywords. • The literature should either cover (discuss) the recent technological advancements or developments in terms of efficiency, reliability, and commercial readiness or the cost factors that influence commercialisation, development and research on these systems. • Include studies from 2016 – 2023.
Exclusion criteria	• Non-English Articles. • Opinion pieces and non-peer-reviewed sources were excluded to maintain dataset quality.
Search databases	Searches were conducted using the following databases: • ScienceDirect, • Scopus, • IEEE Xplore, • Web of Science, • Emerald Insight Journals.
Keywords	The databases were searched using the Boolean string ("Magnesium" AND "Energy Storage" AND "Technology")
Quality Assessment Criteria	• All duplicate literature was excluded. • Recovered literature will be checked for relevance. • Ensure the aims and objectives align with the study. • Ensure that clear links between data, interpretations and conclusions exist. • Papers with unclear scope and context to be excluded. • Papers with unanswered research questions to be excluded. • Papers with a lack of credibility, reliability, and validity will be excluded.

2.3 Step 3: Establish relevance criteria

Using the keywords listed in Table 1, the five databases were searched, and the records were screened for title, abstract, and keywords against pre-specified inclusion/exclusion criteria. Studies were included if they addressed magnesium-based electrochemical storage and reported materials/electrolyte/cell or system advances and/or cost, techno-economic, safety, reliability, efficiency, or commercial readiness. Studies were excluded if they focused on non-Mg chemistries or non-electrochemical storage, lacked clear scope/methods/outcomes, or were not peer-reviewed. Screening was conducted following PRISMA principles.

2.4 Step 4: Search and retrieve from literature

Using the research search protocol in Table 1; ScienceDirect, Scopus, Web of Science, IEEE Xplore, and Emerald Insight Journals were subjected to the search strategy. Figure 1 illustrates a graphical overview of the retrieval process. The five databases were searched using the keywords, resulting in 69 research papers/studies being identified.

2.5 Step 5: Selection of studies

The identified research papers/studies were screened based on the protocol stipulated in *Step 1*. These studies were evaluated by removing all duplicates. This resulted in 31 articles being eligible for inclusion, as can be seen in Figure 1.

2.6 Step 6: Quality assessment

In order to assess the quality of each of the selected 31 studies, the following criteria were utilised as a guide for final inclusion, resulting in 25 full-text assessments, as can be seen in Figure 1.

a) All duplicate literature was excluded from assessment.
b) Recovered literature is checked for relevance.
c) Ensure the aims and objectives align with the research purpose and objectives.
d) Ensure clear links between data, interpretations and conclusions.
e) Papers with unclear scope and context were excluded.
f) Papers with unanswered research questions were excluded.
g) Papers with a lack of credibility, reliability, and validity were excluded.

Each study was also evaluated against transparency, methodological rigor, and industrial relevance, in line with systematic review guidance in engineering research. Although a numerical scoring rubric was considered, structured exclusion criteria were applied to maintain consistency with the SAIIE35 template and ensure clarity and replicability of study selection.

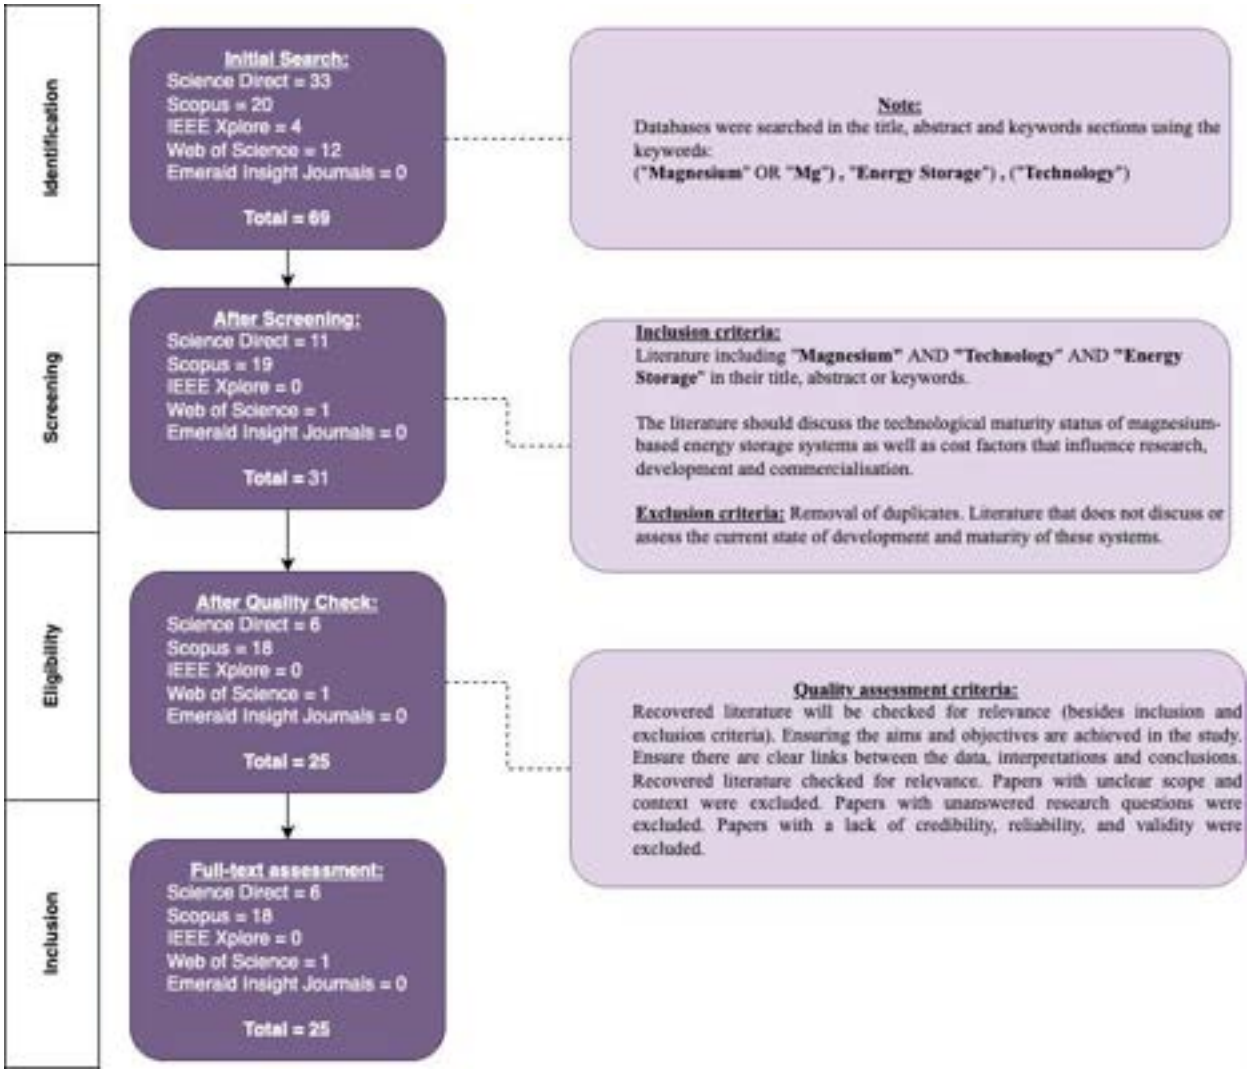

Figure 1: PRISMA flow diagram of study selection (keywords: "Magnesium", Energy storage", "Technology")

This ensured that only robust and contextually relevant studies were included, allowing for the synthesis to be meaningfully linked to industrial engineering and large-scale deployment challenges.

For brevity and to comply with the SAIIE35 conference template requirements, the detailed table of included studies and the thematic Sankey diagram have been omitted. These materials are available from the authors upon request.

3 FINDINGS

The findings (steps 7 & 8) from following the systematic literature review methodology are discussed in the following sub-sections.

3.1 Step 7: Data extraction

After finalising the list of studies to be included, their full texts were studied, and data were extracted.

The research themes identified from the data extraction can be categorised as follows:

- **Advancement & Development**: Characterizing the progression of battery technology and system maturity in magnesium-based energy storage, including breakthroughs in electrode materials, electrolytes, and cell design. Emphasis was placed on strategies to improve energy density, cycling stability, and safety.
- **Cost Effectiveness:** Examining the cost factors that influence the development, scalability, and commercialization of magnesium-based storage technologies, such as material cost, manufacturing processes, and economic viability compared to established systems.
- **Energy Storage Applications:** Reviewing use cases and technological advancements for magnesium-based energy storage, particularly for grid-scale integration, renewable energy support, and stationary storage solutions. By contrast, comparatively little attention was given to emerging or niche applications, such as off-grid electrification, remote industry, or hybrid battery systems, thereby highlighting an important research gap.

Most of these selected studies focused on stationary and grid-scale applications, reflecting current priorities for long-duration and cost-effective energy storage to support renewable energy deployment. Few studies reported field prototypes, and remain at TRL 3-4, underscoring the gap between laboratory performance and deployment readiness.

3.2 Step 8: Synthesis of studies (analysis)

The synthesis phase involved the critical evaluation and integration of findings from the 25 studies selected for full-text assessment. This analysis identified prevailing trends, technological milestones, and persistent gaps in the development of magnesium-based energy storage systems.

A comparative analysis revealed that while polymer-based electrolytes demonstrated Coulombic efficiencies of 97% with stable cycling beyond 100 cycles, chloride-based liquid electrolytes often suffer from side reactions and lower long-term stability. Similarly, MoS_2 nanostructured cathodes achieve reversable intercalations as around 110 mAh/g, whereas conventional oxide cathodes rarely exceed 60 mAh/g. These differences illustrate where promising material innovations have advanced TRLs from 2 to 3-4, while traditional chemistries remain stalled at early-stage readiness.

An analysis of the publication years revealed a marked increase in research activity on magnesium-based energy storage systems since 2019, reflecting academic and industry interest in the field.

Figure 2 shows the number of publications per year, highlighting strong growth from fewer than 5 papers annually before 2018 to more than 10 papers per year after 2020. This trend demonstrates accelerating research momentum but does not yet translate into higher TRL demonstrations.

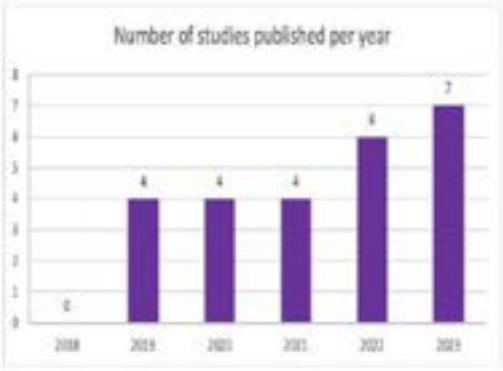

Figure 2: Annual publications on magnesium-based energy storage (2016-2023)

A word cloud illustrated in Figure 3, was generated from the full-text analysis of the selected articles visually highlighted the most frequent discussed topics, aligning closely with the study's keywords and search terms. Dominant terms include "magnesium", "energy storage", "battery", "electrolyte", and "cathode", indicating a concentrated research focus on fundamental battery chemistry and system-level challenges.

Figure 3 highlights this concentration on core chemistry, reinforcing that research remains focused at TRL 2-3 stages, with limited emphasis on scaling, cost modelling, or demonstration beyond laboratory settings.

Figure 3: Word cloud generated from keywords in selected studies

4 TECHNOLOGY READINESS LEVEL OF MAGNESIUM-BASED ENERGY STORAGE SYSTEMS

4.1 Technology Readiness Level (TRLs): a framework for assessments

Technology Readiness Levels (TRLs) provide a structured framework for evaluating the maturity of a technology, from concept development through to full commercialisation [22]. This framework, originally developed by NASA, has been widely adopted in energy and industrial engineering to benchmark technological progress. Table 2 summarises the nine levels.

Table 2: Technology Readiness Levels (TRL 1-9) with definitions, adapted from NASA [22]

TRL	Description	Context of Mg-based systems
1	Basic principles observed and reported	Fundamental materials research (electrochemistry concepts)
2	Technology concept formulated	Initial laboratory hypotheses for Mg-ion storage
3	Experimental proof-of-concept	Early Mg cell assembly tested at lab scale
4	Technology validated in laboratory	Small prototype cells with controlled testing

5	Technology validated in relevant environment	Prototype cells tested under conditions resembling grid use
6	System/Subsystems model demonstrated in relevant environment	Pre-commercial pilot cells with extended cycling
7	System prototype demonstrated in operational environment	Demonstration projects under field/grid conditions
8	Actual system completed and qualified	Fully engineered Mg battery system, ready for deployment
9	Actual system proven in operational environment	Commercial-scale Mg energy storage deployed

In the context of magnesium-based energy storage, most developments are concentrated at TRL 2-4, with limited hybrid Mg/Li systems approaching TRL 5. No systems have yet reached TRL 7-9, highlighting the gap between laboratory advances and field-ready prototypes.

4.2 Research Question 1: What is the technology maturity status of magnesium-based energy storage systems?

Recent studies, such as those by Ma *et al.*, [6] highlight steady improvements in magnesium-based energy storage systems (Mg-ESS), particularly in capacity, stability, rate capability, and operating voltage. These advances reinforce magnesium's advantages over lithium, including higher safety, broader abundance, and greater volumetric capacity [5]. Despite these promising attributes, most developments remain at low Technology Readiness Level (TRL 2-3), with only a few hybrid Mg/Li systems approaching TRL 4-5.

Materials innovations has been central to this progress. Biradar *et al.*,[10] emphasise that magnesium's favourable charge-to-mass ratio and comparable ionic radius to lithium make MIBs attractive alternatives, yet divalent Mg^{2+} insertion continues to pose significant challenges. Limited cathode compatibility, dissolution of active organics, and instability of many electrolytes hinder reliable performance. Attempts to overcome these limitations through molecular reengineering of rylene imides and their polymer derivatives have delivered incremental improvements, but issues with cycling stability and output voltage remain.

Further progress has been driven by two-dimensional materials such as graphene, black phosphorus, and MXenes [13]. Graphene has improved electron transfer, capacity, and rate performance but its practical use is constrained by irreversible capacity loss during early cycles. Black phosphorus offers high theoretical capacity but suffers from air sensitivity and complex, costly synthesis methods. MXenes show considerable promise as electrode materials, yet they still require substantial optimisation before achieving commercial viability. In contrast to lithium-ion systems, which already have field-ready prototypes, magnesium systems remain limited in laboratory stages underscoring their early TRL positioning.

4.3 Research Question 2: What are the cost and scalability challenges of magnesium-based systems?

Although material and design innovations have shown promise, the scalability of magnesium-based batteries remains constrained by high production costs and limited manufacturability. Many of the effective cathodes require complex or expensive synthesis, while lower-cost alternatives generally underperform. As a result, most advances remain confined to laboratory prototypes at TRL 3-4, with limited pathways for scaling towards industrial production.

Zhang *et al.* [12] demonstrated the potential of povidone iodine (PVPI) cathodes, which achieved improved capacities and stability compared to earlier Mg-storage materials. However, issues such as shuttle effect and active material loss continue to undermine long-term reliability, limiting their commercial feasibility. Similarly, Lui *et al.* [15] reported on novel magnesium-air battery design incorporating an "all-in-one" Mg anode, achieving an efficiency of 69.7% and a sustained operation time of 506 hours. While this represents an

important step forward, it remains a laboratory-scale prototype and highlights the gap between technical feasibility and scalable manufacturing.

Cost pressures are not confined to electrodes. Electrolyte preparation is also resource intensive, and solid-state alternatives, while safer, currently require complex processing. Promising systems such as vanadium-based electrodes and Magnesium Cobalt Oxide ($MgCo_2O_4$) cathodes demonstrate strong electrochemical performance but present stability and manufacturing barriers that restrict their progression beyond experimental scales. Furthermore, life-cycle assessments of magnesium-sulphur batteries such as the study by Montenegro *et al.* [17], reveal that although current prototypes perform poorly relative to lithium-ion technologies, optimised designs could potentially surpass them. This reinforces the conclusion that scaling strategies must consider both economic viability and environmental performance.

Compared with sodium- and zinc-based systems, which have advanced to TRL 6-8 through pilot demonstrations, magnesium systems remain confined below TRL5, reinforcing scalability barriers.

While progress has been made in demonstrating new electrode and electrolyte systems, cost and scalability remain key bottlenecks that limit readiness and constrain advancements beyond TRL 4 prototypes.

4.4 Research Question 3: What are the applications and research gaps for magnesium-based systems?

Current research on magnesium-based energy storage systems is concentrated primarily on stationary and grid-scale applications, reflecting the urgent demand for long-duration and cost-effective storage to support renewable energy integration. However, there has been comparatively little focus on niche applications such as off-grid electrification, remote industrial operations, or hybrid storage systems. Across the literature, most report developments remain at TRL 3-4, and no applications have progressed to consistent field demonstrations beyond TRL 5.

Hybrid systems offer one of the most promising avenues for bridging these gaps. Magnesium-lithium batteries (MLIBs), for instance, combine the rapid kinetics of lithium with the high capacity of magnesium. Dong *et al.* [9] showed that rutile-type MoO_2 cathodes achieved discharge capacities of 253 mAh/g with stable performance over 100 cycles. Aqueous hybrid systems such as Mg/Na and Mg/Zn have also demonstrated encouraging results, although their readiness remains at early stages. These examples underscore the potential of hybridisation to overcome the sluggish Mg^{2+} diffusion kinetics that limit pure magnesium systems.

Other exploratory applications include magnesium-sulphur (Mg-S) systems, which have been assessed through life-cycle analysis. Montenegro *et al.* [17] concluded that while Mg-S prototypes compare poorly with lithium-ion batteries in terms of efficiency and resource demand, optimised designs could eventually outperform both lithium-ion and lithium-sulphur technologies. Nonetheless, the absence of real-world validation and reliance on hypothetical optimisation scenarios demonstrate that these systems are still confined to laboratory research.

Both Mg-S and Mg-air chemistries illustrate potential long-term advantages over LIBs, yet their readiness is still constrained to laboratory prototypes without field validation.

While magnesium batteries have been positioned mainly for grid-scale storage, there is a notable lack of exploration into alternative applications that could serve as practical entry points for deployment. Progress remains limited to experimental demonstrations, with no evidence of operational prototypes at TRL 5-6 across these niches.

4.5 Research Question 4: What are the implications for research and policy?

For magnesium-based energy storage systems to advance toward higher Technology Readiness Levels (TRL 7-8) and eventually commercialisation, coordinated action is required across research, industry, and policy. The literature demonstrates steady laboratory-scale progress, but the absence of field prototypes and of harmonised reporting standards continue to constrain progress beyond experimental stages.

A recurring challenge is inconsistency in reporting electrochemical performance. Studies often highlight improvements in capacity, Coulombic efficiency, or cycling stability, but differing measurement protocols and incomplete reporting limit comparability across research groups. This lack of standardisation hinders benchmarking of magnesium systems against lithium-ion technologies and slows the identification of genuinely scalable breakthroughs. Field trials at TRL 5-6, which are essential for validating laboratory results in real-world conditions, remain virtually absent across the reviewed studies.

Several works emphasise the need for supportive frameworks. Xu *et al.* [13] highlight that while advances in materials and electrode designs are encouraging, structural improvements and prototype testing are necessary for magnesium technologies to reach long-term stability. Similarly, environmental assessments of Mg-S systems by Montenegro *et al.* [17] indicate that policy and research must be jointly oriented towards sustainable scale-up, including low-carbon manufacturing and integration of recycling pathways. Without such policy interventions, high-cost synthesis methods and limited comparability across studies will continue to delay industrial adoption.

Advancing magnesium-based systems will require a dual emphasise on standardised full-cell reporting and coordinated prototype demonstrations. At present, the lack of comparability and the absence of field validation are major barriers to readiness progression, keeping most systems below TRL 5. Policy measures that incentivise harmonisation, fund demonstration projects, and promote sustainable manufacturing practices are therefore critical to bridging the gap between laboratory research and commercial deployment.

5 CONCLUSIONS AND RECOMMENDATIONS

5.1 Summary of Findings
